Since $\pi$ is finitely generated we know by the rather elementary Exercise 21.3 that the set $\text{Hom}(\pi, G)$ of homomorphisms from $\pi$ to $G$ is finite. We set $n := \# \text{Hom}(\pi, G)$ and we denote by $\beta_1, \ldots, \beta_n : \pi \to G$ the distinct homomorphisms.

Next we consider the homomorphisms $\beta_1 \circ \varphi, \ldots, \beta_n \circ \varphi : \pi \to G$. Since $\varphi$ is an epimorphism we see that these homomorphisms are also distinct. But note they all satisfy $(\beta_i \circ \varphi)(g) = \beta_i(\varphi(g)) = \beta_i(e) = e$. So these $n$ homomorphisms are different from our initial homomorphism $\alpha : \pi \to G$. This means that we have found $n + 1$ distinct homomorphisms from $\pi \to G$. This is a contradiction to the definition of $n$. 

---

This notion is once again named after Heinz Hopf.
Now that we are fully convinced of the value of residually finite groups, let us explore this class of groups in greater detail. The following proposition gives a convenient characterization of residually finite groups.

**Proposition 31.12.** Let \( \pi \) be a group. The following two statements are equivalent.

1. The group is residually finite.
2. Given any non-trivial element \( g \in \pi \) there exists a finite-index subgroup \( \Gamma \) with \( g \not\in \Gamma \).

If \( \pi \) is countable, then the above are also equivalent to the following statement:

3. There exists a sequence \( \pi \supset \pi_0 \supset \pi_1 \supset \pi_2 \supset \ldots \) of finite index normal subgroups of \( \pi \) such that \( \bigcap_{i \in \mathbb{N}} \pi_i = \{e\} \).

The proof of Proposition 31.12 rests on the following group-theoretic concept.

**Definition.** Let \( G \) be a group and let \( H \) be a subgroup. We refer to

\[
H^c := \bigcap_{g \in G} gHg^{-1}
\]

as the **normal core** of \( G \).

The following lemma is the key ingredient for the proof of Proposition 31.12. But note that the lemma is also interesting in its own right.

**Lemma 31.13.** Let \( G \) be a group and let \( H \) be a subgroup.

1. The normal core of \( H \) is a normal subgroup of \( G \).
2. If \( X \) is a subgroup of \( G \) that is contained in \( H \) and that is normal in \( G \), then \( X \subset H^c \).
3. If \( H \) is of finite-index \( d \in \mathbb{N} \) in \( G \), then \( H^c \) is a subgroup of \( G \) of index at most \( d! \), in particular \( H^c \) is also of finite-index in \( G \).

**Proof of Lemma 31.13.**

1. Let \( k \in G \). We have

\[
kH^c k^{-1} = \bigcap_{g \in G} k \cdot gHg^{-1} \cdot k^{-1} = \bigcap_{g \in G} (kg)H(kg)^{-1} = \bigcap_{g \in G} gHg^{-1} = H^c.
\]

2. Let \( X \) be a subgroup of \( G \) that is contained in \( H \) and that is normal in \( G \). Then

\[
X = \bigcap_{g \in G} gXg^{-1} \subset \bigcap_{g \in G} gHg^{-1} = H^c.
\]

Since \( X \) normal in \( G \) since \( X \subset H \)

3. The proof of the last statement is arguably more interesting. Thus let \( H \) be a subgroup of index \( d \in \mathbb{N} \) of \( G \). We consider the set \( G/H \) of right coset of \( G \) with respect to \( H \). We denote by \( \text{Perm}(G/H) \) the group of permutations of \( G/H \), i.e. it is the group of all bijections of the set \( G/H \). Note that \( G/H \) and thus also \( \text{Perm}(G/H) \)
are finite. We consider the map
\[ \varphi : G \mapsto \text{Perm}(G/H), \quad g \mapsto \left( \frac{G/H}{xH} \mapsto \frac{gH}{xH} \right). \]

This map is easily seen to be a homomorphism. Since Perm\((G/H)\) is finite we see that \(\ker(\varphi)\) is a finite-index normal subgroup of \(G\). We claim that \(\ker(\varphi) \subset H\). Thus let \(g \in \ker(\varphi)\). This implies in particular that \(\varphi(g)(H) = H\), but that means that \(gH = H\), i.e. that \(g \in H\). We have thus shown that indeed \(\ker(\varphi) \subset H\). From (2) and the above observation that \(\ker(\varphi)\) is normal in \(G\) we obtain that \(\ker(\varphi) \subset H^c\).

But since the index of \(\ker(\varphi)\) in \(G\) is at most \(d!\) we see that the index of the normal \(H^c\) in \(G\) is also at most \(d!\).

\[ \square \]

**Proof of Proposition 31.12.** Let \(\pi\) be a group.

(1)⇒(2) Let \(g \in \pi\) be a non-trivial element. Since \(\pi\) is residually finite there exists a homomorphism \(\alpha : \pi \to G\) to some finite group \(G\) such that \(\alpha(g)\) is non-trivial. The kernel \(\Gamma := \ker(\alpha)\) is a finite-index subgroup of \(\pi\) with \(g \not\in \Gamma\).

(2)⇒(1) Let \(g \in \pi\) be a non-trivial element and let \(\Gamma\) be a finite-index subgroup of \(\pi\) with \(g \not\in \Gamma\). By Lemma 31.13 we know that the normal core \(\Gamma^c\) is a finite-index normal subgroup of \(\pi\). Thus we see that the homomorphism \(\alpha : \pi \to \pi/\Gamma^c\) is an epimorphism onto a finite group with \(\gamma(g) \neq e\).

(3)⇒(1) This statement is trivial. Note that here we do not need that \(\pi\) is countable.

(1)⇒(3) We outsource the straightforward proof to Exercise 31.9.

The following lemma gives a topological criterion for a (fundamental) group to be residually finite.

**Lemma 31.14.** Let \((X, x_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. The following two statements are equivalent:

1. The group \(\pi_1(X, x_0)\) is residually finite.
2. Given any loop \(\gamma : [0, 1] \to X\) in \((X, x_0)\) that represents a non-trivial element in \(\pi_1(X, x_0)\) there exists a finite covering \(p : (\tilde{X}, \tilde{x}_0) \to (X, x_0)\) such that the corresponding lift \(\tilde{\gamma} : [0, 1] \to \tilde{X}\) is not a loop.

**Proof.** Let \((X, x_0)\) be a topological space that is path-connected, locally path-connected and semi-locally simply connected. First we prove the (1)⇒(2)-implication. Thus we assume that the group \(\pi_1(X, x_0)\) is residually finite. Let \(\gamma : [0, 1] \to X\) be a loop in \((X, x_0)\) that represents a non-trivial element in \(\pi_1(X, x_0)\). By Proposition 31.12 there exists a finite-index subgroup \(\Gamma\) of \(\pi_1(X, x_0)\) such that \([\gamma] \not\in \Gamma\). Since \(X\) is locally path-connected and semi-locally simply connected we know by Proposition 29.5 that there exists a covering \(p : (\tilde{X}, \tilde{x}_0) \to (X, x_0)\) of \(X\) of degree \([\pi : \Gamma]\) with \(p_*(\pi_1(\tilde{X}, \tilde{x}_0)) = \Gamma\). By Lemma 16.15 we know that the corresponding lift \(\tilde{\gamma} : [0, 1] \to \tilde{X}\) is not a loop.

Now we prove the (2)⇒(1)-implication. Let \(g \in \pi_1(X, x_0)\) be a non-trivial element. We pick a representative loop \(\gamma : [0, 1] \to (X, x_0)\). By hypothesis there exists a finite covering
p: (\tilde{X}, \tilde{x}_0) \to (X, x_0) such that the corresponding lift \tilde{\gamma}: [0, 1] \to \tilde{X} is not a loop. By Lemma 16.15 we know that g = [\gamma] does not lie in p_*(\pi_1(\tilde{X}, \tilde{x}_0)) and that this is a finite-index subgroup of \pi_1(X, x_0). It follows from Proposition 31.12 that \pi_1(X, x_0) is residually finite.

**Proposition 31.15.** Every free group is residually finite.

In the following we will provide two proofs of Proposition 31.15. The first is algebraic, very short and elegant. The other proof is topological in nature and great fun. The eagle-eyed reader will notice that the basic ideas of the two proofs are actually not that dissimilar.

**Remark.** In Exercise 19.14 we gave a third proof for Proposition 31.15. Furthermore, a completely different proof of Proposition 31.15 based again on topology, is given in [Hem72].

**First proof of Proposition 31.15.** Let X be a set and let g ∈ \langle X \rangle be a non-trivial element in the free group generated by the set X. We can and will write g as a product \( g = y_1^{\epsilon_1} \cdots y_k^{\epsilon_k} \) with \( y_1, \ldots, y_k \in X \) and \( \epsilon_1, \ldots, \epsilon_k \in \{-1, 1\} \) such that the following condition is satisfied:

\[ (*) \text{ For every } i \in \{1, \ldots, k-1\} \text{ we have } (y_i, \epsilon_i) \neq (y_{i+1}, -\epsilon_{i+1}). \]

It follows easily from (*) that for every \( x \in X \) we can pick a permutation \( \sigma_x \in S_{k+1} \) with the following two properties:

1. For every \( i \in \{1, \ldots, k\} \) with \( x = y_i \) and \( \epsilon_i = 1 \) we have \( \sigma_x(i + 1) = i \).
2. For every \( i \in \{1, \ldots, k\} \) with \( x = y_i \) and \( \epsilon_i = -1 \) we have \( \sigma_x(i) = i + 1 \). In other words, we have \( \sigma_x^{-1}(i + 1) = i \).

By Lemma 19.14 there exists a unique homomorphism \( \varphi: \langle X \rangle \to S_{k+1} \) such that \( \varphi(x) = \sigma_x \) for every \( x \in X \). We claim that \( \varphi(g) \in S_{k+1} \) is a non-trivial permutation. In fact we have

\[
\varphi(g)(k+1) = \varphi(y_1^{\epsilon_1} \cdots y_k^{\epsilon_k})(k+1) = \varphi(y_1)^{\epsilon_1}(\underbrace{\varphi(y_k)^{\epsilon_k}(k+1)}_{=k}) \cdots = \cdots = \varphi(y_1)^{\epsilon_1}(2) = 1.
\]

This shows that the permutation \( \varphi(g) \in S_{k+1} \) sends \( k + 1 \) to \( 1 \), in other words, it is a non-trivial permutation.

**Sketch of second proof of Proposition 31.15.** For simplicity we only provide the proof that the free group on two generators is residually finite. Recall that by Lemma 20.4 we can make an identification \( \langle a, b \rangle = \pi_1(S^1_a \lor S^1_b, \ast) \) where \( a \) and \( b \) correspond to loops around \( S^1_a \) and \( S^1_b \). It follows fairly easily from from Lemma 16.15 and Lemma 31.14 that it remains to show that for any loop \( \gamma = a_1^{m_1} b_1^{n_1} \cdots a_k^{m_k} b_k^{n_k}: [0, 1] \to X = S^1_a \lor S^1_b \) there exists a finite-covering \( p: \tilde{X} \to X \) such that the lift of \( \gamma \) is not a loop. In Figure 1354 we show the following two-step construction of such a covering for the loop \( \gamma = a \ast b \ast \bar{a} \ast \bar{b} \) on \( S^1_a \lor S^1_b \).

1. First we build an "upward turning lift \( \tilde{\gamma} \) of \( \gamma \).
2. Afterward we complete the "image of \( \tilde{\gamma} \)" to a finite covering \( \tilde{X} \).
It is an extraordinary charming exercise to turn the above idea into a rigorous argument for the general case. We would not dream of robbing the reader from this experience.

\[
\tilde{\gamma} = a \ast b \ast \tilde{\pi} \ast \tilde{b}
\]

Figure 554. Illustration for the proof of Proposition 31.15

Basically for free we now get the following result.

**Corollary 31.16.** Every finitely generated free group is Hopfian.

**Proof.** This statement follows immediately from Proposition 31.15 together with Proposition 31.11. An alternative proof of the corollary is given in [MKS76, p. 109].

In Question 22.5 we had asked whether the fundamental group of the surface of genus \(g\) is isomorphic to the free group \(F_{2g}\) on \(2g\) generators. Now we can answer this question in the negative.

**Proposition 31.17.** If \(g \geq 1\), then the group

\[
\pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle
\]

is not isomorphic to the free group \(F_{2g}\) on \(2g\) generators.

In fact Proposition 31.17 is an immediate consequence of the following more general statement.

**Proposition 31.18.** Let \(X = \{x_1, \ldots, x_k\}\) be a finite set with \(k\) elements. If \(r\) is a non-trivial element in the free group \(\langle x_1, \ldots, x_k \mid r \rangle\), then the group \(\langle x_1, \ldots, x_k \mid r \rangle\) is not isomorphic to \(\langle x_1, \ldots, x_k \rangle\).

**Proof.** Let \(X\) is a finite set and let \(r\) be an element in \(\langle X \rangle\). Suppose there exists an isomorphism \(\varphi : \langle X \mid r \rangle \to \langle X \rangle\). We denote by \(\psi : \langle X \rangle \to \langle X \mid r \rangle\) the obvious epimorphism. Then \(\varphi \circ \psi : \langle X \rangle \to \langle X \rangle\) is an epimorphism. It follows from Corollary 31.16 that \(\varphi \circ \psi\) is actually an isomorphism. This implies in particular that \(\psi\) is a monomorphism. But \(r\) lies in the kernel of \(\psi\), this is only possible if \(r = e \in \langle X \rangle\).

Our next goal is to give a useful criterion for a group to be residually finite. To do so we need to introduce the following definition.

**Definition.** Let \(R\) be a ring. We say that a group \(G\) is linear over \(R\) if there exists an \(n \in \mathbb{N}\) and a monomorphism \(G \to \text{GL}(n, R)\).
Examples.

1. In Exercise [19.13] we showed that the free group on two generators is linear over \( \mathbb{Z} \).
2. Let \( G \) be a group and let \( R \) be a ring. In Exercise [31.15] we will show that if \( G \) admits a finite-index subgroup which is linear over \( R \), then \( G \) itself is linear over \( R \).

Now we can formulate the promised proposition.

**Proposition 31.19.** Let \( G \) be a finitely generated group. If \( G \) is linear over \( \mathbb{C} \), then \( G \) is residually finite.

**Sketch of proof.** We only provide a full proof of the following easier claim which is the content of Exercise [19.14] (a).

**Claim.** The group \( \text{GL}(n, \mathbb{Z}) \) is residually finite.

Let \( A = (a_{ij}) \in \text{GL}(n, \mathbb{Z}) \) be a matrix with \( A \neq \text{id} \). We pick some \( m \in \mathbb{N} \) such that \( m > \max\{|a_{ij} - \delta_{ij}| \mid i, j = 1, \ldots, n\} \). The ring homomorphism \( \mathbb{Z} \to \mathbb{Z}_m \) induces a group homomorphism \( \alpha: \text{GL}(n, \mathbb{Z}) \to \text{GL}(n, \mathbb{Z}_m) \). Basically by construction we have \( \alpha(A) \neq \text{id} \). Since \( \text{GL}(n, \mathbb{Z}_m) \) is a finite group we are done. ⊞

Now let \( G \) be a finitely generated subgroup of \( \text{GL}(n, \mathbb{C}) \). The proof that \( G \) is residually finite consists of two steps:

1. First, since \( G \) is finitely generated one sees, almost immediately, that there exists a finitely generated subring \( S \) of \( \mathbb{C} \) such that \( G \subset \text{GL}(n, S) \).
2. Next one needs to show that \( S \) is a "residually finite ring", i.e. one needs to show that given any non-zero \( s \in S \) there exists a ring homomorphism \( \alpha: S \to T \) to some finite ring \( T \) with \( \alpha(s) \neq 0 \). This part requires some input from ring theory.

Once one has proved (1) and (2) it is straightforward to modify the proof of the claim to conclude that \( G \) is residually finite.

The full details for the above proof are given in [Ma40, ?] and also in [Weh73, Theorems 4.1, 4.3] and in [Hem87]. ■

We already mentioned that \( (\mathbb{Q}, +) \) is not residually finite and that \( \mathbb{Z}^{(N)} \) is not Hopfian. These are amusing observations, but most group theorists and geometric topologists restrict their interest to finitely generated groups. Thus the question arises, whether perhaps every finitely generated group is residually finite or Hopfian.

**Proposition 31.20.** Given \( m, n \in \mathbb{N} \) we consider the Baumslag-Solitar group

\[
\text{BS}(m, n) = \langle x, y \mid x^{-1}y^mx = y^n \rangle.
\]

The following statements hold:

1. The group \( \text{BS}(m, n) \) is Hopfian if and only if \( m \) and \( n \) are "meshed", i.e. if and only if \( m \) or \( n \) divides the other or if \( m \) and \( n \) have precisely the same prime divisors.
2. The group \( \text{BS}(m, n) \) is residually finite if and only if \( |m| = 1 \), or if \( |n| = 1 \) or if \( |m| = |n| \).

**Example.** By Proposition [31.20] the group \( \text{BS}(2, 6) \) is Hopfian but not residually finite. This shows, as promised, that the converse to Proposition [31.11] does not hold.
Proof. The first statement was proved in 1962 by Gilbert Baumslag and Solitar \cite{BaS62}. The second statement is proved in \cite[Theorem C]{Mes72} and also \cite[p. 61]{Cam90}.

By Proposition \ref{31.20} we now know that there exist finitely generated groups which do not have “many” finite quotients. The question arises, does every non-trivial group admit at least some finite index subgroups? It is now time to recall the following standard definition from group theory.

**Definition.** A group $G$ is called simple if the only normal subgroups are the trivial group \{e\} and the whole group $G$.

**Example.** One of the most basic statements in the theory of finite groups is the fact that for $n \geq 5$ the alternating group $A_n$ is actually simple, we refer to \cite[Chapter 1.12]{Bog08} for a proof.

It is now natural to ask whether there exist infinite simple groups. The answer is yes, but one needs to be rather creative when it comes to producing such groups. This discussion leads us to the following groups which were introduced by Richard Thompson in 1965.

**Definition.**

(1) A continuous self-homeomorphism $f: [0, 1] \to [0, 1]$ is called dyadic if there exists an $m \in \mathbb{N}$ such that the restriction of $f$ to each interval $[\frac{i}{2^m}, \frac{i+1}{2^m}]$ is linear and the slope on each such interval is a (possibly negative) power of 2.

(2) We say a map $g: S^1 \to S^1$ is dyadic if there exists a dyadic map $f: [0, 1] \to [0, 1]$ such that $g(e^{2\pi it}) = e^{2\pi if(t)}$.

**Figure 555**

We leave it to the reader to verify that the set of dyadic self-homeomorphisms of $[0, 1]$ and of $S^1$ actually form groups. This observation leads us to the key definition.

**Definition.**

(1) Thompson’s group $F$ is defined as the group of dyadic self-homeomorphisms of $[0, 1]$.

(2) Thompson’s group $T$ is defined as the subgroup of the self-homeomorphisms of $S^1$ that is generated by the dyadic self-homeomorphisms together with the homeomorphism given by $z \mapsto -z$.

The following theorem summarizes some of the many interesting properties of Thompson’s groups.

**Theorem 31.21.**

(1) Thompson’s group $F$ and Thompson’s group $T$ are both finitely presented.

(2) The commutator subgroup of Thompson’s group $F$ is simple, in particular Thompson’s group $F$ is not residually finite.

(3) Thompson’s group $T$ is simple, in particular it is not residually finite.
Proof.

(1) The statements are proved in [CFP96] and [Geo08, Chapters 9.2].
(2) By [CFP96] and [Geo08, Chapters 9.2] the commutator subgroup of Thompson’s group $F$ is simple. One can easily verify that Thompson’s group $F$ is non-abelian and torsion-free. It now follows from an elementary argument that it is not residually finite.
(3) It is shown in [CFP96] and [Geo08, Theorem 9.4.3] that Thompson’s group $T$ is simple. Clearly $T$ is infinite, hence it cannot be residually finite. ■

In this section we have shown, among many other statements, that free groups are residually finite. It is natural to ask which of the other friendly groups which we have encountered are actually residually finite. Let us pose two questions:

**Question 31.22.**

(1) Are the fundamental groups of closed 2-dimensional smooth manifolds residually finite?
(2) Is the fundamental group of every knot complement residually finite?

We will return to these questions later on in Proposition 34.10.

---

**Exercises for Chapter 31**

**Exercise 31.1.** Let $H$ be a finite connected graph and let $G$ be a connected non-empty subgraph of $H$. Let $S$ be a spanning tree of $G$. Show that there exists a spanning tree $T$ of $H$ such that $T \cap G = S$.

*Remark.* This exercise is a rather straightforward generalization of Proposition 4.8 (1).

**Exercise 31.2.** Let $\alpha: \langle a, b \rangle \to \mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a) = 1$ and $\alpha(b) = 0$. Furthermore let $X$ be the wedge of two circles $A$ and $B$. As usual we equip $X$ with the CW-structure with one 0-cell $P$ and two 1-cells $a$ and $b$. Furthermore we make the identification $\pi_1(X) = \langle a, b \rangle$.

(a) “Construct” the covering $p: \tilde{X} \to X$ corresponding to $\ker(\alpha)$, i.e. construct the covering $p$ such that $p_* (\pi_1(\tilde{X})) = \ker(\alpha)$. More precisely, give the CW-structure on $\tilde{X}$ and indicate, e.g. using colors, the cellular map $p$.

(b) We know from Proposition 31.4 (2) that $\ker(\alpha)$ is a free group on four generators. Determine four elements of $\ker(\alpha)$ that generate $\ker(\alpha)$ as a free group. You do not have to justify your answer.

**Exercise 31.3.** In Question 30.5 we had considered an explicit 6-fold covering $X \to B$ where $B$ is the 2-dimensional sphere minus three open disks. On page 849 we saw that $X$ has six boundary components. Determine the genus of $X$.

**Exercise 31.4.** Let $g \in \mathbb{N}_{\geq 2}$. Use Proposition 31.5 to show that the fundamental group of the surface of genus $g$ is torsion-free.

*Remark.* We posed this already as Exercise 25.10 but with different instructions.
**Exercise 31.5.** Let $P$ be a property of groups. We say a group $G$ is *virtually* $P$ if $G$ admits a finite-index subgroup that has property $P$. Let $G$ be a finitely generated group. Show that if $G$ is virtually abelian, then there exists a short exact sequence of the form $0 \to \mathbb{Z}^d \to G \to A \to 1$ where $d \in \mathbb{N}_0$ and $A$ is a finite group.

**Exercise 31.6.** Let $p: \tilde{\Sigma} \to \Sigma$ be a covering map of degree $d$ between two closed *non-orientable* connected 2-dimensional smooth manifolds. Show that the following equality holds:

$$\text{genus}(\tilde{\Sigma}) = d \cdot (\text{genus}(\Sigma) - 1) + 1.$$  

*Hint.* Let $\varphi: \mathbb{B}^2 \to \Sigma$ be an embedding. Consider the compact connected 2-dimensional smooth manifolds $M := \Sigma \setminus \varphi(B^2)$ and $\tilde{M} := p^{-1}(M)$. What can you say about the fundamental group and the number of boundary components of $\tilde{M}$?

*Remark.* This exercise is meant as the non-orientable analogue of Proposition 31.6. In Lemma 55.9 we will use “Euler characteristics” to give an alternative proof of this equality.

**Exercise 31.7.** We consider the non-compact 2-dimensional smooth manifold $M$ shown in Figure 556. Does there exists a closed 2-dimensional smooth manifold $N$ such that $M$ is a covering space of $N$?

![Figure 556. Illustration for Exercise 31.7](image)

**Exercise 31.8.** In Exercise [19.14](#) we introduced the notion of a residually finite group and we showed that the free group on two generators is residually finite.

(a) Show that every finitely generated free group is residually finite.  

*Remark.* Use Proposition 31.4 (2).

(b) Show that every free group is residually finite.

**Exercise 31.9.** Let $\pi$ be a countable residually finite group. Show that there exists a descending sequence $\pi \supset \pi_0 \supset \pi_1 \supset \pi_2 \supset \ldots$ of finite index normal subgroups of $\pi$ such that we have $\bigcap_{i \in \mathbb{N}} \pi_i = \{e\}$.

**Exercise 31.10.** Let $G$ be a finitely generated group. Show that given any $n \in \mathbb{N}$ there exist only finitely many subgroups of $G$ of index $n$.

**Exercise 31.11.** Let $G$ be a group. A subgroup $\Gamma$ of $G$ is called *characteristic* if for every automorphism $\varphi: G \to G$ we have $\varphi(\Gamma) = \Gamma$.

(a) Show that if subgroup is characteristic, then it is also normal.

(b) Let $H$ be a subgroup of $G$. Suppose that $G$ is finitely generated. Show that there exists a characteristic subgroup $K \subset G$ with $K \subset H$ and such that $K$ has finite index in $G$.

(c) Show that in (b) we cannot drop the hypothesis that $G$ is finitely generated.

**Exercise 31.12.** Show that the group $(\mathbb{Q}, +)$ is not residually finite.
Exercise 31.13. Let \( \varphi : A \to B \) be a homomorphism between free groups of the same finite rank. Suppose that \( \varphi_* : A_{ab} \to B_{ab} \) is an isomorphism. Show that \( \varphi \) is a monomorphism.  
*Hint.* Use Proposition 31.4 and Corollary 31.16.

Exercise 31.14. Let \( G \) be a group and let \( \varphi : G \to G \) be an automorphism. We suppose that \( G \) is residually finite and finitely generated. Show that the semidirect product \( G \rtimes_\varphi \mathbb{Z} \), that we defined on page 718, is also residually finite.  
*Hint.* Make good use of Exercise 31.11.

Exercise 31.15. Let \( R \) be a ring, let \( G \) be a group and let \( H \) be a subgroup of finite index \( d \in \mathbb{N} \). Suppose there exists a monomorphism \( \varphi : H \to \text{GL}(n,R) \). Show that there exists a monomorphism \( \varphi : G \to \text{GL}(n \cdot d,R) \).

Exercise 31.16.  
(a) Provide an example of an infinitely generated group that is Hopfian.  
(b) Show that every infinite simple group is Hopfian.

Exercise 31.17. Let \( k \in \mathbb{N}_{\geq 2} \). We consider the direct product \( \langle x_1, \ldots, x_k \rangle \times \mathbb{Z} \). Show that given any \( N \in \mathbb{N} \) there exists a finitely generated free group \( F \) of rank \( \geq N \) and an automorphism \( \varphi \) of \( F \) such that \( \langle x_1, \ldots, x_k \rangle \times \mathbb{Z} \) is isomorphic to the semidirect product \( F \rtimes_{\varphi} \mathbb{Z} \).  
*Remark.* Most of the hard work was already done in Exercise 24.17.
32. Hyperbolic geometry

In this chapter we will switch gears and we will introduce some basics on hyperbolic geometry. The reason for doing so is that in Chapter 33 we will see that every surface of genus $\geq 2$ admits a hyperbolic structure, and this fact will be extremely helpful in getting a better understanding of surfaces.

32.1. Hyperbolic space. We start out with the following definition.

**Definition.** Let $V$ be a real vector space. A *symmetric form on $V$* is a map

$$g: V \times V \to \mathbb{R}$$

that is bilinear, i.e. for all $u, v, w \in V$ and $\mu, \lambda \in \mathbb{R}$ we have

$$g(\lambda u + \mu v, w) = \lambda g(u, w) + \mu g(v, w)$$

and that is symmetric, i.e. for all $v, w \in V$ we have

$$g(v, w) = g(w, v).$$

We say $g$ is *positive-definite* if for all $v \in V \setminus \{0\}$ we have

$$g(v, v) > 0.$$

Now we can recall the following key definition from the theory of smooth manifolds, see e.g. [Lee02] Chapter 17.

**Definition.**

1. A Riemannian structure on a smooth manifold $M$ is a smooth map $g$ which assigns to each point $P$ a positive-definite symmetric form $g_P$ on the tangent space $T_PM$.
2. A Riemannian manifold is a pair $(M, g)$ consisting of a smooth manifold $M$ together with a Riemannian structure $g$.

As so often in mathematics, given some structure one is very much interested in maps that preserve the given structure. This leads us to the following definition.

**Definition.**

1. Given a smooth map $f: M \to N$ between smooth manifolds and given $P \in M$ we denote by $Df_P = f_*: T_PM \to T_{f(P)}N$ the differential, i.e. the induced homomorphism from the tangent space $T_PM$ to the tangent space $T_{f(P)}N$.
2. Let $f: M \to N$ be a local diffeomorphism. Given a Riemannian structure $h$ on $N$ we denote by $(f^*h)(v, w) = h(f_*v, f_*w)$ the Riemannian structure on $M$ that at each point $P \in M$ is given by $(f^*h)(v, w) = h(f_*v, f_*w)$.
3. We say that a map $f: (M, g) \to (N, h)$ between Riemannian manifolds is a (local) isometry if $f$ is a (local) diffeomorphism and if $g = f^*h$.  

---

537 Sometimes such a structure is called a *bilinear symmetric form*, but we abbreviate this to *symmetric form*.

538 The notion of "smooth" in this context is made precise in [Lee02] Chapter 17. Once one has digested the definition of a "smooth map" it is straightforward to see that all examples below satisfy this condition.
(4) Given a Riemannian manifold \((M, g)\) we denote by \(\text{Isom}(M, g)\) the group of isometries of \((M, g)\). If \(M\) is orientable, then we denote by \(\text{Isom}^+(M, g)\) the group of orientation-preserving isometries of \((M, g)\).

(5) We say that Riemannian manifolds \((M, g)\) and \((N, h)\) are \textit{isometric} if there exists an isometry from \((M, g)\) to \((N, h)\).

In this chapter and the following chapter we are mostly interested in Riemannian structures on surfaces, and more specifically, in hyperbolic structures. Now we give the definition of hyperbolic space.

**Definition.** The \textit{hyperbolic half-plane} is the smooth manifold

\[
\mathbb{H} = \{(x, y) \in \mathbb{R}^2 \mid y > 0\} = \{z = x + iy \in \mathbb{C} \mid y > 0\}
\]

together with the Riemannian structure that assigns to the tangent space \(T_z \mathbb{H} = \mathbb{R}^2\) at a point \(z = x + iy \in \mathbb{H}\) the positive-definite symmetric form

\[
g : \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}
\]

\[
(v, w) \mapsto \frac{1}{y^2} \langle v, w \rangle
\]

where \(\langle v, w \rangle\) denotes the usual scalar product on \(\mathbb{R}^2\).

**Example.** In Figure 557 we see a decomposition of \(\mathbb{H}\) into angels and devils. With respect to the hyperbolic metric all the angels have the same size and all the devils have the same size, even though they differ in the usual Euclidean sense.

![Figure 557](image_url)

As we mentioned before, we are very much interested in the group \(\text{Isom}^+(\mathbb{H})\) of orientation-preserving isometries of the Riemannian manifold \(\mathbb{H}\). This leads us to the following definition.

**Definition.** A \textit{Möbius transformation} of \(\mathbb{H}\) is a map of the form

\[
z \mapsto \frac{az + b}{cz + d}
\]

where \(a, b, c, d \in \mathbb{R}\) with \(ad - bc = 1\).

\[^{539}\text{It follows from } \text{Lee02 Proposition 13.9} \text{ that } f^*h \text{ is indeed a Riemannian structure on } M. \text{ Note that in the proof, to show that } f^*h \text{ is indeed non-degenerate, one needs that } f \text{ is a local diffeomorphism.} \]

\[^{540}\text{An elementary calculation shows that the image of a Möbius transformation } \mathbb{H} \to \mathbb{C} \text{ does indeed lie again in } \mathbb{H}.\]
Examples. We give three special types of Möbius transformations of $\mathbb{H}$:

1. given $r > 0$ the scalar multiplication $z \mapsto rz = \frac{\sqrt{r} \cdot z + 0}{0 \cdot z + \sqrt{r}}$ is a Möbius transformation,

2. given $d \in \mathbb{R}$ the horizontal translation $z \mapsto z + d = \frac{1 \cdot z + d}{0 \cdot z + 1}$ is a Möbius transformation,

3. the map $z \mapsto -\frac{1}{z} = \frac{0 \cdot z + 1}{(-1) \cdot z + 0}$ is a Möbius transformation.

The third Möbius transformation is the composition of taking the inverse $z \mapsto \frac{1}{z}$ and the reflection $z \mapsto -z$ in the origin. We illustrate this map in Figure 558. For simplicity we refer to the map $z \mapsto -\frac{1}{z}$ as an inversion.

Rather amazingly we are already done with listing all elements in $\text{Isom}^+(\mathbb{H})$. More precisely, we have the following proposition.

**Proposition 32.1.** The map

$$\text{SL}(2, \mathbb{R}) \to \text{Isom}^+(\mathbb{H})$$

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto \left( \mathbb{H} \to \mathbb{H}, \quad z \mapsto \frac{az+b}{cz+d} \right)$$

is a group isomorphism.

**Sketch of proof.** One can easily calculate by hand that each Möbius transformation is an orientation-preserving isometry of $\mathbb{H}$. Furthermore, it is an amusing calculation to verify that the given map is indeed a group homomorphism. It is elementary to see that the map is a monomorphism. The only bit of the proposition which requires some thought is the statement that every orientation-preserving isometry is already a Möbius transformation. This statement is for example shown in [And05, Theorem 3.19]. □

Now that we have seen that every orientation-preserving isometry of $\mathbb{H}$ is a Möbius transformation it makes sense to study Möbius transformations in greater detail.

**Proposition 32.2.** Every Möbius transformation of $\mathbb{H}$ is the composition of scalar multiplications, horizontal translations and inversions.

**Proof.** Let $a, b, c, d \in \mathbb{R}$ with $ad - bc = 1$ and denote by

$$\Phi(z) = \frac{az+b}{cz+d}$$

the corresponding Möbius transformation. If $c = 0$, then

$$\Phi(z) = \frac{a}{d}z + \frac{b}{d}$$
is the composition of the scalar multiplication $z \mapsto \frac{a}{d}z$ with the horizontal translation $z \mapsto \frac{b}{d} + z$. If $c \neq 0$, then

$$\Phi(z) = \frac{az + b}{cz + d} = \frac{acz + bc}{c^2z + dc} = \frac{-1 + a(cz + d)}{c^2z + cd} = \frac{-1}{c^2z + cd} + \frac{a}{c}.$$  

Thus we see that $\Phi$ is the composition of the following maps

$$z \mapsto c^2z, \quad z \mapsto z + dc, \quad z \mapsto \frac{-1}{z} \quad \text{and} \quad z \mapsto z + \frac{a}{c}.$$  

\[\square\]

**Definition.**

1. The hyperbolic disk is the smooth manifold

   $$\mathbb{D} = \{ z \in \mathbb{C} \mid |z|^2 < 1 \}$$

   together with the Riemannian structure which assigns to the tangent space $T_z \mathbb{D} = \mathbb{R}^2$ at a point $z \in \mathbb{D}$ the positive-definite symmetric form

   $$g_z : \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}, \quad (v, w) \mapsto \frac{2}{(1 - |z|^2)^2} \langle v, w \rangle$$

   where, as above, $\langle v, w \rangle$ denotes the usual scalar product on $\mathbb{R}^2$.

2. A Möbius transformation of $\mathbb{D}$ is a map of the form

   $$\mathbb{D} \to \mathbb{D}, \quad z \mapsto e^{i\theta} \cdot \frac{z - a}{1 - \overline{a}z}$$

for some $\theta \in \mathbb{R}$ and $a \in \mathbb{D}$.

**Examples.**

1. In Figure 559 we see three different decompositions of $\mathbb{D}$ into subsets. In each of the three cases these subsets have the same hyperbolic size, even though they differ in the usual Euclidean sense.

**Figure 559**

\[541\] Note that $c = 0$ implies that $1 = ad - bc = ad$, in particular $ad > 0$, hence $\frac{a}{d} > 0$.

\[542\] The hyperbolic disk is often also called the Poincaré model for hyperbolic space.

\[543\] An elementary calculation shows that the image of a Möbius transformation $\mathbb{D} \to \mathbb{C}$ does indeed lie again in $\mathbb{D}$.
(2) If we set $a = 0$ in the definition of a Möbius transformation of $\mathbb{D}$, then we obtain precisely the rotation by the angle $\theta$. Put differently, the Möbius transformations preserving 0 are precisely given by rotations around the origin.

The following proposition will allow us to go back and forth between the hyperbolic half-plane and the hyperbolic disk.

**Proposition 32.3.** The maps

$\Phi : \mathbb{H} \to \mathbb{D}$ and $\Psi : \mathbb{D} \to \mathbb{H}$

have the following properties:

1. $\Phi$ and $\Psi$ are inverses to one another, in particular they are biholomorphisms.
2. they extend to homeomorphisms between $\mathbb{H} = \{z \in \mathbb{C} \mid \text{Im}(z) \geq 0\} \cup \{\infty\}$ and $\mathbb{D} = \{z \in \mathbb{C} \mid |z| \leq 1\}$,
3. they are orientation-preserving,
4. they are isometries,
5. they give a bijection between the Möbius transformations of $\mathbb{D}$ and $\mathbb{H}$.

**Proof.** All five statements follow from a straightforward calculation. The statements can also be deduced, more or less directly, from any book that deals with Möbius transformations, see e.g. [Schwe79, Chapter 6] and [And05, Chapter 2].

**Remark.** Proposition 32.3 says that $\mathbb{D}$ and $\mathbb{H}$ are two equivalent ways to describe hyperbolic space. In fact there are several other ways to describe hyperbolic space, for example we could also use the Beltrami-Klein model

or the hyperboloid model

Some of the connections between these models are explained in the following video of Henry Segerman and Saul Schleimer:

[https://www.youtube.com/watch?v=eCEQ_uuQtYs](https://www.youtube.com/watch?v=eCEQ_uuQtYs)

The following proposition summarizes some of the key properties of Möbius transformations.

**Proposition 32.4.**

1. Compositions of Möbius transformations are again Möbius transformations and the inverse of a Möbius transformation is again a Möbius transformation.

---

544 Here $\mathbb{H}$ has the same topology as defined on page 95.

545 The hyperbolic half-plane $\mathbb{H}$ and the hyperbolic disk $\mathbb{D}$ are both subsets of $\mathbb{C} = \mathbb{R}^2$ and inherit from $\mathbb{C} = \mathbb{R}^2$ the canonical orientation.

546 More precisely, if $\alpha$ is a Möbius transformation of $\mathbb{H}$, then $\Phi \circ \alpha \circ \Psi$ is a Möbius transformation of $\mathbb{D}$ and conversely, if $\alpha$ is a Möbius transformation of $\mathbb{D}$, then $\Psi \circ \alpha \circ \Phi$ is a Möbius transformation of $\mathbb{H}$.
(2) Möbius transformations are biholomorphisms, they are isometries and they are orientation-preserving.

(3) Möbius transformations act transitively, i.e. given any two points \( P \) and \( Q \) there exists a Möbius transformation which sends \( P \) to \( Q \).

(4) Given \( P, Q \in \mathbb{D} \) and non-zero vectors \( v \in T_P \mathbb{D} \) and \( w \in T_Q \mathbb{D} \) with \( \|v\|_g = \|w\|_g \) there exists a Möbius transformation \( \phi \) with \( \phi(P) = Q \) and \( d\phi_P(v) = w \).

(5) Let \( \phi \) and \( \psi \) be two Möbius transformations. Suppose there exists a \( P \in \mathbb{D} \) such that \( \phi(P) = \psi(P) \) and such that \( d\phi_P = d\psi_P \). Then \( \phi = \psi \).

Proof. By Proposition 32.3 it suffices to prove the statements for \( \mathbb{D} \) or for \( \mathbb{H} \), whichever is more convenient.

(1),(2) The first two statements follow from a straightforward calculation, see e.g. [Schwe79, p. 43].

(3) We prove this statement for \( \mathbb{D} \). Note that by (1) it suffices to show that given any \( P \in \mathbb{D} \) there exists a Möbius transformation \( \psi \) with \( \psi(P) = 0 \). But such a Möbius transformation is given by

\[
\psi(z) = \frac{z - P}{1 - \overline{P}z}.
\]

(4) Using (3) we see that we only have to deal with the case that \( P = Q = 0 \). But then the desired Möbius transformation is given by a rotation.

(5) By (3) there exists a Möbius transformation \( \theta \) such that \( \theta(0) = P \) and there exists a Möbius transformation \( \omega \) such that \( \omega(\phi(P)) = \omega(\psi(P)) = 0 \). We consider the Möbius transformations \( \phi' = \omega \circ \phi \circ \theta \) and \( \psi' = \omega \circ \psi \circ \theta \). It follows from our hypothesis that both \( \phi' \) and \( \psi' \) fix 0. As we pointed out above, the only Möbius transformations of \( \mathbb{D} \) that fix 0 are rotations.

By our hypothesis we have \( d\phi'_0 = d\psi'_0 \), which means that the rotations \( \phi' \) and \( \psi' \) agree. But this implies that \( \phi \) and \( \psi \) also agree. ■

Note that Möbius transformations extend in an obvious way uniquely to homeomorphisms of \( \overline{\mathbb{D}} = \{z \in \mathbb{C} \mid |z| \leq 1\} \) and \( \overline{\mathbb{H}} = \{z \in \mathbb{C} \mid \text{Im}(z) \geq 0\} \cup \{\infty\} \). We will denote the extension of a Möbius transformation with the same symbol.

Lemma 32.5. Let \( \{P, Q, R\} \) and let \( \{S, T, U\} \) be two sets of three distinct points on the boundary \( \partial \mathbb{H} = \mathbb{R} \cup \{\infty\} \). Then there exists a Möbius transformation \( \psi \) of \( \mathbb{H} \) with \( \psi(P) = S \) and \( \psi(\{Q, R\}) = \{T, U\} \).

Proof. Let \( P, Q, R \) be three distinct points on \( \partial \mathbb{H} = \mathbb{R} \cup \{\infty\} \). It suffices to show that there exists a Möbius transformation \( \psi \) with \( \psi(P) = \infty \) and with \( \psi(\{Q, R\}) = \{0, 1\} \). We proceed as follows:

(1) We first claim that there exists a Möbius transformation \( \alpha \) with \( \alpha(P) = \infty \). Indeed, if \( P = \infty \) then we just take \( \alpha = \text{id} \). Otherwise we can combine a horizontal translation with the inversion to obtain a Möbius transformation \( \alpha \) with \( \alpha(P) = \infty \). Given such

\[517\text{The statement of the proposition applies to Möbius transformations of } \mathbb{D} \text{ and to Möbius transformations of } \mathbb{H}.\]
\[ \alpha \text{ we write } Q' = \alpha(Q) \text{ and } R' = \alpha(R). \] Note that the points \( Q', R' \) lie on \( \mathbb{R} = \mathbb{H} \setminus \{\infty\}. \) Without loss of generality we can assume that \( Q' < R' \).

(2) Next we pick a horizontal translation such that \( \beta(Q') = 0 \). Note that we still have \( (\beta \circ \alpha)(P) = \beta(\infty) = \infty \). Also note that it follows from \( Q' < R' \) that \( \beta(R') > 0 \).

(3) Finally we pick a scalar multiplication \( \gamma \) such that \( (\gamma \circ \beta)(R') = 1 \). Note that \( \gamma \) fixes 0 and \( \infty \). Thus we see that \( \psi = \gamma \circ \beta \circ \alpha \) has the desired property.

\[ \square \]

**Definition.** A hyperbolic line is a subset of \( \mathbb{D} \) of one of the following two types:

1. it is the intersection of \( \mathbb{D} \) with a Euclidean line through the origin,
2. it is the intersection of \( \mathbb{D} \) with a Euclidean circle that intersects the circle \( S^1 = \partial \mathbb{D} \) orthogonally.

In each of the two cases we refer to the intersection of the Euclidean object with \( S^1 = \partial \mathbb{D} \) as the endpoints of the hyperbolic line. We refer to Figure 560 for an illustration.

![Figure 560](image.png)

**Lemma 32.6.**

1. For any two distinct points \( P \) and \( Q \) in \( \mathbb{D} \) there exists a unique hyperbolic line that contains \( P \) and \( Q \).
2. For any two distinct points \( P \) and \( Q \) in \( \partial \mathbb{D} \) there exists a unique hyperbolic line with \( P \) and \( Q \) as endpoints.
3. Let \( P \) and \( Q \) be two distinct points in \( \partial \mathbb{D} \). Every Möbius transformation \( \phi \) sends the hyperbolic line with endpoints \( P \) and \( Q \) to the hyperbolic line with endpoints \( \phi(P) \) and \( \phi(Q) \).
4. Möbius transformations act transitively on hyperbolic lines, i.e. given any two hyperbolic lines \( g \) and \( h \) there exists a Möbius transformation \( \phi \) with \( \phi(g) = h \).

**Proof.** In principle one can prove the lemma directly in \( \mathbb{D} \). But it is easier to prove it using \( \mathbb{H} \). In \( \mathbb{H} \) the hyperbolic lines are defined to be vertical lines \( \{x + iy \mid y > 0\} \) and Euclidean half-circles such that the origin lies on \( \mathbb{R} \). It is straightforward to see that the diffeomorphisms of Proposition \( \text{[32.3]} \) define a bijection between the hyperbolic lines in \( \mathbb{D} \) and in \( \mathbb{H} \).

The corresponding statements for hyperbolic lines in \( \mathbb{H} \) are straightforward to prove. They can also be obtained from any textbook on hyperbolic geometry, see e.g. [And05] and [Bon09] Chapter 2. \[ \square \]
32.2. **Angles in Riemannian manifolds.** We continue our quick introduction to Riemannian manifolds and hyperbolic space with a short discussion of angles.

**Definition.**

1. Let \( g \) be a positive-definite symmetric form on a real vector space \( V \). Given two non-zero vectors \( v, w \in V \setminus \{0\} \) we define the angle between \( v \) and \( w \) as the unique \( \alpha \in [0, \pi] \) with \( g(v, w) = \cos(\alpha) \cdot \|v\| \cdot \|w\| \).

2. Given a Riemannian manifold \((M, g)\) and non-zero vectors \( v, w \in T_P M \) we use the form \( g_P \) to define the angle between \( v \) and \( w \).

**Examples.**

1. Let \( U \) be an open subset of \( \mathbb{R}^n \) and let \( f : U \to \mathbb{R}_{>0} \) be a smooth function. For any \( P \in U \) we can define a positive-definite symmetric form \( g_P \) on \( T_P U = \mathbb{R}^n \) via \( g_P(v, w) = f(P) \cdot \langle v, w \rangle \), where \( \langle , \rangle \) denotes the usual scalar product. A straightforward calculation shows that in this Riemannian structure the angle at any point is the usual Euclidean angle in \( \mathbb{R}^n \). This argument implies in particular to the Riemannian manifolds \( \mathbb{D} \) and \( \mathbb{H} \), in both cases the hyperbolic angle, defined by the hyperbolic Riemannian structure, is the same as the Euclidean angle.

2. A hyperbolic triangle is defined to be a compact subset of \( \mathbb{H} \) whose boundary is given by segments of three hyperbolic lines. One of the many elegant theorems in hyperbolic geometry, see [And05, Theorem 5.16], says that given such a hyperbolic triangle its angle sum equals \( \pi \) minus its “area”. Even without the definition of “area” it is pretty clear that this result implies that the angle sum of a hyperbolic triangle is always less than \( \pi \). This statement is illustrated in Figure 561.

![Figure 561](image)

The sum of the angles is less than \( \pi \)

The following lemma follows easily from the definitions and from Proposition 32.4 (2).

**Lemma 32.7.** *Local isometries, in particular Möbius transformations, preserve angles.*

**Definition.**

1. Let \( P \in \mathbb{D} \) and let \( g \) be a hyperbolic line through \( P \). Let \( Q \) be one of the two endpoints of \( g \). We refer to the set of points between \( P \) and \( Q \) as a *ray emanating from \( P \).*

2. Let \( P \in \mathbb{D} \) and let \( r, s \) be two rays emanating from \( P \). We refer to the angle between the tangent vectors of \( r \) and \( s \) at \( P \) as the *angle between the rays \( r \) and \( s \).*

---

\[ |g(v, w)| \leq \|v\| \cdot \|w\| \] by the Cauchy-Schwarz inequality, see [Zh11] p. 27.]
Examples.

(1) Given $\varphi \in [0, 2\pi)$ the set $S_\varphi := \{re^{i\varphi} | r \in [0, 1)\}$ is a ray emanating from 0.

(2) It follows from the above discussion of angles in $\mathbb{D}$, that given $\varphi, \theta \in [0, 2\pi)$ the angle between the two rays $S_\varphi$ and $S_\theta$ in $\mathbb{D}$ is the usual Euclidean angle.

**Lemma 32.8.** Let $r, s$ be two rays emanating from $P \in \mathbb{D}$ and let $r', s'$ be two rays emanating from $P' \in \mathbb{D}$. Then the following holds:

There is a Möbius transformation $\phi$ with $\phi(r \cup s) = r' \cup s'$ $\iff$ angle between $r, s = \text{angle between } r', s'$.

Furthermore, if such a Möbius transformation exists, then it is unique.

**Proof.** By Lemma 32.7 Möbius transformations preserve angles and by Proposition 32.4 Möbius transformations act transitively on $\mathbb{D}$. Therefore we can without loss of generality assume that $P = P' = 0$. The lemma follows from the observation, made on page 876, that Möbius transformations preserving 0 are precisely given by rotations around the origin. $\blacksquare$

### 32.3. The distance metric of a Riemannian manifold.

**Definition.** Let $(M, g)$ be a connected Riemannian manifold.

(1) Given $v \in T_PM$ we write $\|v\|_g = \sqrt{g_P(v, v)}$. If $g$ is understood from the context, then we just write $\|v\|$.

(2) Let $\gamma : [a, b] \to M$ be a piecewise smooth path. By definition we can pick a subdivision $a = s_0 < s_1 < \cdots < s_m = b$ such that for $i = 0, \ldots, m - 1$ the map $\gamma|_{[s_i, s_{i+1}]}$ is smooth. We define the length of $\gamma$ as

$$\ell_{(M,g)}(\gamma) := \sum_{i=0}^{m-1} \int_{t=s_i}^{t=s_{i+1}} \|\gamma'(t)\|_g \, dt.$$ 

If $(M, g)$ is understood from the context, then we write $\ell(\gamma)$ instead of $\ell_{(M,g)}(\gamma)$.

(3) Let $P$ and $Q$ be two points on $M$.

$$d_{(M,g)}(P,Q) := \inf \{\ell(\gamma) | \gamma \text{ is a smooth path in } M \text{ from } P \text{ to } Q\}.$$ 

If $(M, g)$ is understood from the context, then we just write $d(P, Q)$.

---

549 Recall that given a smooth path $\delta : [a, b] \to M$ and given any $t \in [a, b]$ the path defines, basically by definition of the tangent space $T_{\delta(t)} M$, an element in $T_{\delta(t)} M$. We denote this vector by $\delta'(t)$. 

We start our discussion of the distance function $d$ on Riemannian manifolds with the following somewhat technical proposition.

**Proposition 32.9.** Let $(M, g)$ be a connected Riemannian manifold. Then the following hold:

1. the pair $(M, d_{(M, g)})$ is a metric space,
2. the topology defined by the metric $d_{(M, g)}$ agrees with the topology of $M$,
3. given any $P \in M$ and given any open neighborhood $U$ of $P$ there exists an $r > 0$ such that

$$\mathcal{B}^{(M, g)}(P) := \{Q \in M \mid d_{(M, g)}(P, Q) < r\} \subset U.$$  

**Proof.** Let $(M, g)$ be a connected $n$-dimensional Riemannian manifold. We first show that $(M, d_{(M, g)})$ is a metric space.

It is clear that $d = d_{(M, g)}$ is symmetric. It follows easily from the definitions and the fact that the concatenation of two piecewise smooth paths is again piecewise smooth that $d$ satisfies the triangle inequality.

Now let $P \neq Q$ be two distinct points in $M$. We need to show that $d(P, Q) > 0$. Since $M$ is Hausdorff and since it is locally diffeomorphic to open subsets of $\mathbb{R}^n$ we can find a chart $\Phi: U \to B_{2r}(0)$ for $P$ with $\Phi(P) = 0$ and such that $Q \notin U$. We write $\Psi = \Phi^{-1}$.

Before we continue we introduce the following definitions:

1. We write $U_r = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| = r\})$ and given a subset $I \subset [0, 2r)$ we write $U_I = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| \in I\})$.
2. For a positive-definite bilinear form $h$ on $\mathbb{R}^n$ we set

$$\|h\| := \min \{\sqrt{h(v, v)} \mid v \in S^{n-1}\}.$$  

Note that $h$ is positive-definite, that $h: \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is continuous and that $S^{n-1}$ is compact. It follows from Lemma 2.40 that the minimum exists and that $\|h\| > 0$.

It is straightforward to see that for any $v \in \mathbb{R}^n$ we have

$$h(v, v) \geq \|h\| \cdot \|v\|_{\text{eucl}}.$$  

3. We set

$$C := \min \{\|(\Psi^*g)_P\| \mid P \in B_r(0)\}.$$  

Since $P \mapsto \|(\Psi^*g)_P\|$ is continuous and since $B_r(0)$ is compact it follows from Lemma 2.40 that $C > 0$.

**Claim.** Let $\gamma: [0, 1] \to M$ be a piecewise smooth path from $P$ to $Q$. There exists a $t \in [0, 1]$ with $\gamma(t) \in U_r$.

Suppose there is no $t \in (0, 1)$ with $\gamma(t) \in U_r$. We consider the sets $A = U_{(0, r)}$ and $B = M \setminus U_{[0, r)}$. The set $A$ is clearly open. Furthermore it follows from Lemma 6.10 that $U_{[0, r]}$ is closed, hence $B$ is open. Since $\gamma([0, 1]) \cap U_r = \emptyset$ we have $[0, 1] = \gamma^{-1}(A) \cup \gamma^{-1}(B)$. But both sets $\gamma^{-1}(A)$ and $\gamma^{-1}(B)$ are open by the continuity of $\gamma$ and both are non-empty since $0 \in \gamma^{-1}(A)$ and $1 \in \gamma^{-1}(B)$. But this contradicts the fact, established with some effort in Proposition 2.55 that $[0, 1]$ is connected. \[\Box\]

Now it suffices to prove the following claim.
Claim. Let $\gamma: [0, 1] \to M$ be a piecewise smooth path from $P$ to $Q$. Then $\ell_g(\gamma) \geq C \cdot r$.

Let $T := \inf\{t \in (0, 1) \mid \gamma(t) \in U_r\}$. By the above claim this definition makes sense since we take the infimum of a non-empty set. By Lemma 6.10 the set $U_r$ is a closed subset of $M$. Since $\gamma$ is continuous we also have $\gamma(T) \in U_r$. Now we have

$$
\ell_g(\gamma) \geq \ell_g(\gamma|_{[0,T]}) = \int_{t=0}^{t=T} \|\Phi \circ \gamma\|_{\text{eucl}} dt \\
\geq \int_{t=0}^{t=T} C \cdot \|\Phi \circ \gamma\|_{\text{eucl}} dt \\
\geq C \cdot \left\| \int_{t=0}^{t=T} (\Phi \circ \gamma)'(t) dt \right\|_{\text{eucl}}
$$

for any $v \in T_{\gamma(T)} B_r(0) = \mathbb{R}^n$ we have

$$
\|v\|_{(\Phi^* g)_T} \geq \left\| (\Phi^* g)_T \| \cdot \|v\|_{\text{eucl}} \\
= C \cdot \left\| (\Phi \circ \gamma)(T) - (\Phi \circ \gamma(0)) \right\|_{\text{eucl}} = C \cdot r.
$$

This concludes the proof of the claim and therefore the proof of statement (1) of the proposition.

Next we turn to the proof of statement (2). This means that we need to show that the topology defined by $d$ is the same as the original topology of $M$. The proof is again somewhat technical and uses ideas similar to the proof of (1). We refer to [Lee97, Lemma 6.2] for the proof.

Finally statement (3) is just an immediate consequence of the definitions and of statement (2).

Lemma 32.10. Let $(M, g)$ and $(N, h)$ be two connected Riemannian manifolds. Furthermore let $f: (M, g) \to (N, h)$ be a local isometry. Then the following hold:

1. For any piecewise smooth path $\gamma: [a, b] \to M$ we have
   $$
   \ell_{(N, h)}(f \circ \gamma) = \ell_{(M, g)}(\gamma).
   $$

2. For any $P, Q \in M$ we have
   $$
   d_{(N, h)}(f(P), f(Q)) \leq d_{(M, g)}(P, Q).
   $$

Proof. Let $f: (M, g) \to (N, h)$ be a local isometry. We start out with the following claim.

Claim.

1. For a smooth path $\gamma: [c, d] \to M$ and $t \in (c, d)$ we have $\|(f \circ \gamma)'(t)\|_{(N, h)} = \|\gamma'(t)\|_{(M, g)}$.
(2) For any piecewise smooth path $\gamma : [a, b] \to M$ we have $\ell_{(N,h)}(f \circ \gamma) = \ell_{(M,g)}(\gamma)$.

Now we provide the proof of the two statements.

(1) The first statement is an immediate consequence of the definitions and the hypothesis that $f$ is a local isometry.

(2) By the additivity of the lengths of piecewise smooth paths it suffices to consider the case that $\gamma : [a, b] \to M$ is a smooth path. But in that case the equality follows immediately from the definitions and from (1).

Now let $P$ and $Q$ be two points on $M$. For any piecewise smooth path $p$ in $M$ from $P$ to $Q$ we have

$$d_{(N,h)}(f(P), f(Q)) \leq \ell_{(N,h)}(f \circ p) = \ell_{(M,g)}(p).$$

It follows that the left-hand side is also less or equal than the infimum over all paths on the right-hand side. Thus $d_{(N,h)}(f(P), f(Q)) \leq d_{(M,g)}(P, Q)$.

32.4. The hyperbolic distance function. We start out with the following definition.

**Definition.** Let $(M, g)$ be a Riemannian manifold. A path $\gamma : [0, a] \to M$ is called a **geodesic** if the following conditions are satisfied:

1. $\gamma$ is smooth,
2. $\|\gamma'(t)\|_g = 1$ for every $t \in [0, a]$ and
3. $\ell(\gamma) = d_{(M,g)}(\gamma(0), \gamma(a))$.

The following proposition summarizes the key facts about the distance metric on $\mathbb{D}$.

**Proposition 32.11.**

1. Let $r \in (0, 1)$ and $\varphi \in \mathbb{R}$. In the Riemannian manifold $\mathbb{D}$ the path

$$\gamma : [0, r] \to \mathbb{D}, \quad t \mapsto te^{i\varphi}$$

is, up to reparametrization, the unique shortest path from $0$ to $re^{i\varphi}$.

2. We have

$$d_{(\mathbb{D},g)}(0, re^{i\varphi}) = \ell(\gamma) = \int_{t=0}^{t=r} \frac{\sqrt{2}}{1 - |\gamma(t)|^2} \|\gamma'(t)\|_{eucl} dt = \int_{t=0}^{t=r} \frac{\sqrt{2}}{1 - t^2} dt.$$

3. Given $\varphi \in \mathbb{R}$ we have

$$\lim_{r \to 1} d_{(\mathbb{D},g)}(0, re^{i\varphi}) = \infty.$$

4. Given any $P$ and $Q$ in $\mathbb{D}$ there is a unique geodesic from $P$ to $Q$.

**Proof.** The first statement can be deduced easily from [Bon09, Lemma 2.4 and Proposition 2.22]. The second statement follows immediately from the first statement, and the third statement is a straightforward consequence of the second statement. For the fourth statement, note that it suffices to prove it for $P = 0$. In that case it is a straightforward consequence of (1).
Lemma 32.12. Let \((P, Q)\) and \((S, T)\) be two pairs of distinct points on \(\mathbb{D}\) such that \(d(P, Q) = d(S, T)\). Then there exists a unique Möbius transformation \(\phi\) with \(\phi(P) = S\) and \(\phi(Q) = T\).

Example. Let \(r \in (0, 1), \varphi \in [0, 2\pi], \psi \in [0, 2\pi]\) and \(\gamma \in (0, \pi)\). We consider the pairs of points \(P = re^{i\varphi}, Q = re^{i(\varphi + \gamma)}\) and \(S = re^{i\psi}, T = re^{i(\psi - \gamma)}\). We then have
\[
d(S, T) = d(T, S) = d(re^{i(\psi - \gamma)}, re^{i\psi}) = d(re^{i\varphi}, re^{i(\varphi + \gamma)}).
\]

Since rotation by \(\varphi + \gamma - \psi\) is an isometry, by Lemma 32.12 there exists a Möbius transformation \(\phi\) with \(\phi(P) = S\) and \(\phi(Q) = T\). This Möbius transformation is illustrated in Figure 564. Recall that from Proposition 32.4 and Lemma 32.6 we know that Möbius transformations preserve hyperbolic lines and that they are orientation-preserving. In particular \(\phi\) sends the hyperbolic line through \(P\) and \(Q\) to the hyperbolic line through \(S\) and \(T\). Since \(\phi\) is orientation-preserving it “swaps” the two sides of the hyperbolic line. We refer to Figure 564 for an illustration.

![Figure 564](image)

Proof of Lemma 32.12. It follows from Proposition 32.4 (3) that, without loss of generality, we can assume that \(P = 0\) and \(S = 0\). We write \(Q = re^{i\varphi}\) and \(T = se^{i\psi}\). It is a direct consequence of Proposition 32.11 (1) and our hypothesis that
\[
d(0, re^{i\varphi}) = d(P, Q) = d(S, T) = d(0, se^{i\psi})
\]
that we have \(r = s\). But this means that we can apply the rotation by the angle \(\varphi - \psi\), which is a Möbius transformation, to turn \((P, Q)\) into \((S, T)\). This proves the existence of \(\phi\). The uniqueness follows from the observation, that we had made already on page 876 that the only Möbius transformations that fix 0 are precisely rotations.

Lemma 32.13. Let \(P \in \mathbb{D}\) and \(r > 0\). Let \(S, T \in B_r(P)\). Then the image of the unique geodesic in \(\mathbb{D}\) from \(S\) to \(T\) lies in \(B_r(P)\).

Proof. As usual, this time by Propositions 32.4, 32.6 and 32.11 it suffices to prove the lemma for \(P = 0\). In this special case the reader will have no troubles providing the elementary argument. We also refer to Figure 565 for an illustration.
32.5. **Complete metric spaces.** We conclude this chapter with a short discussion of complete metric spaces.

**Definition.**

(1) We say that a metric space \((X, d)\) is **complete** if every Cauchy sequence in \((X, d)\) converges.

(2) We say that a connected Riemannian manifold \((M, g)\) is **complete** if the corresponding metric space \((M, d_{(M, g)})\) is complete.

**Examples.**

(1) The metric space given by \(\mathbb{R}^n\) and the Euclidean metric is complete.

(2) The metric space given by the open ball \(B^m\) and the Euclidean metric is not complete.

Indeed the sequence \(a_n = 1 + \frac{1}{n}\) is a Cauchy sequence, but it does not converge in the open ball \(B^m\). Similarly we see that for example the metric space \(\mathbb{C} \setminus \{0, 1\}\) with the usual Euclidean metric is not complete.

The following proposition gives a useful criterion for a metric space to be complete.

**Proposition 32.14.** Every compact metric space is complete.

**Proof.** Let \((X, d)\) be a compact metric space and let \((a_n)_{n \in \mathbb{N}}\) be a Cauchy sequence in \((X, d)\). We want to show that the sequence converges, i.e. we want to show that

\[
\exists x \in X \quad \forall \epsilon > 0 \quad \exists N \in \mathbb{N} \quad \forall n \geq N \quad d(a_n, x) < \epsilon.
\]

Let us assume that no such \(x\) exists. Thus we negate the above statement and we obtain that

\[
\forall x \in X \quad \exists \epsilon > 0 \quad \forall N \in \mathbb{N} \quad \exists n \geq N \quad d(a_n, x) \geq \epsilon.
\]

Given \(x \in X\) we pick \(\epsilon_x > 0\) as above and we write

\[
U_x := B_{\epsilon_x}(x) \quad \text{and} \quad V_x := B_{\epsilon_x/2}(x).
\]

Note each \(U_x\) has the property that it does not contain all but finitely many of the \(a_n\).

The family of open sets \(\{V_x\}_{x \in X}\) covers \(X\). Since \(X\) is compact there exist \(x_1, \ldots, x_k\) such that \(X = V_{x_1} \cup \cdots \cup V_{x_k}\). Now let \(\epsilon := \frac{1}{2} \min\{\epsilon_{x_1}, \ldots, \epsilon_{x_k}\}\). For this \(\epsilon > 0\) we pick \(N \in \mathbb{N}\) as in the definition of a Cauchy sequence. This means in particular that for all \(m \geq N\) we have \(d(a_N, a_m) < \epsilon\).

Since \(X = V_{x_1} \cup \cdots \cup V_{x_k}\) there exists an \(i \in \{1, \ldots, k\}\) with \(a_N \in V_{x_i}\). It suffices to prove the following claim to obtain the desired contradiction.

**Claim.** For any \(m \geq N\) we have \(a_m \in U_x\).
Let \( m \geq N \). We see that
\[
d(x_i, a_m) \leq d(x_i, a_N) + d(a_N, a_m) < \frac{1}{2} \epsilon_{x_i} + \epsilon \leq \frac{1}{2} \epsilon_{x_i} + \frac{1}{2} \epsilon_{x_i} = \epsilon_{x_i}.
\]
This implies that \( a_m \in B_{\epsilon_{x_i}}(x_i) = U_{x_i} \).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{proof.png}
\caption{Illustration of the proof of Proposition 32.14}
\end{figure}

The Riemannian manifolds \( \mathbb{D} \) and \( \mathbb{H} \) are of course not compact, but nonetheless, as we will now see, we can use Proposition 32.14 to show that \( \mathbb{D} \) and \( \mathbb{H} \) are complete.

**Lemma 32.15.** The Riemannian manifolds \( \mathbb{D} \) and \( \mathbb{H} \) are complete.

**Proof.** By Proposition 32.3 the two Riemannian manifolds \( \mathbb{D} \) and \( \mathbb{H} \) are isometric. Therefore it suffices to show that \( \mathbb{D} \) is complete. We denote by \( d = d_{(\mathbb{D}, g)} \) the metric on \( \mathbb{D} \) corresponding to the Riemannian structure. Let \( \{a_n\}_{n \in \mathbb{N}} \) be a Cauchy sequence with respect to \( d \). An elementary argument using the triangle inequality and the definition of a Cauchy sequence shows that there exists a \( C \in \mathbb{R} \) such that \( d(0, a_n) \leq C \) for all \( n \in \mathbb{N} \).

It follows from Proposition 32.11 that there exists an \( r \in (0, 1) \) such that all \( a_n \) are contained in the closed Euclidean ball \( B^{\text{eul}}_r(0) \). By the Heine-Borel Theorem 2.20 this ball is a compact subset of \( \mathbb{R}^2 \), viewed with the usual topology. It follows from Proposition 32.9 that \( B^{\text{eul}}_r(0) \) is also compact in the topology defined by \( d \). Now we see that \( \{a_n\}_{n \in \mathbb{N}} \) is a Cauchy sequence in the compact metric space \( (B^{\text{eul}}_r(0), d) \). It follows from Proposition 32.14 that the sequence converges.

---

**Exercises for Chapter 32**

**Exercise 32.1.** Does the smooth manifold \( B^2 \setminus \{0\} \) admit a complete Riemannian metric?
33. The universal covering of surfaces

Throughout this chapter we mean by a surface a connected 2-dimensional smooth manifold. For example the surface of genus \( g \), \( g \geq 0 \), but also \( \mathbb{C}, \mathbb{C} \setminus \{0, 1\} \) and the result of removing finitely many points from \( \Sigma_g \) are surfaces.

**Definition.** Let \( M \) be a surface. We say that a Riemannian structure \( g \) on \( M \) is hyperbolic if the following two conditions are satisfied:

1. \((M, g)\) is locally isometric to \( \mathbb{D} \), i.e. if given any \( P \in M \) there exists an isometry \( \Phi: U \to V \) from an open neighborhood \( U \) of \( P \) to an open subset \( V \) of \( \mathbb{D} \),
2. \((M, g)\) is complete.

If \( g \) is hyperbolic, then we refer to \((M, g)\) as a hyperbolic surface.

**Remark.** By Proposition 32.14 the condition (2) of the definition is automatically satisfied if \( M \) is a closed surface.

In this chapter we will pursue the following three goals:

1. we want to show that for any \( g \geq 2 \) the surface of genus \( g \) is a complex manifold,
2. we intend to prove that for any \( g \geq 2 \) the surface of genus \( g \) is hyperbolic,
3. given \( g \geq 2 \) we want to determine the universal covering of the surface of genus \( g \).

33.1. **Hyperbolic surfaces.** In this section we will show that the surfaces of genus \( \geq 2 \) are complex manifolds and that they are hyperbolic. In the subsequent subsection we will then consider more general types of surfaces.

**Definition.** Let \( M \) be a 2-dimensional topological manifold without boundary. A Möbius structure for \( M \) is a family of homeomorphisms \( \{\Phi_i: U_i \to V_i\}_{i \in I} \) from open subsets of \( M \) to open subsets of \( \mathbb{D} \) such that \( \bigcup_{i \in I} U_i = M \) and such that for any \( i, j \in I \) the transition map

\[
\Phi_i(U_i \cap U_j) \xrightarrow{\Phi_i|_{U_i \cap U_j}^{-1}} U_i \cap U_j \xrightarrow{\Phi_j|_{U_i \cap U_j}} \Phi_j(U_i \cap U_j)
\]

is given by a Möbius transformation. Sometimes we refer to a smooth manifold together with a Möbius structure as a Möbius manifold.

**Example.**

1. We will always view \( \mathbb{D} \) as equipped with the Möbius structure that is given by the chart \( \text{id}: \mathbb{D} \to \mathbb{D} \).
2. Any open subset of a Möbius manifold is also a Möbius manifold.

The following lemma says that Möbius structures are useful for solving two problems at once: we can use them to show that a smooth manifold is a complex manifold and we can use them to show that a smooth manifold has a hyperbolic structure.
Lemma 33.1. Let $M$ be a surface and let $\{\Phi_i: U_i \to V_i\}_{i \in I}$ be a Möbius structure for $M$. Then the following hold:

1. The charts form a holomorphic atlas for $M$, in particular $M$ is a complex 1-dimensional smooth manifold.

2. (a) The smooth manifold $M$ admits a unique Riemannian structure $g$ such that all the charts in the atlas $\{\Phi_i: U_i \to V_i\}_{i \in I}$ are isometries.

   (b) If the Riemannian structure from (a) is complete, then $(M, g)$ is hyperbolic.

In the following we will always view a Möbius manifold as a 1-dimensional complex manifold and as a Riemannian manifold with the structures coming from Lemma 33.1.

Proof. Let $M$ be a surface and let $\{\Phi_i: U_i \to V_i\}_{i \in I}$ be a Möbius structure for $M$.

1. The first statement is an immediate consequence of the definitions and of the fact, proved in Proposition 32.4 (2), that Möbius transformations are biholomorphisms.

2. (a) We denote by $g$ the Riemannian structure on $D$. We define a Riemannian structure on $M$ as follows. Let $P \in M$. We pick a chart $\Phi_i: U_i \to V_i$ from our Möbius structure and we define $h_P := \Phi_i^*(g_{\Phi_i(P)})$. Now suppose that we had picked a different chart $\Phi_j$ from the Möbius structure. The transition map from $\Phi_i$ to $\Phi_j$ is by definition a Möbius transformation, which is an isometry by Proposition 32.4 (2). It follows easily that $\Phi_j$ gives rise to the same definition of $h_P$. It is now straightforward to verify that this defines a Riemannian structure on $M$ and that it has the desired properties.

   (b) This statement is an immediate consequence of (a) and of the definition of a hyperbolic surface.

The following proposition gives in particular an affirmative answer to Question 12.10.

Proposition 33.2. Let $g \geq 2$. Then the following hold:

1. The surface of genus $g$ admits a Möbius structure.

2. The surface of genus $g$ admits the structure of a 1-dimensional complex manifold.

3. The surface of genus $g$ admits a hyperbolic Riemannian structure.

Proof. We prove the proposition for the case that $g = 2$. The general case is proved by almost the same argument.

We first show that the surface of genus 2 admits a Möbius structure. By [Bon09, Lemma 5.3] (see also [Frie16a, Lemma 21.5]) there exists an $r > 0$ such that the interior angle at any vertex of the hyperbolic octagon $H_8$ in $D$, defined by $Q_k = r e^{2\pi ik/16}$, $k = 1, 3, \ldots, 15$, equals $\frac{\pi}{4}$. This hyperbolic octagon is illustrated in Figure 567.

Let $k \in \{0, 1, 4, 5\}$. By Lemma 32.12 and the example on page 884 there exists a unique Möbius transformation $\Phi_k$ with $\Phi_k(Q_{2k-1}) = Q_{2k+5}$ and $\Phi_k(Q_{2k+1}) = Q_{2k+3}$. The Möbius transformations $\Phi_0$ and $\Phi_1$ are illustrated in Figure 568.

---

550 Here is a sketch for the proof: For $r \to 0$ the interior angle converges to the interior angle of a Euclidean regular octagon, namely $\frac{\pi}{4}$, whereas for $r \to \infty$ the interior angle converges to 0. The interior angle changes continuously with $r$ (that is sort of clear, except that it is somewhat painful to provide a rigorous proof), so by the Intermediate Value Theorem there exists an $r$ such that the interior angle equals $\frac{\pi}{4}$.
Given $k \in \{0, 1, 4, 5\}$ we declare any point $P$ on the edge connecting $Q_{2k-1}$ and $Q_{2k+1}$ to be equivalent to $\Phi_k(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences. It is straightforward to see that $H_8/\sim$ is homeomorphic to the surface of genus 2 that we defined on page 205 as $E_8/\sim$. In the following we denote by $p: H_8 \to H_8/\sim$ the obvious projection map.

Now we will give an explicit Möbius structure for $H_8/\sim$. More precisely, given any $P \in H_8/\sim$ we will give a chart $\psi_P$ such that the transitions maps are given by Möbius transformations. So let $P \in H_8/\sim$.

1. If $P = p(z)$ for some $z \in \hat{H}_8$, then the map

$$\psi_P: p(\hat{H}_8) \to \hat{H}_8$$

$$p(w) \mapsto w$$
is a chart around \( P = p(z) \).

(2) Now suppose that \( P = p(z) \) where \( z \) lies in the interior of one of the eight edges of \( \partial H_8 \). In the following we deal with the case that \( z \) lies on the edge from \( Q_{-1} \) to \( Q_1 \). We pick an \( r > 0 \) such that \( B_{2r}(z) \) does not contain any of the vertices \( Q_1, Q_3, \ldots, Q_{15} \) and does not hit any of the other edges. Then we consider the map

\[
\psi_P: p(B_r(z) \cap H_8) \cup p(\Phi_0(B_r(z)) \cap H_8) \to B_r(z)
\]

\[
p(w) \mapsto \begin{cases} w, & \text{if } w \in B_r(z) \cap H_8 \\ \Phi_0^{-1}(w), & \text{if } w \in \Phi_0(B_r(z)) \cap H_8. \end{cases}
\]

This map is a chart around \( P = p(z) \). We refer to Figure 570 for an illustration of the definition of the map \( \psi_P \).

(3) Finally suppose that \( P = p(Q_1) = \cdots = p(Q_{15}) \). We choose \( r \in (0, \frac{1}{2}d(Q_{-1}, Q_1)) \).

Given \( k \in \{1, 3, \ldots, 15\} \) we define \( \gamma(k) \) via the following table:

<table>
<thead>
<tr>
<th>( k )</th>
<th>1</th>
<th>3</th>
<th>5</th>
<th>7</th>
<th>9</th>
<th>11</th>
<th>13</th>
<th>15</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \gamma(k) )</td>
<td>( \frac{3}{4}\pi )</td>
<td>( \frac{\pi}{4}\pi )</td>
<td>( \frac{5}{4}\pi )</td>
<td>( \frac{1}{2}\pi )</td>
<td>( \frac{7}{4}\pi )</td>
<td>0</td>
<td>( \frac{1}{4}\pi )</td>
<td>( \frac{3}{2}\pi ).</td>
</tr>
</tbody>
</table>

Recall that we had chosen the octagon \( H_8 \) such that the angle at any vertex equals \( \frac{\pi}{4} \).

For \( k = 1, 3, \ldots, 15 \) we can therefore apply Lemma 32.8 to find a unique Möbius transformation \( \theta_k \) with the following two properties:

(a) \( \theta_k(Q_k) = 0 \),

(b) The map \( \theta_k \) applied to the two rays emanating from \( Q_k \) equals the two rays \( \{se^{i\gamma(k)} \mid s \geq 0\} \) and \( \{se^{i(\gamma(k)+\frac{\pi}{2})} \mid s \geq 0\} \) emanating from 0.

We consider the map

\[
\psi_P: p(B_r(Q_1) \cap H_8) \cup \cdots \cup p(B_r(Q_{15}) \cap H_8) \to B_r(0)
\]

\[
p(z) \mapsto \theta_k(z), \quad \text{if } z \in B_r(Q_k) \cap H_8.
\]

We leave it to the reader to verify that \( \psi_P \) is well-defined and that it is indeed a homeomorphism. This map is a chart around \( P = p(z) \). We refer to Figure 571 for an illustration of the definition of the map \( \psi_P \).

It is straightforward to verify that all the transition maps between the above maps are given by Möbius transformations. We have thus shown that the maps \( \{\psi_P\}_{P \in H_8} \) form a Möbius structure for \( H_8/\sim \). This concludes the proof of (1).
Now we turn to the proof of (2). The existence of a Möbius structure together with Lemma 33.1 (2) shows immediately that the surface of genus 2 is a 1-dimensional complex manifold.

Finally we provide the proof of (3). In light of (1) and Lemma 33.1 (2) it suffices to show that the Riemannian manifold \((H_8/\sim, g)\) is complete. By Proposition 32.9 the topology on \(M\) defined by the metric \(d_{(M,g)}\) agrees with the given topology of \(M\). Since \(M\) is compact it now follows from Proposition 32.14 that \((M, g)\) is complete.

33.2. More hyperbolic structures on the surfaces of genus \(g \geq 2\) (*). Now we want to study the question, how many hyperbolic metrics does a surface of genus \(g\) admit. To make this question more precise, we introduce the following definition.

**Definition.** Let \(M\) be a surface of genus \(g \geq 2\) and let \(h, h'\) be two hyperbolic metrics on \(M\). We say \(h\) and \(h'\) are *equivalent* if there exists an isometry from \((M, h)\) to \((M, h')\).

This raises the question, whether a surface of genus \(g \geq 2\) admits non-equivalent hyperbolic metrics. We return to the construction of a hyperbolic metric in Proposition 33.2. In our construction we started out with a regular \(4g\)-gon with interior angle \(\frac{2\pi}{4g}\) and we identified pairs of sides. Two facts were crucial to obtain a hyperbolic metric:

1. the sides were identified via an isometry,
2. the sum of the interior angles equals \(2\pi\).

Or put differently, any choice of a \(4g\)-gon with side lengths \(k_1, \ldots, k_{4g}\) and interior angles \(\alpha_1, \ldots, \alpha_{4g}\) that satisfy the equations

\[ k_1 = k_3, \quad k_2 = k_4, \quad \ldots, \quad k_{4g-3} = k_{4g-1}, \quad k_{4g-2} = k_{4g} \quad \text{and} \quad \alpha_1 + \cdots + \alpha_{4g} = 2\pi \]

gives rise to a hyperbolic metric on a topological space that is homeomorphic to the surface of genus \(g\). It is of course not clear whether different parameters give rise to non-equivalent hyperbolic structures. One way to distinguish them, in principle at least, is to look at the shortest length of a closed curve that is not null-homotopic. We will not elaborate on this procedure.

How many such \(4g\)-gons are there? On the one hand we have parameters \(k_1, k_3, \ldots, k_{4g-1}\) and \(\alpha_1, \ldots, \alpha_{4g}\). On the other hand we have the condition that \(\alpha_1 + \cdots + \alpha_{4g} = 2\pi\). Furthermore we want a \(4g\)-gon, so the last angle and the length of the last edge are determined by the others. Thus we obtain two other conditions. Summarizing we have \(2g + 4g = 6g\) parameters that need to satisfy 3 conditions. Of course it is not clear which of these
Riemannian structures are isometric. This naive discussion suggests that the space of hyperbolic metrics is \((6g - 3)\)-dimensional. Surprisingly this is not too far off the correct answer, in fact in [BP92, Chapter B.4] the following proposition is proved.

**Proposition 33.3.** The space of hyperbolic metrics on a surface of genus \(g \geq 2\) can be viewed as a smooth manifold of dimension \(6g - 6\).

We will not make use of this proposition. The space of hyperbolic metric is called the *Teichmüller space*, more information can be found at

[https://en.wikipedia.org/wiki/Teichmueller_space](https://en.wikipedia.org/wiki/Teichmueller_space)

The theory is named after Oswald Teichmüller (1913-1943) who was a brilliant mathematician and an ardent Nazi, see

and

[http://www-history.mcs.st-andrews.ac.uk/Biographies/Teichmuller.html](http://www-history.mcs.st-andrews.ac.uk/Biographies/Teichmuller.html)

### 33.3. More examples of hyperbolic surfaces.
In this section we will generalize the discussion from the previous section to surfaces that are non-compact.

In the following let \(Q_1 = 1, Q_2 = i, Q_3 = -1\) and \(Q_0 = Q_4 = -i\). We denote by \(H_4\) the closed, non-compact subset of \(\mathbb{D}\) that is bounded by the four hyperbolic lines with endpoints \(Q_k, Q_{k+1}\) where \(k = 0, 1, 2, 3\). We refer to Figure 374 for an illustration.

We consider the Möbius transformations\(^{551}\)

\[
\Phi_1(z) := (-i) \cdot \frac{z - \frac{-1+i}{2}}{1 - \frac{-1-i}{2}z} \quad \text{and} \quad \Phi_2(z) := (-i) \cdot \frac{z + \frac{-1-i}{2}}{1 + \frac{-1+i}{2}z}.
\]

We record a few key properties of \(\Phi_1\) and \(\Phi_2\) in a lemma.

**Lemma 33.4.**

---

\(^{551}\)Recall that a Möbius transformation of \(\mathbb{D}\) is a map of the form \(\psi(z) = e^{i\theta} \cdot \frac{z-a}{1-\overline{a}z}\) for some \(\theta \in \mathbb{R}\) and \(a \in \mathbb{D}\).
33. THE UNIVERSAL COVERING OF SURFACES

(1) We have $\Phi_1(Q_2) = Q_4$ and $\Phi_1(Q_3) = Q_3$ and we also have $\Phi_2(Q_2) = Q_4$ and $\Phi_1(Q_1) = Q_1$.

(2) The restriction of $\Phi_1$ to the hyperbolic line with endpoints $Q_3$ and $Q_2$ is given by reflection in the $x$-axis.\(^{552}\)

(3) The restriction of $\Phi_2$ to the hyperbolic line with endpoints $Q_1$ and $Q_2$ is given by reflection in the $x$-axis.

**Proof.** The first statement follows immediately from plugging in the points. A straightforward, albeit slightly painful calculation shows that for any $\alpha \in \mathbb{R}$ we have

$$\Phi_1(-1 + i + e^{-i\alpha}) = -1 - i + e^{i\alpha}.$$ 

This proves the second statement. The third statement is proved by a similarly tedious calculation. \( \blacksquare \)

**Remark.** We consider the Möbius transformation $\Phi_1$ in more detail. It sends the hyperbolic line with endpoints $Q_3$ and $Q_2$ to the hyperbolic line with endpoints $Q_3$ and $Q_4$. In particular it sends the two halves determined by the hyperbolic lines to one another. Which half gets sent to which half is determined by the fact that $\Phi_1$ is orientation-preserving. We refer to Figure 573 for an illustration of the Möbius transformations $\Phi_1$ and $\Phi_2$.

![Figure 573](image)

Given $k \in \{1, 2\}$ we declare any point $P$ on the line with the endpoints $Q_k$ and $Q_{k+1}$ to be equivalent to $\Phi_{3-k}(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences.

**Proposition 33.5.**

1. The topological space $H_4/\sim$ admits a Möbius structure. In particular it is a 1-dimensional complex manifold.

2. The Riemannian structure on $H_4/\sim$ coming from (1) and Lemma 33.1 is complete.

3. The topological space $H_4/\sim$ admits a hyperbolic metric.

**Proof.** We start out with the proof of (1). We have to show that $H_4/\sim$ admits a Möbius structure. The following argument is almost identical to the proof of Proposition 33.2 (1).

---

\(^{552}\)The Möbius transformation $\Phi_1$ sends the hyperbolic line with endpoints $Q_3$ and $Q_2$ to the hyperbolic line with endpoints $Q_3$ and $Q_4$. There are many such Möbius transformations, but the Möbius transformation we picked has the extra property, that on the hyperbolic line it is the “obvious map”. 
We denote by \( p : H_4 \to H_4 / \sim \) the projection map. In the following let \( P \in H_4 / \sim \).

1. If \( P = p(z) \) for some \( z \in \hat{H}_4 \), then
   \[
   \psi_P : p(\hat{H}_4) \to \hat{H}_4 \\
p(w) \mapsto w
   \]
   is a chart around \( P = p(z) \).

2. Now suppose that \( P = p(z) \) where \( z \) lies on \( \partial H_4 \). In the following we deal with the case that \( z \) lies on the edge from \( Q_1 \) to \( Q_2 \). All other cases are dealt with almost the same way. We pick an \( r > 0 \) such that \( B_{2r}(z) \) intersects no other component of \( \partial H_4 \).

We consider the map
   \[
   \psi_P : p(B_r(z) \cap H_4) \cup p(\Phi_2(B_r(z)) \cap H_4) \to B_r(z) \\
p(w) \mapsto \begin{cases} 
   w, & \text{if } w \in B_r(z) \cap H_4 \\
   \Phi_2^{-1}(w), & \text{if } w \in \Phi_1^{-1}(B_r(z)) \cap H_4.
\end{cases}
   \]
   This map is a chart around \( P = p(z) \).

The charts that we just constructed form an atlas for \( H_4 / \sim \). It follows immediately from the definitions that all transition maps are given by Möbius transformations. It follows that the maps \( \psi_P \) form a Möbius structure for \( H_4 / \sim \). As in the proof of Proposition 33.2 it follows that \( H_4 / \sim \) is a 1-dimensional complex manifold and that these charts satisfy the conditions of Lemma 33.1. This concludes the proof of (1).

We continue with the proof of (2). We have to show that the Riemannian structure on \( H_4 / \sim \) coming from (1) and Lemma 33.1 is complete. The subsequent argument is a variation on the proof of Proposition 32.14.

We denote by \( d \) the metric corresponding to the Riemannian structure on \( H_4 / \sim \). Let \( \{a_n\}_{n \in \mathbb{N}} \) be a Cauchy sequence in \( H_4 / \sim \) with respect to \( d \). As in the proof of Proposition 32.14 we see that there exists a \( C \in \mathbb{R} \) such that \( d(0, a_n) \leq C \) for all \( n \in \mathbb{N} \).

**Claim.** There exists an \( r \in [0, 1) \) such that for any \( z \in H_4 \) with \( d(0, p(z)) \leq C \) we have \( |z| \leq r \).
33. THE UNIVERSAL COVERING OF SURFACES

Given $s \in [0, 1)$ we define

$$g(s) := \int_{t=0}^{t=s} \frac{\sqrt{2}}{1-t^2} \, dt.$$ 

Clearly we have $\lim_{s \to 1} g(s) = \infty$. In particular there exists an $r \in [0, 1)$ such that $g(s) > C + 1$ for all $s \geq \frac{1}{2}r$.

We claim that $r$ has the desired property. So let $z = x + iy \in H_4$ with $|z| > r$. Since $H_4$ is a subset of the square spanned by $\pm 1$ and $\pm i$ we see that we have $|z| \leq |x| + |y|$. Put differently, we have $|x| \geq \frac{1}{2}r$ or $|y| \geq \frac{1}{2}r$. Without loss of generality we can assume that $|x| \geq \frac{1}{2}r$.

We need to show that $d(0, p(z)) \geq C + 1$. It suffices to show that for any piecewise smooth path $\gamma: [0, a] \to H_4/\sim$ with $\gamma(0) = 0$ and $\gamma(a) = p(z)$ we have $\ell(\gamma) \geq C + 1$.

We denote by

$$q: H_4/\sim \to (-1, 1)$$

the projection onto the real part. It follows from Lemma [33.4] that this map is indeed well-defined. A straightforward calculation shows that for all $t \in [0, a]$ we have

$$\|\gamma'(t)\|_{H_4/\sim} \geq \|(q \circ \gamma)'(t)\|_D.$$ 

It follows that

$$\ell(\gamma) = \int_0^a \|\gamma'(t)\|_{H_4/\sim} \, dt \geq \int_0^a \|(q \circ \gamma)'(t)\|_D \, dt \geq d_{(\mathbb{D}, g)}(0, q(\gamma(a))) = g(|x|) \geq C + 1.$$ 

By the above claim the sequence $\{a_n\}_{n \in \mathbb{N}}$ lies in the compact set $p(\{z \in H_4 \mid |z| \leq r\})$. But by Proposition [32.11] the metric space $p(\{z \in H_4 \mid |z| \leq r\})$ is complete, so the sequence $\{a_n\}_{n \in \mathbb{N}}$ converges in $p(\{z \in H_4 \mid |z| \leq r\})$, in particular it converges in $p(H_4) = H_4/\sim$. Thus we have proved that $H_4/\sim$ is complete. This concludes the proof of (2).

Finally statement (3) is an immediate consequence of the definition of a hyperbolic metric and of statement (2).

We had just seen in Proposition [33.5] that $H_4/\sim$ admits a Möbius structure, in particular it is a 1-dimensional complex manifold. It is relatively straightforward to show that $H_4/\sim$ is homeomorphic to the sphere minus three points, or equivalently, to $\mathbb{C}$ minus two points. Now we show the much stronger statement that $H_4/\sim$ is actually biholomorphic to $\mathbb{C} \setminus \{0, 1\}$.

**Proposition 33.6.** There exists a biholomorphism $H_4/\sim \to \mathbb{C} \setminus \{0, 1\}$.

**Remark.** We equip $H_4/\sim$ with the Riemannian metric $g$ coming from the Möbius structure and we equip $\mathbb{C} \setminus \{0, 1\}$ with the usual Euclidean Riemannian metric that we denote by $h$. 
By Proposition 33.5 the metric space \((H_4/\sim, g)\) is complete whereas \((\mathbb{C} \setminus \{0, 1\}, h)\) is evidently not complete. Thus we see that the biholomorphism \(H_4/\sim \to \mathbb{C} \setminus \{0, 1\}\) from Proposition 33.6 is not an isometry.

Sphere minus three points

\[
\begin{array}{c}
\text{neighbourhoods of the points we removed} \\
\text{in hyperbolic geometry the neighbourhoods become infinitely long open annuli, called cusps}
\end{array}
\]

**Figure 575**

**Proof of Proposition 33.6.** We denote by \(\Delta\) the open subset of \(\mathbb{D}\) bounded by the three hyperbolic lines with endpoints \(-1, 1\) and \(i\). (We refer to Figure 576 for an illustration of \(\Delta\).) It follows from applying the Riemann Mapping Theorem 12.11 together with Carathéodory’s Theorem 12.12 that there exists a biholomorphism \(\Psi: \Delta \to \mathbb{D}\) that extends to a homeomorphism \(\Psi: \overline{\Delta} \to \overline{\mathbb{D}}\). We combine \(\Psi\) with the biholomorphism from \(\mathbb{D}\) to \(\mathbb{H}\) coming from Proposition 32.3. This way we obtain a biholomorphism \(\Phi: \Delta \to \mathbb{H}\) that extends to a homeomorphism \(\Phi: \overline{\Delta} \to \mathbb{H}\).

Using Lemma 32.5 we can, if necessary, compose \(\Phi\) with a Möbius transformation of \(\mathbb{H}\), to arrange that \(\Phi(i) = \infty\) and that \(\Phi(\{-1, 1\}) = \{0, 1\}\).

Note that \(\Phi\) restricts to a homeomorphism \(\Phi: \partial \Delta \to \partial \mathbb{H} = \mathbb{R} \cup \{\infty\}\). By the above we have \(\Phi(\partial \Delta) = \mathbb{R} \setminus \{0, 1\}\). Now we consider the map

\[
\Psi: H_4 \to \mathbb{C} \setminus \{0, 1\}, \\
z \mapsto \begin{cases} 
\Phi(z), & \text{if } z \in \Delta, \\
\overline{\Phi(z)}, & \text{if } \overline{z} \in \Delta,
\end{cases}
\]

Note that by the above we have \(f((-1, 1)) = (0, 1)\). Thus it follows from the Schwarz Reflection Principle, see Proposition 12.3, that the restriction of \(\Psi\) to the interior of \(H_4\) is holomorphic. It follows from Lemma 33.4 that if \(P\) and \(Q\) are two equivalent points on \(\partial H_4\), then \(\Psi(P) = \Psi(Q)\). Therefore the map \(\Psi\) factors through a map \(H_4/\sim \to \mathbb{C} \setminus \{0, 1\}\). Using once again the Schwarz Reflection Principle one can show that this map is in fact a biholomorphism. We leave the verification of this step to the reader. ■

**Definition.** Given \(g \in \mathbb{N}_0\) and \(n \in \mathbb{N}_0\) we now denote by \(F_{g,n}\) the surface that is obtained from the surface of genus \(g\) by removing \(n\) points. We refer to \(F_{g,n}\) as the \(n\)-punctured surface of genus \(g\).

For example the three-punctured sphere \(F_{0,3}\) is the sphere with three points removed. As we pointed out above, \(F_{0,3}\) is diffeomorphic to \(\mathbb{C} \setminus \{0, 1\}\). In particular, as we have just seen, the three-punctured sphere admits a hyperbolic structure. The following theorem says that “most” surfaces admit a hyperbolic structure.
Theorem 33.7. Let \( g \in \mathbb{N}_0 \) and let \( n \in \mathbb{N}_0 \). If \( 2g + n - 2 > 0 \), then \( F_{g,n} \) admits a hyperbolic structure.

Sketch of a proof. Let \( g \in \mathbb{N}_0 \) and let \( n \in \mathbb{N}_0 \). If \( 2g + n - 2 > 0 \) then variations on the argument of Propositions 33.2 and 33.5 show that \( F_{g,n} \) admits a hyperbolic metric. In Figure 577 we sketch the constructions needed to show that the once-punctured and the twice-punctured torus have a Möbius structure. The proof that the corresponding Riemannian manifolds are complete is similar to the proof of Proposition 33.5.

Definition. Let \( f : M \to N \) be a map between two Möbius manifolds.

1. We say that \( f \) is a Möbius map if for every two chart \( \Phi : U \to V \) in the Möbius structure of \( M \) and any chart \( \Psi : X \to Y \) in the Möbius structure of \( N \) the restriction of the map

\[
\Phi(U \cap f^{-1}(X)) \xrightarrow{\psi \circ f \circ \Phi^{-1}} \Psi(X \cap f(U))
\]

to any component of \( \Phi(U \cap f^{-1}(X)) \) is given by a Möbius transformation.

2. We say that \( f \) is a Möbius isomorphism, if \( f \) is a Möbius map, if \( f \) is a bijection, and if \( f^{-1} \) is also a Möbius map.

Figure 577
The following lemma is an immediate consequence of the definitions and the fact, proved in Proposition 32.4, that Möbius transformations are biholomorphisms and isometries.

**Lemma 33.8.** Let $M$ and $N$ be two Möbius manifolds and let $f: M \to N$ be a Möbius map. Then the following two statements hold:

1. the map $f$ is a local biholomorphism,
2. the map $f$ is a local isometry.

The following theorem is the main result of this chapter.

**Theorem 33.9. (Hadamard’s Theorem)** Let $g \geq 2$, and let $M = H_{4g}/\sim$ be the surface of genus $g$ with the Möbius structure constructed in Proposition 33.2. Then there exists a covering map $p: \mathbb{D} \to M$ with the following properties:

1. $p$ is a Möbius map,
2. $p$ is a local isometry,
3. $p$ is a local biholomorphism.

The hyperbolic disk $\mathbb{D}$ is of course simply connected. The theorem thus says that for any $g \geq 2$ the hyperbolic disk $\mathbb{D}$ is the universal covering of the surface of genus $g$. Thus we have now answered Question 29.10.

The proof of Theorem 33.9 will require the following two sections.

33.5. **Proof of Theorem 33.9 I.** In this section we will lay the technical foundations for the proof of Theorem 33.9.

In the following lemma we first summarize a few properties of Möbius maps.

**Lemma 33.10.**

1. If $U \subset \mathbb{D}$ is a connected subset and if $f: U \to \mathbb{D}$ is a Möbius map, then $f$ is given by a Möbius transformation.
2. Let $f: M \to N$ be a map between two Möbius manifolds. If $f$ is locally a Möbius map, then $f$ is a Möbius map.
3. The composition of two Möbius maps is again a Möbius map.
4. A bijective Möbius map is a Möbius isomorphism.

**Proof.**

1. Let $U \subset \mathbb{D}$ be a connected subset and let $f: U \to \mathbb{D}$ be a Möbius map. It follows from Proposition 32.4 (4) that given $P \in U$ there exists a unique Möbius transformation $\phi_P$ such that $f = \phi_P$ in an open neighborhood of $P$. We consider the map

$$
\phi: U \to \text{set of all Möbius transformations} \\
P \mapsto \phi_P.
$$

We equip the right-hand side of the map $\phi$ with the discrete topology. It follows from the definitions that this map is continuous. But then it follows from Lemma 2.61 that this map is constant. But that is exactly what we had tried to show.

2. This statement follows immediately from (1) and the definitions.
(3) This statement is an immediate consequence of definitions and the fact, proved in Proposition 32.4, that the compositions of two Möbius transformations is again a Möbius transformation.

(4) Let $f: M \to N$ be a bijective Möbius map. In Proposition 32.4 we saw that the inverse of a Möbius transformation is again a Möbius transformation. It follows that $f^{-1}$ is locally a Möbius map. But then it follows from (2), that $f^{-1}$ is in fact a Möbius map. ■

**Lemma 33.11.** Let $U$ be an open connected subset of $\mathbb{D}$ and let $M$ be a Möbius manifold. Furthermore let $\Phi, \Psi: U \to M$ be two Möbius maps. Suppose one of the following two conditions is satisfied:

1. There exists an open non-empty subset of $U$ on which $\Phi$ and $\Psi$ agree, or
2. there exists a point $Q \in U$ with $\Phi(Q) = \Psi(Q)$ and a non-zero vector $v \in T_Q \mathbb{D}$ such that $D\Phi_Q(v) = D\Psi_Q(v)$,

then the Möbius maps $\Phi$ and $\Psi$ agree on all of $U$.

**Proof.** Let $U$ be an open connected subset of $\mathbb{D}$, let $M$ be a Möbius manifold and let $\Phi, \Psi: U \to M$ be two Möbius maps. We consider one more statement:

(3) There exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $D\Phi_Q = D\Psi_Q$.

Clearly we have $(1) \Rightarrow (3)$. We also have $(2) \Rightarrow (3)$. Indeed, the differentials $D\Phi_Q$ and $D\Psi_Q$ are homomorphisms between two 1-dimensional complex vector spaces. So if they are agree on one non-zero vector, then they agree on all of the vector space $T_Q \mathbb{D}$.

So it suffices to show that if (3) is satisfied, then the maps $\Phi$ and $\Psi$ agree on all of $U$. So suppose that there exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $D\Phi_Q = D\Psi_Q$. We consider

$$Y := \{ P \in U \mid \Phi(P) = \Psi(P) \text{ and } D\Phi_P = D\Psi_P \}.$$ 

By our hypothesis we know that $Y$ contains $Q$, in particular $Y$ is non-empty. Since $\Phi$ and $\Psi$ are smooth it follows that $Y$ is closed. It remains to show that $Y$ is open.

So let $P \in Y$. We pick a map $\Theta: W \to \mathbb{D}$ from the Möbius structure of $M$ such that $W$ is an open neighborhood of $\Phi(P) = \Psi(P)$. We denote by $V$ the component of $\Phi^{-1}(W) \cap \Psi^{-1}(W)$ that contains $P$. Since $\Phi$ and $\Psi$ are Möbius maps it follows from Lemma 33.10 (3) that the maps $\Theta \circ \Phi: V \to \mathbb{D}$ and $\Theta \circ \Psi: V \to \mathbb{D}$ are also Möbius maps. Since $V$ is connected it follows from Lemma 33.10 (1) that both maps are given by Möbius transformations. These two Möbius transformations agree at $P$ and they have the same differential at $P$. It follows from Proposition 32.4 (5) that $\Phi$ and $\Psi$ agree on an open neighborhood of $P$. This shows that $Y$ is also open. ■

**Definition.** Let $M$ be a Möbius manifold and let $Q \in M$ and $r > 0$. We say $B^M_r(Q)$ is *small* if there exists a Möbius isomorphism $\Omega: B^\mathbb{D}_r(0) \to B^M_r(Q)$ with $\Omega(0) = Q$.

---

553 Here we view $U \subset \mathbb{D}$ as equipped with the obvious Möbius structure.
**Proposition 33.12.** Let $M$ be a Möbius manifold and let $Q \in M$. Then there exists an $r > 0$ such that $B^M_r(Q)$ is small.

In the proof of Proposition 33.12 we will make use of the following lemma.

**Lemma 33.13.** Let $(X, g)$ and $(Y, h)$ be Riemannian manifolds. Let $Q \in X$ and $r > 0$. Let $f: B^X_{3r}(Q) \to (Y, h)$ be a local isometry and let $S, T \in B^X_r(Q)$. Then we have

$$d_Y(f(S), f(T)) \leq d_X(S, T).$$

\[ \text{Figure 578. Illustration for Lemma 33.13} \]

**Proof.** Let $S, T \in B^X_r(Q)$. Furthermore let $\epsilon > 0$. By the triangle inequality we have $d_X(S, T) < 2r$. In particular there exists a piecewise smooth path $\gamma$ in $X$ from $S$ to $T$ such that $\ell_X(\gamma) < 2r$ and with $\ell_X(\gamma) < d_X(S, T) + \epsilon$. Given any $t$ we have

$$d_X(Q, \gamma(t)) \leq d_X(Q, S) + d_X(S, \gamma(t)) < r + \ell_X(\gamma) < 3r.$$  

Thus we have shown that the image of $\gamma$ lies in $B^X_{3r}(Q)$. In particular the image of $\gamma$ lies in the domain of $f$. Thus we see that

$$d_Y(f(S), f(T)) \leq \ell_Y(f \circ \gamma) = \ell_X(\gamma) < d_X(S, T) + \epsilon.$$  

Since this inequality holds for all $\epsilon > 0$ we see that $d_Y(f(S), f(T)) \leq d_X(S, T)$.

\[ \text{Proof of Proposition 33.12.} \]

Let $M$ be a Möbius manifold and let $Q \in M$. We pick a map $\Phi: U \to V$ from the Möbius structure of $M$ such that $U$ is an open neighborhood of $Q$. By Proposition 32.4 (3), after possibly composing $\Phi$ with a Möbius transformation, we can furthermore assume that $\Phi(Q) = 0$. We write $\Omega := \Phi^{-1}$. By Proposition 32.9 (3) and by the openness of $V$ there exists an $r > 0$ such that $B^M_{3r}(Q) \subset U$ and such that $B^V_{3r}(0) \subset V$.

It follows immediately from Lemmas 33.8 and 33.13 and from our choice of $r$ that the following holds:

1. For any $S, T \in B^M_r(Q)$ we have $d_B(\Phi(S), \Phi(T)) \leq d_M(S, T)$.
2. For any $S, T \in B^V_r(Q)$ we have $d_M(\Omega(S), \Omega(T)) \leq d_B(S, T)$.

It follows immediately from these two inequalities, from $\Phi(Q) = 0$ and from the fact that $\Phi = \Omega^{-1}$ that $\Omega$ restricts to an isometry $\Omega: (B^V_{3r}(0), d_B) \to (B^M_{r}(Q), d_M)$ of metric spaces which is furthermore a bijection. Furthermore, since $\Phi$ is a Möbius isomorphism,

Note the discrete factor 3 in the radius of the ball.
it follows that the inverse map $\Omega = \Phi^{-1}: (B^\mathbb{D}(0), d_\mathbb{D}) \to (B^M_r(Q), d_M)$ is also a Möbius isomorphism.

**Lemma 33.14.** Let $M$ be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B^M_r(Q)$ is small. Let $\Phi: \mathbb{D} \to M$ be a Möbius map such that $B^M_r(Q) \subset \Phi(\mathbb{D})$. Then the following hold:

1. For any $X \in \Phi^{-1}(Q)$ the map $\Phi$ restricts to a Möbius isomorphism $B^\mathbb{D}_r(X) \to B^M_r(Q)$.
2. Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B^M_s(Q)$. Then there exists an $X \in \Phi^{-1}(Q)$ with $Y \in B^\mathbb{D}_s(X)$.

**Proof.** Let $M$ be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B^M_r(Q)$ is small. We pick a Möbius isomorphism $\Omega: B^\mathbb{D}_r(0) \to B^M_r(Q)$ as in the definition of “small”. Let $\Phi: \mathbb{D} \to M$ be a Möbius map such that $B^M_r(Q) \subset \Phi(\mathbb{D})$.

(1) Let $X \in \Phi^{-1}(Q)$. It follows immediately from the fact that Möbius maps are local isometries and from Lemma 33.13 that $\Phi(B^\mathbb{D}_r(X)) \subset B^M_r(Q)$. Therefore we can consider the Möbius map $\Omega^{-1} \circ \Phi: B^\mathbb{D}_r(X) \to B^\mathbb{D}_r(0)$. By Lemma 33.10 this Möbius map is the restriction of a Möbius transformation. In particular it is a Möbius isomorphism. But since $\Omega$ is a Möbius isomorphism as well we obtain that $\Phi: B^\mathbb{D}_r(X) \to B^M_r(Q)$ is also a Möbius isomorphism.

(2) Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B^M_s(Q)$, i.e., such that $d_M(Q, \Phi(Y)) < s$. By the triangle inequality we have

$$B^M_s(\Phi(Y)) \subset B^M_s(Q) \subset B^M_r(Q).$$

The same argument as in (1) shows that the map $\Phi$ restricts to a Möbius isomorphism $B^\mathbb{D}_s(Y) \to B^M_s(\Phi(Y))$. We have $d_M(Q, \Phi(Y)) < s$, i.e., we have $Q \in B^M_s(\Phi(Y))$. 

---

33. THE UNIVERSAL COVERING OF SURFACES

Figure 579. Illustration for the proof of Proposition 33.12

Figure 580. Illustration for the proof of Lemma 33.14 (1).
Hence there exists an $X \in B^p_s(Y)$ with $\Phi(X) = Q$. We refer to Figure 581 for an illustration.

33.6. **Proof of Theorem 33.9 II.** In this section we will now finally provide the proof of Theorem 33.9. We will only cover the case $g = 2$, the proof of the general case is almost identical.

Throughout this section let $M = H_8/ \sim$ be the surface of genus 2 with the Möbius structure constructed in Proposition 33.2. In the following we will show that there exists a Möbius map $p: \mathbb{D} \to M$ that is in fact a covering map. It then follows from Lemma 33.8 that $p$ is also a local isometry and a local biholomorphism.

For the remainder of the proof we adopt the following notation and conventions.

1. We view $\mathcal{H}_8$ as a subset of $\mathbb{D}$ and also of $H_8/ \sim$.
2. Given $Z \in \mathbb{D}$ we denote by
   
   $\gamma_Z: [0, 1] \to \mathbb{D}$
   
   the radial path from the origin 0 to $Z$.
3. We say that $U \subset \mathbb{D}$ is convex if it is convex in the usual Euclidean sense, i.e., if given any $P, Q \in U$ the points $t \cdot P + (1 - t) \cdot Q$, $t \in [0, 1]$ also lie in $U$. On several occasions throughout the proof we will make use of the following elementary observations:
   (a) convex sets are path-connected,
   (b) the intersection of two convex sets is also convex,
   in particular, combining (a) and (b) we get
   (c) the intersection of two convex sets is path-connected.

   Our first goal is to construct a suitable map $p: \mathbb{D} \to M = H_8/ \sim$. So let $Z \in \mathbb{D}$.

   We write $\gamma = \gamma_Z$. We say $t \in [0, 1]$ is good if there exists a convex open neighborhood $U$ of $\gamma([0, t])$ and a map $Ψ: U \to M$ which has the following properties:
   
   (i) $Ψ$ is a Möbius map,
   (ii) it restricts to the identity on $\mathcal{H}_8 \cap U \subset M$.

   We start out with the following lemma.

   **Lemma 33.15.** The point $t = 1$ is good.

   **Proof.** We set
   
   $T := \{t \in [0, 1] \mid t \text{ is good}\}$. 
We start out with the following observations:

1. We have that \( 0 \in T \) since the identity on the open neighborhood \( \hat{H}_8 \) of 0 has the required properties.\(^{555}\)

2. Being good is clearly an open condition, hence \( T \subset [0, 1] \) is open.

We want to show that \( T = [0, 1] \). By the above, and since \([0, 1]\) is connected, it suffices to show that \( s := \text{sup}(T) \) is good.

Since \( 0 \in S \) and since \( T \) is open we see that \( s > 0 \). Therefore there exists an increasing sequence \( \{t_n\}_{n \in \mathbb{N}} \) of good numbers \( t_n \in [0, t) \) that converges to \( s \). Since each \( t_n \) is good we can pick for each \( n \) a convex open neighborhood \( U_n \) of \( \gamma([0, t_n]) \) and a map \( \Psi_n: U_n \to M \) that has the desired properties (i) and (ii).

Let \( m, n \in \mathbb{N} \). The Möbius maps \( \Psi_m \) and \( \Psi_n \) agree on the non-empty open connected subset \( \hat{H}_8 \cap U_n \cap U_m \). It follows from Lemma 33.11 that the maps \( \Psi_m \) and \( \Psi_n \) agree on \( U_n \cap U_m \).

By the continuity of \( \gamma \) the sequence \( \{\gamma(t_n)\}_{n \in \mathbb{N}} \) converges to \( \gamma(t) \), in particular it is a Cauchy sequence with respect to \( \mathcal{D}_r \). It follows from Lemma 33.10 that \( \{\Psi_n(\gamma(t_n))\}_{n \in \mathbb{N}} \) is a Cauchy sequence with respect to \( \mathcal{D}_M \).\(^{556}\) It follows from Proposition 33.2 that the metric space \( (M = H_8/\sim, \mathcal{D}_M) \) is complete. Therefore the Cauchy sequence \( \{\Psi_n(\gamma(t_n))\}_{n \in \mathbb{N}} \) converges to a point \( S \in M \).

It follows from Proposition 33.12 that there exists an \( r > 0 \) and a Möbius isomorphism \( \Omega: \mathcal{B}_r(0) \to \mathcal{B}_r^M(S) \) such that \( \Omega(0) = S \). We pick an \( n \) such that \( \Psi_n(\gamma(t_n)) \in \mathcal{B}_r^M(S) \) and such that \( \mathcal{D}_r(\gamma(t), \gamma(s)) < r \). We write \( t = t_n \), \( \Psi = \Psi_n, U = U_n \) and we write \( X = \gamma(t) \).

Let \( v \in T_x^\mathcal{D} \) be a non-zero vector. We let \( w := \mathcal{D}(\Omega^{-1} \circ \Psi)_X(v) \). The Möbius maps \( \Omega \) and \( \Psi \) are in particular local isometries, therefore we have \( ||w|| = ||v|| \). It follows from Proposition 34.4(4) that there exists a Möbius transformation \( \Theta \) with \( \Theta(X) = \Omega^{-1}(\Psi(X)) \) and such that \( \mathcal{D}_X \Theta(v) = w \).

The situation is illustrated in Figure 582. The Möbius maps \( \Omega \circ \Theta: \mathcal{B}_r^\mathcal{D}(X) \to M \) and \( \Psi: U \to M \) agree at \( X = \gamma(t) \) and we have \( \mathcal{D}(\Omega \circ \Theta)_X(v) = \mathcal{D}_\Psi_X(v) \). It follows from Lemma 33.11 that \( \Omega \circ \Theta \) and \( \Psi \) agree on the path-connected set \( \mathcal{B}_r^\mathcal{D}(X) \cap U \).

Now we consider the map

\[
\Phi: U \cup \mathcal{B}_r^\mathcal{D}(\gamma(t)) \to M
\]

\[
Q \mapsto \begin{cases} 
\Psi(Q), & \text{if } Q \in U, \\
\Omega^{-1}(\Theta(Q)), & \text{if } Q \in \mathcal{B}_r^\mathcal{D}(\gamma(t)).
\end{cases}
\]

By the above discussion this map is well-defined and it is locally a Möbius map. It follows from Lemma 33.10(3) that this map is a Möbius map. It follows from \( \mathcal{D}_\mathcal{D}(\gamma(t), \gamma(s)) < r \)

\(^{555}\)Here we use that for each point \( Z \in \hat{H}_8 \) the identity map \( \text{id}: \hat{H}_8 \to \hat{H}_8 \) is part of the Möbius structure of \( M \).

\(^{556}\)Indeed, suppose we have \( \epsilon > 0 \). Since \( \{\gamma(t_n)\}_{n \in \mathbb{N}} \) is a Cauchy sequence there exists an \( N \) such that \( \mathcal{D}_\mathcal{D}(\gamma(t_m), \gamma(t_n)) < \epsilon \) for all \( m, n \geq N \). Now let \( m, n \geq N \). Without loss of generality we have \( m > n \). Then

\[
d_M(\Psi_m(\gamma(t_m)), \Psi_n(\gamma(t_n))) = d_M(\Psi_m(\gamma(t_m)), \Psi_m(\gamma(t_n))) \leq d_M(\gamma(t_m), \gamma(t_n)) < \epsilon.
\]

since \( \Psi_m \) and \( \Psi_n \) agree on \( \gamma|[0, t_m]| \). Lemma 33.10
and the fact that \( \gamma \) is a geodesic in \( \mathbb{D} \) that \( \gamma([t, s]) \subset B^B_r(\gamma(t)) \), in particular \( U \cup B^B_r(\gamma(t)) \) is an open subset of \( \mathbb{D} \) that contains \( \gamma([0, t]) \cup \gamma([t, s]) = \gamma([0, s]) \). It is now straightforward to see that we can find a convex open subset \( W \) of \( U \cup B^B_r(\gamma(t)) \) that contains \( \gamma([0, s]) \). The Möbius map \( \Phi: W \to M \) now certifies that \( s \) is also good.

Thus we have now shown that there exists a convex open neighborhood \( U \) of \( \gamma([0, 1]) \) and a local isometry \( \Psi: U \to H_s/\sim \) which agrees with the identity map on \( U \cap \hat{H}_s \). We define \( p(Z) := \Psi(Z) \). By Lemma \ref{lem:local_homeomorphism} this definition does not depend on the choice of \( U \) and \( \Psi \).

**Lemma 33.16.** The map \( p: \mathbb{D} \to M \) is a Möbius map.

**Proof.** By Lemma \ref{lem:local_homeomorphism} (2) it suffices to show that \( p \) is locally a Möbius map. This means that it suffices to show that every point \( P \in \mathbb{D} \) admits an open neighborhood \( W \) such that the restriction of \( p \) to \( W \) is a Möbius map. Thus let \( P \in \mathbb{D} \). By the above claim there exists a convex open neighborhood \( U \) of \( \gamma_P([0, 1]) \) and a Möbius map \( \Psi: U \to H_s/\sim \) which restricts to the identity on \( U \cap \hat{H}_s \). Since \( U \) is open we can find an \( r > 0 \) such that for all \( Q \in B^B_r(P) \) the image of the radial path \( \gamma_Q \) from 0 to \( Q \) also lies in \( U \). (We refer to Figure 583 for an illustration.) This implies that we can use the Möbius map \( \Psi: U \to M \) to define \( p \) for any \( Q \in B^B_r(P) \). Put differently, \( p = \Psi \) on \( B^B_r(P) \). We have thus shown that the restriction of \( p \) to the open neighborhood \( W = B^B_r(P) \) of \( P \) is a Möbius map.

The following lemma now concludes the proof of Theorem \ref{thm:holomorphic_extension}.
Lemma 33.17. The map \( p : \mathbb{D} \to M = H_8/ \sim \) is a covering map.

Proof. First we show that the map \( p : \mathbb{D} \to M = H_8/ \sim \) is surjective. Recall that by construction \( p \) is the identity on \( \hat{H}_8 \). Since \( p \) is continuous, it follows that the restriction of \( p \) to \( H_8 \to M = H_8/ \sim \) is surjective.

It remains to show that every \( Q \in M \) admits a uniformly covered neighborhood. Let \( Q \in M \). By Proposition 33.12 there exists an \( r > 0 \) such that \( B_r^M(Q) \) is small. We claim that \( B_r^M(Q) \) is uniformly covered. More precisely, we make the following claims:

1. \( p^{-1}(B_r^M(Q)) = \bigcup_{X \in p^{-1}(Q)} B_r^D(X) \)
2. For \( X \neq X' \in p^{-1}(Q) \) we have \( B_r^D(X) \cap B_r^D(X') = \emptyset \)
3. For any \( X \in p^{-1}(Q) \) the restriction of \( p \) to \( B_r^D(X) \to B_r^M(Q) \) is a homeomorphism.

We apply Lemma 33.14 to the map \( p : \mathbb{D} \to M \). It gives us the following three facts:

a. If \( Y \in \mathbb{D} \) satisfies \( p(Y) \in B_r^M(Q) \), then there exists an \( X \in p^{-1}(Q) \) with \( Y \in B_r^D(X) \).

b. For any \( X \in p^{-1}(Q) \) the restriction of \( p \) to \( B_r^D(X) \to B_r^M(Q) \) is a Möbius isomorphism, in particular it is a homeomorphism.

c. For any \( X \in p^{-1}(Q) \) the restriction of \( p \) to \( B_{2r}^D(X) \) is injective.

Now the desired properties (1) and (3) follow immediately from (a) and (b). It remains to prove (2). Suppose that we have \( X \neq X' \in p^{-1}(Q) \) with \( B_r^D(X) \cap B_r^D(X') \neq \emptyset \). We need to show \( X = X' \). We pick \( Y \in B_r^D(X) \cap B_r^D(X') \). The triangle inequality implies that \( X' \in B_{2r}^D(X) \). But \( p \) restricted to \( B_{2r}^D(X) \) is injective by (c). Hence \( X = X' \).

33.7 Picard’s Theorem \( \clubsuit \). We also have the following variation on Theorem 33.9.

Proposition 33.18. Let \( H_4/ \sim \) be the three-punctured sphere with the Möbius structure constructed in Proposition 33.5. Then there exists a covering map \( p : \mathbb{D} \to H_4/ \sim \) with the following properties:

1. \( p \) is a Möbius map,
2. \( p \) is a local isometry,
3. \( p \) is a local biholomorphism.

Proof. The proof of Proposition 33.18 is almost the same as the proof of Theorem 33.9.

In the proof of Theorem 33.9 we used that \( H_8/ \sim \) is complete. In the present case it follows from Proposition 33.5 (3) that \( H_4/ \sim \) is complete. The construction of the Möbius map \( \Phi : \mathbb{D} \to H_4/ \sim \) is verbatim the same as the construction of the Möbius map \( \Phi : \mathbb{D} \to H_8/ \sim \).

The same argument as before shows that \( \Phi : \mathbb{D} \to H_4/ \sim \) is surjective and that it is a covering map.
Remark. We consider again the covering $p: \mathbb{D} \to H_8/\sim$ that we had just constructed. It follows from Corollary 29.4 that the interior of $H_8$ is uniformly covered. In particular we see that

$$\mathbb{D} \setminus p^{-1}(\partial H_8) = \bigsqcup \text{1-dimensional copies of } \hat{H}_8.$$ 

Put differently, up to the “one-dimensional” subset $p^{-1}(\partial H_8)$ we can cover $\mathbb{D}$ by infinitely many disjoint copies of the open hyperbolic octagon. Such a decomposition is often called a tessellation. This tessellation is shown in Figure 584 on the left. The same argument also applies to the covering $\mathbb{D} \to H_4/\sim$ that we also had just constructed. The corresponding tessellation of $\mathbb{D}$ is shown in Figure 584 on the right.

![Figure 584](image)

At the end of this chapter we return to complex analysis. There are different types of holomorphic functions defined on $\mathbb{C}$.

1. There are the (rather dull) constant functions.
2. There are holomorphic functions $f: \mathbb{C} \to \mathbb{C}$ that are surjective. For example it is an easy consequence of the fundamental theorem of algebra that all maps defined by non-constant polynomials are surjective.
3. There are also non-constant maps that are not surjective, for example the exponential function $z \mapsto \exp(z)$ is never zero, in fact its image is $\mathbb{C} \setminus \{0\}$.

On the other hand it is fairly easy prove, using Liouville’s Theorem 12.1 that the image of a non-constant holomorphic function on $\mathbb{C}$ is dense.

Now we can prove Picard’s Theorem which is a significantly stronger statement than the above statement that the image is dense.

**Theorem 33.19. (Picard’s Theorem)** Let $f: \mathbb{C} \to \mathbb{C}$ be a non-constant holomorphic function. Then there exists at most one $z \in \mathbb{C}$ which does not lie in the image of $f$.

---

560 Why not?
561 Emile Picard (1856-1941) was a French mathematician. Many readers will have encountered him already in real analysis, as one of the two namesakes of the Picard-Lindelöf Theorem.
Proof. Let \( f : \mathbb{C} \to \mathbb{C} \) be a holomorphic function such that there exist two different complex numbers \( a, b \) that do not lie in the image of \( f \). We need to show that \( f \) is constant. We consider the biholomorphism

\[
\alpha : \mathbb{C} \setminus \{a, b\} \to \mathbb{C} \setminus \{0, 1\}
\]

\[
\begin{align*}
z & \mapsto \frac{z-a}{b-a}.
\end{align*}
\]

Furthermore we denote by \( \beta : \mathbb{C} \setminus \{0, 1\} \to H_4/ \sim \) the biholomorphism from Proposition \[33.6\] Now we consider the following diagram of maps

\[
\begin{array}{ccc}
\mathbb{D} & \xrightarrow{\Phi} & H_4/ \sim \\
\downarrow & & \downarrow \\
\mathbb{C} \xrightarrow{f} \mathbb{C} \setminus \{a, b\} \xrightarrow{\alpha} \mathbb{C} \setminus \{0, 1\} \xrightarrow{\beta} H_4/ \sim
\end{array}
\]

where \( \Phi : \mathbb{D} \to H_4/ \sim \) is the covering map from Proposition \[33.18\] Recall that \( \Phi \) is a Möbius map which implies by Lemma \[33.8\] that \( \Phi \) is a local biholomorphism.

Since \( \mathbb{C} \) is simply connected we can appeal to Proposition \[29.2\] to obtain a lift of the map \( \beta \circ \alpha \circ f : \mathbb{C} \to H_4/ \sim \) to the universal covering. More precisely, there exists a map \( \tilde{\beta} \circ \alpha \circ f : \mathbb{C} \to \mathbb{D} \) such that the following diagram commutes

\[
\begin{array}{ccc}
\mathbb{D} & \xrightarrow{\Phi} & H_4/ \sim \\
\downarrow & & \downarrow \\
\mathbb{C} \xrightarrow{f} \mathbb{C} \setminus \{a, b\} \xrightarrow{\alpha} \mathbb{C} \setminus \{0, 1\} \xrightarrow{\beta} H_4/ \sim
\end{array}
\]

Note that it follows from the fact that \( \beta \circ \alpha \circ f \) is holomorphic and the fact that \( \Phi \) is a local biholomorphism, that the map \( \beta \circ \alpha \circ f : \mathbb{C} \to \mathbb{D} \) is also holomorphic. But \( \mathbb{D} \) is of course bounded. Therefore it follows from Liouville’s Theorem \[12.1\] that \( \beta \circ \alpha \circ f \) is constant. But then \( \beta \circ \alpha \circ f \) is also constant. Since \( \alpha \) and \( \beta \) are biholomorphisms this implies that \( f \) itself is already constant. \( \blacksquare \)

Remark. In the literature Theorem \[33.19\] is sometimes referred to as Picard’s Little Theorem, to distinguish it from Picard’s Great Theorem which says that if \( z_0 \) is an essential singularity of a holomorphic function, then in any neighborhood of \( z_0 \) the function \( f \) assumes all, but possibly one, value infinitely many times. We refer to \[Con78\] Section 12 for details.

33.8. Triangle groups \( (\ast) \). In this short bonus section we will discuss the triangle groups. But before we can do so we need to introduce the notion of the reflection in a hyperbolic plane.

Definition. We define the reflection in the hyperbolic line \( l := \{x + 0i \mid x \in (-1, 1)\} \subset \mathbb{D} \) to be the orientation-reversing isometry

\[
\rho_l : \mathbb{D} \to \mathbb{D}
\]

\[
\begin{align*}
z = x + iy & \mapsto \bar{z} = x - iy.
\end{align*}
\]
Now let \( k \) be any hyperbolic line in \( \mathbb{D} \). By Lemma [32.6] there exists a Möbius transformation \( \Phi \) with \( \Phi(k) = l \). We define the reflection in \( k \) to be the map

\[
\rho_k : \mathbb{D} \rightarrow \mathbb{D} \\
x \mapsto \Phi^{-1} \circ \rho_l \circ \Phi
\]

In Exercise [33.1] we will see that the definition of \( \rho_k \) does not depend on the choice of \( \Phi \).

Next recall that given any two distinct points \( P, Q \in \mathbb{D} \) there exists by Lemma [32.6] a unique hyperbolic line \( g(P, Q) \) through \( P \) and \( Q \). Now we can formulate the key proposition of this section.

**Proposition 33.20.** Let \( l, m, n \in \mathbb{N} \) with \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1 \).

(1) There exists a hyperbolic triangle \( \Delta_{ABC} \) with interior angles \( \frac{\pi}{l}, \frac{\pi}{m} \) and \( \frac{\pi}{n} \) at the vertices \( A, B \) and \( C \).

Let \( G \) be the subgroup of that is generated by the reflections in the hyperbolic lines \( g(C, A), g(A, B) \) and \( g(B, C) \). The following statements hold:

(2) (a) Given any \( g \neq h \in G \) the intersection \( g \cdot \Delta_{ABC} \cap h \cdot \Delta_{ABC} \) is either empty or a vertex or a side.

(b) \( \bigcup_{g \in G} g \cdot \Delta_{ABC} = \mathbb{D} \).

(3) The map

\[
\langle x, y, z | x^2, y^2, z^2, (xy)^l = (yz)^m = (zx)^n \rangle \rightarrow G \\
x \mapsto \text{reflection in } g(C, A) \\
y \mapsto \text{reflection in } g(A, B) \\
z \mapsto \text{reflection in } g(B, C).
\]

is an isomorphism.

![Diagram of Proposition 33.20](image)

**Figure 585.** Illustration of Proposition 33.20

**Proof.**

(1) This statement is shown in [Rat19] Theorem 3.5.6. In fact in that reference it is also shown that the triangle is unique up to an isometry.

(2) The statements (2a) and (2b) are both shown in [Cara54] p. 177-182 or alternatively in [Mask71].

(3) (a) First note that the map is actually well-defined. In fact this follows from the observation that every reflection has order 2 and that \( xy, yz \) and \( zx \) get sent to a rotation around a vertex with rotation angles \( \frac{2\pi}{l}, \frac{2\pi}{m} \) and \( \frac{2\pi}{n} \).
(b) The fact that the map is in fact an isomorphism is shown in [Mag74, Theorem 2.8]. ■

Remark.

(1) A decomposition of the euclidean plane \( \mathbb{R}^2 \) or the hyperbolic disk \( \mathbb{D} \) into isometric geometric shapes that only overlap on the boundary is called a tessellation. Proposition 33.20 thus shows that the hyperbolic disk \( \mathbb{D} \) can be tessellated by any hyperbolic triangle with angles \( \frac{\pi}{l}, \frac{\pi}{m}, \frac{\pi}{n} \) for \( l, m, n \in \mathbb{N} \) with \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1 \). Tessellations for various values of \((l, m, n)\) are shown in Figure 586.

(2) Note that, as illustrated in Figure 584, Hadamard’s Theorem 33.9 and Proposition 33.18 also provide tessellations of \( \mathbb{D}^2 \).

![Tessellations](image)

**Figure 586**

Proposition 33.20 partly motivates the following definition.

**Definition.** Let \( l, m, n \in \mathbb{N} \).

(1) The group \( T^*(l, m, n) := \langle x, y, z \mid x^2, y^2, z^2, (xy)^l = (yz)^m = (zx)^n \rangle \)

is called the \((l, m, n)\)-triangle group.

(2) The group

\[
T(l, m, n) := \ker\left\{ T^*(l, m, n) \rightarrow \mathbb{Z}_2 \quad x, y, z \mapsto 1 \right\}
\]

is called the \((l, m, n)\)-von Dyck group.

**Remark.** Let \( l, m, n \in \mathbb{N} \).

(1) (a) If \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1 \), then we saw in Proposition 33.20 that \( T^*(l, m, n) \) is isomorphic to the subgroup of \( \text{Isom}(\mathbb{D}) \) generated by reflections in the hyperbolic lines defined by a hyperbolic triangle with interior angles \( \frac{\pi}{l}, \frac{\pi}{m}, \frac{\pi}{n} \).

(b) If \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} = 1 \), then it is shown in [Mag74, Section II.4] that \( T^*(l, m, n) \) is isomorphic to the subgroup of \( \text{Isom}(\mathbb{R}^2) \) generated by reflections in the euclidean lines defined by a euclidean triangle with interior angles \( \frac{\pi}{l}, \frac{\pi}{m}, \frac{\pi}{n} \).

(c) Finally, if \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} > 1 \), then it is shown in [Mag74, Section II.4] that \( T^*(l, m, n) \) is isomorphic to the subgroup of \( \text{Isom}(S^2) \) generated by reflections in the great circles defined by a spherical triangle with interior angles \( \frac{\pi}{l}, \frac{\pi}{m}, \frac{\pi}{n} \).

(2) In each of the three cases above the \((l, m, n)\)-von Dyck group is the intersection of the \((l, m, n)\)-triangle group with the subgroup of orientation-preserving isometries.
The following lemma gives a particularly simple presentation of the von Dyck groups.

**Lemma 33.21.** Given any \( l, m, n \in \mathbb{N} \) the map

\[
\langle a, b \mid a^l, b^m, (ab)^n \rangle \to T(l, m, n)
\]

\[
a \mapsto xy \\
b \mapsto yz
\]

is an isomorphism.

**Proof.** We will prove Lemma 33.21 in Exercise 33.2.

We conclude this chapter with the following corollary to Proposition 33.20.

**Corollary 33.22.** Let \( l, m, n \in \mathbb{N} \). If \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1 \), then the triangle group \( T^*(l, m, n) \) and the von Dyck group \( T(l, m, n) \) are infinite.

**Proof.** Let \( l, m, n \in \mathbb{N} \) with \( \frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1 \). We denote by \( G \) the group introduced in Proposition 33.20. Note that it follows from Proposition 33.20 (2), the fact that \( \Delta_{ABC} \) is compact and the fact that \( \mathbb{D} \) is non-compact that \( G \) is infinite. By Proposition 33.20 (3) this implies that the triangle group \( T^*(l, m, n) \) is infinite. The index two subgroup \( T(l, m, n) \) is evidently also infinite.

---

**Exercises for Chapter 33**

**Exercise 33.1.** We define reflection in the hyperbolic line \( l := \{ x \mid x \in (-1, 1) \} \subset \mathbb{D} \) to be the map

\[
\rho_l : \mathbb{D} \to \mathbb{D} \\
z = x + iy \mapsto \overline{z} = x - iy.
\]

Now let \( k \) be any hyperbolic line in \( \mathbb{D} \). By Lemma 32.6 there exists a Möbius transformation \( \Phi \) with \( \Phi(k) = l \). We define the reflection in \( k \) to be the map

\[
\rho_k : \mathbb{D} \to \mathbb{D} \\
x \mapsto \Phi^{-1} \circ \rho_l \circ \Phi
\]

Show that the definition of \( \rho_k \) does not depend on the choice of \( \Phi \).

**Exercise 33.2.** Let \( l, m, n \in \mathbb{N} \). Show that the map

\[
\langle a, b \mid a^l, b^m, (ab)^n \rangle \to T(l, m, n)
\]

\[
a \mapsto xy \\
b \mapsto yz
\]

is an isomorphism.

**Hint.** First use Proposition 27.32 to find an explicit presentation for \( T(l, m, n) \).
34. The deck transformation group and its relation to fundamental groups.

The following definition introduces the main actor of this chapter.

**Definition.** Let \( p: X \to B \) be a covering.

1. A **deck transformation** is a homeomorphism \( d: X \to X \) such that \( p(d(x)) = p(x) \) for all \( x \), i.e. such that the following diagram commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{d} & X \\
\downarrow{p} & \sim & \downarrow{p} \\
B & & B
\end{array}
\]

The group of deck transformations \( D \) is called the **deck transformation group** of the covering \( p: X \to B \) and we denote it by \( D(p: X \to B) \).

2. We say that the covering is **regular** if for every \( b \in B \) the deck transformation group \( D \) acts transitively on \( p^{-1}(b) \), i.e. if given any two points \( x, x' \) with \( p(x) = p(x') = b \) there exists a deck transformation \( d \) with \( d(x) = x' \). Otherwise we say that the covering is **irregular**.

For completeness’ sake we also mention the following definition even though we will barely make use of it:

3. Let \( P \) be a property of isomorphism types of groups, e.g. cyclic, free, nilpotent, solvable etc. We say the covering \( p: X \to B \) is a \( P \)-covering if the covering is regular and if the deck transformation group has the property \( P \).

---

**Example.**

1. We consider the covering

\[
p: S^1 \to S^1 \\
z \mapsto z^2.
\]

Then the map \( d: S^1 \to S^1 \) given by \( d(z) := -z \) is a deck transformation. It is now clear that the covering is regular.

---

562 Why do deck transformations form a group?
(2) Let \( p: \tilde{X} \to X \) be a 2-fold covering. We define

\[
f: \tilde{X} \to \tilde{X}
Q \mapsto \text{the unique other point in } p^{-1}(p(Q)).
\]

In Lemma\[\text{16.4}\] we saw that \( f \) is a deck transformation. It follows immediately that any 2-fold covering is regular.

(3) As an important special case of (2) consider a non-orientable path-connected smooth manifold \( M \). As in the proof of Proposition\[\text{17.3}\] we consider the 2-fold covering

\[
\tilde{M} := \{(Q, O) \mid Q \in M \text{ and } O \text{ an orientation of } T_Q M\} \to M
(Q, O) \mapsto Q.
\]

It is easy to show that the map \( d: \tilde{M} \to \tilde{M} \) given by \( d((Q, O)) := (Q, -O) \) is a deck transformation of \( p \).

(4) We consider again the first two coverings of topological graphs from Figure\[\text{313}\] which are also shown again in Figure\[\text{588}\]. The covering maps are the ones suggested by the colors and the directions. We first make the following observations. A deck transformation \( d \) does the following:

(a) it sends a vertex again to a vertex,
(b) it sends a blue edge to a blue edge, preserving the orientation,
(c) it sends a red edge to a red edge, preserving the orientation,
(d) if \( e \) is an edge with endpoints \( P \) and \( Q \), then \( d(e) \) is an edge with endpoints \( d(P) \) and \( d(Q) \), in particular if \( e \) is a loop, then \( d(e) \) is also a loop.

Now we consider the two examples.

(a) The example on the left admits one non-trivial deck transformation, namely the map that is given by “rotation by \( \pi \)” around the center of the topological graph. The covering is now easily seen to be regular.

(b) The loop \( a_3 \) in the topological graph on the right is the only red loop, so any deck transformation has to send it to itself. It follows that there can be no deck transformation that sends the vertex to the right to any of the other vertices.\[\text{563}\]

Thus the covering on the right is irregular.

(5) Finally we consider the 4-fold coverings illustrated in Figure\[\text{589}\] They are both regular coverings. For the topological graph on the left the deck transformation group is isomorphic to \( \mathbb{Z}_4 \), a generator is given by “rotation by \( \frac{\pi}{2} \)”. The deck transformation group on the right is isomorphic to \( \mathbb{Z}_2 \oplus \mathbb{Z}_2 \), here one \( \mathbb{Z}_2 \) summand is given by “rotation by \( \pi \)” and the other one corresponds to “swapping the inner and the outer circle”.

**Lemma 34.1.** Let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed path-connected topological spaces and let \( d_1 \) and \( d_2 \) be two deck transformations of \( p \). Then the following holds

\[
d_1 = d_2 \iff d_1(x_0) = d_2(x_0).
\]

**Proof.** Evidently we only need to show the “\( \iff \)”-direction. Thus let \( d \) be a deck transformation of \( p \). One way of stating that \( d \) is a deck transformation is to state that the

---

\[\text{563}\] Does this covering admit any deck transformation?
a deck transformation is given by rotation by $\pi$ around $P$

a deck transformation has to send the red loop $a_3$ to another loop, but $a_3$ is the only red loop

regular covering

dek transformation group $\mathbb{Z}_2$

irregular covering

dek transformation group $\mathbb{Z}_2 \oplus \mathbb{Z}_2$

Figure 588

following diagram commutes:

\[
\begin{array}{ccc}
(X, x_0) & \xrightarrow{d} & (X, d(x_0)) \\
\downarrow p & & \downarrow p \\
(X, x_0) & \xrightarrow{p} & (B, b_0).
\end{array}
\]

Put differently, the map $d$ can be viewed as a lift of the map $(X, x_0) \to (B, b_0)$ to the covering $(X, d(x_0)) \to (B, b_0)$. By the uniqueness of lifts\(^5\) that we showed in Proposition 29.2 (2), we now see that two deck transformations $d_1$ and $d_2$ of $p$ with $d_1(x_0) = d_2(x_0)$ agree. \(\blacksquare\)

**Example.** We let $B = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1, a) \sim (1, b)$, i.e. $B$ is the wedge of two circles and we consider

\[
X = (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/(e^{2\pi in/5} \sim (1, n)) \text{ for } n \in \mathbb{Z}_5,
\]

\(^5\)Here we use that $X$ is path-connected.
i.e. $X$ is a circle with five circles attached at the points $e^{2\pi ik/5}$, $k = 0, \ldots, 4$. Then the map

$$ p: (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/\sim \rightarrow G = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1, a) \sim (1, b) $$

that is given by $p(z) = (z^5, a)$ for $z \in S^1$ and $p((z, n)) = (z, b)$ for $(z, n) \in S^1 \times \mathbb{Z}_5$, is a covering map of degree five. This covering illustrated in Figure 590.

We consider the map

$$ Z_5 \rightarrow D(p: X \rightarrow B) $$

$$ m \mapsto \begin{pmatrix} X \rightarrow X \\ z \mapsto e^{2\pi im/5}z, & \text{for } z \in S^1 \\ (z, n) \mapsto (z, m+n) & \text{for } (z, n) \in S^1 \times \mathbb{Z}_5 \end{pmatrix} $$

In Figure 590 this corresponds to “rotation of $X$ by the angle $2\pi m/5$”. It is straightforward to show that this map is well-defined, i.e. the maps on the right are deck transformations, and using Lemma 34.1 one can easily see that this map is an isomorphism. Also one can now convince oneself easily that the covering $p: X \rightarrow B$ is regular.

**Figure 590**

dele transformation is given by rotation by $\frac{2\pi}{5}$

**Lemma 34.2**. Let $X$ be a path-connected topological space on which a group $G$ acts continuously and discretely. We consider the corresponding covering $p: X \rightarrow X/G$. Then $p: X \rightarrow X/G$ is regular and the map

$$ \Phi: G \rightarrow D(p: X \rightarrow X/G) $$

$$ g \mapsto \begin{pmatrix} X \rightarrow X \\ x \mapsto gx \end{pmatrix} $$

is an isomorphism of groups.

**Proof.** It is straightforward to see that the maps $x \mapsto gx$ are indeed deck transformations. It follows almost immediately that the covering $p: X \rightarrow X/G$ is regular. Also it follows easily from the axioms of a group action that $\Phi$ is a homomorphism of groups. Furthermore it is clear that $\Phi$ is a monomorphism.

It remains to show that $\Phi$ is an epimorphism. So let $d \in D(p: X \rightarrow X/G)$ be a deck transformation. We pick $x \in X$. Since $p(d(x)) = p(x)$ we have $d(x) = gx$ for some $g \in G$. Since $X$ is path-connected it follows from Lemma 34.1 that $d(y) = gy$ for all $y \in X$. This shows that $\Phi$ is an epimorphism.

**Lemma 34.3**. Any 2-fold covering of path-connected topological spaces is regular and the deck transformation group contains precisely two elements.
Proof. Let \( p: X \to B \) be a 2-fold covering of path-connected topological spaces. By Lemma 16.4 we know that
\[
d: X \to X
x \mapsto \text{the unique other element of } p^{-1}(p(x))
\]
is a deck transformation. Evidently it is regular. It follows easily from Lemma 34.1 and our hypothesis that \( X, B \) are path-connected that any deck transformation of \( p \) is either the identity or it equals the above deck transformation \( d \).

We recall the following important, albeit somewhat technical, definition.

**Definition.** Let \( G \) be a group and let \( H \subset G \) be a subgroup. The *normalizer* \( N(H) \) of the subgroup \( H \subset G \) is defined as
\[
N(H) := \{ g \in G \mid g^{-1}Hg = H \}.
\]

The following lemma summarizes a few elementary properties of the normalizer of a subgroup.

**Lemma 34.4.** Let \( G \) be a group and let \( H \subset G \) be a subgroup.

1. The subgroup \( H \) of \( G \) is normal if and only if \( N(H) = G \).
2. The normalizer \( N(H) \) of \( H \subset G \) is a subgroup of \( G \).
3. The normalizer \( N(H) \) of \( H \subset G \) is the largest subgroup of \( G \) which contains \( H \) as a normal subgroup, in the sense that if \( A \) is a subgroup of \( G \) which contains \( H \) as a normal subgroup, then \( A \subset N(H) \).

Proof. Both statements are easily verified. Alternatively see [Isa94, p. 26] for the elementary proof.

We return to topology and we consider one more example in detail.

**Example.** Let \( Y \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let \( y_0 \in Y \). Furthermore let \( \Gamma \subset \pi = \pi_1(Y, y_0) \) be a subgroup. By Proposition 29.5 there exists a path-connected covering \( p: (X, x_0) \to (Y, y_0) \) of pointed topological spaces such that \( p_\ast(\pi_1(X, x_0)) = \Gamma \). We recall the construction of \( X \). We first considered
\[
P := \{ \text{all paths in } Y \text{ with starting point } y_0 \}
\]
and for \( u, v \in W \) we wrote
\[
u \sim v \iff u \text{ and } v \text{ have the same endpoint and } [u * v] \in \Gamma.
\]
We defined \( X = P/\sim \) and the projection map \( p: P/\sim \to Y \) that is given by \([w] \mapsto w(1)\).

We then showed that, with an appropriate topology on \( P/\sim \), the map \( p: P/\sim \to Y \) is a path-connected covering with \( p_\ast(\pi_1(P/\sim, x_0)) = \Gamma \).

As in the proof of Proposition 29.12 we now would like to construct deck transformations by precomposing elements in \( P \) by a loop in \( y_0 \). More precisely, let \( g \) be a loop in \( (Y, y_0) \). We consider the map
\[
P \to P
w \mapsto g * w
\]
We need to check that the map respects our equivalence relation \( \sim \) on \( P \). So suppose that \( u, v \in P \) are equivalent. Then \( g \ast u \) and \( g \ast v \) still have the same endpoint. Now we need to consider the second condition. We have

\[
[(g \ast u) \ast (g \ast v)] = [g \ast u \ast v \ast g] = [g] \ast [u \ast v] = [g]^{-1}.
\]

In general it is not the case that the right-hand side lies again in \( \Gamma \). But it is true if \([g]\) lies in the normalizer of \( \Gamma \). As in the proof of Proposition 29.12 it is now straightforward to see that the map

\[
\Psi: N(\Gamma)/\Gamma \to D(p: X \to Y)
\]

\[
[g] \mapsto \left( \frac{P/\sim}{[u]} \mapsto [g \ast u] \right)
\]

is a well-defined homomorphism. We will see in Proposition 34.5 that this in fact an isomorphism of groups.

Now we want to consider the general case of a covering. So let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed path-connected topological spaces. Write \( \pi := \pi_1(B, b_0) \) and \( \Gamma := p_*(\pi_1(X, x_0)) \). Now the question arises whether there is a connection between the groups \( \pi, \Gamma \) and \( D(p: X \to B) \).

Similar to the proof of Theorem 16.16 we can consider the following map

\[
\Phi: D(p: X \to B) \to \pi/\Gamma
\]

\[
d \mapsto [p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))].
\]

It is straightforward to see that this map is well-defined, i.e. it does not depend on the choice of the path.

The question now arises, whether this map \( \Phi \) is a group isomorphism. But in general this is not the case, after all, if \( \Gamma \) is not normal in \( \pi \), then \( \pi/\Gamma \) is not even a group. But we have the following proposition:

**Proposition 34.5.** Let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces. We suppose that \( X \) and \( B \) are both path-connected and locally path-connected. We write \( \pi := \pi_1(B, b_0) \) and \( \Gamma := p_*(\pi_1(X, x_0)) \). The above map

\[
\Phi: D(p: X \to B) \to \pi/\Gamma
\]

\[
d \mapsto [p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))].
\]

restricts to an isomorphism of groups

\[
\Phi: D(p: X \to B) \to N(\Gamma)/\Gamma.
\]

**Proof.** Let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed path-connected topological spaces. We write \( \pi := \pi_1(B, b_0) \), \( \Gamma := p_*(\pi_1(X, x_0)) \) and \( D := D(p: X \to B) \).

(A) First we have to show that \( \Phi(D) \) lies indeed in \( N(\Gamma)/\Gamma \). Thus let \( d \in D \). We need to show that \( \Phi(d) \) lies in \( N(\Gamma)/\Gamma \). Thus let \( f \) be a loop in \( (X, x_0) \) and let \( g \) be a

\[\text{Recall that by Corollary 16.14 the induced map } p_*: \Gamma \to \pi \text{ is injective, thus } \Gamma \cong \pi_1(X, x_0).\]

\[\text{We denote hereby with } [p \circ f] \text{ not only the equivalence class of the loop } p \circ f \text{ in } \pi, \text{ but also its equivalence class } \pi/\Gamma, \text{ since the notation } [p \circ f]_{\Gamma} \text{ is too cumbersome.}\]
path in \(X\) from \(x_0\) to \(d(x_0)\). We have to verify that \([p \circ f]\cdot[p \circ g]\cdot[p \circ f] \in \Gamma\). Indeed the following holds
\[
[p \circ f]\cdot[p \circ g]\cdot[p \circ f] = [p \circ (\overline{f} \cdot g \cdot f)] \in p_*(\pi_1(X,x_0)) = \Gamma.
\]

(B) Now we have to show that \(\Phi\) is a group homomorphism. So let \(d\) and \(e\) be two deck transformations. We pick a path \(g\) from \(x_0\) to \(d(x_0)\) and we pick a path \(h\) from \(x_0\) to \(e(x_0)\). Then

\[
\text{endpoint of } g \text{ equals starting point of } d \circ h \quad \Phi(d) \cdot \Phi(e) = [p \circ g] \cdot [p \circ h] = [p \circ (d \circ h)] = \Phi(e \circ d).
\]

\[\text{definition of } \Phi(e) \text{ and } \Phi(d) \quad \text{since } p \circ d = p \quad \text{since } g \circ (d \circ h) \text{ is a path from } x_0 \text{ to } d(e(x_0)), \text{ see Figure 591} \]

\[\text{Figure 591} \]

(C) Now we will construct a map \(\Psi: N(\Gamma)/\Gamma \rightarrow D\) in the inverse direction. Thus let \([f] \in N(\Gamma) \subset \pi = \pi_1(B,b_0)\) where \(f\) is a loop in \((B,b_0)\). Let \(x_1\) be the endpoint of the lift \(\tilde{f}\) of \(f\) to the starting point \(x_0\). We have \(p(x_1) = p(\tilde{f}(1)) = f(1) = x_0\). Thus we obtain the following diagram of maps of pointed topological spaces:

\[
\begin{array}{ccc}
(X, x_1) & \xrightarrow{p} & (B, b_0) \\
\downarrow & & \\
(X, x_0) & \xrightarrow{p} & (B, b_0).
\end{array}
\]

Then
\[
p_*(\pi_1(X,x_1)) = \{ [p \circ (\overline{f} \cdot g \cdot \tilde{f})] | [g] \in \pi_1(X,x_0) \} = [f]p_*(\pi_1(X,x_0))[f]^{-1} = p_*(\pi_1(X,x_0)).
\]

by Proposition \[14.11\] since \(\tilde{f}\) is a path from \(x_0\) to \(x_1\)

\[\text{by Corollary } [16.13\text{] the definition of } x_1 \text{ does not depend on the choice of the representative of } [f] \in N(\Gamma).\]
It follows from Proposition 29.2  that there exists a lift \( \widetilde{p} : (X, x_0) \to (X, x_1) \) of \( p \), i.e. there exists a map \( \widetilde{p} \) such that the following diagram commutes:

\[
\begin{array}{ccc}
& (X, x_1) & \\
\downarrow & \downarrow p & \\
(X, x_0) & \to & (B, b_0).
\end{array}
\]

The map is \( \widetilde{p} \) is now by definition a deck transformation.

We have thus constructed a map \( N(\Gamma) \to D \). We still need to show that this map descends to a map \( N(\Gamma)/\Gamma \to D \). So let \([f] \in N(\Gamma)\) and let \([g] \in \Gamma\). We denote by \( \widetilde{f} \) the lift of \( f \) to the starting point \( x_0 \). Similarly we define \( g \ast f \). By the above we only need to show that the endpoints of \( \widetilde{f} \) and \( g \ast f \) agree. In fact we have

\[
g \ast f(1) \uparrow = \text{endpoint of the lift of } f \text{ to the starting point } \widetilde{g}(1) \uparrow = \text{endpoint of the lift of } f \text{ to the starting point } x_0 = \widetilde{f}(1)
\]

Lemma [29.3] by Lemma [16.15] (2) (1) since \([g] \in p_*(\pi_1(X, x_0))\)

(D) Now we want to show that \( \Phi \) is a bijection. It suffices to show that \( \Psi \circ \Phi = \text{id} \) and \( \Phi \circ \Psi = \text{id} \).

First let \( d \in D \). Then

\[
\Psi(\Phi(d)) = \Psi(\text{loop } f \text{ in } (B, b_0) \text{ that lifts to a path from } x_0 \text{ to } d(x_0)) = \text{deck transformation that sends } x_0 \text{ to } d(x_0) = d
\]

Lemma [34.1]

This shows that \( \Psi \circ \Phi \) is the identity.

Now let \( g \in N(\Gamma)/\Gamma \). We pick a representative loop \( s \) in \( B_0 \) and we denote by \( \widetilde{s} \) the lift of \( s \) to the starting point \( x_0 \). We denote by \( x_1 \) the endpoint of \( \widetilde{s} \). Then

\[
\Phi(\Psi(g)) = [p \circ (\text{path in } X \text{ from } x_0 \text{ to } \Psi(g)(x_0))]) = [p \circ \widetilde{s}] = [s] = g.
\]

This shows that \( \Phi \circ \Psi \) is the identity.

In most applications we will use the following special case of Proposition [34.5].

**Proposition 34.6.** Let \((X, x_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let \( \gamma : \pi_1(X, x_0) \to G \) be an epimorphism onto a group \( G \). We denote by \( p : (\widetilde{X}, \widetilde{x}_0) \to (X, x_0) \) the covering corresponding to \( \ker(\gamma) \) that is given by Proposition [29.5] and that is unique up to covering equivalence by Proposition [29.8]. Then the map

\[
\Phi : D(p : \widetilde{X} \to X) \to \pi_1(X, x_0)/p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) \xrightarrow{\gamma} G.
\]

\[
d \mapsto [p \circ (\text{path from } x_0 \text{ to } d(x_0))]
\]

is an isomorphism.
Proof. First note that $p_*(\pi_1(\tilde{X}, \tilde{x}_0)) = \ker(\gamma)$ is a normal subgroup of $\pi_1(X, x_0)$. Therefore the normalizer of $\Gamma := p_*(\pi_1(\tilde{X}, \tilde{x}_0))$ equals $\pi_1(X, x_0)$. It now follows immediately from Proposition \[34.5\] that the homomorphism on the left is an isomorphism. The homomorphism on the right is an isomorphism since $p_*(\pi_1(\tilde{X}, \tilde{x}_0)) = \ker(\gamma)$.

The following corollary now gives a complete characterization of regular coverings.

**Corollary 34.7.** Let $p: (X, x_0) \rightarrow (B, b_0)$ be a covering of pointed topological spaces that are path-connected and locally path-connected. Then the following statements are equivalent:

1. The covering is regular.
2. The deck transformation group $D(p: X \rightarrow B)$ acts transitively on $p^{-1}(b_0) \subset X$.
3. The subgroup $p_*(\pi_1(X, x_0))$ is a normal subgroup of $\pi_1(B, b_0)$.
4. There exists a group $G$ which acts discretely on $X$ and there exists a homeomorphism $f: X/G \rightarrow B$ such that the following diagram commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{q} & X/G \\
\downarrow{p} & & \downarrow{f} \\
B & \xrightarrow{\phantom{q}} & B
\end{array}
\]

where $q: X \rightarrow X/G$ is the canonical projection map.

If $p$ is a finite covering then the above statements are furthermore equivalent to

5. $\#D(p: X \rightarrow B) = [X : B]$.

**Remark.** Let $p: (X, x_0) \rightarrow (B, b_0)$ be a 2-fold covering of path-connected pointed topological spaces. In Lemma \[34.3\] we saw that $p$ is regular, which by Corollary \[34.7\] means that the index two subgroup $p_*(\pi_1(X, x_0))$ of $\pi_1(B, b_0)$ is normal. In fact we already showed in Exercise \[17.1\] that any index 2 subgroup $\Gamma$ of a group $\pi$ is normal.\[568\]

**Proof.** Let $p: (X, x_0) \rightarrow (B, b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B, b_0)$, $\Gamma := p_*(\pi_1(X, x_0))$ and $D = D(p: X \rightarrow B)$. The following four steps prove the equivalence of (1), (2), (3) and (4).

1. $\Leftrightarrow$ (2) Recall that a covering is regular if for every $b \in B$ the group $D$ acts transitively on $p^{-1}(b)$. Thus (1) $\Rightarrow$ (2) is trivial. Now suppose that $d$ acts transitively on $p^{-1}(b_0)$. Let $b$ be some other point in $B$. Since $B$ is path-connected there exists a path $s$ from $b$ to $b_0$.

Now let $x, x'$ be two points in $p^{-1}(b)$. We denote by $\tilde{s}$ the lift of $s$ to the starting point $x$ and similarly we define $\tilde{s}'$. We denote by $x_0$ and $x'_0$ the endpoints of $\tilde{s}$ and $\tilde{s}'$. Since $D$ acts transitively on $p^{-1}(b_0)$ there exists a deck transformation $d$ with $d(x_0) = x'_0$. By the uniqueness of lifts to a starting point we then also have $d \circ \tilde{s} = \tilde{s}'$. But then we also have that $d$ turns the starting point of $\tilde{s}$ into the starting point of $\tilde{s}'$, i.e. we have $d(x) = x'$.

\[568\]We already made use of this fact in the proof of Corollary \[17.4\]
We consider again the map
\[ \Phi: D(p: X \rightarrow B) \mapsto \pi/\Gamma \]
\[ d \mapsto [p \circ \text{path in } X \text{ from } x_0 \text{ to } d(x_0)]. \]

We first prove the following claim.

**Claim.** We have the following equivalence of statements:

\[ D \text{ acts transitively on } p^{-1}(b_0) \subset X \quad \iff \quad \Phi: D \rightarrow \pi/\Gamma \text{ is surjective.} \]

First suppose that \( D \) acts transitively on \( p^{-1}(b_0) \subset X \). Let \( g \in \pi/\Gamma \) and pick a loop \( f \) that represents \( g \). We denote by \( \tilde{f} \) the unique lift of \( f \) to the starting point \( x_0 \) and we denote by \( \tilde{x}_0 \) the endpoint of \( \tilde{f} \). Since \( D \) acts transitively there exists a deck transformation \( d \) with \( d(x_0) = \tilde{x}_0 \). Now
\[ \Phi(d) = [p \circ \text{path in } X \text{ from } x_0 \text{ to } d(x_0)] = [p \circ (d \circ \tilde{f})] = [p \circ \tilde{f}] = [f] = g. \]

Now suppose that \( \Phi: D \rightarrow \pi/\Gamma \) is surjective. Let \( \tilde{x}_0 \in p^{-1}(b_0) \). We pick a path \( \tilde{f} \) from \( x_0 \) to \( \tilde{x}_0 \) and we denote by \( f \) the loop \( p \circ \tilde{f} \). Since \( \Phi \) is surjective there exists a deck transformation \( d \) with \( \Phi(d) = [f] \). But then \( d(x_0) = \tilde{x}_0 \). \[ \Box \]

Now we have the following equivalences
\[ D \text{ acts transitively on } p^{-1}(b_0) \subset X \quad \iff \quad \Phi: D \rightarrow \pi/\Gamma \text{ is surjective} \]
\[ \quad \iff \quad \pi = N(\Gamma) \iff \Gamma \text{ is normal in } \pi. \]

(1) \( \Rightarrow \) (4) We will show that the deck transformation group \( D \) has the desired properties.

We first show that the deck transformation group acts discretely on \( X \). So let \( x \in X \). We write \( b = p(x) \). Since \( p: X \rightarrow B \) is a covering there exists a connected open neighborhood \( U \) of \( b \) that is uniformly covered. This means that the restriction of \( p \) to each component of \( p^{-1}(U) \) is a homeomorphism. Now let \( V \) be the component of \( p^{-1}(U) \) that contains \( x \). Then \( gV \cap V = \emptyset \) for each non-trivial \( g \). This shows that the action of \( D \) is discrete.

The map \( p: X \rightarrow B \) has the property that \( p(gx) = p(x) \) for all \( g \in D \). Therefore the map \( p \) factors through a map \( f: X/D \rightarrow B \). The map \( f \) is clearly surjective. Furthermore it is injective since we suppose that \( D \) acts transitively on each \( p^{-1}(b) \). Finally the map \( f \) is not only continuous but, as follows easily from Lemma \([16.3] \) (1), it is also open. Thus \( f \) is a homeomorphism.

(4) \( \Rightarrow \) (1) Now suppose that such a homeomorphism \( f: X/G \rightarrow B \) exists. First note that for each \( g \in G \) the map \( x \mapsto gx \) not only defines a deck transformation of the covering \( q: X \rightarrow X/G \) but also of the covering \( p: X \rightarrow B \). Now let \( b \in B \) and let \( x, x' \in X \) with \( p(x) = p(x') \). Since \( f \) is a homeomorphism we also have \( q(x) = q(x') \). Hence there exists a \( g \in G \) with \( gx = x' \).

Now we suppose that \( p \) is a finite covering. We show the following equivalence:
We have the following equivalences:

Lemma 16.15 (3) Proposition 34.5

\[ \#D = [X : B] \iff \#D = [\pi : \Gamma] \iff [N(\Gamma) : \Gamma] = [\pi : \Gamma] \iff \Gamma \subset \pi \text{ is a normal subgroup.} \]

We conclude this chapter with the following proposition which often, rather conveniently, allows us to replace an irregular covering by a regular covering.

**Proposition 34.8.** Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces that are path-connected, locally path-connected and semi-locally simply connected. If \( p \) is a finite-degree covering, then there exists a covering \( q : (Y, y_0) \to (X, x_0) \) such that \( p \circ q : (Y, y_0) \to (B, b_0) \) is a finite-degree regular covering. For convenience this statement is summarized in the following diagram:

\[
\begin{array}{ccc}
(Y, y_0) & \downarrow & (3) \text{ such that } p \circ q \text{ is a finite-degree regular covering} \\
\downarrow & & \\
(X, x_0) & \downarrow & (2) \text{ there exists a covering } q \downarrow \\
\downarrow & & \\
(B, b_0). & & (1) \text{ given a finite-degree covering } p
\end{array}
\]

Now we can provide the proof of Proposition 34.8

**Proof.** Let \( p : (X, x_0) \to (B, b_0) \) be a finite-degree covering of pointed topological spaces that are path-connected, that are locally path-connected and that are semi-locally simply connected. In the following we write \( G := \pi_1(X, x_0) \) and \( H := p_*(\pi_1(B, b_0)) \). By Lemma 16.15 we know that \( H \) is a finite-index subgroup of \( G \). It follows from Lemma 31.13 that the normal core \( H^c \) of \( H \) in \( G \) is a finite-index normal subgroup of \( G \) that is contained in \( H \). Since \( B \) is locally path-connected and semi-locally simply connected we obtain from Proposition 29.5 a finite-degree path-connected covering \( r : (Y, y_0) \to (B, b_0) \) of pointed topological spaces such that \( r_*(\pi_1(Y, y_0)) = H^c \).

The existence of the desired covering map \( q : (Y, y_0) \to (X, x_0) \) with \( r = p \circ q \) is an immediate consequence of Proposition 29.8 and the fact that \( H^c \) is contained in \( H \). ■

**34.2. Fundamental groups of surfaces.** In this section we combine the results from the previous section with the main result from Chapter 33 to draw some interesting consequences on the structure of fundamental groups of surfaces. First we have the following proposition.

**Proposition 34.9.** Let \( g \in \mathbb{N}_{\geq 2} \). We denote by \( \Sigma_g \) the surface of genus \( g \). We pick a base point \( x_0 \in \Sigma_g \). There exists a monomorphism \( \pi_1(\Sigma_g, x_0) \to \text{SL}(2, \mathbb{R}) \).

**Proof.** Throughout the proof we will make use of the notion of a Möbius structure, of a Möbius manifold and of a Möbius map between Möbius manifolds. We refer to pages 887 and 897 for the definitions, in case the reader needs a refresher.

\( \text{Where do we actually use in the argument that the covering is finite?} \)
Now let \( g \geq 2 \). As in the proof of Proposition 33.2 we can and will make the identification \( \Sigma_g = H_{4g}/ \sim \) where \( H_{4g} \) is a regular hyperbolic \( 4g \)-gon in \( \mathbb{D} \) with interior angle \( \frac{\pi}{2g} \).

Furthermore, as in the proof of Proposition 33.2 we equip \( \Sigma_g = H_{4g}/ \sim \) with the canonical Möbius structure. By Hadamard’s Theorem 33.9 there exists a covering map \( p: \mathbb{D} \rightarrow \Sigma_g \) such that \( p \) is a Möbius map.

**Claim.** Every deck transformation of the covering map \( p: \mathbb{D} \rightarrow \Sigma_g \) is a Möbius transformation.

Let \( f: \mathbb{D} \rightarrow \mathbb{D} \) be a deck transformation. Recall that this means that the following diagram commutes:

\[
\begin{array}{ccc}
\mathbb{D} & \xrightarrow{f} & \mathbb{D} \\
p & \downarrow & \downarrow p \\
\Sigma_g & \xrightarrow{} & \Sigma_g
\end{array}
\]

Since \( p \) is a Möbius map and since \( p \) is a local diffeomorphism we see that \( f \) is locally a Möbius map. By Lemma 33.11 (2) this implies that \( f \) is in fact a Möbius map. It now follows from Lemma 33.11 (1) that \( f \) is in fact a Möbius transformation. \(\blacksquare\)

Now we can easily conclude the proof of the proposition, indeed we have the following isomorphisms:

\[
\pi_1(\Sigma_g, x_0) \cong D(p: \mathbb{D} \rightarrow \Sigma_g) \subset \text{group of Möbius transformations of } \mathbb{D} \cong \text{SL}(2, \mathbb{R}).
\]

by Proposition 34.5

by the claim

by Proposition 32.1 \(\blacksquare\)

The following proposition gives in particular a positive answer to Question 31.22.

**Proposition 34.10.** Let \( \Sigma \) be a closed connected 2-dimensional smooth manifold. We pick a base point \( x_0 \in \Sigma \). The following two statements hold:

1. The group \( \pi_1(\Sigma, x_0) \) is linear over \( \mathbb{R} \).
2. The group \( \pi_1(\Sigma, x_0) \) is residually finite.

**Remark.**

1. In [NewM85, Lemma 1], see also [Scot78, Section 3] together with [Bou81, Chapitre V, §4, Section 4], it shown that \( \pi_1(\Sigma, x_0) \) is in fact linear over \( \mathbb{Z} \).
2. There are many other proofs that \( \pi_1(\Sigma, x_0) \) is residually finite, see e.g. [Chis99, Corollary 4.9] and [Hem72] for alternative arguments.

**Proof.** Let \( \Sigma \) be a closed connected 2-dimensional smooth manifold. By Proposition 17.3 we know that there exists a finite covering \( p: (\bar{\Sigma}, \bar{x}_0) \rightarrow (\Sigma, x_0) \) such that \( \bar{\Sigma} \) is a closed orientable connected 2-dimensional smooth manifold. By Proposition 34.9 we know that \( \pi_1(\bar{\Sigma}, \bar{x}_0) \) is isomorphic to a subgroup of \( \text{SL}(2, \mathbb{R}) \). In particular we see that \( \pi_1(\bar{\Sigma}, \bar{x}_0) \) is linear over \( \mathbb{R} \).

By Corollary 16.14 and Lemma 16.15 we know that \( \pi_1(\bar{\Sigma}, \bar{x}_0) \) is isomorphic to a finite-index subgroup of \( \pi_1(\Sigma, x_0) \). Thus it follows from the above together with Exercise 31.15 that \( \pi_1(\Sigma, x_0) \) is also linear over \( \mathbb{R} \). By Proposition 31.19 this implies that \( \pi_1(\Sigma, x_0) \) is residually finite. \(\blacksquare\)
Exercises for Chapter 34

Exercise 34.1. In Figure 592 below we show two coverings $p: Y \to X = S^1 \vee S^1$ and $q: Z \to X = S^1 \vee S^1$.

(a) Determine which coverings are regular.
(b) For the regular covering(s) in (a), determine the isomorphism type of the deck transformation group.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure592.png}
\caption{Illustration for Exercise 34.1}
\end{figure}

Exercise 34.2. Let $\Sigma$ be the surface of genus 2. Does there exists a regular covering $p: \tilde{\Sigma} \to \Sigma$ such that the deck transformation group is isomorphic to the permutation group $S_3$?

Exercise 34.3. Let $G$ be a finite group. Show that there exists a closed orientable 2-dimensional smooth manifold that admits a free and transitive action by $G$.

Exercise 34.4. Let $p: \tilde{X} \to X$ be a covering with deck transformation group $G$ and let $K \subset \tilde{X}$ be a compact subset. We suppose that $X$ is Hausdorff and locally compact. Show that the set $\{g \in G \mid g \cdot K \cap K \neq \emptyset\}$ is finite.

Remark. In [Scot78] Lemma 1.2 claims that the same conclusion holds without the hypothesis that $X$ is locally compact. Try to prove this more general statement.
35. Related constructions in algebraic geometry and Galois theory (*)

In this short chapter we indicate some connections between the topics that we have covered so far to algebraic geometry and Galois theory. Since the author of these notes does not know much about either field the following discussion should be taken with a grain of salt. In particular for an expert the subsequent discussion will certainly look too simplistic.

35.1. The fundamental group of an algebraic variety (*).

Definition. Let \( K \) be a field.\(^{570}\)

1. Given a set of multivariable polynomials \( S \), i.e. given a subset \( S \subset K[t_1, \ldots, t_n] \) we denote by
   \[
   V(S) = \{ (x_1, \ldots, x_n) \in K^n \mid f(x_1, \ldots, x_n) = 0 \text{ for all } f \in S \}
   \]
   the vanishing set of \( S \), i.e. the set of all points in \( K^n \) where all the polynomials in \( S \), viewed as maps \( K^n \to K \), vanish.
2. We say \( U \subset K^n \) is Zariski open\(^{571}\) if there exists a subset \( S \) of \( K[t_1, \ldots, t_n] \) such that \( U = K^n \setminus V(S) \).

Remark. Let \( S \) be a subset of \( K[t_1, \ldots, t_n] \). Since the ring \( K[t_1, \ldots, t_n] \) is Noetherian there exists a finite set \( \{ f_1, \ldots, f_k \} \subset K[t_1, \ldots, t_n] \) such that \( V(S) = V(f_1, \ldots, f_k) \).

Lemma 35.1. Let \( K \) be a field. The Zariski open subsets form a topology on \( K^n \).

Remark.

1. The topology defined by the Zariski open subsets is of course called the Zariski topology on \( K^n \).
2. If \( K = \mathbb{R} \) or \( K = \mathbb{C} \), then every Zariski open subset is also open with respect to the usual topology on \( \mathbb{R}^n \) or \( \mathbb{C}^n = \mathbb{R}^{2n} \). But for \( n \geq 1 \) the converse does not hold, in fact “most” subsets that are open with respect to the usual topology are not open with respect to the Zariski topology.

Proof. Let \( K \) be a field.

1. The vanishing set of the empty set, i.e. \( V(\emptyset) \) is all of \( K^n \), hence the empty set \( \emptyset = K^n \setminus V(\emptyset) \) is open.
2. The vanishing set of the constant polynomial \( f = 1 \) is the empty set, therefore \( K^n = K^n \setminus V(1) \) is open.
3. We need to show that the intersection of finitely many Zariski open sets is again Zariski open. By induction it suffices to consider the case of two Zariski open sets. So suppose we are given Zariski open sets \( X = K^n \setminus V(S) \) and \( Y = K^n \setminus V(T) \). Then
   \[
   K^n \setminus (X \cap Y) = (K^n \setminus X) \cup (K^n \setminus Y) = V(S) \cup V(T) = V(\{ s \cdot t \}_{s \in S, t \in T}).
   \]

For example we could take \( K = \mathbb{Q}, \mathbb{R}, \mathbb{C} \) but \( K \) could also be a field of non-zero characteristic, e.g. for a prime \( p \) we could take \( K = \mathbb{F}_p \) or \( K \) could be the algebraic closure \( \overline{\mathbb{F}_p} \) of \( \mathbb{F}_p \).

Oscar Zariski (1899-1986) was a Russian-American mathematician working in algebraic geometry.
(4) We need to show that the union of Zariski open sets is again Zariski open. So suppose we are given a family of Zariski open sets \( X_i = \mathbb{K}^n \setminus V(S_i), \ i \in I \). Then
\[
\mathbb{K}^n \setminus \bigcup_{i \in I} X_i = \bigcap_{i \in I} (\mathbb{K}^n \setminus X_i) = \bigcap_{i \in I} V(S_i) = V\left( \bigcup_{i \in I} S_i \right).
\]
Thus we have verified that the Zariski open sets have all the properties of a topology. ■

**Definition.** Let \( \mathbb{K} \) be a field.

1. A variety over \( \mathbb{K} \) is defined as the vanishing set of a set of multivariable polynomials.
2. The Zariski topology on a variety \( V \subset \mathbb{K}^n \) is defined as the subspace topology on \( V \) induced from the Zariski topology on \( \mathbb{K}^n \).

**Example.** Let \( \mathbb{K} \) be a field and let \( f(s,t) = s^2 + t^2 - 1 \). We define
\[
S^1_{\mathbb{K}} := V(f) = \{(x, y) \in \mathbb{K}^2 \mid f(x, y) = x^2 + y^2 - 1 = 0\} = \{(x, y) \in \mathbb{K}^2 \mid x^2 + y^2 = 1\}.
\]
For \( \mathbb{K} = \mathbb{R} \) we obtain the usual circle \( S^1 \).

Any variety \( V \) is again a topological space, so in principle one could study the usual fundamental group. But in many cases, e.g. if the characteristic of \( \mathbb{K} \) is non-zero, one will see that all continuous maps \( S^1 \to V \) are constant, hence the usual fundamental group is trivial.

The correct analogue of a finite covering \( p : X \to B \) between topological spaces for varieties is a finite étale morphism. The precise definition of a finite étale morphism is irrelevant for our purpose.\(^{572}\) A heuristic fact is that varieties tend to have many finite étale morphisms, but there is no well-behaved analogue of an infinite covering in the context of varieties. In particular usually there is no concept of a “universal” étale morphism. The question is now, whether one can recover the notion of a fundamental group from the knowledge of finite covers.

Given a variety \( V \) we can consider all finite regular étale morphisms \( p_i : W_i \to V \), \( i \in I \). The corresponding deck transformations groups \( D(p_i : W_i \to V) \), \( i \in I \) are finite groups that form an inverse system. Now we can define the étale fundamental group of \( V \) as
\[
\pi_1^\text{ét}(V) := \varprojlim_i D(p_i : W_i \to V).
\]
By Proposition\(^{25,18}\) the étale fundamental group \( \pi_1^\text{ét}(V) \) is naturally a compact topological group. In algebraic geometry the étale fundamental group of a variety plays a role similar to the role of the fundamental group of a topological space in topology.

If \( V \) is a complex variety without singularities, then the étale fundamental group is isomorphic to the profinite completion\(^{573}\) of the usual topological fundamental group \( \pi_1(V) \), i.e. we have
\[
\pi_1^\text{ét}(V) \cong \widehat{\pi_1(V)}.
\]
We refer to [Groth71] for a proof of this statement.

\(^{572}\)Furthermore it is unknown to the author of these lecture notes.

\(^{573}\)Recall that on page 755 we introduced the profinite-completion \( \widehat{\pi} \) of a group \( \pi \).
More information on this topic can be found at

https://en.wikipedia.org/wiki/etale_fundamental_group

35.2. Galois theory (*). The theory of coverings of topological spaces has some similarities to the Galois theory of field extensions.

Throughout this section let \( K \) be a field of characteristic zero and let \( L/K \) be a field extension of \( K \), i.e. \( L \) is a field which contains \( K \) as a subfield. The dimension of \( L \) as a \( K \) vector space is denoted by \([L : K]\). We consider the group

\[ \text{Gal}(L/K) = \text{all field automorphisms of } L \text{ which are the identity on } K. \]

Put differently, a field automorphism \( f : L \rightarrow L \) lies in \( \text{Gal}(L/K) \) if and only if the following diagram commutes:

\[
\begin{array}{ccc}
K & \xleftarrow{f} & L \\
\downarrow & & \downarrow \\
L & \xrightarrow{f} & L
\end{array}
\]

We consider two examples:

1. \( \mathbb{Q}(\sqrt{2})/\mathbb{Q} \) is a field extension with \([\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2 \) and \( \text{Gal}(\mathbb{Q}(\sqrt{2})/\mathbb{Q}) \) consists of the identity and the homomorphism \( a + b\sqrt{2} \mapsto a - b\sqrt{2} \).

2. \( \mathbb{Q}(\sqrt[3]{2})/\mathbb{Q} \) is a field extension with \([\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3 \) and the group \( \text{Gal}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}) \) consists only of the identity.

Given a field \( K \) we denote by \( \overline{K} \) the algebraic closure of \( K \). A field extension \( L/K \) is called Galois, if for each \( f \in \text{Gal}(\overline{K}/K) \) we have \( f(L) = L \).\(^{575}\) In the usual course on Galois theory one shows that \( L/K \) is Galois if and only if each polynomial in \( K[x] \) which admits a zero in \( L \) splits over \( L \), i.e. all other zeros of \( f \) lies also in \( L \). For a Galois extension \( L/K \) we refer to \( \text{Gal}(L/K) \) as the Galois group of the field extension.

We return to the above two examples:

1. \( \mathbb{Q}(\sqrt{2})/\mathbb{Q} \) is a Galois field extension.

2. \( \mathbb{Q}(\sqrt[3]{2})/\mathbb{Q} \) is not a Galois field extension, since \( \sqrt[3]{2} \) is a zero of \( x^3 - 2 \), but the complex zero \( \sqrt[3]{2}e^{2\pi i/3} \) of \( f \) does not lie in \( \mathbb{Q}(\sqrt[3]{2}) \).\(^{576}\)

If \( L/K \) is a finite extension, then the main theorem of Galois theory says that the following two statements are equivalent:

1. The field extension \( L/K \) is Galois.

2. \( \# \text{Gal}(L/K) = [L : K] \).

The statement is formally very similar to the statement of Corollary 34.7, which says that for some finite covering \( p : X \rightarrow B \) of topological spaces the following statements are equivalent:

1. The covering \( p : X \rightarrow B \) is regular.

---

\(^{574}\)This restriction to characteristic zero is not necessary, but it simplifies the discussion.

\(^{575}\)Strictly speaking this is the definition of a normal extension, but since \( K \) is a field of characteristic zero, a normal extension is already Galois.

\(^{576}\)We put \( z = \sqrt[3]{2} \) and \( w = e^{2\pi i/3} \). It is a good exercise to show that \( \mathbb{Q}(z, w)/\mathbb{Q} \) is a normal field extension with \([\mathbb{Q}(z, w) : \mathbb{Q}] = 6 \). The group \( \text{Gal}(\mathbb{Q}(z, w)/\mathbb{Q}) \) is isomorphic to the permutation group \( S_3 \).
The analogy between Galois theory and covering theory goes considerably further. Many statements about the Galois group of a Galois extension have a corresponding statement for the deck transformation group of a normal covering. For example, given a finite extension $L/K$ the (normal) subgroups of Galois group $\text{Gal}(L/K)$ correspond to (normal) intermediate fields and (normal) subgroups of the deck transformation group correspond to (regular) intermediate coverings.

Now let $L/K$ be a Galois extension of infinite degree. All finite intermediate Galois extensions of $K$, i.e. all finite Galois extensions $F/K$ with $F \subset L$, form a preordered set via the inclusion. The corresponding Galois groups form an inverse set. Indeed, given two finite Galois extensions $F/K$ and $G/K$ with $F \subseteq G$ the restriction of an automorphism of $G$ to an automorphism of $F$ defines a group homomorphism $\text{Gal}(G/K) \to \text{Gal}(F/K)$. Therefore we can form the inverse limit of these Galois groups. By [FJ08, Section 1.3] there exists a canonical isomorphism of groups

$$\text{Gal}(L/K) = \lim_{\longleftarrow} \text{Gal}(F/K).$$

On the right-hand side we consider the inverse limit of an inverse system of finite groups. It follows from Proposition 25.18 that the right-hand side, and thus also the Galois group $\text{Gal}(L/K)$, is naturally a compact topological group. This topology on $\text{Gal}(L/K)$ is called the Krull topology.

**Example.** Let $p$ be a prime. We denote by $\mathbb{F}_p$ the finite field with $p$ elements and we denote by $\overline{\mathbb{F}}_p$ its algebraic closure. It is shown in [FJ08, Section 1.5] that there exists a canonical isomorphism

$$\text{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p) \cong \hat{\mathbb{Z}}$$

where $\hat{\mathbb{Z}}$ denotes the profinite completion of $\mathbb{Z}$, or equivalently the profinite integers that we introduced on page 751.
Part V

CW-complexes and Cofibrations
36. CW-complexes I: Definitions, basic properties and constructions

In this chapter we will introduce CW-complexes. Initially the definition of a CW-complex might look rather confusing and artificial. But in this and in Chapters 37 and 38 we will see that the notion of a CW-complex strikes the right balance:

(1) CW-complexes are topological space that have many desirable properties,
(2) the notion is flexible enough so that most of the topological spaces that we are interested in are actually CW-complexes.

36.1. Definition of finite-dimensional CW-complexes and examples. We start out with the definition of a finite-dimensional CW-complex and its topological realization.

Definition.

(a) A CW-complex $X$ of dimension $\leq -1$ is defined to be the empty set. Its topological realization $|X|$ is also defined to be the empty set.

(b) We define inductively higher dimensional CW-complexes. Let $n \in \mathbb{N}_0$. A CW-complex $X^n$ of dimension $\leq n$ is a pair $(X^{n-1}, \{\{\varphi_i: S^{n-1} \to |X^{n-1}|\}_{i \in I_n}\})$ where the following holds:
   (i) $X^{n-1}$ is a CW-complex $X^{n-1}$ of dimension $\leq n - 1$, with topological realization denoted by $|X^{n-1}|$,
   (ii) $\{\{\varphi_i: S^{n-1} \to |X^{n-1}|\}_{i \in I_n}\}$ is a set of maps.
   The topological realization $|X^n|$ of $X^n$ is defined as the topological space $|X^n| := (|X^{n-1}| \sqcup \bigsqcup_{i \in I_n} \overline{B^n}) / \sim$
   where for each $i \in I_n$ we use the map $\varphi_i$ to identify the points on the corresponding copy of $S^{n-1} = \partial B^n$ with the corresponding points in $|X^{n-1}|$.

(c) A CW-structure for a topological space $Y$ is a CW-complex $X$ together with a homeomorphism $f: |X| \to Y$.

Remark.

(1) Let $X$ be a CW-complex as above and let $n \in \mathbb{N}_0$. It follows from Lemma 3.44 (4) that the obvious map $|X^{n-1}| \to |X^n|$ is an embedding. Thus we can and will view $|X^{n-1}|$ as a subspace of $|X^n|$.

(2) Note that $\overline{B^0}$ consists of a point and that $S^{-1} = \emptyset$. It follows from the above definition that a CW-complex of dimension $\leq 0$ is exactly the same as set of points with the discrete topology.

(3) CW-complexes were introduced by John H. C. Whitehead\footnote{John Henry Constantine Whitehead (1904-1960) was a British mathematician.}. The name comes from “C” for “closure-finite”, and the “W” for “weak topology”. We will explain on pages 941 and 954 what “closure-finite” and “weak topology” mean. Some people also say it goes back to the initials C. W. of Whitehead. Some authors, see e.g. [Lee00, p. 132] and [Mun84, p. 214] require “closure-finiteness” as part of the definition, but as we will see, this property follows from the definition as given.
(4) In the notation we usually do not distinguish between the CW-complex and its topological realization, i.e. we usually denote the topological realization of a CW-complex $X$ again by $X$.

Before we discuss a long list of examples of CW-complexes we want to introduce a few more definitions.

**Definition.** Let $X$ be a CW-complex as above and let $k \in \mathbb{N}_0$. We continue with the notation used in the previous definition

1. The images of the $B^k_i$, $i \in I_k$, in $X$ are called the *$k$-dimensional cells*, or often short *$k$-cells*, of $X$.
2. The images of the $B^k_i$, $i \in I_k$, in $X$ are called the *open $k$-cells* of $X$.
3. The maps $\varphi_i : S^k_i \to X$ are called the *attaching maps* of the $k$-cells and the obvious maps $B^k_i \to X$ are referred to as the *characteristic maps* of the $k$-cells.
4. We refer to the CW-complex $X^k$ as the *$k$-skeleton* of $X$.
5. If $X$ is empty, then we define its dimension to be $-1$. If $X$ is non-empty, then we define the *dimension* $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ as the maximal dimension of a cell.

**Remark.** At times, when we say that “a CW-complex $X$ is $k$-dimensional”, we allow the possibility, that the highest dimension of a cell is actually less than $k$. This slightly fuzzy language should not pose a problem in practice.

**Example.** We consider the topological space which is sketched in Figure 593, namely

$$Y := ([−1, 1] \times [−1, 1]) \cup \{(x, y) \in \mathbb{R}^2 \mid x^2 + (y − 1)^2 = 1 \text{ and } y \geq 1\}.$$ 

The topological space $X$ thus consists of a square together with a semicircle.

![Figure 593](image)

Our goal is to find a CW-structure for $X$. First we consider the 0-dimensional CW-complex which consists of the 4 vertices of the square. Next we add a 1-cell. To do so we consider the map $\varphi$ which sends $\partial \overline{B^1} = \{\pm 1\}$ to the two points $\pm 1 \times -1$. The topological space $X^0 \cup_\varphi \overline{B^1}$ consists of the four points $\{\pm 1, \pm 1\}$ together with an edge which connects the lower two points. This topological space is sketched in the center of Figure 594. The same way we attach four more 1-cells and we obtain the 1-dimensional CW-complex which is sketched on the right of Figure 594. Finally we attach a 2-cell to $X^1$ with the attaching map shown in Figure 595 and we obtain a CW-complex $X^2$ whose topological realization is homeomorphic to $Y$.

Now we will see that most of the topological spaces that we have encountered so far can be described as CW-complexes.

---

578 Here we already use the convention that in our notation we do not distinguish between a CW-complex and its topological realization.
(1) It follows almost immediately from the definitions that every topological graph, as defined on page 223, admits naturally the structure of a one-dimensional CW-complex where the vertices correspond precisely to the 0-cells and the edges correspond precisely to the 1-cells. Conversely, every 1-dimensional CW-complex admits naturally the structure of a topological graph. Therefore in the following we will freely go back and forth between these objects.

(2) As a special case of (1) we see that $S^1$ can be viewed as a CW-complex with one 0-cell and one 1-cell. Furthermore we can view the wedge $S^1 \vee S^1$ as a CW-complex with one 0-cell and two 1-cells. Finally $\mathbb{R}$ can be viewed as a CW-complex where the 0-cells are given by the integers $\mathbb{Z}$ and the 1-cells are given by the intervals $[k, k + 1]$ with $k \in \mathbb{Z}$. We refer to Figure 596 for an illustration.

(3) Now we consider the torus $T = ([0, 1] \times [0, 1]) / \sim$. We denote by $p: [0, 1] \times [0, 1] \to T$ the obvious projection map. We can view $T$ as a CW-complex with one 0-cell corresponding to the point $p(0, 0) = p(0, 1) = p(1, 0) = p(1, 1)$, two 1-cells corresponding to...

\text{torus } [0, 1] \times [0, 1]/ \sim

\text{torus as subset of } \mathbb{R}^3

\text{Figure 597. The torus as CW-complex.}

(4) Next we consider the Klein bottle \( K = ([0, 1] \times [0, 1])/ \sim \). As usual we denote by
\[ p: [0, 1] \times [0, 1] \to K \text{ the projection map. Similar to the torus we can view } K \text{ as}
\[ \text{CW-complex with one 0-cell corresponding to } p(0, 0) = p(0, 1) = p(1, 0) = p(1, 1), \text{ two}
\[ \text{1-cells corresponding to } p(0 \times [0, 1]) = p(1 \times [0, 1]) \text{ and to } p([0, 1] \times 0) = p([0, 1] \times 1)
\[ \text{and one 2-cell corresponding to } p([0, 1] \times [0, 1]) \text{ with the attaching map sketched in}
\[ \text{Figure 598}. \text{ The 1-skeleta of the torus and the Klein bottle are both wedges of two circles. Further-
\[ \text{more both CW-complexes have precisely one 2-cell. The difference between the}
\[ \text{torus and the Klein bottle is that the attaching maps for the 2-cells are different.}

(5) In Figure 599 we show that we can endow the torus with different CW-structures.

(6) In Figure 600 we sketch how we can view the surface of genus 2, the projective
\[ \text{plane } \mathbb{R}P^2, \text{ the non-orientable surface of genus 3 and the Möbius band as CW-com-
\[ \text{plexes}. \]

\[ \mathbf{579} \text{Strictly speaking the attaching map is given by}
\[ S^1 \to T^1
\[ e^{it} \to \begin{cases}
\frac{p(\frac{2\pi}{3}, 0), \text{ if } t \in [0, \frac{\pi}{3}]}
\frac{p(1, \frac{2\pi}{3}(t - \frac{\pi}{3})), \text{ if } t \in [\frac{\pi}{3}, \frac{\pi}{2}]}
\frac{p(1 - \frac{2\pi}{3}(t - \frac{\pi}{3}), 1), \text{ if } t \in [\frac{\pi}{2}, \frac{3\pi}{3}]}n
\frac{p(0, 1 - \frac{2\pi}{3}(t - \frac{\pi}{3})), \text{ if } t \in [\frac{3\pi}{3}, 2\pi]}
\end{cases}
\]

\text{But writing out the attaching map with explicit formulas is clearly not very instructive.}

\[ \mathbf{580} \text{Evidently, as in Footnote } \mathbf{579} \text{ one could spell out the attaching map with precise formulas, but}
\[ \text{there is no point in doing it.}

\[ \mathbf{581} \text{What does the 1-skeleton of the given CW-structure for the surface of genus two look like, if we}
\text{view the surface } \Sigma \text{ as a “physical object” in } \mathbb{R}^3?\]
Figure 598. The Klein bottle as CW-complex.

Figure 599. The torus with three different CW-structures.

Figure 600

(7) We conclude this discussion of surfaces with the 2-sphere. Since it makes no difference, we will immediately discuss the case of any sphere. We can describe the $n$-dimensional sphere $S^n$ as a CW-complex $X$ as follows: We take a single 0-cell given by a point $P$ and one $n$-cell where the attaching map $\varphi: S^{n-1} \rightarrow X^0 = \{P\}$ sends the whole boundary $S^{n-1}$ to the point $P$. The topological realization of $X$ is thus given by

$$X^0 \cup_\varphi \overline{B^n} = \{P\} \cup_{P=\partial B^n} \overline{B^n} = \overline{B^n}/S^{n-1} \xrightarrow{\cong} S^n.$$  

identification from page [182]

We refer to this CW-structure on $S^n$ as the canonical CW-structure on $S^n$. Note that the identification on page [182] identifies unique 0-cell to the left with the North
Pole $(0, \ldots, 0, 1)$. Unless we say something else we will equip $S^n$ with the above CW-structure.

We continue the discussion of CW-complexes with two more explicit examples, namely the real projective spaces and the complex projective spaces which we had already defined on page [94]. In the following let $A = \mathbb{R}$ or $A = \mathbb{C}$. We denote by $\sim$ the equivalence relation on $A^{n+1} \setminus \{0\}$ given by multiplication by an element in $A \setminus \{0\}$ and we define

$$AP^n := (A^{n+1} \setminus \{0\})/\sim.$$ 

On page [287] and Lemma [12.5] we saw that $AP^n$ is a smooth manifold. Given a point $(v_0, \ldots, v_n) \in A^{n+1} \setminus \{0\}$ we denote by $[v_0 : \ldots : v_n]$ its equivalence class. For $k \leq n$ the map

$$AP^k \to AP^n$$

$$[v_0 : \ldots : v_k] \mapsto [v_0 : \ldots : v_k : 0 : \ldots : 0]$$

is easily seen to be a smooth embedding and we use it to view $AP^k$ as a submanifold of $AP^n$.

We can give an explicit description of $\mathbb{R}P^n$ and $\mathbb{C}P^n$ as CW-complexes.

**Lemma 36.1.** Let $n \in \mathbb{N}_0$.

1. We can view $\mathbb{R}P^n$ as a CW-complex with the following properties:
   a. the CW-structure has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells,
   b. for each $k \leq n$ the $k$-skeleton of $\mathbb{R}P^n$ is given by $\mathbb{R}P^k$.
2. We can view $\mathbb{C}P^n$ as a CW-complex with the following properties:
   a. the CW-structure has exactly one cell in the dimensions $0, 2, \ldots, 2n$ and no other cells,
   b. for each $k \leq n$ the $2k$-skeleton of $\mathbb{C}P^n$ is given by $\mathbb{C}P^k$.

**Proof.**

1. We prove the statement by induction on $n$. For $n = 0$ the topological space $\mathbb{R}P^0$ consists of a single point which means that it is a CW-complex with a single $0$-cell. Now suppose that we have equipped $\mathbb{R}P^{n-1}$ with a CW-structure with the properties stated in (a) and (b). We view $\mathbb{R}P^{n-1}$ as the subspace of $\mathbb{R}P^n$ that is given by setting the last coordinate to zero. We consider the attaching map

$$\varphi : S^{n-1} \to \mathbb{R}P^{n-1}$$

$$(x_1, \ldots, x_n) \mapsto [x_1 : \ldots : x_n].$$

It remains to show that there exists a homeomorphism $\mathbb{R}P^{n-1} \cup_\varphi \overline{B^n} \to \mathbb{R}P^n$ that restricts to the identity on $\mathbb{R}P^{n-1}$. We consider the map

$$\Theta : \mathbb{R}P^{n-1} \cup_\varphi \overline{B^n} \to \mathbb{R}P^n$$

$$[P] \mapsto \begin{cases} [x_1 : \ldots : x_n : 0], & \text{if } P = [x_1 : \ldots : x_n] \in \mathbb{R}P^{n-1}, \\ [P : 1 - \|P\|], & \text{if } P \in \overline{B^n}. \end{cases}$$

It follows immediately from the definition of $\varphi$ that the map $\Theta$ is well-defined. Furthermore it follows easily from Lemma [3.22] that the map $\Theta$ is continuous. It is
basically clear that the map $\Theta$ is a surjection and it is straightforward to verify that the map $\Theta$ is an injection. Using Proposition 3.40, Lemma 3.22 and Proposition 2.43 one can easily verify that the map is a homeomorphism. Finally it is clear that the restriction of the map $\Theta$ to $\mathbb{R}P^{n-1}$ is the identity.

(2) The proof for $\mathbb{C}P^n$ is basically identical to the proof of (1). We just need to view $S^{2n-1}$ and $B^{2n}$ as subsets of $\mathbb{C}^n$. We leave it to the reader to make the necessary minuscule modifications.

To enhance the reader’s interest in CW-complexes we now give a sneak preview of a later result.

**Theorem 64.5**  Every compact connected $n$-dimensional smooth manifold $M$ admits a finite CW-structure with the following properties:

1. the maximal dimension of a cell is $n$,
2. the boundary $\partial M$ is a subcomplex.

Furthermore, if $M = A \cup B$ is a decomposition into two $n$-dimensional submanifolds such that $A \cap B$ is a union of boundary components of $A$ and a union of boundary components of $B$, then we can find a CW-structure on $M$ which has all the above properties and such that $A$ and $B$ are subcomplexes.

In the above discussion we have seen that many of the topological spaces we are interested in can be viewed as CW-complexes. But note that not every topological space can be described as a CW-complex. For example consider the topological space $X$ which consists of precisely two points $P$ and $Q$ and which is endowed with the trivial topology. (Recall that this means that the only open sets are the empty set and all of $X$.) Then we cannot view $X$ as CW-complex since any CW-complex with finitely many points consists only of 0-cells together with the discrete topology. For the same reason $\{0\} \cup \{\frac{1}{n} | n \in \mathbb{N}\}$ is not a CW-complex.

### 36.2. Two topologies on $\mathbb{R}^\infty$.

In the next section we want to introduce infinite-dimensional CW-complexes. Before we do so we want to get more acquainted with $\mathbb{R}^\infty$ and topologies on the set $\mathbb{R}^\infty$. First of all we write

$$\mathbb{R}^\infty := \mathbb{R}^{(\mathbb{N})} := \{(x_1, x_2, \ldots) | \text{only finitely many } x_i \text{ are non-zero}\}.$$ 

As in the finite-dimensional case we can equip $\mathbb{R}^\infty$ with the Euclidean metric

$$d((x_1, x_2, \ldots), (y_1, y_2, \ldots)) := \sqrt{\sum_{i=1}^{\infty} |x_i - y_i|^2}.$$ 

By Lemma 2.1 the metric $d$ defines a topology on $\mathbb{R}^\infty$, more precisely

$$S := \{U \subset \mathbb{R}^\infty | \text{for every } P \in U \text{ there exists an } \epsilon > 0 \text{ such that } B_{\epsilon}(P) \subset U\}$$

is a topology on $\mathbb{R}^\infty$.

This topology might feel like it is the “right topology” on $\mathbb{R}^\infty$. But the next two examples might sow some doubts.

---

Note that the series on the right is in fact a finite sum, since all but finitely many terms are zero. It is again straightforward to verify that $d$ is a metric.
Examples.

(1) We claim that the function
\[
\alpha : \mathbb{R}^\infty \to \mathbb{R}, \quad (x_1, x_2, \ldots) \mapsto \sum_{i=1}^{\infty} 2^i \cdot x_i
\]
is not continuous with respect to \( \mathcal{S} \). To show this claim we consider the open subset \((-1, 1) \subset \mathbb{R} \), then \( \alpha^{-1}((-1, 1)) \) contains the origin \( 0 \). We claim that there is no \( \epsilon > 0 \) with \( B_\epsilon(0) \subset \alpha^{-1}((-1, 1)) \). Indeed, suppose such \( \epsilon > 0 \) exists. We pick \( i \in \mathbb{N} \) with \( \frac{1}{2^i} < \epsilon \) and we consider the point
\[
Q = (0, \ldots, 0, \frac{1}{2^i}, 0, \ldots).
\]
Then \( Q \in B_\epsilon(0) \) but \( \alpha(Q) = 1 \), i.e. \( Q \notin \alpha^{-1}((-1, 1)) \).

(2) Let \( B \) be the infinite diagonal matrix where the diagonal entries are given by \( 2^i \) for \( i = 1, 2, \ldots \), i.e. let
\[
B := \begin{pmatrix}
2 & 0 & 0 & \ldots \\
0 & 4 & 0 & \ldots \\
0 & 0 & 8 & \ldots \\
\vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
\]
We claim that the map
\[
\beta : \mathbb{R}^\infty \to \mathbb{R}^\infty, \quad x \mapsto B \cdot x
\]
is not continuous with respect to \( \mathcal{S} \). Indeed, an argument similar to (1) shows that the preimage of the open set \( U = B_1(0) \) is not open.

The maps \( \alpha \) and \( \beta \) feel quite natural, so we might want to look around for a different topology on \( \mathbb{R}^\infty \) for which these two maps are in fact continuous. Of course that would be achieved by equipping \( \mathbb{R}^\infty \) with the discrete topology, but clearly that’s not what we want. Another reasonable condition on the desired topology is that for any \( n \in \mathbb{N}_0 \) the inclusion map
\[
\iota_n : \mathbb{R}^n \hookrightarrow \mathbb{R}^\infty, \quad (x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_n, 0, \ldots)
\]
should also be continuous. This immediately eliminates the discrete topology as a contender for the “right topology”.

In fact this last condition leads us almost immediately to an alternative topology on \( \mathbb{R}^\infty \). We saw in the proof of Proposition 25.1 that in the category of topological spaces we have
\[
\lim_{\rightarrow} \mathbb{R}^n = \mathbb{R}^\infty,
\]
where \( \mathbb{R}^\infty \) is equipped with the “weak topology”, i.e. with the topology
\[
\mathcal{T} := \{ U \subset \mathbb{R}^\infty \mid \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n \}.
\]
Put differently, a map \( f : \mathbb{R}^\infty \to X \) to a topological space \( X \) is continuous with respect to \( \mathcal{T} \) if and only if for each \( n \in \mathbb{N} \) the map \( \mathbb{R}^n \to \mathbb{R}^\infty \xrightarrow{f} X \) is continuous.

**Examples.**

1. By definition of \( \mathcal{T} \) the inclusion map \( \mathbb{R}^n \to \mathbb{R}^\infty \) is continuous with respect to \( \mathcal{T} \).
2. The above map \( \alpha : \mathbb{R}^\infty \to \mathbb{R} \) is continuous with respect to the topology \( \mathcal{T} \). Indeed, for any \( n \in \mathbb{N} \) the restriction \( \mathbb{R}^n \to \mathbb{R}^\infty \to \mathbb{R} \) is a linear map, hence continuous.
3. In Exercise 36.2 we will see that \( \mathbb{S} \) is a topological space with respect to the topology \( \mathcal{T} \). This implies in particular that the identity map defines a continuous map \( (\mathbb{R}^\infty, \mathcal{T}) \to (\mathbb{R}^\infty, \mathcal{S}) \).
4. Let \( a_i, b_i, i \in \mathbb{N} \) be real numbers. The infinite hyperrectangle

\[
(a_1, b_1) \times (a_2, b_2) \times (a_3, b_3) \times \ldots
\]

is easily seen to be an open subset of \((\mathbb{R}^\infty, \mathcal{T})\).\(^{583}\)

The following lemma shows in particular that the above map \( \beta : \mathbb{R}^\infty \to \mathbb{R}^\infty \) is continuous with respect to the topology \( \mathcal{T} \).

**Lemma 36.2.** Let \( C = (c_{ij})_{i,j \in \mathbb{N}} \) be an infinite diagonal matrix. Then the map\(^{581}\)

\[
\gamma : \mathbb{R}^\infty \to \mathbb{R}^\infty \\
x \mapsto C \cdot x
\]

is continuous with respect to the topology \( \mathcal{T} \).

**Proof.** Let \( U \in \mathcal{T} \). We need to show that \( \gamma^{-1}(U) \) lies in \( \mathcal{T} \). So given any \( n \in \mathbb{N} \) we need to show that \( \gamma^{-1}(U) \cap \mathbb{R}^n \) is an open subset of \( \mathbb{R}^n \). So let \( n \in \mathbb{N} \). Given \( m \in \mathbb{N} \) we denote by \( C_{m,n} \) the submatrix of \( C \) given by the top left \( m \times n \)-submatrix of \( C \) and we denote by \( \gamma_{m,n} : \mathbb{R}^n \to \mathbb{R}^m \) the map given by \( x \mapsto C_{m,n} \cdot x \). We have\(^{587}\)

\[
\gamma^{-1}(U) \cap \mathbb{R}^n = \left\{ x \in \mathbb{R}^n \mid C \cdot x \in U \right\} = \bigcup_{m \in \mathbb{N}} \left\{ x \in \mathbb{R}^n \mid C \cdot x \in U \cap \mathbb{R}^m \right\} = \bigcup_{m \in \mathbb{N}} \left\{ x \in \mathbb{R}^n \mid C_{m,n} \cdot x \in U \cap \mathbb{R}^m \right\}.
\]

This shows that \( \gamma^{-1}(U) \cap \mathbb{R}^n \) is a union of open subsets of \( \mathbb{R}^n \), hence itself is open. \(\blacksquare\)

This discussion shows hopefully that the following convention is reasonable.

**Convention.** Unless we say something else we will view \( \mathbb{R}^\infty \) as a topological space with the topology \( \mathcal{T} \). Put differently, we think of \( \mathbb{R}^\infty \) as \( \mathbb{R}^\infty = \lim_{\to} \mathbb{R}^n \). Similarly we define \( \mathbb{C}^\infty = \lim_{\to} \mathbb{C}^n \) as topological spaces.

---

\(^{581}\)This example is less obvious. The topology \( \mathcal{T} \) has more open sets than \( \mathcal{S} \) which made it easier in (2) to argue that the map \( \alpha \) is continuous. But here in (3) it also makes it harder, since we have to check the continuity for more open sets on the right-hand side.

\(^{587}\)Does this also work for any infinite-square matrix?

\(^{583}\)For each \( k \in \mathbb{N} \) we view \( \mathbb{R}^k \) as a subset of \( \mathbb{R}^\infty \) via the inclusion \( \iota_k \).
**Remark.** In Exercise 36.3 we will verify that the map
\[
C^\infty \rightarrow \mathbb{R}^\infty
(\, x_1 + iy_1, x_2 + iy_2, \ldots \, ) \rightarrow (\, x_1, y_1, x_2, y_2, \ldots \, )
\]
is a homeomorphism. At times we will use this homeomorphism to make the identification \( C^\infty = \mathbb{R}^\infty \).

In the future, the more we work with \( \mathbb{R}^\infty \) and \( C^\infty \), the more we will see that the “direct limit topology” is in fact the “right” topology to work with.

To get acquainted with this new topological space we want to prove the following lemma.

**Lemma 36.3.** Given any compact subset \( K \) of \( \mathbb{R}^\infty \) there exists an \( n \in \mathbb{N} \) with \( K \subseteq \mathbb{R}^n \).

**Proof.** So let \( K \subseteq \mathbb{R}^\infty \) be a compact set. Suppose that there is no \( n \in \mathbb{N} \) such that \( K \subseteq \mathbb{R}^n \). Then there exists an infinite increasing sequence \( n_1, n_2, n_3, \ldots \) of natural numbers and points \( x_1, x_2, x_3, \ldots \) in \( K \) such that \( x_i \in \mathbb{R}^{n_i} \setminus \mathbb{R}^{n_i-1} \). We denote by \( X \) the set whose elements are precisely the \( x_i \).

**Claim 1.** The set \( X \) is a discrete subset of \( \mathbb{R}^\infty \).

To simplify the notation we assume that \( n_i = i \) for all \( i \in \mathbb{N} \). For each \( i \) we denote by \( z_i \) the \( i \)-coefficient of \( x_i \). Put differently, \( z_i \) is the highest non-zero coefficient of \( x_i \). Furthermore for each \( i \in \mathbb{N} \) we pick \( \epsilon_i \in (0, \frac{\|z_i\|}{2}) \). Finally, given \( x \in \mathbb{R} \) and \( \epsilon > 0 \) we write \( I_\epsilon(x) = (x - \epsilon, x + \epsilon) \). We define
\[
\begin{align*}
U_1 & = I_{\epsilon_1}(z_1) \times I_{\epsilon_2}(0) \times I_{\epsilon_3}(0) \times I_{\epsilon_4}(0) \times \ldots \\
U_2 & = \mathbb{R} \times I_{\epsilon_2}(z_2) \times I_{\epsilon_3}(0) \times I_{\epsilon_4}(z_4) \times \ldots \\
U_3 & = \mathbb{R} \times \mathbb{R} \times I_{\epsilon_3}(z_3) \times I_{\epsilon_4}(0) \times \ldots \\
& \vdots
\end{align*}
\]
As we remarked on page 938 each \( U_i \) is an open subset of \( \mathbb{R}^\infty \). Evidently \( U_i \) contains \( x_i \) and thus each \( U_i \) is an open neighborhood of \( x_i \). Furthermore the sets \( U_i, i \in \mathbb{N} \) are easily seen to be disjoint. But this shows, by definition of the subspace topology, that \( X \) is discrete. \( \Box \)

**Claim 2.** The set \( X \) is a closed subset of \( K \).

We need to show that \( X \setminus K \) is open. By definition of the subspace topology it suffices to show that \( \mathbb{R}^\infty \setminus X \) is open. In the following we continue with the notation from the previous claim. Thus let \( y \in \mathbb{R}^\infty \). We pick \( n \in \mathbb{N} \) such that \( y \in \mathbb{R}^n \). In \( \mathbb{R}^n \) we can and will pick an open neighborhood \( U \) of \( (y_1, \ldots, y_n) \) that does not contain \( x_1, \ldots, x_n \in \mathbb{R}^n \). One can now verify easily that
\[
V : = U \times I_{\epsilon_{n+1}}(0) \times I_{\epsilon_{n+2}}(0) \times \ldots
\]
is an open neighborhood of \( y \in \mathbb{R}^\infty \) that does not intersect \( X \). \( \Box \)

It follows from Claim 1, Claim 2 and Lemma 2.18 (2) that \( X \) is indeed finite. But that is a contradiction to our assumption that there is no \( n \in \mathbb{N} \) such that \( K \) is contained in \( \mathbb{R}^n \). \( \blacksquare \)
We conclude this section with a short discussion of the infinite-dimensional sphere $S^\infty$.

**Definition.** We refer to

$$S^\infty := \{ x \in \mathbb{R}^\infty \mid d(x, \text{origin}) = 1 \} = \{ (x_1, x_2, \ldots) \in \mathbb{R}^\infty \mid \sum_{i=1}^{\infty} x_i^2 = 1 \},$$

equip with the subspace topology coming from $\mathbb{R}^\infty$, as the infinite-dimensional sphere.

Even though we did not show it yet, we strongly expect that the finite-dimensional spheres $S^n$ are not contractible. In contrast to this expectation we have the following mind-bending lemma.

**Lemma 36.4.** The infinite-dimensional sphere $S^\infty$ is contractible.

**Proof.** We want to show that $S^\infty$ is contractible. We recall that by Lemma 18.13 it suffices to show that there exists a homotopy $H$ from $\text{id}_{S^\infty}$ to a constant map. Our goal is to find such $H$. We set

$$X := \{ (0, p_2, p_3, \ldots) \in \mathbb{R}^\infty \mid p_i \in \mathbb{R} \}.$$

Next we consider the maps

$$F: \mathbb{R}^\infty \times [0, 1] \to \mathbb{R}^\infty \quad \text{and} \quad G: X \times [0, 1] \to \mathbb{R}^\infty,$$

$$(P, t) \mapsto P \cdot (1 - t) + (0, P) \cdot t \quad \text{and} \quad (P, t) \mapsto P \cdot (1 - t) + (1, 0, \ldots) \cdot t,$$

$\neq 0$ if $P \neq 0$

For non-zero $P \in \mathbb{R}^\infty$ and $P \in X$ we define $\tilde{F}(P, t)$ and $\tilde{G}(P, t)$ to be the normalization of $F(P, t)$ and $G(P, t)$ to length one. Next we consider the map

$$H: S^\infty \times [0, 1] \to S^\infty \quad \text{where} \quad (P, t) \mapsto \begin{cases} \tilde{F}(P, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ \tilde{G}(\tilde{F}(P, 1), 2t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

Clearly $H_0 = \text{id}$ and it is straightforward to see that $H_1$ is a constant map. It is tempting to conclude that we are done. But in fact we still need to show the following claim.

**Claim.** The map $H$ is continuous.

By Lemma 14.3 it suffices to show that the restriction of $H$ to the subsets $S^\infty \times [0, \frac{1}{2}]$ and $S^\infty \times [\frac{1}{2}, 1]$ are continuous. Since intervals are regionally compact it follows from Lemma 25.1 that it suffices to show for each $n \in \mathbb{N}$ the restrictions of $H$ to the subsets $S^n \times [0, \frac{1}{2}]$ and $S^n \times [\frac{1}{2}, 1]$ are continuous. But now we are in familiar territory and the continuity is a consequence of elementary arguments. □

36.3. Infinite-dimensional CW-complexes. The following definition now generalizes the notion of a CW-complex.

**Definition.**

(a) A CW-complex $X$ is defined as a sequence

$$X^{-1} := \emptyset \subset X^0 \subset X^1 \subset X^2 \subset \ldots$$
of CW-complexes (in the sense of the definition of page 930) such that for each \( m \leq n \) the CW-complex \( X^m \) is the \( m \)-skeleton of \( X^n \). Let \( n \in \mathbb{N}_0 \). We adopt the following language:

(i) The (open) \( n \)-cells of \( X^n \) are called the (open) \( n \)-cells of \( X \).

(ii) We refer to \( X^n \) as the \( n \)-skeleton of \( X \).

(b) We define the topological realization \(|X|\) of such a CW-complex \( X \) as

\[
|X| := \lim_{\rightarrow} |X^n|.
\]

Recall that on page 930 we argued that for each \( n \in \mathbb{N}_0 \) we can view \(|X^n|\) as a subset of \(|X^{n+1}|\). Thus it follows from Lemma 25.3 that we can and will write

\[
|X| := \bigcup_{n \in \mathbb{N}_0} |X^n|
\]

where a subset \( U \subset |X| \) is open if and only if for every \( n \in \mathbb{N}_0 \) the intersection \( U \cap |X^n| \) is an open subset of \(|X^n|\). As before, in the notation we usually do not distinguish between the notation for a CW-complex and its topological realization.

(c) We define the dimension \( \dim(X) \in \mathbb{N}_0 \cup \{\infty\} \) of a non-empty CW-complex \( X \) as the maximal dimension of a cell. We define the dimension of the empty CW-complex to be \(-1\).

(d) We say a CW-complex is finite if it has only finitely many cells and we say it is countable if it has only countably many cells.

(e) A CW-structure for a topological space \( Y \) is a CW-complex \( X \) together with a homeomorphism \( f : |X| \to Y \).

Remark.

(1) Let \( X \) be a CW-complex and let \( n \in \mathbb{N}_0 \). By Lemma 25.3 we know that the inclusion map \(|X^n| \to |X|\) is an embedding. Thus we can and will view the \( n \)-skeleton as a subset of \( X \).

(2) The topology given in (b) on a union of topological spaces is sometimes called the weak topology. This explains the "W" of the name CW-complex.

(3) It follows almost immediately from the definitions that the topological realization \(|X|\) of a CW-complex is, as a set, the disjoint union of all the open cells.

(4) On a few occasions we will refer to \( X^\infty := X \) as the \( \infty \)-skeleton.

Examples.

(1) We consider the infinite sphere

\[
S^\infty = \{ x \in \mathbb{R}^\infty \mid d(x, \text{origin}) = 1 \} = \left\{ (x_1, x_2, \ldots) \in \mathbb{R}^\infty \bigg| \sum_{i=1}^{\infty} x_i^2 = 1 \right\}
\]

which equip with the subspace topology coming from \( \mathbb{R}^\infty \). It follows easily from the fact that \( \mathbb{R}^\infty = \lim_{\rightarrow} \mathbb{R}^n \) that we have the equality \( S^\infty = \lim_{\rightarrow} S^n \). We consider iteratively the spheres \( S^n \) as CW-complexes, where \( S^0 \) consists of two 0-cells and where \( S^n \) is built starting from \( S^{n-1} \) by attaching two \( n \)-cells (the upper hemisphere

\[\text{Here we define } \dim(X) := \infty \text{ if } X \text{ admits cells of arbitrarily large dimensions.}\]
and the lower hemisphere”) to \( S^{n-1} \). We then obtain an ascending sequence

\[ S^0 \subset S^1 \subset S^2 \subset \ldots \]

of CW-complexes which satisfies precisely the required properties of a CW-complex as defined above. This shows that the sphere \( S^\infty \) is an infinite-dimensional CW-complex. We refer to Figure 601 for an illustration.\(^{587}\)

![Figure 601](image)

**Figure 601**

(2) Let \( I \) be a set and for each \( i \in I \) let \( n_i \in \mathbb{N} \). In Exercise 36.10 we will see that the wedge \( \bigvee_{i \in I} S^{n_i} \) has a natural CW-structure with one 0-cell and where for each \( n \in \mathbb{N}_0 \) the \( n \)-cells correspond precisely to the \( n \)-dimensional spheres in our family of spheres \( \{ S^{n_i} \}_{i \in I} \).

The following definition and notation is the obvious infinite-dimensional analogue of the finite-dimensional definitions introduced on page 194.

**Definition.** Let \( A = \mathbb{R} \) or \( A = \mathbb{C} \).

1. We define the **infinite-dimensional projective space** \( \mathbb{A}P^\infty \) as the set

\[ \mathbb{A}P^\infty = (A^\infty \setminus \{0\})/(A \setminus \{0\}) \]

together with the quotient topology.

2. Given a point \( (x_1, x_2, \ldots) \in A^\infty \setminus \{0\} \) we denote its equivalence class in \( \mathbb{A}P^\infty \) by \( [x_1 : x_2 : \ldots] \).

3. Given \( n \in \mathbb{N} \) we view \( \mathbb{A}P^n \) as a subset of \( \mathbb{A}P^\infty \) via the inclusion map

\[ \mathbb{A}P^n \rightarrow \mathbb{A}P^\infty \]

\[ [x_0 : \cdots : x_n] \mapsto [x_0 : \cdots : x_n : 0 : \ldots]. \]

The following lemma shows in particular that we can view the real infinite projective space \( \mathbb{R}P^\infty \) as an infinite-dimensional CW-complex.

**Lemma 36.5.**

1. For each \( n \in \mathbb{N} \) the obvious map \( \mathbb{R}P^n \rightarrow \mathbb{R}P^\infty \) is an embedding. Furthermore these maps define a homeomorphism \( \lim \mathbb{R}P^n \cong \mathbb{R}P^\infty \).

2. The topological space \( \mathbb{R}P^\infty \) admits a CW-structure such that for every \( n \in \mathbb{N} \) the \( n \)-skeleton is given by \( \mathbb{R}P^n \rightarrow \mathbb{R}P^\infty \) where \( \mathbb{R}P^n \) is equipped with the CW-structure coming from Lemma 36.7.\(^{587}\)

---

\(^{587}\)If we equip \( S^\infty \) with the topology \( S \) coming from the Euclidean metric on \( \mathbb{R}^\infty \), then this argument does not work and it is not clear (and presumably wrong), that \((S^\infty, S)\) is a CW-complex.
(3) The infinite real projective space $\mathbb{R}P^\infty$ admits a CW-structure which has precisely one $n$-cell for every $n \in \mathbb{N}_0$.

(4) (a) The action $\{\pm 1\} \times S^\infty \to S^\infty$ given by $(\epsilon, v) \mapsto \epsilon \cdot v$ is continuous and discrete.
(b) The obvious projection $S^\infty \to S^\infty / x \sim -x$ is a 2-fold covering.
(c) The map
\[
S^\infty / x \sim -x \to \mathbb{R}P^\infty \quad \quad [(x_1, x_2, \ldots)] \mapsto [x_1 : x_2 : \ldots]
\]
is a homeomorphism.

Proof (\textbf{*}).

(1) We leave it as a very mildly interesting exercise to the reader to show that for each $n \in \mathbb{N}$ the obvious map $\mathbb{R}P^n \to \mathbb{R}P^\infty$ is an embedding. Next we note that we have the following equalities:

\[
\text{homeomorphism by Lemma 25.5}
\lim_{\to} \mathbb{R}P^n = \lim_{\to} (\mathbb{R}^{n+1} \setminus \{0\}) / (\mathbb{R} \setminus \{0\}) \xrightarrow{\text{homeomorphism by Lemma 25.5}} \lim_{\to} (\mathbb{R}^{n+1} \setminus \{0\}) / (\mathbb{R} \setminus \{0\}) = (\mathbb{R}^\infty \setminus \{0\}) / (\mathbb{R} \setminus \{0\}) = \mathbb{R}P^\infty.
\]

It follows easily from the definitions that this homeomorphism is the inclusion induced map.

(2) This statement follows immediately from (1) and the definition of a CW-complex on page 940.

(3) This statement is an immediate consequence of (2) and the definition of the CW-structure on each $\mathbb{R}P^n$.

(4) (a) The statement is not difficult to prove, but one needs to argue carefully with the given topology on $S^\infty$. We will fill in the details in Exercise 36.4.
(b) This statement follows from (a) and Proposition 16.9.
(c) It is straightforward to verify that the given map is a bijection. We leave it to the reader to verify that the map is continuous and that its inverse is continuous. ■

The following lemma is the complex sibling of Lemma 36.5.

Lemma 36.6.

(1) For each $n \in \mathbb{N}$ the obvious map $\mathbb{C}P^n \to \mathbb{C}P^\infty$ is an embedding. Furthermore the maps $\mathbb{C}P^n \to \mathbb{C}P^\infty$ define a homeomorphism $\lim_{\to} \mathbb{C}P^n \xrightarrow{\cong} \mathbb{C}P^\infty$.

(2) The topological space $\mathbb{C}P^\infty$ admits a CW-structure such that for every $n \in \mathbb{N}$ the 2n-skeleton is given by $\mathbb{C}P^n \to \mathbb{C}P^\infty$ where $\mathbb{C}P^n$ is equipped with the CW-structure coming from Lemma 36.7.

(3) The infinite complex projective space $\mathbb{C}P^\infty$ admits a CW-structure which has precisely one $n$-cell for every even $n \in \mathbb{N}_0$.

Proof. The proof of this lemma is basically verbatim the same as the proof of the corresponding parts of Lemma 36.5. ■
**Convention.** We will use Lemmas [36.5.1](#) and [36.6](#) as an excuse to view each $\mathbb{RP}^n$ as a subset of $\mathbb{RP}^\infty$ and to view each $\mathbb{CP}^n$ as a subset of $\mathbb{CP}^\infty$.

The following lemma says that characteristic maps are continuous and it gives a convenient approach to showing that a map starting at a CW-complex is continuous.

**Lemma 36.7.** Let $X$ be a CW-complex. We denote by $\{\Phi_i : \overline{B^n}_i \to X\}_{i \in I}$ the characteristic maps of all the cells of $X$. The following four statements hold:

1. Every characteristic map $\Phi_i$ is continuous.
2. A subset $U \subset X$ is open if and only if for each $i \in I$ the preimage of $U$ under the characteristic map $\Phi_i$ is open, i.e. if each $\Phi_i^{-1}(U) \subset \overline{B^n}_i$ is an open subset of $\overline{B^n}_i$.
3. The statement in (2) also holds if we replace “open” by “closed”.
4. A map $f : X \to Y$ to a topological space $Y$ is continuous if and only if each map $f \circ \Phi_i : \overline{B^n}_i \to Y$ is continuous.

**Proof.** (1). Given $n \in \mathbb{N}_0$ we denote by $I_n \subset I$ the indices corresponding to the characteristic maps of the $n$-dimensional cells.

(1) Let $i \in I_n$. The characteristic map $\Phi : \overline{B^n} \to X$ is the composition of the maps

$$\overline{B^n} = \overline{B^n}_i \to |X^{n-1}| \cup \bigcup_{j \in I_n} \overline{B^n}_j \to |X^n| = \left( |X^{n-1}| \cup \bigcup_{j \in I_n} \overline{B^n}_j \right) / \sim \to |X| = \lim_{\to} |X^k|.$$

All these maps are obviously continuous, hence the composition is also continuous.

(2) Once one has unraveled the definition of the topology on a CW-complex one sees that the first statement of the lemma is obvious. In the following we will try to convince the reader that this glib statement is actually correct.

Thus let $U \subset X$ be a subset. By the definition on page 941 we know that $U$ is open if and only if for each $n \in \mathbb{N}_0$ the intersection $U \cap |X_n|$ is an open subset of $|X_n|$. The statement follows from this observation together with the following claim.

**Claim.** Let $n \in \mathbb{N}$ and let $U$ be a subset of $|X_n|$. The following two statements are equivalent:

(a) $U$ is an open subset of $|X_n|$.
(b) $U \cap |X_{n-1}|$ is an open subset of $|X_{n-1}|$ and for every $i \in I_n$ the preimage $\Phi_i^{-1}(U)$ is an open subset of $\overline{B^n}_i$.

By the definition on page 930 we have

$$|X^n| = \left( |X^{n-1}| \cup \bigcup_{i \in I_n} \overline{B^n}_i \right) / \sim \text{ where } \Phi_i(x) \sim x \text{ for } x \in \partial \overline{B^n}_i.$$

The statement now follows easily from the definition of the quotient topology and the disjoint union topology Lemma [3.44](#)(4). We leave it to the reader to weave these slogans into a coherent argument.

(3) The “only if”-direction follows from Lemma [36.7](#)(1). The “if”-direction follows from (1) and a slight generalization of Lemma [2.34](#) which one can easily prove using Lemma [1.3](#)(7). We leave it to the reader to make sense of this cryptic remark.
(4) Let \( f : X \to Y \) be a map to a topological space. If \( f \) is continuous, then it follows from Lemma [36.7] (1) that each map \( f \circ \Phi_i : \overline{B}^n \to Y \) is continuous. Now suppose conversely that each map \( f \circ \Phi_i : \overline{B}^n \to Y \) is continuous. Let \( U \subset Y \) be an open subset. We need to show that \( f^{-1}(U) \) is an open subset of \( X \). By (1) it suffices to show that each preimage \( \Phi_i^{-1}(f^{-1}(U)) \) is an open subset of \( \overline{B}^n \). But this follows from the observation that \( \Phi_i^{-1}(f^{-1}(U)) = (f \circ \Phi_i)^{-1}(U) \) and the hypothesis that each \( f \circ \Phi_i \) is continuous.

\[ \square \]

36.4. Homotopies on infinite CW-complexes (*). On several occasions throughout these notes, in particular in the next section, we will want to construct a homotopy on an infinite-dimensional CW-complex by working our way up through the skeleta. In the end one needs to combine infinitely many homotopies which obviously leads to continuity issues. This rather technical section deals with these issues. It is best to initially skip this section and to go back to it if later on one really wants to know how an argument works.

For the undaunted reader we start out with the following subtle lemma.

**Lemma 36.8.** Let \( X \) be a CW-complex. The following three topologies on \( X \times [0,1] \) agree:

1. The product topology on the product \( X \times [0,1] \).
2. The topology on \( X \times [0,1] \) viewed as the direct limit \( \lim \rightarrow (X^k \times [0,1]) \).
3. The topology which is defined on the set \( X \times [0,1] \) by the condition that a given subset \( U \subset X \times [0,1] \) is open if and only if for each characteristic map \( \Phi : \overline{B}^n \to X \) the preimage \( (\Phi \times \text{id})^{-1}(U) \) is an open subset of \( \overline{B}^n \times [0,1] \).

**Proof.** Let \( X \) be a CW-complex. First note that it follows immediately from the fact that \( X = \lim \rightarrow X_k \) together with Lemma 3.8 (1c) that any subset that is open with respect to (1) is also open with respect to (2). Furthermore it follows from Lemma 36.7 (1) together with Lemma 3.8 (2b) that any subset that is open with respect to (2) is also open with respect to (3). Thus it suffices to show that any set that is open with respect to (3) is also open with respect to (1).

Let \( W \subset X \times [0,1] \) be a subset that is open with respect to (3). We need to show that \( W \) is also open with respect to the product topology on \( X \times [0,1] \). Let \((x_0,t_0) \in W \) be a point. By Lemma 3.11 it suffices to show the following statement:

(*) There exists a neighborhood \( V \) of \( x_0 \in X \) and a neighborhood \( K \) of \( t_0 \in [0,1] \) such that \( V \times K \) is contained in \( W \).

To prove (*) we start out with the following claim.

**Claim.** There exists a compact neighborhood \( K \) of \( t_0 \in [0,1] \) such that \( \{x_0\} \times K \subset W \).

Let \( \Phi : \overline{B}^n \to X \) be the characteristic map of the open cell that contains \( x_0 \). Note that \( \Phi : B^n \to X \) is injective. Thus there exists a unique \( y_0 \in B^n \) with \( \Phi(y_0) = x_0 \). We write \( \Psi := \Phi \times \text{id}_{[0,1]} \). Since \( W \) is open with respect to (3) we know that \( \Psi^{-1}(W) \) is an open

---

\[ ^{588} \text{Recall that we showed in Lemma 25.3 that this is the topology where a given subset } W \text{ of } X \times [0,1] = \lim \rightarrow (X^k \times [0,1]) \text{ is open if and only each intersection } W \cap (X^k \times [0,1]) \text{ is an open subset of } X^k \times [0,1]. \]
subset of $B^n \times [0, 1]$. Since $(y_0, t_0) \in \Psi^{-1}(W)$ we obtain from the definition of the product topology on $B^n \times [0, 1]$ there exists in particular an open neighborhood $J$ of $t_0 \in [0, 1]$ such that $\{y_0\} \times J \subset \Psi^{-1}(W)$. Since $[0, 1]$ is regionally compact we see that there exists a compact neighborhood $K$ of $t_0$ that is contained in $J$. Now we see that

$$\{x_0\} \times K = \Phi(\{y_0\}) \times K = \Psi(\{y_0\} \times K) \subset \Psi(\{y_0\} \times J) \subset \Psi(\Psi^{-1}(W)) \subset W.$$  

Thus $K$ has the desired property.

Thus $K$ has the desired property.

Next we consider $V := \{x \in X \mid \{x\} \times K \subset W\}$. By the choice of $K$ we have $x_0 \in V$. Thus to prove $(\ast)$ it remains to prove the following claim.

**Claim.** The subset $V$ is open in $X$.

We use Lemma 36.7 (2) to show that $V$ is open in $X$. Thus let $\Phi : B^n \to X$ be the characteristic map of an $n$-cell of $X$. We need to show that the preimage $\Phi^{-1}(V)$ is open in $B^n$. We write $U := (\Phi \times \text{id}_{[0, 1]})^{-1}(W)$. Since $W$ is open with respect to (3) we see that $U$ is an open subset of $B^n \times [0, 1]$. Basically by definition we have the equality

$$\Phi^{-1}(V) = \{y \in B^n \mid \{y\} \times K \subset U\}.$$

It follows from elementary point-set topology, see Exercise 3.10, that the set on the right-hand side is indeed open. This concludes the proof of the second claim and thus of the lemma.

Later on we will frequently need the following corollary.

**Corollary 36.9.** Let $X$ be a CW-complex and let $\Phi : X \times [0, 1] \to Y$ be a map to a topological space $Y$. The following statements are equivalent:

1. The map $f$ is continuous.
2. For every $k \in \mathbb{N}_0$ the restriction of $f$ to $X^k \times [0, 1]$ is continuous.
3. For every characteristic map $\Phi : B^n \to X$ the map

$$B^n \times [0, 1] \xrightarrow{(v, t) \mapsto (\Phi(v), t)} X \times [0, 1] \xrightarrow{f} Y$$

is continuous.

**Proof.** The corollary follows immediately from the equivalence of the three topologies in Lemma 36.8.
36.5. **Properties of CW-complexes.** We have seen, as promised, that many topological spaces that we are interested in are indeed CW-complexes. In this section we will prove a somewhat technical proposition that shows that CW-complexes have, again as promised, many nice topological properties.

To formulate the key result of this section we need the following definition which we will explore in much greater detail in the subsequent section.

**Definition.** A subcomplex of a CW-complex $X$ is a subset of $X$ that is the union of arbitrarily many cells of $X$. We say a subcomplex is finite it contains only finitely many cells of $X$.

Now we can state the main result of this section.

**Proposition 36.10.**

1. Every point on a CW-complex is closed.
2. (a) CW-complexes are Hausdorff.
   (b) CW-complexes are normal.
3. (a) Every cell of a CW-complex $X$ is compact and it is a closed subset of $X$.
   (b) Every finite CW-complex is compact.
   (c) The closure of an open cell is the corresponding cell. More precisely, given a characteristic map $\Phi: B^n \to X$ the closure of $\Phi(B^n)$ is indeed $\Phi(B^n)$.
   (d) If a closed subset of $X$ contains an open cell, then it also contains the corresponding cell.
4. Let $X$ be a CW-complex, let $x \in X$ and let $U$ be an open neighborhood $U$ of $x$.
   (a) There exists an open neighborhood $V$ of $x$ that is contained in $U$ and that admits a deformation retraction to $\{x\}$.
   (b) There exists a closed neighborhood $V$ of $x$ that is contained in $U$ and that admits a deformation retraction to $\{x\}$.
5. Every point on a CW-complex is good in the sense of the definition on page 604.
6. CW-complexes are locally contractible, locally path-connected, locally simply-connected and semi-locally simply connected.
7. Let $X$ be a CW-complex. The following statements are equivalent:
   (a) $X$ is connected.
   (b) $X$ is path-connected.
   (c) The 1-skeleton $X^1$ is connected.
   (d) The 1-skeleton $X^1$ is path-connected.
   (e) Given any two distinct points $P, Q$ in the 0-skeleton of $X$ there exists an embedding $\gamma: [0, 1] \to X^1$ with $\gamma(0) = P$, $\gamma(1) = Q$ and such that $\gamma([0, 1])$ is a subcomplex of $X^1$.
8. There exists a map $\Phi$ which assigns to each subcomplex $A$ a subset $\Phi(A) \subset X$ such that the following statements hold:
   (a) for each subcomplex $A$ the set $\Phi(A)$ is an open neighborhood of $A$ such that $A$ is a deformation retract of $\Phi(A)$,
(b) for any two subcomplexes $A_1$ and $A_2$ we have
\[ \Phi(A_1 \cap A_2) = \Phi(A_1) \cap \Phi(A_2) \quad \text{and} \quad \Phi(A_1 \cup A_2) = \Phi(A_1) \cup \Phi(A_2), \]
(c) for any two subcomplexes $A$ and $B$ with $A \subseteq B$ we have $\Phi(A) \subseteq \Phi(B)$.

Figure 604. Illustration of Proposition 36.10 (8).

Remark.

(1) In a slightly simplified form Proposition 36.10 (8) says that we can assign to each subcomplex $A$ in a “systematic way” an open neighborhood $\Phi(A)$ that deformation retracts to $A$.

(2) In Proposition 36.10 (8) it is essential that $A$ is a subcomplex. For example, if we consider $X = \mathbb{R}$ and $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$, then $A$ does not admit an open neighborhood $U$ such that $A$ is a deformation retract of $U$.

(3) Proposition 36.10 (6) sounds somewhat technical, but it ensures that later on we can apply Proposition 29.5 to obtain coverings of CW-complexes.

(4) Many other useful properties of CW-complexes are proved in [LW69] Section II.3.

(5) There is a limit to what degree CW-complexes are nice, for example in Exercise 18.35 we saw that the wedge $\bigvee_{\epsilon \in \mathbb{N}_0} [0, 1]$, which is easily seen to be a CW-complex, is not metrizable.

Proof (*). We start out with the following notation. Given a subset $A$ of $\overline{B}^n$ and $\epsilon > 0$ we denote by
\[ N_\epsilon(A) := \{ x \in \overline{B}^n \mid \text{there exists an } y \in A \text{ with } \|x - y\| < \epsilon \} \]
the $\epsilon$-neighborhood around $A$. One easily verifies that $N_\epsilon(A)$ is an open subset of $\overline{B}^n$. Furthermore given two non-empty subsets $X$ and $Y$ of $\overline{B}^n$ we follow the notation introduced on page 175 and we write
\[ d(X, Y) := \inf \{\|x - y\| \mid x \in X \text{ and } y \in Y\}. \]

Note that we need (1) in the proof of (2), thus we cannot just use Lemma 2.13 to deduce (2) from (1).

Recall that on page 125 we introduced the definition that a topological space $X$ is called normal if any two disjoint closed subsets $A$ and $B$ of $X$ are separated by neighborhoods, i.e. if there exist disjoint neighborhoods $U$ of $A$ and $V$ of $B$. Why not?
Furthermore, if \( X \) or \( Y \) is empty, then we define \( d(X, Y) = \infty \) and evidently we write \( \infty > 0 \).

Now let \( X \) be a CW-complex. We denote by \( \Gamma \) the set of cells of \( X \) and given \( n \in \mathbb{N}_0 \) we denote by \( \Gamma_n \) the set of \( n \)-cells. Given a cell \( \gamma \) we denote by \( \Phi_\gamma \) the corresponding characteristic map.

Let \( A \subset X \) be a subset and let \( \epsilon \) be a map that assigns to each \( \gamma \in \Gamma \) a positive number \( \epsilon_\gamma \). Given \( n \in \mathbb{N}_0 \) we define a subset \( N_\epsilon^n(A) \) inductively as follows:

(i) For \( n = 0 \) we define \( N_\epsilon^0(A) := A \cap X^0 \).

(ii) Suppose that \( N_\epsilon(A)^n \) has already been defined. We define

\[
N_\epsilon^{n+1}(A) := N_\epsilon^n(A) \cup \bigcup_{\gamma \in \Gamma_{n+1}} \Phi_\gamma \left( N_\epsilon(\Phi_\gamma^{-1}(A)) \cup (1 - \epsilon_\gamma, 1] \times \Phi_\gamma^{-1}(N_\epsilon^n(A)) \right).
\]

It is straightforward to verify that each \( N_\epsilon^n(A) \) is an open neighborhood of \( A \cap X^n \) in \( X^n \). The definition of \( N_\epsilon^{n+1}(A) \) is illustrated in Figure 605. Finally we set \( N_\epsilon(A) := \bigcup_{n \in \mathbb{N}} N_\epsilon^n(A) \).

It follows easily from the definition of the topology of a CW-complex that \( N_\epsilon(A) \) is an open neighborhood of \( A \) in \( X \). The definition of \( N_\epsilon(A) \) is illustrated in Figure 606.

Now we turn to the proofs of the eight statements:

(1) This statement follows fairly easily from Lemma 3.44. We will fill in the details in Exercise 36.6.

(2) Since by (1) we know that points are closed it suffices to show that CW-complexes are normal. Thus let \( A \) and \( B \) of \( X \) be disjoint closed subsets of \( X \). We need to show that there exist open disjoint neighborhoods of \( A \) and \( B \).

So let \( A \) and \( B \) be two disjoint closed subsets of \( X \). We will find \( \epsilon \) as above such
that \( N_\epsilon(A) \) and \( N_\epsilon(B) \) are disjoint. We will define the values of \( \epsilon \) inductively on the dimension of the cells. For 0-cells we take \( \epsilon = 1 \). Now suppose that we have already found disjoint open sets \( N_\epsilon(A) \) and \( N_\epsilon(B) \). Let \( \gamma \) be an \((n+1)\)-cell with characteristic map \( \Phi_\gamma: \overline{B}^{n+1} \to X \).

**Claim.** We have the following inequalities:

1. \( \mu_1 := d(\Phi_\gamma^{-1}(N_\epsilon^n(A)), \Phi_\gamma^{-1}(B)) > 0 \),
2. \( \mu_2 := d(\Phi_\gamma^{-1}(N_\epsilon^n(B)), \Phi_\gamma^{-1}(A)) > 0 \),
3. \( \mu_3 := d(\Phi_\gamma^{-1}(B), \Phi_\gamma^{-1}(A)) > 0 \).

We deal with the three inequalities separately:

(a) We first consider \( \mu_1 \). Suppose that \( \mu_1 = 0 \). If this was the case then there would exist a sequence of points in \( \Phi_\gamma^{-1}(B) \) that converges to a point of \( \Phi_\gamma^{-1}(B) \) in \( \partial \overline{B}^{n+1} \) of distance zero from \( \Phi_\gamma^{-1}(N_\epsilon^n(A)) \). But this is impossible since \( \Phi_\gamma^{-1}(N_\epsilon^n(B)) \) is a neighborhood of \( \Phi_\gamma^{-1}(B) \cap \partial \overline{B}^{n+1} \) in \( \partial \overline{B}^{n+1} \) which is disjoint from \( \Phi_\gamma^{-1}(N_\epsilon^n(A)) \).

(b) The proof of the second inequality \( \mu_2 > 0 \) is proved exactly the same as the proof of the inequality \( \mu_1 > 0 \).

(c) It follows from Lemma 36.7 (1) and our hypothesis that \( A \) and \( B \) are disjoint closed subsets that the preimages \( \Phi_\gamma^{-1}(A) \) and \( \Phi_\gamma^{-1}(B) \) are disjoint closed subsets of \( \overline{B}^n \).

By Lemma 2.17 (1) we know that they are in fact disjoint compact subsets of \( \overline{B}^n \). Thus it follows from Corollary 3.19 (2) that \( \mu_3 = d(\Phi_\gamma^{-1}(B), \Phi_\gamma^{-1}(A)) > 0 \). □

We set \( \epsilon_\gamma := \frac{1}{2} \min\{\mu_1, \mu_2, \mu_3\} \). We do this for all \((n+1)\)-cells \( \gamma \). It then follows immediately from the definitions that \( N_\epsilon^{n+1}(A) \) and \( N_\epsilon^{n+1}(B) \) are disjoint.

3. (a) Every \( k \)-cell is the image of the compact set \( \overline{B}^k \), hence it is compact by Lemma 2.40.

It follows from Lemma 2.17 (2) and the fact, proved in (2), that \( X \) is Hausdorff that every \( k \)-cell is also a closed subset of \( X \).

(b) A finite CW-complex is the union of finitely many cells. Thus it follows from (3a) together with Lemma 2.16 that a finite CW-complex is compact.

(c) Let \( \Phi: \overline{B}^n \to X \) be a characteristic map. We have the following inclusions

\[
\Phi(\overline{B}^n) \subset \overline{\Phi(B^n)} = \bigcap \text{closed subsets containing } \Phi(B^n) \subset \Phi(\overline{B}^n).
\]

\[
\uparrow \quad \uparrow \quad \uparrow \text{by (3a)}
\]

Lemma 2.33 definition of the closure

We have thus shown that we indeed have \( \overline{\Phi(\overline{B}^n)} = \Phi(\overline{B}^n) \).
36. CW-COMPLEXES I: DEFINITIONS, BASIC PROPERTIES AND CONSTRUCTIONS 951

(d) This statement follows immediately from (3b) and the definition of the closure of a set.

(4) Let \( x \in X \) and let \( U \) be an open neighborhood of \( x \). We need to prove the following two statements:

(a) There exists an open neighborhood \( V \) of \( x \) that is contained in \( U \) and that admits a deformation retraction to \( \{ x \} \).

(b) There exists a closed neighborhood \( V \) of \( x \) that is contained in \( U \) and that admits a deformation retraction to \( \{ x \} \).

In the following we will prove Statement (a). We leave it to the reader to make the slight modifications to obtain Statement (b).

So let us start with the proof of Statement (a). We leave it to the long-suffering reader to show that there exists an \( \epsilon \) such that \( N_\epsilon(x) \) is contained in \( U \).

It remains to show that \( N_\epsilon(x) \) admits a deformation retraction to \( \{ x \} \). We denote by \( m \) the unique natural number with \( x \in X^m \setminus X^{m-1} \). It follows easily from the definitions that \( N_\epsilon^n(x) \) is an open ball around \( x \), in particular \( N_\epsilon^n(x) \) deformation retracts onto \( \{ x \} \). Therefore it suffices to find a deformation retraction from \( N_\epsilon(x) \) to \( N_\epsilon^m(x) \).

First note that for \( n > m \) “sliding radially outward” we obtain a deformation retraction

\[
R(n): N_\epsilon^n(x) \times [0,1] \to N_\epsilon^n(x)
\]

from \( N_\epsilon^n(x) \) to \( N_\epsilon^{n-1}(x) \). We denote by \( r_n := R(n)_1: N_\epsilon^n(x) \to N_\epsilon^{n-1}(x) \) the corresponding retraction. For each \( k \in \mathbb{N}_{\geq m+1} \) we consider the map

\[
f_k: N_\epsilon(x) \to N_\epsilon^{k-1}(x)
\]

\[
y \mapsto \begin{cases} (r_k \circ \cdots \circ r_1)(y), & \text{if } y \in N^l(x) \text{ and } l \geq k, \\ y, & \text{if } y \in N_\epsilon^{k-1}(x). \end{cases}
\]

It follows from Corollary 36.9 that this map \( f_k \) is continuous. Now we consider the following map

\[
F: N_\epsilon(x) \times [0,1] \to N_\epsilon(x)
\]

\[
(y,s) \mapsto \begin{cases} y, & \text{if } x \in N^k_\epsilon(x) \text{ and } s \in [0,\frac{1}{2^k+1}], \\ r_k(y,2^{k+1}(s-\frac{1}{2^{k+1}})), & \text{if } x \in N^k_\epsilon(x) \text{ and } s \in [\frac{1}{2^{k+1}},\frac{1}{2^k}], \\ f_k(y), & \text{if } x \in N^k_\epsilon(x) \text{ and } s \in [\frac{1}{2^k},1]. \end{cases}
\]

We refer to Figure 613 for an illustration. It follows from Lemma 14.3 that the restriction of \( F \) to each \( N^k_\epsilon(x) \times [0,1] \) is continuous. Thus it follows from Corollary 36.9 that \( F: N_\epsilon(x) \times [0,1] \to N_\epsilon(x) \) is continuous. This map is the desired deformation retraction.

(5) This statement follows immediately from (2) and (4).

(6) Note that this statement follows immediately from (4) since every topological space that admits a deformation retraction to a point is contractible, and since every contractible topological space is path-connected and simply connected. Finally note that a topological space that is locally simply connected is in particular semi-locally simply connected.
(7) By Lemma 2.72 an locally path-connected topological space is connected if and only if it is path-connected. This shows the equivalence (a) \(\Leftrightarrow\) (b) and (c) \(\Leftrightarrow\) (d). It follows from Lemma 4.1 (5) and the discussion on page 932 that we also have (d) \(\Leftrightarrow\) (e). We will prove (d) \(\Rightarrow\) (b) and (a) \(\Rightarrow\) (c) in Exercise 36.7.

(8) We pick an \(\epsilon \in (0,1)\). Given a subcomplex \(A\) of \(X\) we set \(\Phi(A) := N_\epsilon(A)\). In each cell of \(X \setminus A\) the set \(N_\epsilon(A)\) is a product neighborhood of the boundary of this cell. So a deformation retraction of \(N_\epsilon(A)\) onto \(A\) can be constructed as in (4). We leave the details to the reader. It is clear that \(\Phi\) has all the other desired properties.

Our next goal is to formulate an addendum to Proposition 36.10. To do so we need to introduce the following definition.

**Definition.** We say that a CW-complex is **locally finite** if every cell is disjoint from all but finitely many cells of \(X\).

**Examples.** The CW-complex \(\mathbb{C}P^\infty\) is not locally finite, whereas the CW-complexes illustrated in Figure 609 are locally finite.

**Figure 608.** Examples of locally finite CW-complexes.

The following proposition is the promised addendum to Proposition 36.10.

**Proposition 36.11.** A CW-complex is regionally compact if and only if it is locally finite.

**Proof.** We will not make use of Proposition 36.11 except that in the negative sense, that now we know that many CW-complexes we are interested in are unfortunately not regionally compact. The proposition is proved in [Geo08 Proposition 10.1.8].

One of the curses of the working topologist is the unfortunate fact that a bijection continuous map between topological spaces does not need to be a homeomorphism. The following lemma gives a nice criterion for a map between CW-complexes to be a homeomorphism.
Lemma 36.12. Let \( f: X \to Y \) be a map between CW-complexes. Suppose the following three conditions are satisfied:

1. \( f \) is a bijection,
2. \( f \) is continuous,
3. the images of the cells of \( X \) are precisely the cells of \( Y \).

Then \( f: X \to Y \) is a homeomorphism.

Proof (\(*\)). We denote by \( g = f^{-1}: Y \to X \) the inverse of \( f \). It remains to show that \( g \) is continuous. Let \( \{ \Phi_i: \overline{B}^{m_i} \to X \}_{i \in I} \) be the characteristic maps of the CW-complex \( X \) and let \( \{ \Phi_j: \overline{B}^{n_j} \to Y \}_{j \in J} \) be the characteristic maps of the CW-complex \( Y \). By Lemma 36.7 it suffices to show that for each \( j \in J \) the map \( g \circ \Psi_j: \overline{B}^{n_j} \to X \) is continuous. We consider the cell \( \Psi_j(\overline{B}^{n_j}) \). By hypothesis (3) there exists an \( i \in I \) such that \( f(\Phi_i(\overline{B}^{m_i})) = \Psi_j(\overline{B}^{n_j}) \). Since \( \Phi_i(\overline{B}^{m_i}) \) is compact and since we know by Proposition 36.10 that \( \Psi_j(\overline{B}^{n_j}) \subset Y \) is Hausdorff it follows from Proposition 2.43 (3) that \( f(\Phi_i(\overline{B}^{m_i})) \to \Psi_j(\overline{B}^{n_j}) \) is a homeomorphism. But this implies that \( f^{-1} = g \) is continuous on \( \Psi_j(\overline{B}^{n_j}) \). It follows that, as desired, the map \( g \circ \Psi_j \) is continuous. \( \square \)

We conclude this section with the following proposition.

Proposition 36.13. Every CW-complex is paracompact.

Proof. As always, when it comes to CW-complexes, the proof is slightly delicate. Since we will not really make use of the proposition we refer instead to [FrPi90a, Theorem 1.3.5], or alternatively to [Hat2, Proposition 1.20], [Lee00, Theorem 5.22], [LW69, Theorem II.4.2] and [Miy52], for a proof. \( \blacksquare \)

36.6. The Finiteness Theorem for CW-complexes. The following proposition is one of the key technical results about infinite CW-complexes.

Theorem 36.14. (Finiteness Theorem for CW-complexes) Every compact (connected) subset of a CW-complex \( X \) is contained in a finite (connected) subcomplex.

Remark. The statement of the proposition and also its proof have more than a passing resemblance with Lemma 36.3.

Example. We consider the wedge \( X := \bigvee_{i \in N_0} S^1_i \). As discussed on page 942, we can view \( X \) as a CW-complex with one 0-cell, given by the wedge point, and 1-cells indexed by \( i \in N_0 \). It follows from Theorem 36.14 that each compact subset of \( X \) is contained in the union of finitely many \( S^1_i \). In fact this statement already follows from Exercise 18.33.

Before we start out with the proof of Theorem 36.14 we formulate the following pretty corollary.

Corollary 36.15. A CW-complex is compact if and only if it is finite.

Proof. In Proposition 36.10 (3) we showed that every finite CW-complex is compact. Now we want to prove the converse. Thus let \( X \) be a compact CW-complex. It follows from
Theorem 36.14 that \( X \) is contained in a finite subcomplex \( Y \) of \( X \). But from \( X \subseteq Y \subseteq X \) it follows that \( X = Y \), i.e. \( X \) is a finite CW-complex. \( \blacksquare \)

The proof of Theorem 36.14 will be a fairly straightforward consequence of the following rather technical lemma.

**Lemma 36.16.** Let \( X \) be a CW-complex.

1. Let \( A \subseteq X \) be a subset. If every open cell of \( X \) contains at most one point of \( A \), then \( A \) is closed and discrete.
2. If \( C \subseteq X \) is a compact subset, then \( C \) is contained in a finite union of open cells.
3. Every cell of \( X \) is contained in a finite subcomplex of \( X \). \( \textit{592} \)

**Remark.** Lemma 36.16 (3) together with Proposition 36.10 (3a) and (3c) shows in particular that the closure of each open cell is contained in the union of finitely many open cells. This property is sometimes referred to as \( X \) being “closure finite” which explains the “C” in the name CW-complex.

**Proof of Lemma 36.16** \((\ast)\). We start out with the following claim.

**Claim.** Let \( Y \) be a CW-complex. Then the statements (1), (2) and (3) are equivalent.

Let \( Y \) be a CW-complex. First we show \((1) \Rightarrow (2)\). Let \( C \subseteq Y \) be a compact subset. For each cell that intersects \( C \) we pick a single point. We denote the resulting set of points by \( A \). By (1) the set \( A \) is closed and discrete. Since \( A \) is a closed subset of compact set we obtain from Lemma 2.17 (1) that \( A \) is compact. Since \( A \) is compact and discrete we obtain from Lemma 2.18 (1) that \( A \) is in fact finite. But that means that \( C \) intersects only finitely many cells, i.e. \( C \) is contained in a finite union of open cells as claimed.

Now we will prove \((2) \Rightarrow (3)\). So let \( C_\sigma \subset Y \) be an \( n \)-cell. We denote by \( U_\sigma \) the corresponding open cell. By Proposition 36.10 (3) and by definition of a cell we know that \( C_\sigma \setminus U_\sigma \) is a compact subset of the \((n-1)\)-skeleton \( Y^{n-1} \). It follows from (2) that the subset \( C_\sigma \setminus U_\sigma \) is contained in a finite union of open cells of dimension \( \leq n-1 \). By the same argument each of these lower-dimensional closed cells is again contained in a finite union of open cells of smaller dimension, except again for the cell itself. A straightforward induction argument now shows that we end up with finitely many cells which form a subcomplex of \( Y \).

Next we will show \((3) \Rightarrow (1)\). Let \( A \subset Y \) be a subset such that no two points lie in the same open cell. We consider the intersection of \( A \) with a closed cell. By (3) this intersection is contained in a finite subcomplex \( Y' \). Since \( A \) has at most one point in common with any open cell this intersection \( A \cap Y' \) must be finite and hence closed in \( A \cap Y' \) by Proposition 36.10 (2). By Proposition 36.10 (3) the finite subcomplex \( Y' \) is a closed subset of \( X \). Hence \( A \cap Y' \) is a closed subset of \( X \). For any point \( x \in A \) the set \( A \setminus \{x\} \) also satisfies the hypothesis for \( A \), and so it must also be a closed subset of \( X \). Hence \( \{x\} \) is open in \( A \), so \( A \) is discrete. \( \blacksquare \)

Now let \( X \) be a CW-complex. First note that statement (1) holds for \( X^0 \) by definition of the topology on \( X^0 \). Now suppose we know (1) for the \( n \)-skeleton \( X^n \) for some \( n \in \mathbb{N}_0 \).

\( \textit{592} \)Recall that by definition, see page 947, a subcomplex is \( \textit{finite} \) if it contains only finitely many cells of \( X \). So even a subcomplex that is given by a single cell might a priori contain many other cells.
By claim we know that (2) and (3) also for \(X^n\). But the proof of (2) \(\Rightarrow\) (3) for a given \(n\)-cell only used (2) for subsets of \(X^{n-1}\). Thus we actually have (3) for \(X^{n+1}\). Thus we also have (1) for \(X^{n+1}\). Summarizing we have all three statements for \(X^n\) for all \(n\). But any cell lies in some \(X^n\), and so we know (3) for \(X\) itself, and by the claim this implies that (1) and (2) also hold for \(X\). ■

Now we can provide the proof of Theorem 36.14.

**Proof of Theorem 36.14** Let \(X\) be a CW-complex and let \(C \subset X\) be a compact subset. By Lemma 36.16 (2) the subset \(C\) is contained in a union of finitely many open cells. By Lemma 36.16 (3) each of these open cells is contained in a finite sub complex. The union of these finitely many finite subcomplexes is a finite subcomplex \(Z\) which contains \(C\).

If \(C\) is connected, then we take the component of \(Z\) that contains \(C\). By Lemma 36.21 (3) this is again a subcomplex. ■

### 36.7. Cellular maps

Before we move on to considering subcomplexes and constructions of CW-complexes let us quickly introduce the type of maps between CW-complexes that are reasonable.

**Definition.**

1. A map \(g: X \to Y\) between two CW-complexes is called **cellular** if for each \(n \in \mathbb{N}_0\) we have \(g(X^n) \subset Y^n\).
2. A map \(g: X \to Y\) between two CW-complexes is called a **cellular isomorphism** if \(f\) is cellular, if \(f\) is a bijection and continuous, and if \(f^{-1}\) is also cellular.

**Example.** In general maps between CW-complexes are not cellular. For example consider the CW-complex \(X = [0, 1]\) with two 0-cells and one 1-cell and we consider the CW-complex \(Y = [0, 1] \times [0, 1]\) with four 0-cells, two 1-cells and one 2-cell. Then the diagonal map

\[
g: X = [0, 1] \to Y = [0, 1] \times [0, 1] \\
t \mapsto (t, t)
\]

which is illustrated in Figure 610 is not a cellular map.

![](diagram.png)

**Figure 610**

It is clear that the composition of two cellular maps is again cellular. This leads us to the following definition.

**Definition.** We call the category \(\mathcal{CW}\) with

\[
\text{Ob}(\mathcal{CW}) := \text{all CW-complexes,} \\
\text{Mor}(X, Y) := \text{all cellular maps from } X \text{ to } Y,
\]
together with the usual composition of maps the category of CW-complexes. This category should not be confused with the full category of CW-complexes that is given by

\[
\begin{align*}
\text{Ob}(\text{FullCW}) & := \text{all CW-complexes}, \\
\text{Mor}(X,Y) & := \text{all continuous maps from } X \text{ to } Y.
\end{align*}
\]

Now is as good as any other moment to introduce a little more categorical language.

**Definition.** A covariant functor \( F: C \to D \) between two categories is called **faithful** if for every two objects \( X, Y \in \text{Ob}(C) \) the map \( \text{Mor}(X,Y) \to \text{Mor}(F(X),F(Y)) \) is an injection. If the map is in fact a bijection, then we call the functor fully faithful. The same definition applies, with the obvious modifications, to contravariant functors.

To practice the definitions we formulate the following lemma.

**Lemma 36.17.** The maps

\[
\begin{align*}
\text{CW-complex } X & \mapsto |X| \\
(f: X \to Y) & \mapsto (f: |X| \to |Y|)
\end{align*}
\]

define a covariant functor from the category \( CW \) of CW-complexes to the category of topological spaces. The functor is faithful but not fully faithful. The maps also define a covariant functor from the full category \( \text{FullCW} \) of CW-complexes to the category of topological spaces, this time the functor is fully faithful.

**Proof.** The statements are basically obvious. The fact that we just found a continuous map which is not cellular gives us that the functor \( CW \to \text{Top} \) is not fully faithful.

---

36.8. **Subcomplexes.** In this section we will discuss in great detail the concept of a subcomplex. We defined the notion on a subcomplex in a perfunctory way on page 947, but to give the concept its due prominence let us repeat the definition.

**Definition.** A subcomplex of a CW-complex \( X \) is a subset of \( X \) that is the union of arbitrarily many cells of \( X \).

**Examples.**

1. In Figure 611 we consider the smooth manifold \( X \) that is given by removing an open disk from a torus. We see that \( X \) has the structure of a CW-structure such that the boundary \( \partial X \) is a CW-subcomplex.

   \[
   X \text{ is the torus } [0,1] \times [0,1]/\sim \text{ with an open disk removed}
   \]

   \[
   \partial X \text{ is a subcomplex with one 0-cell and one 1-cell}
   \]

   **Figure 611**

2. Let \( X \) be a CW-complex. For each \( n \in \mathbb{N}_0 \) the \( n \)-skeleton \( X^n \) is a subcomplex.

   The name “subcomplex” suggests that a subcomplex should again be a CW-complex. That is indeed the case.
Lemma 36.18. Let $X$ be a CW-complex and let $A$ be a subcomplex of $X$.

1. The subset $A$ admits a CW-structure such that for each $n \in \mathbb{N}_0$ we have the equality $|A^n| = A \cap |X^n|$ and such that the characteristic maps of $A$ correspond precisely to the characteristic maps of $X$ that take values in $A$.

2. The inclusion map $A \to X$ is a closed embedding, in particular $A$ is a closed subset of $X$.

Proof. We start out with the proof of Statement (1). We set $Y^{-1} = |Y^{-1}| := \emptyset$. For $n = 0, 1, 2, 3, \ldots$ we iteratively do the following:

1. Let $\{\varphi_i: S^{n-1} \to |Y^{n-1}|\}_{i \in I}$ be the attaching maps from the CW-structure of $X$ that correspond to $n$-cells that lie in $A$. We define $Y^n = (Y^{n-1}, \{\varphi_i: S^{n-1} \to |Y^{n-1}|\}_{i \in I})$.

2. We set $|Y^n| := \left( |Y^{n-1}| \cup \bigcup_{i \in I} B^n \right) / \sim$.

Finally we define $Y$ to be the CW-complex that is given by the sequence of CW-complexes $Y_{-1} \subset Y_0 \subset Y_1 \subset \ldots$.

Since $A$ is by definition the union of cells we see that the obvious map $\varphi: |Y| \to A$ is a bijection. It remains to show that the map $\varphi$ is actually a homeomorphism. Note that by definition, if $\Phi: B^n \to |Y|$ is a characteristic map of the CW-complex $Y$, then $\varphi \circ \Phi: B^n \to |X|$ is a characteristic map of the CW-complex $X$. Thus it follows from Lemma 36.16(1) and (4) that $\varphi$ is continuous.

By Lemma 2.42(1) it remains to show that the map $\varphi: |Y| \to X$ is a closed map.

Claim. The map $\varphi: |Y| \to X$ is a closed map.

Let $C \subset |Y|$ be a closed subset. We need to show that $\varphi(C)$ is also a closed subset of $A$. By Lemma 36.16(1) and (3) it suffices to show that for each cell $e \subset X$ the set $\varphi(C) \cap e$ is closed. By Lemma 36.16 we know that $e$ intersects only finitely many cells. In particular there are only finitely many cells contained in $A \cap e$. We denote these by $a_1, \ldots, a_m$. Now we see that

\[
\varphi(C) \cap e = \varphi(C) \cap (A \cap e) = \varphi(C) \cap \bigcup_{i=1}^{m} a_i = \bigcup_{i=1}^{m} (\varphi(C) \cap a_i)
\]

since $\varphi(C) \subset A$, $A$ is a subcomplex, $C$ is closed in $|Y|$ and since $a_1, \ldots, a_m \in S$ are cells of $Y$.

Now we turn to the proof of Statement (2). In fact this follows immediately from the claim. Indeed, evidently $|Y|$ is a closed subset of $|Y|$ and from the claim we obtain that $\varphi(|Y|)$ is a closed subset of $X$. But $\varphi(|Y|) = A$. Thus we have shown that $A$ is a closed subset of $X$.

Definition. Let $A$ and $X$ be CW-complex. A map $f: A \to X$ is called a cellular embedding if $f$ is injective and if the image of a cell of $A$ is a cell of $X$. 

Lemma 36.19. (*) Let \( f: A \to X \) be a cellular embedding between two CW-complexes. The following statements hold:

1. The image \( f(A) \) is a subcomplex of \( A \) and the map \( f: A \to f(A) \) is a cellular isomorphism.
2. The map \( f: A \to X \) is a closed embedding.

Proof. (*) It follows immediately from the above definition of a subcomplex and of a cellular embedding that the image of a cellular embedding \( f: A \to X \) is a subcomplex. Next we consider the map \( f^{-1}: f(A) \to A \). We deduce from Lemma 36.7 together with Proposition 2.43 (3) that the map \( f^{-1}: f(A) \to A \) is continuous. It follows almost immediately that \( f: A \to f(A) \) is a cellular isomorphism. Finally we obtain from the above together with Lemma 36.18 that \( f: A \to X \) is a closed embedding. ■

Lemma 36.20. Let \( X \) be a CW-complex and let \( \{X_i\}_{i \in I} \) be a family of subcomplexes such that \( \bigcup_{i \in I} X_i = X \). The following three statements hold:

1. A subset \( U \subset X \) is open if and only if each \( X_i \cap U \) is an open subset of \( X_i \).
2. A subset \( A \subset X \) is closed if and only if each \( X_i \cap A \) is a closed subset of \( X_i \).
3. A map \( f: X \to Y \) to a topological space \( Y \) is continuous if and only if each map \( f|_{X_i}: X_i \to Y \) is continuous.

Proof. [1] This statement is an easy consequence of Lemma 36.7 (2). [2] The “only if”-direction is an immediate consequence of Lemma 2.4 (2). The “if”-direction follows from (1) and Lemma 2.34 (1) \( \Rightarrow \) (2). [3] The “only if”-direction is an immediate consequence of Lemma 2.30 (3). The “if”-direction follows from (1) and Lemma 2.34 (1) \( \Rightarrow \) (3). ■

The following lemma shows in particular that some straightforward constructions provide examples of subcomplexes.

Lemma 36.21. Let \( X \) be a CW-complex.

1. For any \( n \in \mathbb{N}_0 \) the \( n \)-skeleton \( X^n \) is a subcomplex of \( X \).
2. The union and also the intersection of arbitrarily many subcomplexes is again a subcomplex.
3. Every path-component of a complex is again a subcomplex.

Proof. [1] This statement is clear. [2] This statement is also clear. [3] This statement is basically obvious since each closed ball is path-connected. ■

We conclude this section with the following proposition.
Proposition 36.22. Let $X$ be a CW-complex and let $Y = Y_0 \subset Y_1 \subset Y_2 \subset \ldots$ be a sequence of subcomplexes such that the following two conditions are satisfied:

1. we have $X = \bigcup_{i \in \mathbb{N}} Y_i$,
2. each $Y_i$ is a deformation retract of $Y_{i+1}$.

Then $Y_0$ is a deformation retract of $X$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{proof_diagram.png}
\caption{Illustration of Proposition 36.22.}
\end{figure}

Proof. By hypothesis there exists for each $k \in \mathbb{N}_0$ a deformation retraction

$$R(k): Y_k \times [0, 1] \rightarrow Y_{k-1}.$$ 

We denote by $r_k := R(k)_1: Y_k \rightarrow Y_{k-1}$ the corresponding retraction. For each $k \in \mathbb{N}_0$ we consider the map

$$f_k: X \times [0, 1] \rightarrow Y_{k-1} \times [0, 1],$$

$$(x, t) \mapsto \left\{
\begin{array}{ll}
(r_k \circ \cdots \circ r_1)(x), & \text{if } x \in Y_i \text{ and } l \geq k, \\
x, & \text{if } x \in Y_{k-1}.
\end{array}
\right.$$

It follows from Corollary 36.9 that this map $f_k$ is continuous. Now we consider the following map

$$F: X \times [0, 1] \rightarrow X,$$

$$(x, t) \mapsto \left\{
\begin{array}{ll}
x, & \text{if } x \in Y_k \text{ and } t \in \left[0, \frac{1}{2^{k+1}}\right], \\
n_k(x, 2^{k+1} \cdot (t - \frac{1}{2^{k+1}})), & \text{if } x \in Y_k \text{ and } t \in \left[\frac{1}{2^{k+1}}, \frac{1}{2^k}\right], \\
f_k(x), & \text{if } x \in Y_k \text{ and } t \in \left[\frac{1}{2^k}, 1\right].
\end{array}
\right.$$

We refer to Figure 613 for an illustration. It follows from Lemma 14.3 that the restriction of $F$ to each $Y_k \times [0, 1]$ is continuous. Thus it follows from Corollary 36.9 that $F: X \times [0, 1] \rightarrow X$ is continuous. This map is the desired deformation retraction.

\caption{Illustration for the proof of Proposition 36.22.}
\end{figure}
36.9. Products of CW-complexes I. Let \( X \) and \( Y \) be two CW-complexes. We can form the product topological space \( X \times Y \). Ideally one would like to equip \( X \times Y \) with a CW-structure. Throughout this section we use the homeomorphism from Proposition 2.53 (2) to identify the \( n \)-dimensional closed ball \( \overline{B}^n \) with the \( n \)-dimensional cube \( I^n = [0, 1]^n \) and we use it to make the identification \( S^{n-1} = \partial I^n \). For \( p + q = n \) we evidently have \( I^n = I^p \times I^q \) and we have

\[
\partial(I^n) = \partial I^p \times I^q \cup I^p \times \partial I^q.
\]

The idea is now to define a CW-structure on \( X \times Y \) such that the product of a \( p \)-cell in \( X \) with a \( q \)-cell in \( Y \) corresponds to a \((p + q)\)-cell in \( X \times Y \).

In the following we want to execute this idea rigorously. First, to be on the safe side, we consider the case of two finite complexes.

**Definition.** Let \( X \) and \( Y \) be two CW-complexes. Given \( p \in \mathbb{N}_0 \) let \( \{ \varphi_j : S^{p-1} \to X^{p-1} \}_{j \in J_p} \) and \( K_p := \{ \psi_k : S^{p-1} \to Y^{p-1} \}_{k \in K_p} \) be the set of attaching maps of \( p \)-dimensional cells of \( X \) and \( Y \). Furthermore we denote by \( \{ \Phi_j : \overline{B}^p \to X^p \}_{j \in J_p} \) and \( \{ \Psi_k : \overline{B}^p \to Y^p \}_{k \in K_p} \) the corresponding characteristic maps of the cells. We define a new CW-complex \( Z \) as follows:

1. We put \( Z^{-1} = \emptyset \).
2. Suppose \( Z^{n-1} \) is already defined for some \( n \in \mathbb{N}_0 \). Given \( j \in J_p \) and \( k \in K_{n-p} \) we define:

\[
\theta_{(j,k)} : \partial I^n = \partial I^p \times I^{n-p} \cup I^p \times \partial I^{n-p} \to Z^{n-1}
\]

\[
(x, y) \mapsto (\Phi_j(x), \Psi_k(y)).
\]

We set

\[
Z^n := \left( Z^{n-1} \cup \bigsqcup_{p+q=n} \bigcup_{j \in J_p, k \in K_{n-p}} (I^p \times I^{n-p}) \right) / \sim
\]

where for each \( j \in J_p, k \in K_{n-p} \) we define \((x, y) \in (I^p \times I^{n-p})_{(j,k)}\) with the point

\[
\theta_{(i,j)}(x, y) \in Z^{n-1}.
\]

3. Given \( j \in J_p \) and \( k \in K_{n-p} \) we denote by \( \Theta_{(j,k)} : I^n = I^p \times I^{n-p} \to Z^n \) the corresponding characteristic map.

4. We set \( Z := \lim_{\longrightarrow} Z^n \).

As the discussion suggests, the above construction does indeed (often) define a CW-structure on the topological space \( X \times Y \). To simplify the initial discussion we first consider the case that \( X \) and \( Y \) are two finite CW-complexes.

**Proposition 36.23.** Let \( X \) and \( Y \) be two CW-complexes. We use the notation from the above definition.

1. The above data turns \( Z \) into a CW-complex.
2. The characteristic maps \( \Theta_{(i,j)} \) define a continuous bijection \( \Theta : Z \to X \times Y \).
3. Suppose we are in one of the following two settings:
   (a) \( X \) and \( X \) are both finite CW-complexes, or

\[503\] Why does the image of this attaching map lie in \((X \times Y)^{n-1}\)?
(b) \( Y = [0, 1] \) where \( Y \) is equipped with the usual CW-structure with two 0-cells and one 1-cell, then the map \( \Theta: Z \to X \times Y \) from (2) is a homeomorphism. In particular the topological space \( X \times Y \) has a CW-structure such that for each \( n \in \mathbb{N}_0 \) we have

\[
(X \times Y)^n = \bigcup_{p+q=n} X^p \times Y^q.
\]

**Definition.** Let \( X \) and \( Y \) be finite CW-complexes. Suppose we are in one of the two settings of Proposition 36.23 (3).

1. We refer to the above CW-structure on \( X \times Y \) as the product CW-structure.
2. Given a \( p \)-cell \( e \) for \( X \) and given a \( q \)-cell for \( Y \) we denote by \( e \times f \) the corresponding \((p + q)\)-cell for \( X \times Y \).

**Remark.** The second case of Proposition 36.23 (3) might appear somewhat random, but it will actually prove important for showing that several constructions, like mapping cylinders and mapping cones, give rise to CW-complexes.

**Proof (\( \ast \)).** Let \( X \) and \( Y \) be two CW-complexes.

1. This statement follows basically immediately from the definitions.
2. It follows from Lemma 36.7 (4) that the map \( \Theta: Z \to X \times Y \), which is defined via the characteristic maps \( \Theta_{i,j} \), is continuous.
3. (a) Suppose that \( X \) and \( X \) are both finite CW-complexes. In this case \( Z \) has only finitely many cells, hence \( Z \) is compact by Corollary 36.15. Furthermore note that \( X \times Y \) is Hausdorff by Proposition 36.10 (2) and Proposition 3.12. It follows from Proposition 2.43 (3) that \( \Theta: Z \to X \times Y \) is indeed a homeomorphism.
   (b) Suppose we have \( Y = [0, 1] \) with the obvious CW-structure. It follows basically immediately from the equivalence of the topologies (1) and (3) of Lemma 36.8 that the map \( \Theta: Z \to X \times Y \) is a homeomorphism.

Since \( \Theta: Z \to X \times Y \) is a homeomorphism and since \( Z \) is a CW-complex we have endowed \( X \times Y \) with a CW-structure. The statement about the skeleta follows immediately from the definition of the CW-structure on \( Z \).

**Examples.**

1. If we equip \( S^1 = [0, 1]/0 \sim 1 \) with the usual CW-structure with one 0-cell and one 1-cell, then the product CW-structure on the torus \( S^1 \times S^1 = ([0, 1] \times [0, 1])/ \sim \) is precisely the CW-structure that we had already encountered on page 933. We refer to Figure 614 for an illustration.

![Figure 614](image-url)
(2) Given $a = s_0 < s_1 < \cdots < s_k = b$ and $c = t_0 < t_1 < \cdots < t_l = d$ we can view the intervals $[a, b]$ and $[c, d]$ as CW-complexes where the 1-cells are given precisely by the intervals $[s_i, s_{i+1}]$, $i = 0, \ldots, k - 1$ and $[t_j, t_{j+1}]$, $j = 0, \ldots, l - 1$. The product CW-complex is the topological space $[a, b] \times [c, d]$ where the 2-cells are given by the rectangles $[s_i, s_{i+1}] \times [t_j, t_{j+1}]$ with $i \in \{0, \ldots, k - 1\}$ and $j \in \{0, \ldots, l - 1\}$. The analogous statement holds also for higher-dimensional hyperrectangles. For example, given $k \in \mathbb{N}$ and $n \in \mathbb{N}$ we can equip the cube $[0, 1]^n$ with a CW-structure where the $n$-cells are precisely given by the cubes $[\frac{s_1}{k}, \frac{s_{1+1}}{k}] \times \cdots \times [\frac{s_n}{k}, \frac{s_{n+1}}{k}]$ with $s_1, \ldots, s_n \in \{0, \ldots, k - 1\}$.

![Diagram](image)

**Figure 615**

The formulation of Proposition 36.23 already suggests that the conclusion does not hold without some assumptions on $X$ and $Y$. In fact, the following lemma, which goes back to [Dow52], shows that there are indeed examples of CW-complexes $X$ and $Y$ such that the map $\Theta : Z \to X \times Y$ is not a homeomorphism. In other words, in general the “naïve” attempt to endow a product of CW-complexes with a CW-structure fails.

**Lemma 36.24.** Let $S := \{(s_1, s_2, \ldots) \mid s_i \in \mathbb{N}\}$ be the set of all infinite sequences of positive integers. Let $X = \bigvee_{s \in [0, 1]}$ be the wedge of uncountably many copies of $[0, 1]$, obtained by wedging all the $0 \in [0, 1]$. Similarly we form the wedge $Y = \bigvee_{j \in \mathbb{N}}$ of countably many copies of $[0, 1]$. We equip $X$ and $Y$ with the “obvious CW-structure”, see e.g. Lemma 36.32 (4). In this setting the map $\Theta : Z \to X \times Y$ from Proposition 36.23 is not a homeomorphism.

**Proof.** For $s \in S$ and $j \in \mathbb{N}$ we consider $(\frac{1}{s_j}, \frac{1}{s_{j+1}}) \in [0, 1]_s \times [0, 1]_j \in X \times Y$. We denote by $P \subset X \times Y$ the subset defined by all these points. Since each 2-cell of the CW-complex $Z$ contains a single point of $P$ we obtain from Lemma 36.7 (3) that $P$ is a closed subset of $Z$. To show that $\Theta$ is not a homeomorphism it remains to prove the following claim.

**Claim.** The set $P$ is not closed with respect to the product topology on $X \times Y$.

We denote by $x_0 \in X$ and $y_0 \in Y$ the wedge points. Note that $(x_0, y_0) \notin P$. Thus it suffices to show that every neighborhood of $(x_0, y_0)$ in $X \times Y$ contains a point of $P$. In fact, by definition of the product topology, see page 162, it suffices to show that any subset $U \times V$ of $X \times Y$ of the form $U = \bigvee_{s \in S} [0, a_s] \subset X$ and $V = \bigvee_{j \in \mathbb{N}} [0, b_j] \subset Y$ contains a point of $P$. We pick a sequence $t = (t_1, t_2, \ldots) \in S$ such that for every $j \in \mathbb{N}$ we have $t_j > j$ and such that $t_j > \frac{1}{a_t}$. Furthermore we pick a $k \in \mathbb{N}$ with $k > \frac{1}{a_t}$. It follows that $t_k > k > \frac{1}{a_t}$,
which implies that $\frac{1}{t_k} < a_t$. Recall that by construction we also have $\frac{1}{t_k} < b_k$. Thus we see that $(\frac{1}{t_k}, \frac{1}{t_k})$ is a point of $P$ that lies in $[0, a_t] \times [0, b_k]$. Hence it also lies in $U \times V$. ■

36.10. Products of CW-complexes II (*). In this section we will discuss the product of two infinite CW-complexes in somewhat greater detail. We will not make use of the results of this and the coming section, thus these two sections can be skipped safely.

First we mention the following proposition which can be viewed as a generalization of Proposition 36.23.

Proposition 36.25. Let $X$ and $Y$ be two CW-complexes. If at least one of the two CW-complexes has only countably many cells, then the map $\Theta: Z \to X \times Y$ from Proposition 36.23 (2) is a homeomorphism, in particular $X \times Y$ has a natural CW-structure.

Proof. This statement is proved in [LW69, Theorem II.5.2]. If one of $X$ or $Y$ is a finite CW-complex, then the statement is also proved in [Hat02, Theorem A.6]. If both CW-complexes have countably many cells, then the statement is also proved in [FrPi90a, Proposition 2.2.3] or [Miln56b, Lemma 2.1]. ■

Definition. Let $X$ and $Y$ be two CW-complexes.

(1) If at least one of the two CW-complexes has only countably many cells, then we refer to the above CW-structure on $X \times Y$ as the product CW-structure.

(2) Following [LW69, p. 56] we denote by $X \otimes Y$ the topological space whose underlying set is given by $X \times Y$ but whose topology is the unique topology that turns the map $\Theta: Z \to X \times Y$ from Proposition 36.23 into a homeomorphism.

Remark. Note that [Brooke17, Theorem 1] gives a necessary and sufficient condition for the product of two CW-complexes to be a CW-complex.

We conclude this section with a short discussion on the relationship between $X \otimes Y$ and $X \times Y$.

Proposition 36.26. (*) Let $X$ and $Y$ be two CW-complexes.

(1) The identity map $\text{id}: X \otimes Y \to X \times Y$ is a continuous bijection.

(2) A subset $K \subset X \otimes Y$ is compact if and only if it is compact in $X \times Y$.

(3) Given any $(x, y) \in X \times Y$ the induced map $\pi_1(X \otimes Y, (x, y)) \to \pi_1(X \times Y, (x, y))$ is an isomorphism.

(4) If at least one of the two CW-complexes has only countably many cells, then the map $X \otimes Y \to X \times Y$ is a homeomorphism.

The proof of Proposition 36.26 (3) is mostly outsourced to the following lemma.

Lemma 36.27. (*) Let $\Theta: A \to B$ be a continuous bijection between two topological spaces which has the property that a subset $K \subset A$ is compact if and only if $\Theta(K) \subset B$ is compact. If $A$ is Hausdorff, then for any $a_0 \in A$ the map $\Theta_*: \pi_1(A, a_0) \to \pi_1(B, f(a_0))$ is an isomorphism.

Proof (*). We write $b_0 := f(a_0)$. The proof of the lemma naturally breaks up into showing that $\Theta_*: \pi_1(A, a_0) \to \pi_1(B, b_0)$ is an epimorphism and that it is a monomorphism.
Let us first show that the map $\Theta_*$ is an epimorphism. Suppose we are given an element $[f: (S^1,*) \to (B,b_0)] \in \pi_1(B,b_0)$. By Lemma 2.40 we know that $L := f(S^1)$ is a compact subset of $B$. We set $K := \Theta^{-1}(L)$. Since $\Theta$ is a bijection we have $\Theta(K) = L$. It follows from our hypothesis that $K$ is a compact subset of $A$. Since $\Theta$ is a bijection, since $K$ is compact and since $L$ is Hausdorff we obtain from Proposition 2.43 (3) that $\Psi := \Theta|_K: K \to L$ is a homeomorphism. In particular the inverse map $\Psi^{-1}: L \to K$ is continuous. Next we set $g := \Psi^{-1} \circ f: (S^1,*) \to (A,a_0)$. We have $\Theta_*([g]) = [\Theta \circ g] = [\Theta|_K \circ \Psi^{-1} \circ f] = [f]$. Thus we have shown that $\Theta_*$ is an epimorphism.

The proof that $\Theta_*$ is a monomorphism is quite similar. The key observation is that the image of a homotopy in $B$ between two loops is a compact subset. We leave it to the reader to fill in the few remaining details.

![Illustration for the proof of Lemma 36.27](image)

**Figure 616. Illustration for the proof of Lemma 36.27.**

**Proof of Proposition 36.26 (\(*)**. Let $X$ and $Y$ be two CW-complexes.

1. It follows immediately from Proposition 36.23 (2) and the definition of the topological space $X \times Y$ that the identity map $\text{id}: X \times Y \to X \times Y$ is a continuous bijection.
2. Let $K \subset X \times Y$. If $K$ is compact in $X \times Y$. It follows from (1) and Lemma 2.40 that $K$ is also compact in $X \times Y$. Now suppose conversely that $K$ is compact in the product topological space $X \times Y$.
   
   a. Note that $X \times Y$ is Hausdorff by Proposition 36.10 (2) and Proposition 3.12. Thus it follows from Lemma 2.17 (2) that $K$ is a closed subset of $X \times Y$. It follows from (1) that $K$ is closed in $X \times Y$.
   
   b. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the obvious projections. It follows from Lemma 2.40 that $p(K)$ and $q(K)$ are compact. By Theorem 36.14 we know that there exist finite subcomplexes $X' \subset X$ and $Y' \subset Y$ such that $p(K) \subset X'$ and $q(K) \subset Y'$. But this implies that $K$ is contained in the finite subcomplex $X' \times Y'$ of $X \times Y$. By Theorem 36.14 we know that $X' \times Y'$ is compact. Together with (a) we see that $K$ is a closed subset of $X \times Y$ that is contained in a compact subset $X' \times Y'$. It follows from Lemma 2.17 (1) that $K$ itself is compact.

3. This statement follows immediately from (1) and (2), the fact that $X \times Y$ is Hausdorff and Lemma 36.27.

4. This statement is just a reformulation of Proposition 36.23 (3). ■

36.11. A convenient category of topological spaces (\(*)**. Let $X$ and $Y$ be two CW-complexes. We can equip the set $X \times Y \!:= \!\{(x,y) \mid x \in X \text{ and } y \in Y\}$ with two different topologies, namely the familiar product topology from page 162 and the less familiar topology $X \otimes Y$ from the previous section. As we saw in Lemma 36.24, in general these two topologies are different.
This is quite a nuisance. In this section we will discuss one approach to addressing this issue. We will not make much use of the ideas discussed in this section, thus the reader can safely move on to the next section.

Let us first reflect about what “product” is supposed mean in the first place. After contemplating on the concept of “product” for a while one will surely arrive at the following definition.

**Definition.** Let $\mathcal{C}$ be a category and let $X, Y \in \text{Ob}(\mathcal{C})$ be two objects. A product of $X$ and $Y$ in the category $\mathcal{C}$ is some object $P \in \text{Ob}(\mathcal{C})$ together with two morphisms $p: P \to X$ and $q: P \to Y$ such that the following property is satisfied: Whenever we are given two morphisms $f: Z \to X$ and $g: Z \to Y$ there exists a unique morphism $\Phi: Z \to P$ such that $f = p \circ \Phi$ and $g = q \circ \Phi$. The situation is summarized in the following diagram

\[
\begin{array}{ccc}
Z & \xrightarrow{\Phi} & P \\
\downarrow{f} & & \downarrow{p} \\
X & & X \\
\downarrow{g} & & \downarrow{q} \\
Y & & Y
\end{array}
\]

Sometimes we refer to $P$ also as the categorical product of $X$ and $Y$ if we want to distinguish it from the usual set-theoretic product.

**Remark.** The definition of the product can be formulated in terms of inverse limits. More precisely, we consider the set $I = \{\ast, \ast\}$ with the trivial preorder. An inverse system over $I$ in a category $\mathcal{C}$ is just the data of two objects $X$ and $Y$ in $\mathcal{C}$. The corresponding inverse limit, if it exists, is by definition precisely a product of $X$ and $Y$ in $\mathcal{C}$.

The usual “formal nonsense” shows that the product, if it exists, is unique up to a canonical isomorphism. Thus we will use usual parlance and we will speak of the product, if it exists.

**Examples.**

1. Let $\text{Set}$ be the category of sets and let $X, Y \in \text{Ob}(\text{Set})$. One can easily verify that the product is given by the set $X \times Y := \{(x, y) \mid x \in X \text{ and } y \in Y\}$ together with the obvious maps $X \times Y \to X$ and $X \times Y \to Y$.

2. Let $\text{Top}$ be the category of topological spaces and let $(X, A), (Y, B) \in \text{Ob}(\text{Top})$. Let $\mathcal{P}$ be the product topology on the set $X \times Y$ that we defined on page 162. It follows almost immediately from Lemma 3.6 (2) that in the category of topological space the product is given by the topological space $(X \times Y, \mathcal{P})$ together with the obvious maps $X \times Y \to X$ and $X \times Y \to Y$.

3. Let $\text{PTop}$ be the category of pointed topological spaces that we introduced on page 476. Furthermore let $(X, x_0), (Y, y_0) \in \text{Ob}(\text{PTop})$ together with the obvious maps. In Exercise 36.12 we will see that the product in $\text{PTop}$ is given by the smash product $(X, x_0) \wedge (Y, y_0)$ that we introduced on page 577 together with the obvious morphisms $(X, x_0) \wedge (Y, y_0) \to (X, x_0)$ and $(X, x_0) \wedge (Y, y_0) \to (Y, y_0)$.

---

\[594\] We refer to page 745 for the definition of an inverse limit.
The following theorem shows that if we move from considering all topological spaces to a slightly more constrained setup, then we can combine the two concepts of products that we introduced for CW-complexes.

**Theorem 36.28.** There exists a full subcategory $\mathcal{C}$ of the category of topological spaces with the following properties:

1. Every regionally compact Hausdorff space is an object of $\mathcal{C}$.
2. Every CW-complex is an object of $\mathcal{C}$.
3. Every direct system in $\mathcal{C}$ has a direct limit and every inverse system in $\mathcal{C}$ has an inverse limit.
4. If $X$ and $Y$ are two CW-complexes, then the CW-complex $X \otimes Y$ is in fact the product in $\mathcal{C}$.

**Remark.** A category as in Theorem 36.28 is often called a convenient category. Note though that the notion of a convenient category might be used somewhat differently by different authors. In fact there are many “convenient categories”, possibly with somewhat different properties from the ones we stated. We refer to [Stee67, Miln59, Spa63, VogR71, McCor67, Stri, Pre02, BrownR63] and [Stro11, Chapter 3.4] for more examples and for the discussion of various notions of a “convenient category”.

We will outline the proof of Theorem 36.28 by giving an explicit example of a convenient category. We will need the following definitions.

**Definition.**

1. A subset $A$ of a topological space $X$ is called compactly closed if for every map $\varphi: K \to X$, where $K$ is a compact Hausdorff space, the preimage $\varphi^{-1}(A)$ is a closed subset of $K$.
2. A topological space $X$ is called compactly generated if every compactly closed subset of $X$ is actually closed.
3. A topological space $X$ is called weakly Hausdorff if for every map $\varphi: K \to X$, where $K$ is a compact Hausdorff space, the image $\varphi(K)$ is closed.
4. A topological space $X$ is called a CGWH-space if it is compactly generated and if it is weakly Hausdorff.

First, for the readers who like weird topological spaces we give some non-examples.

**Examples.**

1. We equip the set $X = (\mathbb{N} \times \mathbb{N}) \cup \{\ast\}$ with the topology where $U \subset X$ is open if one of the following holds:
   a. the point $\ast$ is contained in $U$, or
   b. for all but finitely many $n \in \mathbb{N}$ the set $U$ contains all but finitely many points in $\{n\} \times \mathbb{N}$.

   It follows from Lemma 2.32 that every closed subset of $X$ is actually compactly closed.

   Sometimes in the literature a compactly generated topological space is also called a $k$-space.

   By Lemma 2.17 (2) we know that a topological space that is Hausdorff is also, as it should be, weakly Hausdorff.

   Evidently the acronym CGWH stands for Compactely Generated and Weakly Hausdorff.
In Exercise 36.13 we will see that $X$ is not compactly generated.

(2) We consider $X = \mathbb{R} \setminus \{ \frac{1}{n} | n \in \mathbb{N} \}$ and we consider $Y = \mathbb{R}/\mathbb{Z}$ where $\mathbb{Z} \subset \mathbb{R}$ is the subset given by integers.\footnote{We use this cumbersome notation to make sure that we do not confuse the quotient space $\mathbb{R}/\mathbb{Z}$ with the quotient of $\mathbb{R}$ by the obvious action of the group $(\mathbb{Z}, +)$ on the topological space $\mathbb{R}$.} In Exercise 36.16 we will see that the product topological space $X \times Y$ is not compactly generated.

(3) In Exercise 36.17 we will give an example of a topological space that is weakly Hausdorff but that is not Hausdorff.

We proceed with an actual example of a CGWH-space.

**Proposition 36.29.** Every CW-complex is a CGWH-space.

**Proof.** Let $X$ be a CW-complex.

(1) Let $A$ be a compactly closed subset of $X$. It follows easily from Lemma 36.7 (3) that $A$ is in fact a closed subset of $X$.

(2) By Proposition 36.10 (2) we know that $X$ is Hausdorff. It follows from Lemma 2.17 (2) that $X$ is in fact weakly Hausdorff. ■

We continue with the following simple-minded definition.

**Definition.** The category $\text{CGWH}$ of CGWH-spaces is the full subcategory of the category of topological spaces whose objects are precisely the CGWH-spaces.

**Remark.** The category of CGWH-spaces was introduced by Michael McCord [McCor69], building on work by Norman Steenrod [Stee67].

The following theorem shows that the category of CGWH-spaces has many charming properties. The theorem provides us in particular with a proof of Theorem 36.28.

**Theorem 36.30.** The category $\text{CGWH}$ of CGWH-spaces has the following properties:

1. The category $\text{CGWH}$ is a full subcategory of the category of topological spaces.
2. Every regionally compact Hausdorff space is an object of $\text{CGWH}$.
3. Every CW-complex is an object of $\text{CGWH}$.
4. Every inverse system in $\text{CGWH}$ has a direct limit and every inverse system in $\text{CGWH}$ has an inverse limit.
5. Given any two objects $X$ and $Y$ in $\text{CGWH}$ there exists a product in the category $\text{CGWH}$.

(a) The product of $X$ and $Y$ in $\text{CGWH}$ is given by the set $X \times Y$ together with a topology $\mathcal{T}$ that contains the usual product topology $\mathcal{P}$. In particular the identity map

$$(X \times Y, \mathcal{T}) \to (X \times Y, \mathcal{P})$$

is a bijection and continuous.

(b) If $X$ and $Y$ are compact and Hausdorff, then $\mathcal{T} = \mathcal{P}$, i.e. the map in (a) is a homeomorphism.
(c) If $X$ and $Y$ are two CW-complexes, then the identity map $(X \times Y, \mathcal{T}) \to X \otimes Y$ is a homeomorphism.

Remark. Let $X$ and $Y$ be two CGWH-spaces. We denote by $X \tilde{\times} Y$ the categorical product of $X$ and $Y$ in the category of CGWH-spaces. Theorem 36.10 (4) can be reformulated as saying that we have a continuous bijection $X \tilde{\times} Y \to X \times Y$. Furthermore, if $X$ and $Y$ are two CW-complexes, then the identity map $X \tilde{\times} Y \to X \otimes Y$ is a homeomorphism.

Sketch of proof. Most of the statements below were first proved by Michael McCord [McCord69], building on work by Norman Steenrod [Steen67]. Arguably the best account of the proof is given in [Stri]. In the following we show that our theorem, as formulated, can be deduced from the statements in [Stri].

(0) This statement holds by definition.

(1) [Stri], Proposition 1.7] says that every regionally compact Hausdorff space is in fact a CGWH-space.

(2) In Proposition 36.29 we just saw that every CW-complex is a CGWH-space.

(3) In [Stri], Propositions 2.23 and 2.30] it is shown that every direct system and every inverse system in the category of CGWH-spaces actually has a limit in the category of CGWH-spaces.

(4) As we discussed on page 965, this is just a special case of (3).

(5) Let $X$ and $Y$ be two topological spaces. Let $\mathcal{T}$ be the usual product topology on $X \times Y$. Furthermore let $\mathcal{P}$ be the topology on $X \times Y$ that is generated by all compactly closed subsets of $(X \times Y, \mathcal{T})$. By Lemma 2.32 we know that every closed subset is compactly closed, thus we see that $\mathcal{T} \subset \mathcal{P}$. It follows from [Stri] Proposition 2.4 and Corollary 2.16] that $(X \times Y, \mathcal{P})$ is the product in the category of CGWH-spaces.

(a) This statement follows immediately from the above discussion.

(b) Now suppose that $X$ and $Y$ are compact and Hausdorff. By Proposition 3.12 we know that the product topological space $X \times Y$ is also compact and Hausdorff. But it follows almost immediately from the definitions that in a compact Hausdorff space a subset is compactly closed if and only if it is closed. Thus we see that $\mathcal{P} = \mathcal{T}$.

(c) Now let $X$ and $Y$ be CW-complexes. We denote by $\mathcal{X}$ the topology of $X \tilde{\times} Y$ that we introduced on page 963. We need to show that $\mathcal{P} = \mathcal{X}$. We make the following two observations:

(i) By definition a subset $A \subset X \times Y$ is closed in $\mathcal{P}$ if and only if the intersection of $A$ with each compact subset of $(X \times Y, \mathcal{T})$ is closed.

(ii) By definition a subset $A \subset X \times Y$ is closed in $\mathcal{X}$ if and only if the intersection of $A$ with each cell of the CW-complex $X \otimes Y$ is closed.

Using Lemma 36.7 (3), Theorem 36.14 and Exercise 3.14 one can show that $\mathcal{P}$ and $\mathcal{X}$ have the same closed subsets. We leave it to the reader to fill in the details.

Remark. Given CGWH-spaces $X$ and $Y$ it is also convenient to equip $X \tilde{\times} Y$ with a slight modification of the usual compact-open topology. We refer to [Stri], Proposition 2.24] for details.
We conclude this section with the following proposition that gives us three other convenient properties of the category of CGWH-spaces. The reader who has struggled with the intricacies of Theorem 5.16 and Proposition 5.23 will surely appreciate these statements.

**Proposition 36.31.**

1. Let \( f : X \to Y \) be a bijection between two topological spaces. If \( f \) is proper, i.e. if the preimage of every compact subset of \( Y \) is a compact subset of \( X \), and if \( X \) and \( Y \) are CGWH-spaces, then \( f \) is actually a homeomorphism.

2. Let \( f : W \to X \) and \( g : Y \to Z \) be quotient maps. If \( W, X, Y, \) and \( Z \) are CGWH-spaces, then \( f \times g : W \times Y \to X \times Z \) is also a quotient map.

3. Let \( X \) and \( Y \) be topological spaces and let \( B \subset Y \) be a closed subset. If \( X \) and \( Y \) are CGWH-spaces, then the obvious map \((X \times Y)/(X \times B) \to X \times (Y/B)\) is a homeomorphism.

**Proof.** This proposition is proved in [Stri, Propositions 2.20, 2.40 and 3.17].

**Remark.** The category of CGWH-spaces admits a fully faithfully embedding into the category of “quasiseparated condensed sets”. The category of “quasiseparated condensed sets” is particularly well-suited for dealing with technical problems that arise in topology. We refer to [Scho19, Theorem 2.16] and [Scho19b, Proposition 1.2] for details.

36.12. **Constructions of more CW-complexes.** In this section we will see how one can build new CW-complexes out of given CW-complexes. We start out with the following lemma.

**Lemma 36.32.**

1. Let \( \{X_i\}_{i \in I} \) be a family of CW-complexes. The disjoint union \( \bigsqcup_{i \in I} X_i \) admits a natural CW-structure such that each \( X_i \) is a subcomplex.

2. Let \( X \) and \( Y \) be CW-complexes, let \( A \) be a subcomplex of \( X \) and let \( f : A \to Y \) be a cellular map. As on page 197 we consider the topological pushout:

\[
X \cup_A Y := (X \sqcup Y)/\sim \quad \text{where } a \sim f(a) \text{ for } a \in A
\]

Furthermore we consider the following pushout diagram:

\[
\begin{array}{ccc}
A & \xrightarrow{f} & X \\
\downarrow & & \downarrow_{x \mapsto [x]} \\
Y & \xrightarrow{y \mapsto [y]} & X \cup_A Y.
\end{array}
\]

The following statements hold:

(a) The map pushout \( X \cup_A Y \) admits a natural CW-structure.

(b) The map \( Y \to X \cup_A Y \) is a cellular embedding and for any subcomplex \( B \) of \( X \) that is disjoint from \( A \), the map \( B \to X \cup_A Y \) is also a cellular embedding.

(c) If \( f : A \to Y \) is cellular embedding, then the opposite map \( X \to X \cup_A Y \) is also a cellular embedding.

3. Let \( X \) be a CW-complex and let \( A \) be a subcomplex. The quotient \( X/A \) admits a natural CW-structure such that the projection map \( X \to X/A \) is cellular and where
the cells of $X/A$ are in one-to-one correspondence to the cells of $X$ that do not entirely lie in $A$ together with one 0-cell given by the point $[A]$.

(4) Let $\{X_i\}_{i \in I}$ be a family of CW-complexes and suppose that for each $i \in I$ we are given a point $a_i \in X_i^0$. If we use these points to form the wedge $\bigvee_{i \in I} X_i$, then the wedge admits a natural CW-complex structure such that each $X_i$ is a subcomplex.

(5) (*) Let $(X, x_0)$ and $(Y, y_0)$ be pointed CW-complexes. If at least one of $X$ or $Y$ has only countably many cells, then the smash product

$$X \wedge Y = (X \times Y)/((X \times \{y_0\}) \cup (\{x_0\} \times Y)),$$

as defined in Exercise 18.30 has a natural CW-structure.

(6) (*) Let $X$ be a CW-complex, let $A$ be a complex of $X$ and let $f : A \to X$ be a cellular map with the following properties:

(a) For each $n$-cell $\sigma$ of $A$ we have either $f(\sigma) \subset X^{n-1}$ or $f|_{\sigma}$ is a homeomorphism.

(b) The image of $f$ is contained in a subcomplex of $X$ that is disjoint from $A$.

Then $X/\sim$, where $a \sim f(a)$ for all $a \in A$, admits a natural CW-structure such that for any subcomplex $B$ that is disjoint from $f(A)$ the natural map $B \to X/\sim$ is a cellular embedding.

(We point out that by Lemma 36.19 we know that the image of a cellular embedding is in fact a cellular homeomorphism onto a subcomplex and we will often use this cellular isomorphism to identify the domain with its image.)

Convention. When we form the wedge of a family of a CW-complexes, then we always use a point that lies in the 0-skeleton, so that we can view the wedge in a natural way as a CW-complex.

Proof (*).

(1) The first statement is basically obvious.

(2) First note that it is pretty clear what the CW-structure on $X \cup_A Y$ should be. The problem that arises is that one needs to show that the topology of the new CW-complex agrees in fact with the intended topology. If $X$ (and $Y$) are finite CW-complexes then this follows easily from Proposition 2.43. The general case gets more technical. We refer to [LW69, p. 60 and Theorem 3.11] or alternatively to [FrP90a, Theorem 2.31 on p. 62] for complete proofs. The remaining two statements follow easily from the actual definition of the CW-structure on $X \cup_A Y$.

(3) Note that this statement is the special case of (2) where we consider the constant map $f : A \to Y = \{\ast\}$ where $Y = \{\ast\}$ is a topological space consisting of a single point.

(4) This follows easily from (1) and (2).
Example. In Figure 617 we see the torus together with a CW-structure \( X \) that has two 2-dimensional cells. It follows from Lemma 36.33 (1) that \( X/X^1 = X^2/X^1 \) is homeomorphic to the wedge of two spheres.

\[ \text{torus } X \]

\[ \text{1-skeleton } X^1 \]

\[ X/X^1 \text{ is homeomorphic to} \]

\[ \text{Figure 617} \]

Proof (*)

(1) First note that it is basically clear that the given map \( f \) is a bijection. Furthermore it follows immediately from Lemma 36.23 that \( f \) is continuous. We use Lemma 36.32 to view both sides of Lemma 36.33 as CW-complexes. The map \( f \) gives a bijection between the cells of the two sides. Thus it follows from Lemma 36.12 that \( f \) is a homeomorphism.

(2) This statement follows immediately from (1).
(3) Since we remove a “top-dimensional” open cell from $X^{n+1}$ it follows immediately from the definitions that $X^{n+1} \setminus \Phi_i(B_i^{n+1})$ is a subcomplex of $X^{n+1}$. Similar to the argument in (1) we now see that the map is a homeomorphism.

Lemma 36.34. Let $f_i : X_i \to X_{i+1}$, $i \in \mathbb{N}$ be a sequence of cellular inclusion maps between CW-complexes. Then the direct limit $\lim_{\longrightarrow} X_i = \bigcup_{i \in I} X_i$ admits a CW-structure such that each $X_i$ is a subcomplex of $\lim_{\longrightarrow} X_i = \bigcup_{i \in I} X_i$.

Example. Lemma 36.34 allows us to view the line with infinitely many spheres attached as a CW-complex. We refer to Figure 618 for an illustration.

Proof. We leave it to the reader to write down the, notationally messy but mathematically elementary, proof.

We conclude this section with the following corollary that shows that several constructions that we are familiar with can also be performed in the category of CW-complexes.

Corollary 36.35. Let $X$ be a CW-complex.

1. The cone
   $$\text{Cone}(X) = (X \times [0, 1])/\sim \quad \text{where} \quad (x, 0) \sim (y, 0) \quad \text{for every} \quad x, y \in X$$
   admits a natural CW-structure such that the inclusion map $X \to \text{Cone}(X)$ given by $x \mapsto [(x, 1)]$ is a cellular embedding.

2. The suspension
   $$\Sigma(X) = (X \times [-1, 1])/\sim \quad \text{where} \quad \text{for every} \quad x, y \in X \quad \text{we have} \quad (x, -1) \sim (y, -1)$$
   $$\quad \text{and} \quad (x, 1) \sim (y, 1)$$
   admits a natural CW-structure such that the map $X \to \Sigma(X)$ given by $x \mapsto [(x, 0)]$ is a cellular embedding.

3. If $A$ is a CW-complex and if $f : A \to X$ is a cellular map, then the mapping cone
   $$\text{Cone}(f : A \to X) = (\_)/\sim \quad \text{where} \quad (a, 1) \sim f(a) \quad \text{for all} \quad a \in A$$

---

602 We write explicitly “direct limit” to remind the reader that, according to the discussion on page 731, the topology on $\lim_{\longrightarrow} X_i = \bigcup_{i \in I} X_i$ is given by the condition that a subset $U$ is open if and only if each intersection $U \cap X_i$ is an open subset of $X_i$.

603 It follows from Proposition 2.45 that the topology on the “line with infinitely many spheres” coming from $\mathbb{R}^3$ agrees with the topology coming from the CW-structure.
and the mapping cylinder

\[ \text{Cyl}(f: A \to X) = (A \times [0, 1] \sqcup X) / \sim \] where \((a, 1) \sim f(a)\) for all \(a \in A\)

admit natural CW-structures. Furthermore the obvious maps \(X \to \text{Cone}(f: A \to X)\) and \(\text{Cyl}(f: A \to X)\) are cellular embeddings and the map \(A \mapsto \text{Cyl}(f: A \to X)\) given by \(a \mapsto [(a, 0)]\) is a cellular embedding.

(4) If \(f: X \to X\) is a cellular map, then the mapping torus

\[ \text{Tor}(X, f) := (X \times [0, 1]) / \sim \] where \((x, 0) \sim (f(x), 1)\) for all \(x \in X\)

admits a natural CW-structure such that the map \(X \to \text{Tor}(X, f)\) given by \(x \mapsto (x, 0)\) is a cellular embedding.

(As in the statement of Lemma 36.32 we point out that often we will use a cellular embedding to identify the domain with its image.)

**Proof.** All four statements can be proved fairly easily using Proposition 36.23 (3b) and Lemma 36.32. We only point out that the CW-structure on the mapping torus \(\text{Tor}(X, f)\) is obtained in a 2-stage process, first we equip the mapping cylinder \(\text{Cyl}(f: X \to X)\) with the natural CW-structure given by (3). Afterwards we apply Lemma 36.32 (6). We leave it to the reader to fill all the other details. 

We conclude this discussion of constructions of CW-structures with the following slightly sobering proposition.

**Proposition 36.36.** There exists a finite 3-dimensional CW-complex that admits an open subset that does not admit a CW-structure.

**Proof.** This statement is proved in [Cau92, Exemple 2].

---

**36.13. Coverings of CW-complexes.** In this section we will see that a covering of a CW-complex inherits a natural CW-structure.

**Proposition 36.37.** Let \(p: \tilde{X} \to X\) be a covering of a connected CW-complex \(X\). We can equip \(\tilde{X}\) with a natural structure of a CW-complex such that the following statements hold:

1. The map \(p: \tilde{X} \to X\) is a cellular map.

---

\(^{004}\)Strictly speaking, or Bourbakily speaking if that’s an adverb, we should really specify in each case what the “natural CW-structure” is. But this should hopefully be clear in each case, and we do not encumber the reader with unnecessary extra notation.
For any \( k \in \mathbb{N}_0 \) we have\(^{605}\)

\[
\#k\text{-cells of } \tilde{X} = [\tilde{X} : X] \cdot \#k\text{-cells of } X.
\]

(3) The dimension of \( \tilde{X} \) is the same as the dimension of \( X \).

**Remark.** Proposition 36.37 is a generalization of Proposition 31.1 where we showed that any covering of a topological graph is again a topology graph. In fact, as we will see, the proofs are structurally very similar.

**Proof.** Let \( p: \tilde{X} \to X \) be a covering of a connected CW-complex \( X \) of degree \( n := [\tilde{X} : X] \). Let \( \psi: B^k \to X \) be a characteristic map of a \( k \)-cell of \( X \). We write \( x = \psi(0) \). We consider the following diagram

\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\tilde{\psi}} & \tilde{X} \\
\downarrow p & & \downarrow p \\
B^k & \xrightarrow{\psi} & X.
\end{array}
\]

Since \( B^k \) is simply connected and locally path-connected we can apply Proposition 29.2 which says in this context that for each \( \tilde{x} \in p^{-1}(x) \) there exists a unique lift \( \tilde{B}^k \to \tilde{X} \) with \( \tilde{\psi}(0) = \tilde{x} \). By the definition on page 495 the degree \( n = [\tilde{X} : X] \) of the covering equals the cardinality of \( p^{-1}(x) \). Thus we see that \( \psi \) gives rise to \( n \) maps \( \tilde{B}^k \to \tilde{X} \). It is straightforward to verify that all these lifts of the characteristic maps for the cells of \( X \) define a CW-structure for \( \tilde{X} \). We leave the joyful task of verifying the details to the reader. Alternatively we refer to [Bre93, Theorem IV.8.10] for details.

It follows immediately from the above construction and the definitions that the CW-structure we had just defined on \( \tilde{X} \) has the desired properties (1) to (3).

**Examples.**

(1) We equip \( S^1 \) with the CW-structure consisting of one 0-cell and one 1-cell. We denote by \( p: \mathbb{R} \to S^1, \quad t \mapsto e^{2\pi i t} \) the universal covering of \( S^1 \). If we apply the construction of the CW-structure on \( \mathbb{R} \) given in the proof of Proposition 36.37, then we end up equipping \( \mathbb{R} \) with the CW-structure where the 0-cells correspond to \( \mathbb{Z} \) and the 1-cells are precisely the intervals \([k,k+1]\), with \( k \in \mathbb{Z} \). We illustrate the CW-structure of \( \mathbb{R} \) in Figure 620.

---

\(^{605}\)Note that this is an equality of cardinalities. For example, if \([\tilde{X} : X]\) is infinite countable and if \( X \) has finitely many \( k \)-cells, then \( \tilde{X} \) has infinitely many, but countably many, \( k \)-cells.
(2) Almost the same approach as in (1), applied to the universal covering \( \mathbb{R}^2 \to S^1 \times S^1 \), endows \( \mathbb{R}^2 \) with a CW-structure that is illustrated in Figure 621.

\[
\begin{array}{c}
p: \mathbb{R}^2 \to S^1 \times S^1
\end{array}
\]

\textbf{Figure 621}

(3) In the proof of Hadamard’s Theorem \[33.9\] we constructed an explicit covering map \( \mathbb{D} \to H_8/ \sim \cong E_8/ \sim \). If we equip \( E_8/ \sim \) with the “usual” CW-structure then we obtain from Proposition \[36.37\] the CW-structure on \( \mathbb{D} \) that is shown in Figure 622.

\[
\begin{array}{c}
\mathbb{D} \to E_8/ \sim
\end{array}
\]

\textbf{Figure 622}

\( \text{induced CW-structure on } \mathbb{D} \)

\( \text{CW-structure on the surface of genus 2} \)

---

**Exercises for Chapter 36**

**Exercise 36.1.**

(a) Does every compact subset of \( \mathbb{R}^2 \) admit a CW-structure?

(b) Let \( n \in \mathbb{N} \). Does the open ball \( B^n_1(0) \) admit a CW-structure?

(c) Let \( C \) be the Cantor set as defined on page 100. Does \( C \) admit a CW-structure?

**Exercise 36.2.**

(a) We equip \( \mathbb{R}^\infty \) with the metric that is given by

\[
d((x_1, x_2, \ldots), (y_1, y_2, \ldots)) : = \sqrt{\sum_{i=1}^{\infty} |x_i - y_i|^2}.\]

We consider the following two topologies on \( \mathbb{R}^\infty \):

\[
\mathcal{S} := \{ U \subset \mathbb{R}^\infty \mid \text{for every } P \in U \text{ there exists } \epsilon > 0 \text{ such that } B_\epsilon(P) \subset U \}
\]

and

\[
\mathcal{T} := \{ U \subset \mathbb{R}^\infty \mid \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n \}.
\]

Show that \( \mathcal{S} \subset \mathcal{T} \).

(b) We view \( \mathbb{R}^\infty \) as equipped with the topology \( \mathcal{S} \). Does the Heine-Borel Theorem hold in \( \mathbb{R}^\infty \)? More precisely, is every bounded closed subset of \( \mathbb{R}^\infty \) compact?
(c) We view $\mathbb{R}^\infty$ as equipped with the topology $\mathcal{T}$. Show that the projection map $p: \mathbb{R}^\infty \rightarrow \mathbb{R}^n$ is continuous and open.

**Exercise 36.3.** Show that the map

$$C^\infty \rightarrow \mathbb{R}^\infty$$

$$(x_1 + iy_1, x_2 + iy_2, \ldots) \rightarrow (x_1, y_1, x_2, y_2, \ldots)$$

is a homeomorphism.

**Exercise 36.4.** Show that the action

$$\{\pm 1\} \times S^\infty \rightarrow S^\infty$$

$$(\epsilon, v) \mapsto \epsilon \cdot v$$

of the group $\{\pm 1\}$ on the topological space $S^\infty$ is continuous and discrete.

**Exercise 36.5.** Let $P, Q \in S^\infty$. Show that there exists a homeomorphism $h$ of $S^\infty$ with $h(P) = Q$.

**Exercise 36.6.** Let $X$ be a CW-complex and let $x \in X$. Show that $\{x\}$ is a closed subset of $|X|$.

*Hint.* Make good use of Lemma 3.44

**Exercise 36.7.** Let $X$ be a CW-complex.

(a) Show that if the 1-skeleton $X^1$ is path-connected, then $X$ itself is path-connected.

(b) Show that if $X$ is connected, then $X^1$ is also connected.

*Hint.* Make good use of Lemmas 2.57, 2.58 and 2.62

**Exercise 36.8.** Show that a CW-complex is locally finite if and only if it is regionally compact.

**Exercise 36.9.** We equip $\mathbb{RP}^2$ with the CW-structure with one cell in dimensions 0, 1, 2. Let $p: S^2 \rightarrow \mathbb{RP}^2 = S^2/\pm 1$ be the usual 2-fold covering. The CW-structure on $\mathbb{RP}^2$ induces a CW-structure on $S^2$. What does this CW-structure on $S^2$ look like?

**Exercise 36.10.** Let $I$ be a set and for each $i \in I$ let $n_i \in \mathbb{N}$. Show that the wedge $\bigvee_{i \in I} S^{n_i}_i$ has a natural CW-structure with one 0-cell and where for each $n \in \mathbb{N}_0$ the $n$-cells correspond precisely to the $n$-dimensional spheres in the family of spheres $\{S^{n_i}_i\}_{i \in I}$.

*Hint.* Use Lemma 3.28 and use the fact, shown on page 182, that for each $n \in \mathbb{N}$ the sphere $S^n$ is homeomorphic to $\tilde{B}^n/S^{n-1}$.

**Exercise 36.11.** Let $X$ be a finite CW-complex. Show that there exists an $n \in \mathbb{N}_0$ and a map $\varphi: |X| \rightarrow \mathbb{R}^n$ that is an embedding.

**Exercise 36.12.** Recall that we denote by $\mathcal{PTop}$ the category of pointed topological spaces. Suppose we are given $(X, x_0), (Y, y_0) \in \text{Ob}(\mathcal{PTop})$. Show that the direct product of $(X, x_0)$ and $(Y, y_0)$ in $\mathcal{PTop}$ is given by the smash product $(X, x_0) \wedge (Y, y_0)$ that we introduced on page 577.
Exercise 36.13. We consider the set $X = (\mathbb{N} \times \mathbb{N}) \cup \{\ast\}$. We say $U \subset X$ is open if $\ast \not\in U$ or if for all but finitely many $n \in \mathbb{N}$ the set $U$ contains all but finitely many points in $\{n\} \times \mathbb{N}$.

(a) Show that these open sets do indeed define a topology on $X$.
(b) Show that $X$ is Hausdorff.
(c) Show that every infinite subset of $X$ contains an infinite closed and discrete subset.
(d) Show that every compact subset of $X$ is finite.
(e) Show that the compactly generated topology on $X$ is the discrete topology.

These steps show that $X$ is not compactly generated.

Exercise 36.14. Let $\mathcal{C}$ be a convenient category of topological spaces, i.e., let $\mathcal{C}$ be a full subcategory $\mathcal{C}$ of the category of topological spaces that has the properties stated in Theorem 36.28. Let $X$ and $Y$ be CW-complexes. Show that if the usual product $X \times Y$ lies in $\mathcal{C}$, then $X \times Y$ is homeomorphic to the product CW-complex $X \otimes Y$.

Exercise 36.15. Let $X$ and $Y$ be CGWH-spaces. We denote by $X \tilde{\times} Y$ the product in the category of CGWH-spaces, which exists by Theorem 36.30 (4). Show that for each $n \in \mathbb{N}$, each $x_0 \in X$ and $y_0 \in Y$ the natural maps $p : X \tilde{\times} Y \to X$ and $q : X \tilde{\times} Y \to Y$ induce an isomorphism $p_* \times q_* : \pi_n(X \tilde{\times} Y, (x_0, y_0)) \cong \pi_n(X, x_0) \times \pi_n(Y, y_0)$.

Remark. The exercise is to verify that the proofs of Propositions 16.20 and 40.8 also apply to $X \tilde{\times} Y$ instead of the usual product topological space $X \times Y$.

Exercise 36.16. We consider $X = \mathbb{R} \setminus \{1/n \mid n \in \mathbb{N}\}$ and we consider $Y = \mathbb{R}/\mathbb{Z}$ where $\mathbb{Z} \subset \mathbb{R}$ is the subset given by integers. We consider the subset $A = \{(1/i + a_i/i, 1/j + a_j/j) \in X \times Y \mid i, j \in \mathbb{N}\}$ where $a_i = \frac{1}{2}(\frac{1}{i} - \frac{1}{i+1})$.

(a) Show that the closure of $A$ contains $(0, [0])$.
(b) Show that for any compact subset $K \subset X \times Y$, the set $K \cap A$ has only finitely many points.
(c) Show that $X$ is not compactly generated.

Exercise 36.17.

(a) We consider $X := \{0\} \cup \bigcup_{n,m \in \mathbb{N}} \{1/n + 1/m + n\} \subset \mathbb{R}$.

We equip $X$ with the usual metric coming from $\mathbb{R}$. We set $x := 0$.

(i) Show that each point in $X \setminus \{x\}$ is open.
(ii) Show that $X$ is not regionally compact at $x$.

(b) Let $X$ be a countable metric space which admits a point $x \in X$ such that the following conditions are satisfied:

(i) Each point in $X \setminus \{x\}$ is open.
(ii) The topological space $X$ is not regionally compact at $x$. 

Let $Y := X \cup \{\infty\}$ be the one-point compactification as defined in Exercise 2.66.

(a) Show that compact sets of $Y$ are closed. (This implies that $Y$ is weakly Hausdorff.)

(b) Show, by considering the points $x$ and $\infty$, that $Y$ is not Hausdorff.

Remark. The combination of (a) and (b) shows that there exist topological spaces that are weakly Hausdorff but not Hausdorff.

Exercise 36.18. Let $X$ be a CW-complex with countably many cells.

(a) Show that there exists a sequence $A_1 \subset A_2 \subset \ldots$ of finite subcomplexes $A_i$ of $X$ such that $X = \bigcup_{i \in \mathbb{N}_0} A_i$.

(b) If $X$ is connected, then show that we can arrange in (a) that every $A_i$ is connected.
37. CW-complexes II: Fundamental groups

In this chapter we will consider fundamental groups of CW-complexes. First we collect a few general statements. Then we will show that fundamental groups of 1-dimensional CW-complexes are free groups. Finally we will see how can calculate fundamental groups of more general CW-complexes in practice.

37.1. Fundamental groups of CW-complexes. Using Proposition 36.10 we can now prove the following very useful version of the Seifert–van Kampen Theorem 22.1. In view of Theorem 64.5 which we mentioned already on page 936, this can be viewed as a generalization of the Seifert–van Kampen Theorem 22.2 for smooth manifolds.

**Theorem 37.1. (Seifert–van Kampen Theorem for CW-complexes)** Let \( X \) be a CW-complex and let \( X = A \cup B \) be a decomposition of \( X \) in two subcomplexes such that \( A \cap B \) is path-connected. Let \( x_0 \in A \cap B \). Then

\[
\pi_1(X,x_0) \cong \pi_1(A,x_0) \ast \pi_1(A \cap B,x_0) \ast \pi_1(B,x_0).
\]

**Examples.**

1. Let \( X \) be the wedge of two circles. We can view \( X \) as a CW-complex with one 0-cell \( x_0 \) and two 1-cells \( a \) and \( b \). Then \( A = \{x_0,a\} \) and \( B = \{x_0,b\} \) are subcomplexes, each of which is homeomorphic to \( S^1 \). We refer to Figure 623 for an illustration. It follows, as on page 606 that

\[
\pi_1(X,x_0) \cong \pi_1(A,x_0) \ast \pi_1(A \cap B,x_0) \ast \pi_1(B,x_0) \cong \langle a \rangle \ast \langle b \rangle = \langle a,b \rangle.
\]

2. We consider

\[
K := (S^1 \times S^1) \cup (\overline{B^2} \times \{1\}),
\]

i.e. \( K \) is given by a torus where the “central hole” is filled in with a disk. We refer to Figure 624 for an illustration. In the above definition of \( K \) we already wrote \( K \) as the union of two subsets. It is quite straightforward to see that \( K \) can be given a CW-structure such that \( A \) and \( B \) are subcomplexes. We pick the base point

\[\text{Figure 623}\]

\[\text{Figure 624}\]
\[ x_0 = (1, 1). \] We obtain that
\[
\pi_1(K, x_0) \cong \pi_1(A, x_0) \ast_{\pi_1(A \cap B, x_0)} \pi_1(B, x_0) \cong \langle x, y \mid [x, y] \ast \{e\} \rangle \cong \langle y \rangle.
\]

\[ A = S^1 \times S^1 \]
\[ B = B^2 \times \{1\} \]

\[ \text{Kiachelorl} \]

\textbf{Figure 624}

\textbf{Proof of Theorem 37.1 (\textast)} Let \( X \) be a CW-complex and let \( X = A \cup B \) be a decomposition of \( X \) in two subcomplexes such that \( A \cap B \) is path-connected. Note that \( A \cap B \) is also a subcomplex. Let \( x_0 \in A \cap B \).

We use the notation of Proposition 36.10 (8). We write \( U = \Phi(A) \) and \( V = \Phi(B) \). Note that by Proposition 36.10 (8b) we have \( U \cap V = \Phi(A \cap B) \). Since \( A \cap B \) is path-connected and since \( A \cap B \) is a deformation retract of \( \Phi(A \cap B) \) we see that \( U \cap V = \Phi(A \cap B) \) is also path-connected. Therefore we can apply the Seifert–van Kampen Theorem 22.1 to the decomposition \( X = U \cup V \). We obtain the following commutative diagram
\[
\begin{array}{ccc}
\pi_1(U, x_0) \ast_{\pi_1(U \cap V, x_0)} \pi_1(V, x_0) & \cong & \pi_1(X, x_0) \\
\uparrow & & \uparrow \\
\pi_1(A, x_0) \ast_{\pi_1(A \cap B, x_0)} \pi_1(B, x_0) & \rightarrow & \pi_1(X, x_0),
\end{array}
\]

where the two vertical maps are induced by the inclusions. By Proposition 36.10 (8a) and Proposition 18.16 (2) the three inclusion induced maps \( \pi_1(A, x_0) \rightarrow \pi_1(U, x_0) \), \( \pi_1(B, x_0) \rightarrow \pi_1(V, x_0) \) and \( \pi_1(A \cap B, x_0) \rightarrow \pi_1(U \cap V, x_0) \) are isomorphisms. The top horizontal map is an isomorphism by the Seifert–van Kampen Theorem 22.1. It follows that the bottom horizontal map is also an isomorphism. \( \blacksquare \)

Next we want to compute the fundamental group of a CW-complex that is obtained by gluing two subcomplexes of a connected CW-complex. We recall and introduce the following two definitions.

\textit{Definition.} Let \( X \) be a topological space, let \( A \) be a subset of \( X \) and let \( f : A \rightarrow X \) be an embedding. Following the discussion on page 761 we define
\[ X(f) := X(f: A \rightarrow X) := X/ \sim \]
where \( f(a) \sim a \) for every \( a \in A \).

Furthermore we define the \textit{partial mapping torus} \[ \text{Tor}(f) := \{X \sqcup (A \times [0, 1])\}/ \sim \]
where \( (a, 0) \sim a \) and \( (a, 1) \sim f(a) \) for every \( a \in A \).

\textsuperscript{08} The proof is very similar to the proof of the Seifert–van Kampen Theorem for Smooth Manifolds 22.2

\textsuperscript{09} If \( A = X \), then one can easily show that the partial mapping torus is naturally homeomorphic to the mapping torus that we introduced on page 711
Continuing with the above notation, note that the projection $A \times [0, 1] \to A$ induces a map $p: \text{Tor}(f) \to X(f)$. In Proposition 38.5 we will see that under reasonably mild hypotheses the map $p: \text{Tor}(f) \to X(f)$ is a homotopy equivalence. In particular by Proposition 18.16 we see that $p$ induces an isomorphism of fundamental groups.

Now we can formulate, prove and discuss the following theorem.

**Theorem 37.2. (HNN-Seifert–van Kampen Theorem for CW-complexes)** Suppose we are given a path-connected CW-complex $X$ and two path-connected disjoint subcomplexes $A$ and $B$. Let $f: A \to B$ be a cellular isomorphism. We pick a base point $x_0 \in A$. Let $\gamma: [0, 1] \to X$ be an embedding with $\gamma(0) = x_0$ and with $\gamma(1) = f(x_0)$ such that $\gamma([0, 1])$ is a subcomplex of the 1-skeleton $X^1$. We write $\Gamma = \pi_1(A, x_0)$. Finally we denote by

$$\alpha: \Gamma = \pi_1(A, x_0) \to \pi_1(X, x_0)$$

the inclusion induced map and we denote by

$$\beta: \Gamma = \pi_1(A, x_0) \xrightarrow{f_*} \pi_1(B, f(x_0)) \to \pi_1(X, f(x_0)) \xrightarrow{\gamma_*} \pi_1(X, x_0)$$

the concatenation of the maps induced by $f$, the inclusion and the base point change isomorphism from Proposition 14.11 using the path $\gamma$. Then there exists an isomorphism

$$\Phi: \pi_1(\text{Tor}(f), x_0) \xrightarrow{\cong} \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$$

which has the following two properties:

1. The diagram

$$\begin{array}{ccc}
\pi_1(X, x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\
\pi_1(\text{Tor}(f), x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle
\end{array}$$

with the obvious diagonal maps commutes.

2. The closed loop in $\text{Tor}(f)$ given by the composition of $\gamma$ with the path $s \mapsto [(x_0, 1-s)]$ corresponds under the isomorphism $\Phi$ to $t$. 

**Remark.**

1. Basically the same way that we obtained the HNN-Seifert–van Kampen Theorem 26.3 from the Seifert–van Kampen Theorem 22.1 one can also obtain the above HNN-Seifert–van Kampen Theorem 37.2 for CW-complexes from the Seifert–van Kampen Theorem 37.1 for CW-complexes. Below we will give a different proof of the

\[\text{Note that it follows from our hypothesis that } X \text{ is path-connected together with Proposition 36.10 (7) that such } \gamma \text{ exists.}\]
HNN-Seifert–van Kampen Theorem 26.3 for CW-complexes which is easier than the argument provided in the proof of the HNN-Seifert–van Kampen Theorem 37.2.

(2) The original HNN-Seifert–van Kampen Theorem 26.3 is more general than the above HNN-Seifert–van Kampen Theorem 26.3 for CW-complexes, but for most applications the latter result will be just fine.

(3) Using Proposition 38.5 one can also deal with certain situations where the map \( f: A \to B \) is not a cellular isomorphism. We leave it to the reader to figure out what these generalized statements might be.

**Sketch of a proof of Theorem 37.2.** Let \( X \) be a path-connected CW-complex \( X \) and let \( f: A \to B \) be a cellular isomorphism between two path-connected disjoint subcomplexes of \( X \). Let \( x_0 \in A \) and let \( \gamma: [0, 1] \to X \) be an embedding with \( \gamma(0) = x_0 \) and with \( \gamma(1) = f(x_0) \) such that \( C := \gamma([0, 1]) \) is a subcomplex.

It follows from Proposition 36.23 (3b) and Lemma 36.32 that Tor(\( f \)) is equipped with a natural CW-structure such that we can view \( A \times [0, 1] \) and \( X \) as subcomplexes of Tor(\( f \)).

We consider \( Y := (X \cup \{x_0\} \times [0, 1])/\sim \) where \( (x_0, 0) \sim x_0 \) and \( (x_0, 1) \sim f(x_0) \). We view \( Y \) as a CW-complex given by attaching a single 1-cell to \( X \). We denote by \( D \) the image of \( \{x_0\} \times [0, 1] \) in \( Y \). Furthermore we denote by \( \delta: [0, 1] \to D \) the path given by \( s \mapsto (x_0, 1 - s) \). Now note that we have the following two isomorphisms:

\[
\pi_1(Y, x_0) \cong \pi_1(X, x_0) *_{\pi_1(C, x_0)} \pi_1(C \cup D, x_0) \cong \pi_1(X, x_0) * (t = [\gamma * \delta])
\]

Seifert–van Kampen Theorem 37.1 since \( C \) is contractible and since \( C \cup D \) is homeomorphic to \( S^1 \)

and

\[
\pi_1(A, x_0) * \pi_1(B, f(x_0)) \cong \pi_1(A, x_0) * \pi_1(D \cup B, x_0) \cong \pi_1(A \cup D \cup B, x_0).
\]

by the Seifert–van Kampen Theorem 37.1 and the base point change \( f(x_0) \mapsto x_0 \) induced by \( \delta \)

Finally we also have the isomorphism:

\[
\pi_1(\text{Tor}(f), x_0) \cong \pi_1(Y, x_0) *_{\pi_1(A \cup D \cup B, x_0)} \pi_1(A \times [0, 1], x_0).
\]

by the Seifert–van Kampen Theorem 37.1 here we use that \( Y \cap (A \times [0, 1]) = A \cup D \cup B \) is connected

Note that in the above discussion basically all maps are induced by the obvious inclusion maps. We leave it to the intrepid reader to go through the explicit descriptions of the various maps.
homomorphisms and the description of the amalgamated product in Proposition 21.21 to show that we do indeed end up with the promised description of $\pi_1(\text{Tor}(f), x_0)$. 

![Illustration for the proof of Theorem 37.2](image)

We conclude this section with the following proposition that is an immediate consequence of Proposition 25.7 and the Finiteness Theorem 36.14.

**Proposition 37.3.** Let $X$ be a CW-complex and let $X_1 \subseteq X_2 \subseteq X_3 \subseteq \ldots$ be a sequence of subcomplexes such that $X = \bigcup_{i \in \mathbb{N}} X_i$. Then for any $w \in X$ we have

$$\pi_1(X, w) = \lim_{\uparrow} \pi_1(X_i, w).$$

**Examples.**

1. We have

$$\pi_1(\mathbb{R}P^\infty) = \pi_1\left(\bigcup_{n \in \mathbb{N}} \mathbb{R}P^n\right) = \lim_{\uparrow} \pi_1(\mathbb{R}P^2) = \lim_{\uparrow} \pi_1(\mathbb{R}P^n) = Z_2 \cong Z_2.$$

(2) In Exercise 37.1 we will use Proposition 37.3 to show that there exists a CW-complex $X$ with $\pi_1(X) \cong (\mathbb{Q}, +)$.

### 37.2. The Euler characteristic of a CW-complex

In the following sections we will give a complete calculation of the fundamental group of a 1-dimensional CW-complex. In the subsequent discussion it will be convenient to have the following definition at our disposal.

**Definition.** Given a finite CW-complex $X$ we define its Euler characteristic $\chi(X)$ as follows:

$$\chi(X) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{number of } n\text{-cells}.$$ 

**Examples.**

1. If $G$ is a finite topological graph, then, according to the discussion on page 932 we can view $G$ as a 1-dimensional CW-complex where the number of 0-cells equals

---

By Corollary 16.18 we know that $\pi_1(\mathbb{R}P^n) \cong Z_2$ for $n \geq 2$. But why is $\pi_1(\mathbb{R}P^1) \cong Z$?
the number of vertices and the number of 1-cells equals the number of edges of $G$. Thus it follows immediately from the definitions that in this case the above Euler characteristic agrees with the definition of the Euler characteristic of a topological graph that we gave on page 228.

(2) For the CW-structures provided by Lemma 36.1 we have $\chi(\mathbb{RP}^n) = \frac{1}{2}(1 + (-1)^n)$ and $\chi(\mathbb{CP}^n) = n + 1$.

(3) A short glance at the three examples in Figure 599 shows that these three different CW-structures for the torus have the same Euler characteristic. Later on, in Chapter 55, we will find out whether or not that is a coincidence.

The following three propositions give us several convenient statements about the Euler characteristic of a finite CW-complex.

**Proposition 37.4.** Let $p: \tilde{X} \to X$ be a finite covering of a finite CW-complex $X$. We equip $\tilde{X}$ with the structure of a CW-complex given by Proposition 36.37. Then

$$\chi(\tilde{X}) = [\tilde{X} : X] \cdot \chi(X).$$

**Proof.** Let $d := [\tilde{X} : X]$. As we mentioned in Proposition 36.37 (2), it follows immediately from the construction of the CW-structure on $\tilde{X}$ that for each $k$ we have

$$#k\text{-cells of } \tilde{X} = [\tilde{X} : X] \cdot #k\text{-cells of } X.$$  
The proposition is an immediate consequence of this equality. ■

The following lemma can be viewed as a generalization of Lemma 18.32.

**Lemma 37.5.** Let $X$ be a finite CW-complex and let $A$ be a subcomplex. We equip the quotient $X/A$ with the CW-structure given by Lemma 36.32 (3). Then

$$\chi(X/A) = \chi(X) - \chi(A) + 1.$$  

**Proof.** It follows immediately from the construction of the CW-structure on $X/A$ given in Lemma 36.32 (3) that for each $k \in \mathbb{N}_0$ we have the following equalities:

$$#k\text{-cells of } X/A = \begin{cases} #k\text{-cells of } X \text{ not in } A, & \text{if } k > 0, \\ #k\text{-cells of } X \text{ not in } A + 1, & \text{if } k = 0. \end{cases}$$

Evidently these equalities implies the equality $\chi(X/A) = \chi(X) - \chi(A) + 1$. ■

**Proposition 37.6.** Let $X$ be a non-empty finite connected 1-dimensional CW-complex. Then $\chi(X) = 0$ if and only if $X$ is contractible.

**Proof.** This statement is an immediate consequence of Proposition 20.5 and the fact that we can view any 1-dimensional CW-complex as a topological graph of the same Euler characteristic. ■

We have now assembled enough information to get us through this chapter. Later on in Chapter 55, we will give a much more elaborate discussion of the Euler characteristic of a CW-complex.
37.3. The fundamental group of 1-dimensional CW-complexes. The goal in this section is to show that the fundamental group of a non-empty connected 1-dimensional CW-complex $X$ is a free group. The idea is quite simple:

1. If the CW-complex $X$ has a single 0-cell, then it follows basically from Proposition 20.7 that $\pi_1(X)$ is a free group.
2. In the general case we show that $X$ is homotopy equivalent to a 1-dimensional CW-complex with a single 0-cell.

The following definition is the key to proving Statement (2).

**Definition.**

1. A tree is a 1-dimensional CW-complex that admits a deformation retraction to a 0-cell.
2. Let $G$ be a 1-dimensional CW-complex. A spanning tree is a subcomplex $T$ that is a tree and that contains all vertices of $G$.

**Remark.**

1. On page 228 we defined a tree to be a finite connected non-empty topological graph with Euler characteristic 1. It follows from Proposition 37.6 that the above definition of a tree is consistent with the definition that we had given on page 228.
2. We leave it to the reader to show that for a finite topological graph the above definition of a spanning tree is equivalent to the one we had given on page 229.
3. A spanning tree is often also called a maximal tree.

**Figure 628**

In Figure 628 we give examples of spanning trees in topological graphs. We see in particular that in general there is no unique spanning tree.

**Proposition 37.7.**

1. Given any connected 1-dimensional CW-complex $G$ and given any tree $S \subset G$ there exists a spanning tree $T$ that contains $S$ and such that $S$ is a deformation retract of $T$.
2. Every connected non-empty 1-dimensional CW-complex admits a spanning tree.

**Remark.** A somewhat different proof of Proposition 37.7 is given in [FrPi90a, Lemma 2.6.3].

**Proof.** Statement (2) follows from Statement (1) by applying Statement (1) to a tree that is given by a single vertex. Thus it remains to prove Statement (2). Now let $G$ be a connected 1-dimensional CW-complex and let $S \subset G$ be a tree.
There exists a sequence $S = Y_0 \subset Y_1 \subset Y_2 \subset \ldots$ of subcomplexes of $G$ with the following properties:

1. The union $Y := \bigcup_{i \in \mathbb{N}} Y_i$ contains all 0-simplices of $G$.
2. Each $Y_i$ is a deformation retract of $Y_{i+1}$.

To prove the claim we first construct a sequence $S = X_0 \subset X_1 \subset X_2 \subset \ldots$ of subcomplexes of $G$ as follows.

(a) We set $X_0 := S$.
(b) Given $X_i$ we define $X_{i+1}$ to be the union of $X_i$ with all 1-dimensional cells which contain at least one 0-cell of $X_i$.

We make the following observations:

(i) It follows from Lemma 36.21 (2) that $X_{i+1}$ is a subcomplex of $G$.
(ii) We claim that $G = \bigcup_{i \in \mathbb{N}} X_i = X$. This can be seen as follows. Basically by construction we have for each characteristic map\footnote{For $n = 0$ the statement is a tautology. For $n = 1$ note that if $\Phi^{-1}(X) \neq \emptyset$, then there exists an $i$ with $\Phi^{-1}(X_i) \neq \emptyset$. Since $X_i$ is a subcomplex we see that $\Phi^{-1}(X_i)$ contains at least one 0-cell. But by construction this means that $\Phi^{-1}(X_{i+1}) = \overline{B}^1$.} $\Phi: \overline{B}^n \to G$, $n = 0, 1$ that $\Phi^{-1}(X) = \emptyset$ or $\Phi^{-1}(X) = \overline{B}^n$. Since $G$ is 1-dimensional it follows from Lemma 36.7 that $X$ is a subset of $G$ that is closed and that is open. Since $G$ is connected and since $X$ is non-empty we see that $X = G$.

Next we do the following iterative construction:

(a) We set $Y_0 := X_0 = S$.
(b) Suppose we are given $Y_i$. For each 0-cell $v$ in $Y_{i+1}$ that is not contained in $Y_i$ we pick precisely one 1-cell $e_v$ of $Y_{i+1}$ that contains $v$. We define $Y_{i+1}$ to be the union of $Y_i$ with all these 1-cells. By Lemma 36.21 (2) we know that $Y_{i+1}$ is a subcomplex of $Y_i$.

By construction the 0-cells of each $Y_i$ are precisely the 0-cells of $X_i$. It follows from (ii) that $Y := \bigcup_{i \in \mathbb{N}} Y_i$ contains all 0-cells of $G$. It remains to show that each $Y_i$ is a deformation retract of $Y_{i+1}$. As we will see, this is almost obvious, except that we need to worry a little bit about continuity issues. Let $V$ be the set of 0-cells in $Y_{i+1}$ that are not contained in $Y_i$. Note that the corresponding 1-cell $e_v$ contains two 0-cells, namely $v$ and one 0-cell $w$ in $Y_i$. Let $\varphi_v: e_v \times [0, 1] \to e_v$ be the obvious deformation retraction to $w$. Finally we consider the map

$$F: \left( Y_i \cup \bigcup_{v \in V} e_v \right) \times [0, 1] \to Y_{i+1} = Y_i \cup \bigcup_{v \in V} e_v$$

$$( [P], t ) \mapsto \begin{cases} P, & \text{if } P \in Y_i; \\ \varphi_v(P, t), & \text{if } P \in e_v. \end{cases}$$

It follows almost immediately from Corollary 36.9 that the map is continuous. It is now basically clear that $F$ defines a deformation retraction from $Y_{i+1}$ to $Y_i$. 

\[\square\]
We set \( Y := \bigcup_{i \in \mathbb{N}} Y_i \). By Lemma 36.21 (2) we know that \( Y \) is a subcomplex of \( G \). We need to show that \( Y \) is contractible. Since \( S \) is contractible it follows from Lemma 18.11 (2) and Lemma 18.14 that it suffices to show that \( S \) is a deformation retract of \( Y \). But this is an immediate consequence of Statement (2) of the claim together with Proposition 36.22. \( \blacksquare \)

**Figure 629.** Illustration for the proof of Proposition 37.7.

**Proposition 37.8.** Let \( X \) be a 1-dimensional CW-complex.

1. For every spanning tree \( T \) of \( X \) the following holds:
   a. The projection \( p: X \to X/T \) is a homotopy equivalence.
   b. The quotient \( X/T \) is homeomorphic to a wedge of circles. If \( X \) is finite, then \( X/T \) is homeomorphic to the wedge of \( 1 - \chi(X) \) circles.
2. If \( X \) is connected and non-empty, then \( X \) is homotopy equivalent to the wedge of circles. Furthermore if \( X \) is finite, then \( X \) is homotopy equivalent to the wedge of \( 1 - \chi(X) \) circles.

**Remark.**

1. Proposition 37.8 is a fairly straightforward generalization of Proposition 18.31. In fact the proof below is at times verbatim the same as the proof of Proposition 18.31.
2. Later on, in Corollary 39.10, we will generalize Proposition 37.8 in a suitable way to the case of arbitrary CW-complexes.

**Proof.** Let \( X \) be a 1-dimensional CW-complex.

1a. Let \( T \) be a spanning tree of \( X \). By hypothesis and by definition there exists a 0-cell \( t_0 \) of \( T \) such that there exists a deformation retraction from \( T \) to \( \{t_0\} \), i.e. there exists a homotopy \( R: T \times [0,1] \to T \) such that \( R_1 = \text{id} \) and such that \( R_0 = c_{t_0} \) is the constant map. For notational convenience we make the obvious identification \( \mathbb{B}^1 = [-2,2] \).

Now let \( \{\Phi_i: [-2,2] \to X\}_{i \in I} \) be the characteristic maps of the 1-cells of \( X \) that are not contained in \( T \). We write \( a_i = \Phi_i(-2) \) and \( b_i = \Phi_i(2) \).

By Lemma 36.32 (3) we can view \( X/T \) as a 1-dimensional CW-complex with a single 0-cell \( * \) and one 1-cell for each \( i \in I \). We denote by \( \{\Psi_i: [-2,2] \to X/T\}_{i \in I} \) the characteristic maps of these 1-cells. We consider the map

\[
q: X/T \to X
\]

\[
\begin{align*}
x & \mapsto \\
R(a_i, y - 1), & \quad \text{if } x = \Psi_i(y) \text{ for some } y \in [-2, -1], \\
\Psi_i(2 \cdot y), & \quad \text{if } x = \Psi_i(y) \text{ for some } y \in [-1, 1], \\
R(b_i, y - 1), & \quad \text{if } x = \Psi_i(y) \text{ for some } y \in [1, 2].
\end{align*}
\]
It follows from Lemma 36.7 (1) and (4) that \( q \) is continuous. (We refer to Figure 362 from a long time ago for an illustration of \( q \).) It remains to prove the following claim.

**Claim.** The maps \( p \) and \( q \) are homotopy inverses of one another.

The proof of the claim is fairly elementary, just notationally a little messy. First we consider the following map

\[
F: (X/T) \times [0, 1] \to X/T \quad (x, t) \mapsto \begin{cases} 
* & \text{if } x = \Psi_i(y) \text{ for some } y \in [-2, -1 - t], \\
\Psi_i(\frac{2y}{1+t}) & \text{if } x = \Psi_i(y) \text{ for some } y \in [-1 - t, 1 + t], \\
* & \text{if } x = \Psi_i(y) \text{ for some } y \in [1 + t, 2].
\end{cases}
\]

Using Corollary 36.9 (3) one can easily show that \( F \) is continuous. It follows immediately from the definitions that \( F_0 = p \circ q \) and \( F_1 = \text{id}_{X/T} \). Next we consider the following map

\[
G: X \times [0, 1] \to X \quad (x, t) \mapsto \begin{cases} 
R(x, t) & \text{if } x \in T, \\
R(a_i, y + 2 + t) & \text{if } x = \Phi_i(y) \text{ for some } y \in [-2, -1 - t], \\
\Phi_i(\frac{2y}{1+t}) & \text{if } x = \Phi_i(y) \text{ for some } y \in [-1 - t, 1 + t], \\
R(b_i, -y + 2 + t) & \text{if } x = \Phi_i(y) \text{ for some } y \in [1 + t, 2].
\end{cases}
\]

Again, using Corollary 36.9 (3) one can easily show that \( G \) is continuous. Furthermore it follows again immediately from the definitions that \( G_0 = q \circ p \) and \( G_1 = \text{id}_X \).

(1b) Let \( T \) be a spanning tree of \( X \). We denote by \( I \) the set of 1-cells of \( X \) that are not contained in \( T \). As mentioned in (1), it follows from Lemma 36.32 (3) that we can view \( X/T \) as a 1-dimensional CW-complex with a single 0-cell \( * \) and one 1-cell for each \( i \in I \). By Lemma 36.33 we know that \( X/T \) is homeomorphic to the wedge \( \bigvee_{i \in I} S^1 \).

Finally we suppose that \( X \) is finite. At this point it suffices to show that \( X/T \) is homeomorphic to the wedge of \( 1 - \chi(X) \) circles, in other words, we want to show that \( |I| = 1 - \chi(X) \). This in turn follows from the following calculation:

\[
1 - |I| = \chi \left( \bigvee_{i \in I} S^1 \right) = \chi(X/T) = \chi(X) - \chi(T) = \chi(X).
\]

(2) Now we assume that \( X \) is connected and non-empty. By Proposition 37.7 we know that \( X \) admits a spanning tree \( T \). The desired conclusion now follows from (1) together with (2).

Now we no longer have any troubles with computing the fundamental group of 1-dimensional CW-complexes. More precisely, we have the following theorem which generalizes Proposition 20.5 and 31.2.
Theorem 37.9. Let $X$ be a non-empty connected 1-dimensional CW-complex. Furthermore let $x_0 \in X$. Then the following holds:

1. The group $\pi_1(X, x_0)$ is isomorphic to a free group. In fact, if $T$ is a spanning tree for $X$, then the cardinality of the generating set of the free group equals the cardinality of the set of edges in $X \setminus T$.

2. If $X$ is a finite CW-complex, then $\pi_1(X, x_0)$ is a free group with $1 - \chi(X)$ generators.

3. An explicit description of the isomorphism in (1) is given as follows. Pick a base point $x_0$ in the spanning tree and for each 1-cell $e$ that is not contained in $T$ we pick a path $\alpha_e$ from $p$ to one of the endpoints and pick a path $\beta_e$ from the other endpoint back to $1$, and let $t_e$ be the loop given by first going along $\alpha_e$, then going through $e$ and then going back to the base point via $\beta_e$. Then the map

$$\langle \{x_e\} \rangle \to \pi_1(X, x_0)$$

$$x_e \mapsto [t_e]$$

is an isomorphism.

\[\begin{figure}
\centering
\begin{tikzpicture}
\node (X) at (0,0) {
\begin{tikzpicture}[scale=0.5]
\draw (0,0) -- (1,1) -- (2,0) -- cycle;
\draw (0,0) -- (1,-1) -- (2,0) -- cycle;
\end{tikzpicture}
};
\node (T) at (3,0) {
\begin{tikzpicture}[scale=0.5]
\draw (0,0) -- (1,1) -- (2,0) -- cycle;
\draw (0,0) -- (1,-1) -- (2,0) -- cycle;
\end{tikzpicture}
};
\node (X0) at (5,0) {CW-complex $X$};
\node (T0) at (8,0) {spanning tree $T$};
\end{figure}\]

Proof. Let $X$ be a non-empty connected 1-dimensional CW-complex. By Proposition \[37.7\] we know that $X$ admits a spanning tree $T$. We denote by $E$ the set of 1-cells of $X$ that are not contained in $T$. Let $x_0$ be a point in $T$. We denote by $p: X \to X/T$ the projection map. We write $* = p(x_0)$. We have the following isomorphisms:

$$\pi_1(X, x_0) \xrightarrow{p_*} \pi_1(X/T, *) \xrightarrow{\cong} \pi_1\left( \bigvee_{e \in E} S^1_e, * \right) \xleftarrow{\cong} \langle \{x_e\} \rangle.$$

by Proposition \[37.8\] we know that the map $p: X \to X/T$ is a homotopy equivalence, from Proposition \[18.16\] (1a) we obtain that $p_*$ is an isomorphism.

If one goes through the explicit isomorphism, then one sees that the map given in (3) is indeed an isomorphism.

Finally suppose that $X$ is a finite 1-dimensional CW-complex. It is not terribly hard to show directly that $E$ has cardinality $1 - \chi(X)$. But since we proved the desired statement regarding the rank of $\pi_1(X, x_0)$ already in Proposition \[20.5\] we will not work out the details of the argument.

We conclude this discussion of CW-complexes with an application to group theory, namely to the study of free groups. Recall that in Proposition \[31.4\] we used topological...
graphs to show that if $F$ is a free group of countable rank, then every subgroup is also a free group. Now that we have developed the theory of CW-complexes we can remove the slightly artificial restriction on the cardinality of the generating set. More precisely, we have the following corollary to our previous results.

**Corollary 37.10.** Every subgroup of a free group (of any rank) is again a free group.

**Remark.** Even for free groups of countable rank the proof of Corollary 37.10 might be of interest, since it differs somewhat from the proof of Proposition 31.4.

**Proof.** Let $F = \langle S \rangle$ be a free group on a set $S$ and let $G$ be a subgroup of $F$.

1. By attaching one 1-cell for each $s \in S$ to a one-point set $\{P\}$ we obtain a 1-dimensional CW-complex $X$ with one 0-cell $P$ and with one 1-cell for each $s \in S$. By Theorem 37.9 we have $\pi_1(X, P) \cong F$. By Proposition 36.10 (6) and Proposition 29.5 there exists a covering $p: (Y, Q) \to (X, P)$ of degree $[F : G]$ such that $p_*(\pi_1(Y, Q)) = G$. By Corollary 16.14 the map $p_*$ is injective. Thus we see that $\pi_1(Y, Q)$ itself is isomorphic to $G$. By Proposition 36.37 we can equip $Y$ with the structure of a 1-dimensional CW-structure. We deduce from Theorem 37.9 that $G \cong \pi_1(Y, Q)$ is a free group.

2. Now suppose that $F$ is a free group of finite rank $m$ and suppose that $G$ is a finite-index subgroup of $F$. By Proposition 37.4 we know that $\chi(Y) = [F : G] \cdot \chi(X)$. It is now a consequence of Theorem 37.9 that $\operatorname{rank}(G) - 1 = [F : G] \cdot (\operatorname{rank}(F) - 1)$. ■

**Example.** Let $G$ be the CW-complex consisting of one 0-cell $v$ and two 1-cells which we denote by $s$ and $t$. By a slight abuse of notation we denote the corresponding elements in $\pi_1(G, v)$ by $s$ and $t$ as well. By Proposition 20.5 we can identify $\pi_1(G, v)$ with the free group $\langle s, t \rangle$ on the generators $s$ and $t$. Now let $\phi: \pi_1(G, v) = \langle s, t \rangle \to \mathbb{Z}$ be the homomorphism that is given by $\phi(s) = 0$ and $\phi(t) = 1$. By Proposition 29.3 there exists a covering $q: (\tilde{G}, \tilde{v}) \to (G, v)$ with $q_*(\pi_1(\tilde{G}, \tilde{v})) = \ker(\phi)$, furthermore by Proposition 29.8 this covering is unique up to equivalence, in the sense of the definition on page 832.

We consider the infinite covering illustrated in Figure 313, which is very similar to the finite covering studied on pages 914. For $i \in \mathbb{Z}$ we denote by $x_i$ the loop in $(\tilde{G}, \tilde{v})$ as illustrated in Figure 632. We denote by $x_i$ also the corresponding element in $\pi_1(\tilde{G}, \tilde{v})$. It follows from Theorem 37.9 that $\pi_1(\tilde{G}, \tilde{v})$ equals the free group $\langle \ldots x_2, x_{-1}, x_0, x_1, x_2 \ldots \rangle$. It is straightforward to see that $p_*(x_i) = t^i s t^{-i}$.

By Corollary 16.14 the homomorphism $p_*$ is a monomorphism. Thus we see that $t^i s t^{-i}$, $i \in \mathbb{Z}$, generate an infinitely generated free subgroup of the finitely generated generated $\mathbb{Z}$.

---

614This covering can also be described rigorously. More precisely, we view $G$ as the union of two copies $A$ and $B$ of $S^1$ glued along the common point 1. We define

$$\tilde{G} = (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/\sim$$

for $n \in \mathbb{Z}$. Then the projection map

$$p: (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/\sim \to G = (S^1 \times \{A\} \sqcup S^1 \times \{B\}))/\sim \sim (1, B)$$

is given by $p(x) = (e^{2\pi i x}, A)$ for $x \in \mathbb{R}$ and $p((z, n)) = (z, B)$ for $(z, n) \in S^1 \times \mathbb{Z}$. 

Then the projection map
free group \(\langle s, t \rangle\). Furthermore we see that \(p_*(\pi_1(\tilde{G}, \tilde{v})) \subseteq \ker(\phi: \pi_1(G, v) \to \mathbb{Z})\). It is easy to see that the deck transformation group is isomorphic to \(\mathbb{Z}\).

Now we claim that the coverings \(p: \tilde{G} \to G\) and \(q: \tilde{G} \to G\) are equivalent. By Proposition \ref{prop:covering_isomorphism}, it suffices to show that \(p_*(\pi_1(\tilde{G}, \tilde{v})) = q_*(\pi_1(\tilde{G}, \tilde{v}))\). We consider the following sequence of maps

\[
\mathbb{Z} \cong D(p: \tilde{G} \to G) \cong \pi_1(G, v)/p_*(\pi_1(\tilde{G}, \tilde{v})) \to \pi_1(G, v)/\ker(\phi: \pi_1(G, v) \to \mathbb{Z}) = \mathbb{Z}
\]

Thus, reading from left to right, we get an epimorphism from \(\mathbb{Z}\) onto itself. But any such epimorphism has to be an isomorphism. It follows that the third map is also an isomorphism, i.e. \(p_*(\pi_1(\tilde{G}, \tilde{v})) = \pi_1(G, v)/\ker(\phi: \pi_1(G, v) \to \mathbb{Z})\), but the latter group is precisely \(q_*(\pi_1(\tilde{G}, \tilde{v}))\). So we get the desired equality of subgroups.

The deck transformation is given by translation by \(n \in \mathbb{Z}\)

\[
\begin{array}{c}
  \text{Figure 631} \\
  \text{the } i\text{-th generator } x_i \text{ of } \pi_1(\tilde{G}, \tilde{v}) = \langle \ldots, x_{-2}, x_{-1}, x_0, x_1, x_2, \ldots \rangle
\end{array}
\]

\[
\begin{array}{c}
  \text{Figure 632}
\end{array}
\]

37.4. Fundamental groups of CW-complexes. In this section we will discuss fundamental groups of CW-complexes. For the statement of our first proposition it is useful to introduce the following definition.

The following definition is evidently inspired by the definition of a CW-complex.

**Definition.** Let \(X\) be a topological space and let \(\varphi: S^{n-1} \to X\) be a map. We refer to \(X \cup_{\varphi} \overline{B}^n\) as the topological space \(X\) with an \(n\)-cell attached via the attaching map \(\varphi\). We refer to the image of \(\overline{B}^n\) in \(X \cup_{\varphi} \overline{B}^n\) as an \(n\)-cell.

**Remark.** On page 692 we gave an explicit homeomorphism \(\text{Cone}(S^{n-1}) \simeq \overline{B}^n\). Using this homeomorphism one sees almost immediately that, using the notation from the above definition, we have a homeomorphism \(\text{Cone}(\varphi: S^{n-1} \to X) \simeq X \cup_{\varphi} \overline{B}^n\) which is the identity on \(X\). In other words, attaching a cell is just a special case of taking a mapping cone.

The following proposition now tells us how attaching a cell affects the fundamental group of a given topological space.
Proposition 37.11. Let $X$ be a topological space, let $n \geq 1$, let $\varphi: S^{n-1} \to X$ be a map and let $x_0$ be a point in $\varphi(S^{n-1})$. Then the following hold:

$(n > 2)$ The inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B^n}, x_0)$ is an isomorphism.

$(n = 2)$ The map $\varphi: S^1 \to X$ defines an element in $\pi_1(X, x_0)$ that we denote by $[\varphi]$, and the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B^n}, x_0)$ descends to an isomorphism

$$\pi_1(X, x_0)/\langle\langle[\varphi]\rangle\rangle \cong \pi_1(X \cup_\varphi \overline{B^2}, x_0).$$

$(n = 1)$ Let $\epsilon \in \{-1, 1\}$ such that $x_0 = \varphi(\epsilon)$. We set $y_0 := \varphi(-\epsilon)$.

(a) Suppose that $x_0$ and $y_0$ lie in the same path-component of $X$. Let $\gamma$ be a loop in $X \cup_\varphi \overline{B^1}$ that is given by the concatenation of the obvious path in the 1-cell from $x_0 = \varphi(\epsilon)$ to $y_0 = \varphi(-\epsilon)$ and some path in $X$ from $y_0 = \varphi(-\epsilon)$ to $x_0 = \varphi(\epsilon)$. With this notation the map

$$\pi_1(X, x_0) \ast \langle t \rangle \to \pi_1(X \cup_\varphi \overline{B^1}, x_0)$$

that is given by the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B^1}, x_0)$ and given by $t \mapsto [\gamma]$ is an isomorphism.

(b) Suppose that $x_0$ and $y_0$ lie in two different path components of $X$. Then we get an isomorphism

$$\pi_1(X, x_0) \ast \pi_1(X, y_0) \to \pi_1(X \cup_\varphi \overline{B^1}, x_0).$$

Figure 633. Illustration of Proposition 37.11 $(n = 1)$ (a).

Examples.

(1) Let $X = S^1$ and let $n \in \mathbb{N}$. We attach to $S^1$ a 2-cell via the attaching map $\varphi: S^1 \to S^1$ that is given by $\varphi(z) = z^n$. Then\footnote{We leave it to the reader to show that for $n = 2$ the topological space $S^1 \cup_\varphi \overline{B^2}$ is actually homeomorphic to $\mathbb{R}P^2$.}

$$\pi_1(S^1 \cup_\varphi \overline{B^2}, 1) = \pi_1(S^1, 1)/\langle[\varphi]\rangle = \langle x \rangle/\langle x^n \rangle \cong \mathbb{Z}_n.$$  

by Proposition 37.11 \hspace{1cm} see Proposition 16.17

(2) We attach a 2-cell to $X = \mathbb{R}^2$ via the attaching map $\text{id} = \varphi: S^1 \to S^1$ that is given by the identity. The resulting topological space is illustrated in Figure 634. This topological space is again simply connected by Proposition 37.11.

(3) Using Theorem 37.9 and Proposition 37.11 we can now easily compute fundamental groups of finite CW-complexes. For example, as in Figure 635 we view the surface $\Sigma$ of genus 2 as a CW-complex with one 0-cell $P$, four 1-cells $x_1, y_1, x_2, y_2$ and one 2-cell. We denote by $X$ the 1-skeleton of $\Sigma$ and we denote by $\varphi: S^1 \to X$ the attaching map
of the 2-cell. We have

\[ \pi_1(\Sigma, P) = \pi_1(X \cup_{\varphi} B^2, P) = \pi_1(X, P)/\langle\langle [\varphi] \rangle\rangle = (x_1, y_1, x_2, y_2)/\langle\langle [x_1, y_1][x_2, y_2] \rangle\rangle. \]

\[ \uparrow \]

by Proposition 37.11 by Theorem 37.9 and since \([\varphi] = [x_1, y_1][x_2, y_2]\)

Of course we had obtained the same result much earlier. The advantage of CW-complexes is that Proposition 37.11 absorbs many of the technical arguments we had to deal with in the proof of Proposition 22.3, i.e. in our initial calculation of \(\pi_1(\Sigma, P)\).

**Proof of Proposition 37.11** for \(n \geq 2\) (\(\ast\)). Let \(X\) be a topological space, let \(n \geq 2\), let \(\varphi: S^{n-1} \to X\) be a map and let \(x_0\) be a point in \(\varphi(S^{n-1})\). The key idea of the proof is to apply the Seifert–van Kampen Theorem 22.1 to the following two open\(^{616}\) subsets of \(X \cup_{\varphi} B^2\):

\[ U = X \cup_{\varphi} \{z \in B^n \mid \|z\| > \frac{1}{4}\} \quad \text{and} \quad V = \{z \in B^n \mid \|z\| < \frac{3}{4}\}. \]

The remainder of the proof consists in showing that the resulting isomorphism implies the desired, a priori slightly different, isomorphism.

We pick a point \(x_1 \in U \cap V\) and we pick a path in \(U\) from \(x_0\) to \(x_1\). We refer to Figure 636 for an illustration. Note that \(V\) is a ball, hence \(\pi_1(V, x_1)\) is the trivial group.

---

\(^{616}\)Why are they open subsets?
We consider the following diagram of maps

\[
\begin{array}{c}
\pi_1(X, x_0) \\ \cong \downarrow \\
\pi_1(U, x_0) \\ \cong \downarrow \\
\pi_1(U, x_1) \\
\downarrow \\
\pi_1(U, x_1)/\langle\langle\pi_1(U \cap V, x_1)\rangle\rangle \\ \cong \text{Lemma 21.22} \\
\pi_1(U, x_1) \ast_{\pi_1(U \cap V, x_1)} \pi_1(V, x_1) = \langle e \rangle \\
\cong \text{Seifert–van Kampen} \\
\end{array} \rightarrow 
\begin{array}{c}
\pi_1(X \cup_{\phi} B^n, x_0) \\
\cong \\
\pi_1(X \cup_{\phi} B^n, x_0) \\
\downarrow \\
\pi_1(X \cup_{\phi} B^n, x_0) \\
\downarrow \\
\pi_1(X, x_0)/\langle\langle \phi \rangle\rangle \\
\cong \\
\pi_1(X, x_0)/\langle\langle \phi \rangle\rangle \\
\downarrow \\
\pi_1(X \cup_{\phi} B^n, x_1). \\
\end{array}
\]

We want to prove the following three statements:

(i) the diagram commutes,
(ii) all vertical maps except possibly the third vertical map on the left are isomorphisms,
(iii) the bottom horizontal map is an isomorphism.

The two vertical maps on the second level are the isomorphisms induced by the choice of
base point coming from the chosen path from \(x_0\) to \(x_1\). All the other vertical and horizontal
maps are induced by inclusions or they are the obvious algebraic map. It follows easily
that the diagram commutes.

Most of the maps are obviously isomorphisms. Using Lemma 18.23 one can easily show
that \(X\) is a deformation retract of \(U\). It follows from Lemma 18.14 and Proposition 18.16
(2) that the top left vertical map is an isomorphism. The bottom vertical map on the left
is an isomorphism by Lemma 21.22.

Finally the bottom horizontal map is an isomorphism by the Seifert–van Kampen Theorem 22.1.

Now we consider the case \(n \geq 3\). In this case \(\pi_1(U \cap V, x_1)\) is trivial since \(U \cap V\)
is homotopy equivalent to \(S^{n-1}\) which has trivial fundamental group by Proposition 14.14. It
is now clear that the one missing vertical map on the left is also an isomorphism. Since all
vertical maps are now isomorphisms and since the bottom horizontal map is an isomorphism
it follows that the top horizontal map is an isomorphism.

Finally we consider the case \(n = 2\). In this case \(U \cap V\) is homotopy equivalent to \(S^1\)
which implies that \(\pi_1(U \cap V, x_1) \cong \mathbb{Z}\). Under the isomorphism \(\Phi: \pi_1(X, x_0) \rightarrow \pi_1(U, x_1)\)
this infinite cyclic subgroup corresponds to \(\langle \langle \phi \rangle \rangle\). It is straightforward to see that we get a
commutative diagram

\[
\begin{array}{c}
\pi_1(X, x_0) \\
\cong \\
\pi_1(U, x_1)/\langle\langle\pi_1(U \cap V, x_1)\rangle\rangle \\
\cong \\
\end{array} \rightarrow 
\begin{array}{c}
\pi_1(X \cup_{\phi} B^n, x_0) \\
\cong \\
\pi_1(X \cup_{\phi} B^n, x_0) \\
\downarrow \\
\pi_1(X, x_0)/\langle\langle \phi \rangle\rangle \\
\cong \\
\pi_1(X, x_0)/\langle\langle \phi \rangle\rangle \\
\downarrow \\
\pi_1(X \cup_{\phi} B^n, x_1). \\
\end{array}
\]
This concludes the proof of the proposition. \hfill ■

**Proof of Proposition 37.11** for \( n = 1 \) (\(*\)). The proof of the case \( n = 1 \) is quite similar to the proof of the case \( n \geq 2 \). The only serious difference is that we need to replace the Seifert–van Kampen Theorem 22.1 by Corollary 26.5, which in turn is a corollary to the HNN-Seifert–van Kampen Theorem 26.3. We leave it to the reader to fill in the details. \hfill ■

In the following corollary we will see that every finitely presented group is the fundamental group of a finite CW-complex. The key to proving the corollary is the following construction, which associates to any finite presentation a 2-dimensional CW-complex. The construction is illustrated in Figure 637. If the reader feels comfortable with that illustration it might be best to skip the official definition.

**Construction.** Let \( \langle g_1, \ldots, g_k \mid r_1, \ldots, r_m \rangle \) be a finite presentation. For \( i = 1, \ldots, k \) let \( S^1_i \) be a copy of \( S^1 \). For \( j = 1, \ldots, m \) we do the following:

1. We write the relation \( r_j \) as a reduced word \( g_{s(1)}^{\epsilon_1} \cdots g_{s(n)}^{\epsilon_n} \) with \( \epsilon_1, \ldots, \epsilon_n \in \{ -1, 1 \} \).
2. We denote by \( \varphi_j : S^1_i \rightarrow \bigvee_{i=1}^k S^1_i \) the (hopefully obvious) path which on the interval \( [\frac{i-1}{n}, \frac{i}{n}] \) travels through \( S^1_{s(i)} \) at constant speed in the direction determined by \( \epsilon_i \).

We denote by \( X \) the CW-complex that is given by attaching \( m \) 2-cells to \( \bigvee_{i=1}^k S^1_i \) along the attaching maps \( \varphi_1, \ldots, \varphi_m \). We refer to \( X \) as the CW-complex associated to the presentation. (We refer to Figure 637 for an illustration.)

![2-dimensional CW-complex for the presentation](image)

**Figure 637**

Now we can state the corollary that we promised above.

**Corollary 37.12.** Let \( \langle g_1, \ldots, g_k \mid r_1, \ldots, r_m \rangle \) be a finite presentation for a group \( \pi \). If \( Y \) is the associated 2-dimensional CW-complex, then \( \pi_1(Y) \cong \pi \).

**Proof.** Let \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_m \rangle \) be a finitely presented group. We use the notation introduced in the above construction of the CW-complex associated to \( \pi \). We denote by \( X \) the wedge of the \( k \) circles and we denote by \( x_0 \) the wedge point. Following the discussion on page 606 we can make the identification \( \pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle \). This identification has the property that for \( j = 1, \ldots, m \) the corresponding loop \( \varphi_j : S^1 \rightarrow X \) represents \( r_j \in \pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle \). We write \( Y_0 = X \) and for \( j = 1, \ldots, m \) we iteratively define \( Y_j \) to be the 2-dimensional CW-complex that is given by attaching a 2-cell to \( Y_{j-1} \) with the
attaching map $\varphi_j$. We obtain that

$$\pi_1(Y_m, x_0) \xrightarrow{\text{Proposition 37.11 applied } m \text{ times}} \langle g_1, \ldots, g_k | [\varphi_1] \rangle \cdots \langle [\varphi_m] \rangle = \langle g_1, \ldots, g_k | r_1, \ldots, r_m \rangle.$$  

by Exercise 21.1  

The following proposition says in particular that for many CW-complexes the fundamental group of a CW-complex is the same as the fundamental group of its 2-skeleton.

**Proposition 37.13.** Let $X$ be a connected CW-complex and let $x_0$ be a point in the 0-skeleton of $X$.

1. If $X$ has finitely many cells in each dimension, then the following statements hold:
   a. The inclusion induced map $\pi_1(X^1, x_0) \to \pi_1(X, x_0)$ is an epimorphism.
   b. For any $k \geq 2$ the inclusion induced map $\pi_1(X^k, x_0) \to \pi_1(X, x_0)$ is an isomorphism.

2. If $X$ has only finitely many cells in dimensions 0 and 1, then $\pi_1(X, x_0)$ is finitely generated.

3. If $X$ has only finitely many cells in dimensions 0, 1 and 2, then $\pi_1(X, x_0)$ is finitely presented.

**Remark.** In Proposition 40.9 we will generalize Proposition 37.13 to all connected CW-complexes.

**Example.** Let $X = \mathbb{R}P^\infty$ be the infinite real projective space with the CW-structure from page 942. For this CW-complex the 1-skeleton is $X^1 = \mathbb{R}P^1 \cong S^1$ and the 2-skeleton is $X^2 = \mathbb{R}P^2$. It follows from Proposition 37.13 (1) that $\mathbb{Z} \cong \pi_1(S^1) \to \pi_1(\mathbb{R}P^\infty)$ is an epimorphism and it follows from Proposition 37.13 (1) that $\mathbb{Z}_2 \cong \pi_1(\mathbb{R}P^2) \to \pi_1(\mathbb{R}P^\infty)$ is an isomorphism. This calculation of $\pi_1(\mathbb{R}P^\infty)$ is certainly easier than the argument from page 983.

**Proof.**

1. We first suppose that $X$ is a finite CW-complex. Then the two statements follow immediately from iteratively applying Proposition 37.11 finitely many times. If $X$ is an infinite CW-complex, but with finitely many cells in each dimension, then one can reduce the two statements to the finite case using Propositions 37.3. We leave the details to the reader.

2. Now we turn to the proof of (2). By (1) it suffices to show that the fundamental group of a finite connected 1-dimensional CW-complex is finitely generated, but we showed this in Theorem 37.9.

3. Finally we turn to the proof of (3). By (1) it suffices to show that a finite connected 2-dimensional CW-complex $X$ has a finitely presented fundamental group. We pick $x_0 \in X$. We denote by $\varphi_1, \ldots, \varphi_k$ the attaching maps of the 2-cells. For $i = 1, \ldots, k$,

\[ \pi_1(Y_m, x_0) \xrightarrow{\text{Proposition 37.11 applied } m \text{ times}} \langle g_1, \ldots, g_k | [\varphi_1] \rangle \cdots \langle [\varphi_m] \rangle = \langle g_1, \ldots, g_k | r_1, \ldots, r_m \rangle. \]
we pick a path $p_i$ from $x_0$ to a point on $\varphi_i(S^1)$ and we write $\psi_i = p_i * \varphi_i * p_i$. We then have

$$\pi_1(X) \cong \pi_1(X^1)/\langle \langle [\psi_1] \rangle \rangle \ldots /\langle \langle [\psi_k] \rangle \rangle = \pi_1(X^1)/\langle \langle [\psi_1], \ldots, [\psi_k] \rangle \rangle$$

Propositions 14.11 and 37.11 by Exercise 21.1

$$= \{\text{finitely generated free group} \}/\langle \langle [\psi_1], \ldots, [\psi_k] \rangle \rangle.$$  

Statement (2)

We have thus shown that $\pi_1(X)$ is a finitely presented group. 

Remark. On page 936 we already mentioned Theorem 64.5 which says in particular that every compact smooth manifold admits the structure of a finite CW-complex. Together with Proposition 37.13 (3) we now obtain that the fundamental group of any connected compact smooth manifold $M$ is finitely presented.

The following corollary is an immediate but rather convenient consequence of Proposition 37.13 (1).

Corollary 37.14. Let $X$ be a connected CW-complex with countably many cells. If $X$ has no 1-cells, then $X$ is simply connected, i.e. $\pi_1(X) = 0$.

Examples.

(1) On page 935 we pointed out that for $n \geq 2$ the sphere $S^n$ admits a CW-structure with one 0-cell and one $n$-cell. From Corollary 37.14 we now recover the result from Proposition 14.14 that $S^n$ is simply connected.

(2) It follows from Lemma 36.1 and Corollary 37.14 that for any $n$ we have $\pi_1(\mathbb{C}P^n) = 0$.

Similarly it follows, using Lemma 36.6 that $\pi_1(\mathbb{C}P^\infty) = 0$.

We conclude this chapter with a purely group theoretic result. To put the result in context, first recall that in Exercise 21.2 we saw that every finite-index subgroup of a finitely generated group is finitely generated. Now we can prove the following analogue.

Proposition 37.15. Every finite-index subgroup of a finitely presented group is finitely presented.

Remark. We will provide a proof of Proposition 37.15 that makes heavy use of topological methods. Not surprisingly one can also give a purely group theoretic proof. In fact such a proof can be given by the Reidemeister-Schreier process that we alluded to in Section 27.7. We refer to [LS77, p. 103] and [MKS76, p. 90] for details.

Proof. Let $\pi = \langle g_1, \ldots, g_k | r_1, \ldots, r_m \rangle$ be a finitely presented group. Let $Y$ be the finite 2-complex associated to this presentation that we constructed on page 995. By Corollary 37.12 we know that $\pi_1(Y) \cong \pi$. Now let $\Gamma$ be a finite-index subgroup of $\pi$. By Proposition 36.10 together with Proposition 29.5 there exists a finite covering $p: \tilde{Y} \to Y$ such that $\pi_1(Y) \cong \Gamma$. By Proposition 36.37 (2) the 2-complex $\tilde{Y}$ has finitely many 1-cells and 2-cells. Thus it follows from Proposition 37.13 (3) that $\Gamma \cong \pi_1(\tilde{Y})$ is a finitely presented group. 

■
Exercises for Chapter 37

Exercise 37.1. Let $A = S^1 \times [0, 1]$ be an annulus.

(a) (i) We consider

$$X := \left( \bigcup_{k \in \mathbb{N}} A \times \{k\} \right)/\{(z, 0, k) \sim (z^2, 1, k - 1) \text{ for } z \in S^1, k \in \mathbb{N}\}$$

Determine $\pi_1(X)$.

(ii) We consider

$$Y := \left( \bigcup_{k \in \mathbb{N}} A \times \{-k\} \right)/\{(z, 0, -k) \sim (z^2, 1, -k - 1) \text{ for } z \in S^1, k \in \mathbb{N}\}$$

Determine $\pi_1(Y)$.

In both cases the group you obtain is an abelian group that is isomorphic to a subgroup of $(\mathbb{R}, +)$.

(b) Give an example of topological space $Z$ such that $\pi_1(Z) \cong (\mathbb{Q}, +)$.

Exercise 37.2. Next let $X$ and $Y$ be two finite CW-complexes. On page 961 we introduced the product CW-structure which by Proposition 36.23 is indeed a CW-structure for the topological space $X \times Y$. Is $\chi(X \times Y)$ determined by $\chi(X)$ and $\chi(Y)$?
In this chapter we will prove several key technical theorems on CW-complexes, in particular we will prove the Homotopy Extension Theorem 38.1 and the Cellular Approximation Theorem 38.13. The reader who is in a hurry could just have a look at the Cellular Approximation Theorem 38.13 and then move on.

38.1. The Homotopy Extension Theorem. On several occasions we will need the following somewhat technical theorem.

**Theorem 38.1. (Homotopy Extension Theorem)** Let $X$ be a CW-complex, let $Y$ be a topological space and let $f_0: X \to Y$ be map. Furthermore, suppose that $A \subset X$ is a subcomplex and suppose we are given a homotopy $G: A \times [0, 1] \to Y$ from $g_0 := f_0|_A$ to some map $g_1: A \to Y$. Then there exists a homotopy $F: X \times [0, 1] \to Y$ starting from $f_0$ such that the restriction $F|_{A \times [0, 1]}$ equals $G$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure638}
\caption{Illustration of the Homotopy Extension Theorem 38.1}
\end{figure}

**Remark.** The statement of the Homotopy Extension Theorem does not hold for arbitrary subsets of $X$. For example, let $X = \mathbb{R}$ and $A = (0, 1)$. We write $Y = \mathbb{R} \times \{0\} \cup (0, 1) \times [0, 1]$ and let $f: X \to Y$ be the obvious inclusion map and let $G: (0, 1) \times [0, 1] \to Y$ be the obvious inclusion map. (See Figure 639 for an illustration.) It is an amusing exercise to show that $G$ cannot be extended to a homotopy on all of $\mathbb{R}$. It is an equally amusing exercise to show that the homotopy can be extended if throughout we replace the open interval $A = (0, 1)$ by the closed interval $A = [0, 1]$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure639}
\caption{}
\end{figure}

Before we delve into the long and strenuous proof of the Homotopy Extension Theorem 38.1 let us prove the following neat corollary.

---

\textsuperscript{618} Here is a hint: if there was an extension of $G$ to a homotopy $F: X \times [0, 1] \to Y$, what would/should $F(1, 1)$ be?
Corollary 38.2. Let $X$ be connected CW-complex, let $P$ be a point in the 0-skeleton of $X$ and let $Q$ be some other point on $Y$.

1. Given any path $\gamma: [0, 1] \to X$ with $\gamma(0) = P$ and $\gamma(1) = Q$ there exists a homotopy $F: X \times [0, 1] \to X$ with $F(P, t) = \gamma(t)$ for all $t \in [0, 1]$ and such that $F_0 = \text{id}$.
2. There exists a map $h: X \to X$ with $h(P) = Q$ that is homotopic to the identity.

Example. We consider the CW-complex $X$ and the two points $P$ and $Q$ shown in Figure 640. It should be pretty clear that there is no homeomorphism $f$ of $X$ with $f(P) = Q$. But Corollary 38.2 gives us a decent replacement, namely a map $h: X \to X$ with $h(P) = Q$ which is homotopic to the identity.

![Figure 640](image)

Proof. Let $X$ be connected CW-complex, let $P$ be a point in the 0-skeleton of $X$ and let $Q$ be some other point on $Y$.

1. Let $\gamma: [0, 1] \to X$ be a path with $\gamma(0) = P$ and $\gamma(1) = Q$. We write $A := \{P\}$. Since $P$ is a point in the 0-skeleton of $X$ we see that $A$ is a subcomplex of $A$. We apply the Homotopy Extension Theorem 38.1 to $f_0 = \text{id}: X \to X$, $g_0(P) := P$, $g_1(P) = Q$ and $G(P, t) = \gamma(t)$. The resulting homotopy $F: X \times [0, 1] \to X$ has all the desired properties.

2. Since $X$ is connected we obtain from Proposition 36.10 that there exists a map $\gamma: [0, 1] \to X$ with $\gamma(0) = P$ and $\gamma(1) = Q$. From (1) we obtain a homotopy $F: X \times [0, 1] \to X$ with $F_0 = \text{id}$ and $F_1(P) = Q$. The map $h := F_1$ evidently has all the promised properties.

Before we can provide the proof of Theorem 38.1 we will need to formulate and prove several lemmas.

Lemma 38.3. For any $n \in \mathbb{N}_0$ there exists a deformation retraction from the solid cylinder $\mathcal{B}^n \times [0, 1]$ to the “cup” $\mathcal{B}^n \times \{0\} \cup S^{n-1} \times [0, 1]$.

![Figure 641](image)
Proof. It is straightforward to verify that the map
\[ r: \overline{B}^n \times [0, 1] \rightarrow (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0, 1]) \]
\[ P \mapsto \text{the unique point on } \overline{B}^n \times \{0\} \cup S^{n-1} \times [0, 1] \text{ that gets hit by the ray from } (0, 2) \in \mathbb{R}^n \times \mathbb{R} \text{ through } P. \]
is a retraction. We refer to Figure 642 for an illustration. Since \( \overline{B}^n \times [0, 1] \) is convex we can define the corresponding deformation retraction as follows:
\[ (\overline{B}^n \times [0, 1]) \times [0, 1] \rightarrow \overline{B}^n \times [0, 1] \]
\[ (P, t) \mapsto P \cdot (1 - t) + r(P) \cdot t. \]

\[ \square \]

Lemma 38.4. If \( X \) is a CW-complex and if \( A \) is a subcomplex of \( X \), then there exists a deformation retraction from \( X \times [0, 1] \) to the subcomplex \((X \times \{0\}) \cup (A \times [0, 1])\).

Proof. Let \( X \) be a CW-complex and let \( A \) be a subcomplex. For each \( n \in \mathbb{N}_0 \) we set
\[ Z_n := X \times \{0\} \cup (X^{n-1} \cup A) \times [0, 1]. \]
Note that each \( Z_n \) is a subcomplex of the product CW-complex \( X \times [0, 1] \). Evidently we have a sequence
\[ (X \times \{0\}) \cup (A \times [0, 1]) = Z_0 \subset Z_1 \subset Z_2 \subset \ldots \text{ with } X \times [0, 1] = \bigcup_{n \in \mathbb{N}_0} Z_n. \]
Thus it follows from Proposition 36.22 that it suffices to prove the following claim.

Claim. For every \( n \in \mathbb{N}_0 \) there exists a deformation retraction from \( Z_{n+1} \) to \( Z_n \).

Let \( n \in \mathbb{N}_0 \). We denote by \( \Phi_i: \overline{B}^n \rightarrow X, i \in I \), the characteristic maps of all the \( n \)-cells of \( X \) that do not lie in \( A \). By Lemma 38.3 there exists a deformation retraction \( r: \overline{B}^n \times [0, 1] \times [0, 1] \rightarrow \overline{B}^n \times [0, 1] \) from \( \overline{B}^n \times [0, 1] \) to \( \overline{B}^n \times \{0\} \cup S^{n-1} \times [0, 1] \). The idea
is to apply this retraction to all $k$-cells of $X$ to obtain the desired deformation retraction. More precisely we consider the map

$$r_n: (X \times \{0\} \cup (X^n \cup A) \times [0,1]) \times [0,1] \to (X \times \{0\} \cup (X^n \cup A) \times [0,1]) \times [0,1],$$

$$(P,t,s) \mapsto \begin{cases} \Phi_i(r((Q,t),s)), & \text{if } P = \Phi_i(Q) \text{ with } Q \in B^n \text{ and } i \in I, \\ (P,t), & \text{otherwise.} \end{cases}$$

This map is easily seen to be a deformation retraction from $Z_{n+1}$ to $Z_n$.\[\]

Now we can provide the proof of Theorem 38.1.

**Proof of Theorem 38.1.** Let $X$ be a CW-complex, let $Y$ be a topological space and let $f_0: X \to Y$ be a map. Furthermore, suppose that $A \subset X$ is a subcomplex and suppose we are given a homotopy $G: A \times [0,1] \to Y$ from $g_0 := f_0|_A$ to some map $g_1: A \to Y$. By Lemma 38.4 there exists a retraction

$$H: X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1]).$$

The theorem follows from the following claim.

**Claim.** The map

$$F: X \times [0,1] \overset{H}{\to} (X \times \{0\}) \cup (A \times [0,1]) \to Y$$

$$(x,0) \mapsto f_0(x), \quad (x, t) \mapsto G(a,t), \quad (a,t) \in (A \times [0,1]).$$

has all the desired properties.

First we have to verify that the map is continuous. In fact, for continuity we do have to worry a little bit about the right-hand map. But note that Lemma 36.18 (2) says that the subcomplex $A$ is a closed subset of $X$. Thus we see that the map on the right-hand side is continuous when restricted to the closed subsets $X \times \{0\}$ and $A \times [0,1]$. Thus it is continuous by Lemma 2.35 (2). Note it is clear that $F$ has the desired properties, i.e. that it is a homotopy $F: X \times [0,1] \to Y$ starting from $f_0$ such that the restriction $F|_{A \times [0,1]}$ equals $G$.

The following proposition gives a typical application of the Homotopy Extension Theorem 38.1.

**Proposition 38.5.** Let $f: A \to B$ be a cellular map between CW-complexes that has the following property:

(*) For each $n$-cell $\sigma$ of $A$ we have either $f(\sigma) \subset B^n$ or $f|_\sigma$ is a homeomorphism.

We consider the corresponding mapping cylinder

$$\text{Cyl}(f) := \text{Cyl}(f: A \to B) := ((A \times [0,1]) \cup B)/\sim$$

where $(a,1) \sim f(a)$ for all $a \in A$.\[\]
that we defined on page 697. Finally let \( Y \) be a CW-complex together with a cellular embedding \( i \cup j : A \sqcup B \to Y \). The map

\[
\Phi: (Y \sqcup \text{Cyl}(f: A \to B))/ \sim \to Y/i(a) \sim j(f(a))
\]

\[
[P] \mapsto \begin{cases} [P], & \text{if } P \in Y, \\ [i(a)], & \text{if } P = [(a, t)] \text{ with } a \in A \text{ and } t \in [0, 1], \\ [j(b)], & \text{if } P = [b] \text{ with } b \in B. \end{cases}
\]

is a homotopy equivalence.

**Example.** In many applications the map \( f \) will actually be a cellular isomorphism. In this special case Proposition 38.5 basically says that one can compress a product \( A \times [0, 1] \) to a single copy of \( A \) without changing the homotopy type. Two such examples are shown in Figure 645.

**Remark.** Note that the statement of Proposition 38.5 is related in spirit to the statement of Lemma 39.9 (2).

**Proof.** First note that by Lemma 36.19 we can and will view \( A \sqcup B \) as a subcomplex of \( Y \). In the following let \( R: \text{Cyl}(f: A \to B) \times [0, 1] \to B \) be the natural deformation retraction given by Lemma 24.8. Furthermore note that it follows quite easily from Corollary 36.35 (3) and Lemma 36.32 (2) that we can and will equip \( \text{Cyl}(f) \) and \( (Y \sqcup \text{Cyl}(f))/ \sim \) with natural CW-structures. Finally, it follows from our slightly technical hypothesis on \( f \) together with Lemma 36.32 (6) that \( Y/ \sim \) also admits a natural CW-structure. Next we consider the homotopy

\[
G: (A \sqcup B) \times [0, 1] \to \text{Cyl}(f) \subset (Y \sqcup \text{Cyl}(f))/ \sim
\]

\[
[(Q, t)] \mapsto \begin{cases} R([(Q, 0)], t), & \text{if } Q \in A, \\ Q, & \text{if } Q \in B. \end{cases}
\]
We obtain the following diagram:

\[
\begin{array}{c}
(A \sqcup B) \times \{0\} \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
\downarrow \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \ quad
We start out with a few definitions. Some of them we have encountered before.

**Definition.**

1. A **pointed topological space** is a pair \((X, x_0)\) where \(X\) is a topological space and \(x_0 \in X\) is a point. We refer to \(x_0\) as the *base point* of the pointed topological space.
2. A map \(f: (X, x_0) \to (Y, y_0)\) between pointed topological spaces is a map \(f: X \to Y\) with \(f(x_0) = y_0\).
3. We say that two maps \(f, g: (X, x_0) \to (Y, y_0)\) between pointed topological spaces are *homotopic* if there exists a homotopy \(F: X \times [0, 1] \to Y\) rel \(\{x_0\}\) from \(f\) to \(g\).
4. Given two pointed topological spaces \((X, x_0)\) and \((Y, y_0)\) we write \(\langle (X, x_0), (Y, y_0) \rangle := \{\text{maps } (X, x_0) \to (Y, y_0)\}/\sim\) where \(f \sim g\) if there exists a homotopy in the above sense between \(f\) and \(g\).

**Example.** Let \((X, x_0)\) be a pointed topological space, let \(n \in \mathbb{N}\) and let \(*\) be the usual base point of \(S^n\). By definition we have \(\langle (S^n, *), (X, x_0) \rangle = \pi_n(X, x_0)\).

We have a natural map \(\langle (X, x_0), (Y, y_0) \rangle \to [X, Y]\). It is worth spending a minute on trying to find examples that show that in general this map is neither an injection nor a surjection. In this section we want to give some criteria that give us some control over this map. We start out with the following easy, albeit fairly restrictive, example.

**Proposition 38.6.** Let \((Y, y_0)\) be a path-connected topological space. If \(\pi_1(Y, y_0)\) is abelian, then the map

\[
\langle (S^1, *), (Y, y_0) \rangle \to [S^1, Y] \\
[f] \mapsto [f]
\]

is a bijection.

**Proof.** It follows from the fact that \(Y\) is path-connected together with Proposition 18.33 (1) that the map is a surjection. Furthermore it follows from the hypothesis that \(\pi_1(Y, y_0)\) is abelian together with Proposition 18.33 (2) that the map is an injection.

Now we want to move away from the fairly simple topological space \(S^1\). In the proof of Proposition 18.33 we had to construct fairly explicitly maps on \(S^1\) and \(S^1 \times [0, 1]\). In the following we will now replace \(S^1\) by CW-complexes, we have now developed several tools for building maps out of a CW-complex. This leads us to the following definition.

**Definition.** A **pointed CW-complex** is a pair \((X, x_0)\) where \(X\) is a CW-complex and \(x_0\) is a point in the 0-skeleton \(X^0\) of \(X\).

**Proposition 38.7.** Let \((X, x_0)\) be pointed a CW-complex and let \((Y, y_0)\) be a pointed topological space. We consider the map

\[
\langle (X, x_0), (Y, y_0) \rangle \to [X, Y] \\
[f] \mapsto [f].
\]

---

620 The notation \(\langle X, Y \rangle\) goes back to [Hat02, p. 357], where it says “the notation \(\langle \ldots \rangle\) is intended to suggest pointed homotopy classes.”
The following two statements hold:

(1) If \( Y \) is path-connected, then the map \( \langle (X, x_0), (Y, y_0) \rangle \to [X, Y] \) is a surjection.
(2) If \( Y \) is simply connected, then the map \( \langle (X, x_0), (Y, y_0) \rangle \to [X, Y] \) is a bijection.

**Remark.** In Proposition \( \text{[121.25]} \) we will formulate a variation on Proposition \( \text{[38.7]} \) for CW-complexes with abelian fundamental groups.

For the record we state the following corollary to our results.

**Corollary 38.8.**

(1) Let \( (X, x_0) \) be a path-connected pointed topological space and let \( n \in \mathbb{N} \). If \( n = 1 \), then we assume that \( \pi_1(X, x_0) \) is abelian and if \( n \geq 2 \) we assume that \( \pi_1(X, x_0) \) is trivial. In this setting the map

\[
\langle (S^n, x_0), (X, x_0) \rangle \xrightarrow{[f] \mapsto [f]} [S^n, X]
\]

is a bijection.

(2) Given any \( n \in \mathbb{N} \) and given any base point \( x_0 \in S^n \) the map

\[
\langle (S^n, x_0), (S^n, x_0) \rangle \xrightarrow{[f] \mapsto [f]} [S^n, S^n]
\]

is a bijection.

**Proof of Corollary 38.8**

(1) (a) The case \( n = 1 \) is precisely the content of Proposition \( \text{[38.6]} \).

(b) Now let \( n \in \mathbb{N}_{\geq 2} \). We can and will equip \( S^n \) with a CW-structure such that \( x_0 \) is a 0-cell. The desired statement now follows from Proposition \( \text{[38.7]} \) (2).

(2) This statement follows immediately from (1) and the fact, established in Corollary \( \text{[16.18]} \) and Proposition \( \text{[14.14]} \) that for \( n \geq 2 \) the fundamental group \( \pi_1(S^n) \) is trivial.

Now we turn to the proof of Proposition \( \text{[38.7]} \). This proof relies very much on the following lemma.

**Lemma 38.9.** Let \( (X, x_0) \) and \( (Y, y_0) \) be pointed CW-complexes and let \( F: X \times [0, 1] \to Y \) be a homotopy with \( F_0(x_0) = F_1(x_0) = y_0 \). We consider the loop \( \gamma: [0, 1] \to Y \) that is given by \( \gamma(t) := F(x_0, t) \). If the loop \( \gamma \) is null-homotopic, then there exists a homotopy \( J: X \times [0, 1] \to Y \) with \( J_0 = F_0 \) and \( J_1 = F_1 \) and such that \( J(x_0, t) = y_0 \) for all \( t \in [0, 1] \).

**Proof of Lemma 38.9** We prove the lemma in three easily digestible steps:

(1) We consider the loop \( \gamma: [0, 1] \to Y \) that is given by \( \gamma(t) := F(x_0, t) \). By our hypothesis the loop \( \gamma \) is null-homotopic. By definition this means that there exists a map \( \varphi: [0, 1] \times [0, 1] \to Y \) with \( \varphi(t, 0) = \gamma(t) \) for all \( t \in [0, 1] \) and such that \( \varphi(x, y) = y_0 \) for all other points in \( \partial([0, 1] \times [0, 1]) \).
(2) We consider the map

\[
G: (X \times [0,1]) \times \{0\} \cup (X \times [0,1]) \cup \{x_0\} \times [0,1] \rightarrow Y
\]

It follows from Lemma 36.20 that this map \(G\) is continuous.

(3) By the Homotopy Extension Theorem 38.1 the map \(G\) from (2) extends to a map \(H: (X \times [0,1]) \times [0,1] \rightarrow Y\). It follows basically immediately from the definitions that \(J := H_1: X \times [0,1] \rightarrow Y\) has the desired properties.

\[\begin{align*}
(x, s, t) &\mapsto \\
&\begin{cases}
F(x, s), & \text{if } t = 0, \\
F(x, s), & \text{if } s = 0, 1, \\
\varphi(s, t), & \text{if } x = x_0.
\end{cases}
\]

Now we turn to the actual proof of Proposition 38.7

**Proof of Proposition 38.7** Let \((X, x_0)\) and \((Y, y_0)\) be pointed CW-complexes.

(1) We suppose that \(Y\) is path-connected. Let \(f: X \rightarrow Y\) be map. We set \(y_1 = f(x_0)\).

Since \(Y\) is path-connected there exists a path \(\gamma: [0,1] \rightarrow Y\) with \(\gamma(0) = y_1\) and \(\gamma(1) = y_0\). Since \(\{x_0\}\) is a subcomplex of \(X\) we obtain from Corollary 38.2 that we can extend \(\gamma\), viewed as a homotopy \(\{x_0\} \times [0,1] \rightarrow Y\), to a homotopy \(F: X \times [0,1] \rightarrow Y\). This shows that \(f = F_0\) is homotopic to a map \(g := F_1\) with \(g(x_0) = y_0\). This implies that the map \(((X, x_0), (Y, y_0)) \rightarrow [X, Y]\) is a surjection.

\[\begin{align*}
X \times [0,1] &\rightarrow Y \\
X &\rightarrow Y
\end{align*}\]

\[\begin{align*}
x_0 &\rightarrow y_1 \\
x_0 &\rightarrow y_0
\end{align*}\]

**Figure 647.** Illustration for the proof of Proposition 38.7 (2).

\[\begin{align*}
\text{Secretly we use Proposition 36.23 which tells us in this instance that the product CW-structure } X \times [0,1] \times [0,1] \text{ is indeed a CW-structure for the topological space } X \times [0,1] \times [0,1].
\]
(2) By (1) it remains to show that the map \( \langle (X, x_0), (Y, y_0) \rangle \to [X, Y] \) is injective. Thus let \( f_0, f_1 : (X, x_0) \to (Y, y_0) \) be two maps which represent the same element in \([X, Y]\). This means that there exists a homotopy \( F : X \times [0, 1] \to Y \) with \( F_0 = f_0 \) and \( F_1 = f_1 \). We need to show that there exists a homotopy \( J : X \times [0, 1] \to Y \) with \( J_0 = f_0 \) and \( J_1 = f_1 \) and such that \( J(x_0, t) = y_0 \) for all \( t \in [0, 1] \). We consider the loop \( \gamma : [0, 1] \to Y \) that is given by \( \gamma(t) := F(x_0, t) \). Since \( Y \) is simply connected we know that \( \gamma \) is null-homotopic. Thus we can apply Lemma 38.9 and we obtain the desired homotopy \( J \).

We conclude this section with the following proposition.

**Proposition 38.10.\(^*(\)\)** Let \( X \) be a CW-complex and let \( x_0 \) and \( x_1 \) be two points in the 0-skeleton of \( X \). If \( X \) is connected, then there exists a map \( f : X \to X \) with the following properties:

1. The map \( f \) is homotopic to the identity.
2. We have \( f(x_0) = x_1 \).
3. The map \( f \) defines a homotopy equivalence \( (X, x_0) \to (X, x_1) \) of pointed topological spaces.

**Proof.** Since \( X \) is connected we obtain from Proposition 36.10\((7)\) that there exists a path \( \gamma : [0, 1] \to X \) with \( \gamma(0) = x_0 \) and \( \gamma(1) = x_1 \). Since \( x_0, x_1 \) lie in the 0-skeleton of \( X \) we can apply Corollary 38.2 and we obtain a homotopy \( F : X \times [0, 1] \to X \) with \( F(x_0, t) = \gamma(t) \) for all \( t \in [0, 1] \) and such that \( F_0 = \text{id} \). We set \( f := F_1 \). Evidently \( f \) is homotopic to the identity and \( f(x_0) = x_1 \). It remains to show that \( f : (X, x_0) \to (X, x_1) \) is a homotopy equivalence of pointed topological spaces.

We need to find a homotopy inverse to \( f \). Once again we appeal to Corollary 38.2 to obtain a homotopy \( G : X \times [0, 1] \to X \) with \( G(x_1, t) = \gamma(t) := \gamma(1 - t) \) for all \( t \in [0, 1] \) and such that \( G_0 = \text{id} \). We set \( g := G_1 \). We need to show that \( g \circ f : (X, x_0) \to (X, x_0) \) and \( f \circ g : (X, x_1) \to (X, x_1) \) are homotopic\(^{22}\) to the identity. We consider the homotopy\(^{23}\)

\[
F : X \times [0, 1] \to X
(x, t) \mapsto \begin{cases} F(x, 2t), & \text{if } t \in [0, \frac{1}{2}], \\ G(f(x), 2t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}
\]

Note that this is a homotopy from \( \text{id}_X \) to \( g \circ f : X \to X \). Furthermore note that the loop given by \( \gamma(t) = F(x_0, t) \) is precisely the loop \( \gamma \ast \overline{\gamma} \). By Proposition 14.6\((3)\) we know that this loop is null-homotopic. Thus we can apply Lemma 38.9. We obtain a homotopy \( J : X \times [0, 1] \to X \) with \( J_0 = F_0 = \text{id}_X \), \( J_1 = F_1 = g \circ f \) and \( J(x_0, t) = x_0 \) for all \( t \in [0, 1] \). But that is precisely what we needed.

38.3. Combining infinitely many homotopies and the telescope construction \((\ast)\). In Lemma 18.3 we saw that one can combine finitely many homotopies. Later on we will want to combine infinitely many homotopies of CW-complexes. This slightly delicate procedure can be performed using the following lemma.

\(^{22}\)Here, as a reminder, “homotopic” means “homotopic as maps of pointed topological spaces”.

\(^{23}\)It follows from Lemma 14.3 that \( F \) is indeed continuous.
Lemma 38.11. Let $X$ be a CW-complex, let $A$ be a subset of $X$ and let $Y$ be a topological space. Finally let $W_0 \subset W_1 \subset W_2 \subset \ldots$ be a sequence of subcomplexes of $X$ such that for each $k \in \mathbb{N}_0$ there exists an $l \in \mathbb{N}_0$ such that the $k$-skeleton $X^k$ is contained in $W_l$. (In many applications we have $W_k = X^k$.) Let $f_0, f_1, \ldots$ be maps from $X$ to $Y$. Suppose that for each $k \in \mathbb{N}_0$ we are given a homotopy $H(k) : X \times [0, 1] \to Y$ rel $A \cup W_k$ from $f_k$ to $f_{k+1}$. (Since it is easy to overlook this bit of the hypothesis we stress that $H(k)$ is in particular a homotopy rel $W_k$). We define

$$g : X \to Y$$

$$x \mapsto f_k(x) \quad \text{where } k \in \mathbb{N}_0 \text{ such that } x \in W_k.$$ 

For $k = 0, 1, 2, \ldots$ we write $s_k = \sum_{j=1}^{k} \frac{1}{2^j}$. Then the map

$$H : X \times [0, 1] \to Y$$

$$(x, t) \mapsto \begin{cases} H(k)(x, 2^{k+1} \cdot (t - s_k)), & \text{if } t \in [s_k, s_{k+1}), \\ g(x), & \text{if } t = 1 \end{cases}$$

that is illustrated in Figure 649 is a homotopy rel $A$ from $f_0$ to $g$. We refer to the homotopy $H$ as the combination of $\{H(k)\}_{k \in \mathbb{N}_0}$.

**Proof.** We only need to show that $H$ is continuous. Note that for each $l \in \mathbb{N}_0$ it follows from our choice of maps $f_l$ and Lemma 14.3 that the restriction of $H$ to $W_l \times [0, 1]$ is continuous. Since each $X^k$ is contained in some $W_l$ we see that the restriction of $H$ to each $X^k \times [0, 1]$ is continuous. But now it follows from Corollary 36.9 that $H : X \times [0, 1] \to Y$ is also continuous.\[\]$

$^624$It follows easily from the setup that the map $g$ is well-defined, i.e. given $x \in X$ the point $g(x)$ does not depend on the choice of $k$.\[\]
We conclude this technical section with an application that we will need once, namely in the proof Proposition 1. But the application doubles also as a nice illustration for how to apply the previous lemma.

**Definition.** Let $Z$ be a CW-complex. We equip $[0, \infty)$ with the CW-structure where the 0-skeleton is given by $N_0$. We equip $Z \times [0, \infty)$ with the product CW-structure. We refer to the subcomplex

$$T(Z) := \bigcup_{i \in N_0} Z^i \times [i, i + 1] \subset Z \times [0, \infty)$$

as the **telescope of $Z$**.

![Figure 650](image)

The following lemma shows that the telescope $T(Z)$ is homotopy equivalent to $Z$.

**Lemma 38.12.** Let $Z$ be a CW-complex. The following statements hold:

1. $T(Z)$ is a deformation retract of $Z \times [0, \infty)$.
2. The telescope $T(Z)$ is homotopy equivalent to $Z$.

**Remark.** One can also show that Lemma 38.12 is a consequence of the much more general Proposition 1.10.

**Proof.** First note that $Z = Z \times \{0\}$ is clearly a deformation retract of $Z \times [0, \infty)$. Thus it follows from Lemmas 18.14 and 18.11 that (2) is a consequence of (1). Therefore it remains to prove (1).

As in the definition of the telescope $T(Z)$ we view $[0, \infty)$, $X := Y := Z \times [0, \infty)$ and $T(Z)$ as CW-complexes. It follows from Lemma 38.4 that for each $k \in N_0$ there exists a deformation retraction

$$r_k: (Z \times [0, 1]) \times [0, 1] \to Z \times [0, 1]$$

from $Z \times [0, 1]$ to $(Z^k \times [0, 1]) \cup (Z \times \{1\})$. We denote by

$$\rho_k: Z \times [k, k + 1] \to (Z^{k-1} \times [k, k + 1]) \cup (Z^k \times \{k + 1\})$$

$$z, t \mapsto (r_k(z, t - k) + (0, k), 1)$$

the corresponding retraction, with the intervals shifted by $k$. We make the following preparations:

1. Given $k \in N_0$ we define $W_k := Z^k \times [0, \infty)$. Note that it follows from the definition of the product CW-structure on $Z \times [0, \infty)$ that the $k$-skeleton of $X = Z \times [0, \infty)$ is contained in $W_{k+1}$.
(2) For each \( k \in \mathbb{N}_0 \) we consider the map
\[
f_k : X = Z \times [0, \infty) \to Y = Z \times [0, \infty)
\]
\[
(z, t) \mapsto \left\{ \begin{array}{ll}
(z, t), & \text{if } x \in Z^k \text{ and } t \geq k + 1, \\
\rho_k \circ \cdots \circ \rho_1 \circ \rho_0(x), & \text{if } z \in Z^k \text{ and } t < k + 1.
\end{array} \right.
\]

(3) We consider the map
\[
H(k) : X \times [0, 1] \to Y = Z \times [0, \infty)
\]
\[
((z, t), s) \mapsto \left\{ \begin{array}{ll}
(z, t), & \text{if } t \geq k + 1, \\
r_{k+1}(\rho_k(z, t), s), & \text{if } t < k + 1.
\end{array} \right.
\]

This defines a homotopy from \( f_k \) to \( f_{k+1} \) rel \( W_k \). Note that \( H(0)_1 = \text{id}_X \).

As in the statement of Lemma 38.11, we consider the map
\[
g : X \to Y
\]
\[
x \mapsto f_k(x) \quad \text{where } k \in \mathbb{N}_0 \text{ such that } x \in W_k.
\]

One can easily verify that this is a retraction of \( X = Z \times [0, \infty) \) to the telescope \( T(Z) \). It follows from Lemma 38.11 that there exists a homotopy from \( H(0)_1 = \text{id}_T \) to \( g \), i.e. \( T(Z) \) is in fact a deformation retract of \( X = Z \times [0, \infty) \).

38.4. The Cellular Approximation Theorem. We recall the following definition from page 955.

**Definition.** A map \( g : X \to Y \) between CW-complexes is called **cellular** if for each \( n \in \mathbb{N}_0 \) we have \( g(X^n) \subset Y^n \).

It will be instructive to return to the example of a non-cellular map that we gave on page 955.

**Example.** In general maps between CW-complexes are not cellular. For example consider the CW-complex \( X = [0, 1] \) with two 0-cells and one 1-cell and we consider the CW-complex \( Y = [0, 1] \times [0, 1] \) with four 0-cells, two 1-cells and one 2-cell. Then the diagonal map
\[
g : X = [0, 1] \to Y = [0, 1] \times [0, 1]
\]
\[
t \mapsto (t, t)
\]
which is illustrated in Figure 652 on the left, is not a cellular map.

The following theorem is the main result of this section.
Theorem 38.13. (Cellular Approximation Theorem) Let \( g: X \to Y \) be a map between CW-complexes and let \( A \) be a subcomplex of \( X \) such that the restriction of \( g \) to \( A \) is a cellular map.\textsuperscript{625} The map \( g \) is homotopic rel \( A \) to a cellular map \( \tilde{g}: X \to Y \).

Remark. Let \( g: X \to Y \) be a homeomorphism between CW-complexes. By the Cellular Approximation Theorem \textsuperscript{38.13} we know that \( g \) is homotopic to a cellular map \( h \). But in general we cannot arrange that \( h \) is again a homeomorphism. For example consider the torus \( T = ([0, 1] \times [0, 1]) / \sim = \mathbb{R}^2 / \mathbb{Z}^2 \) with the standard CW-structure from page \textsuperscript{933} which has precisely one 0-cell \(*\) that corresponds to the origin. As in Theorem \textsuperscript{16.16} we make the identification \( \pi_1(\mathbb{R}^n / \mathbb{Z}^2, *) \) with \( \mathbb{Z}^2 \). Let \( P = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \text{GL}(2, \mathbb{Z}) \). We consider the map

\[
\begin{align*}
  f: \mathbb{R}^2 / \mathbb{Z}^2 & \to \mathbb{R}^2 / \mathbb{Z}^2 \\
  v & \mapsto P \cdot v.
\end{align*}
\]

In Lemma \textsuperscript{6.35} we saw that this map is a homeomorphism. Furthermore, in Exercise \textsuperscript{16.16} we saw that the induced map on \( \pi_1(\mathbb{R}^2 / \mathbb{Z}^2, *) = \mathbb{Z}^2 \) is given by multiplication by \( P \). On the other hand the map on \( \pi_1(\mathbb{R}^2 / \mathbb{Z}^2, *) = \mathbb{Z}^2 \) induced by any cellular homeomorphism \( \tilde{g} \) on \( \mathbb{R}^2 / \mathbb{Z}^2 \) is represented by a matrix of the form \textsuperscript{626} \( \begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix} \) or \( \begin{pmatrix} 0 & \pm 1 \\ \pm 1 & 0 \end{pmatrix} \). It follows from Exercise \textsuperscript{18.36} (a) that \( g \) cannot be homotopic, rel \(*\), to any such \( \tilde{g} \).

Example. We consider again the above example of a non-cellular map. More precisely, we consider again the above diagonal map

\[
  g: X = [0, 1] \to Y = [0, 1] \times [0, 1] \\
  t \mapsto (t, t).
\]

We want to deform \( g \) into a cellular map, while keeping the endpoints fixed. Put differently, we want to find a homotopy rel \( A = \{(0, 0), (1, 1)\} \) from \( g \) to a cellular map \( \tilde{g} \). Such a map \( \tilde{g} \) is given by

\[
  \tilde{g}: X = [0, 1] \to Y = [0, 1] \times [0, 1] \\
  t \mapsto \left\{ \begin{array}{ll}
  (2t, 0), & \text{if } t \in [0, \frac{1}{2}] \\
  (1, 2t - 1), & \text{if } t \in [\frac{1}{2}, 1] 
  \end{array} \right.
\]

One way of stating this example is that we turn \( g \) into a cellular map \( \tilde{g} \) by “pushing \( g \)

\[\text{Figure 652}\]

off the high-dimensional cell”. The proof of Cellular Approximation Theorem \textsuperscript{38.13} is built

\textsuperscript{625}For example \( f: X \to Y \) could be any map between CW-complexes, then the hypothesis is satisfied for \( A \) the empty set.

\textsuperscript{626}Why is that?
on the same concept. But somewhat similar to the proof of Proposition 14.14 we have to worry about space-filling curves that exist by Proposition 2.60.

Before we attack the proof of the Cellular Approximation Theorem 38.13 we want to formulate a relative version thereof. To formulate this relative version we need the following semi-obvious definition.

**Definition.** A pair of CW-complexes is a pair $(X, A)$ where $X$ is a CW-complex and $A$ is a subcomplex of $X$.

Now we can formulate the promised theorem.

**Theorem 38.14. (Cellular Approximation Theorem for Pairs)** Suppose we are given a map $g: (X, A) \to (Y, B)$ between pairs of CW-complexes. Let $Z$ be a subcomplex of $A$ such that the restriction of $g$ to $Z$ is a cellular map. Then $g$ is homotopic rel $Z$ to a cellular map $\tilde{g}: (X, A) \to (Y, B)$.

**Proof assuming the Cellular Approximation Theorem 38.13.** The desired homotopy is constructed as follows:

1. By the Cellular Approximation Theorem 38.13 applied to $g|_A: A \to B$ there exists a homotopy $F$ rel $Z$ from $g|_A: A \to B$ to a cellular map.
2. By the Homotopy Extension Theorem 38.1 we can extend the homotopy $F$ from (1) to a homotopy $G: X \times [0, 1] \to Y$. Note that $G$ is still a homotopy rel $Z$. We write $h = g_1: X \to Y$. Note that $h|_A$ is cellular and that $h(A) \subset B$.
3. We apply the Cellular Approximation Theorem 38.13 to $h$ and we obtain a homotopy $H$ rel $A$ from $h$ to a cellular map.
4. The combination of the homotopies $G$ and $H$ has all the desired properties.

Now we turn to the proof of Cellular Approximation Theorem 38.13. The following proposition is the key step towards the desired proof.

**Proposition 38.15.** Let $V$ be a CW-complex and $W$ be a topological space. Furthermore let $\psi: S^{n-1} \to V^{n-1}$ be a map to the $(n-1)$-skeleton of $V$ and let $\varphi: S^{k-1} \to W$ be another map. Finally let $h: V \cup_\psi \overline{B}^n \to W \cup_\varphi \overline{B}^k$ be a map with $h(\psi(S^{n-1})) \subset W$. If $n < k$, then $h$ is homotopic rel $V$ to a map $h'$ such that $h'(B^n)$ does not intersect $B^k$.

![Figure 653. Illustration of Proposition 38.15](image-url)

---

\(^{627}\)Here we refer to page 572 for the discussion on the notion of homotopies of pairs of topological spaces rel a subset.
The statement of Proposition 38.15 is fairly obvious, if there exists a point \( P \in B^k \) that does not get hit by \( h(B^n) \). Indeed, if such a point \( P \) exists, then we can use the deformation retraction \( B^n \setminus \{p\} \to S^{n-1} \) to push \( h \) on \( B^n \) off the ball \( B^k \). Put in general such a point \( P \) does not exist, since even for \( n < k \) there exist continuous surjective maps \( B^n \to B^k \). To get around this problem requires a fairly hard, not particularly inspiring, argument which we will give later on in Section 38.5.

In the following we will use Proposition 38.15 to prove the Cellular Approximation Theorem 38.13.

**Corollary 38.16.** Let \( Z \) be a finite \( n \)-dimensional CW-complex.

1. Let \( g: Z \to Y \) be a map to a \( k \)-dimensional CW-complex \( Y \) with \( g(Z^{n-1}) \subset Y^{n-1} \). Let \( B \) be a subcomplex of \( Z \) with \( g(B) \subset Y^n \). If \( n < k \), then \( g \) is homotopic rel \( Z^{n-1} \cup B \) to a map \( g' \) with \( g'(Z) \subset Y^{k-1} \).

2. Let \( g: Z \to Y \) be a map to a CW-complex \( Y \) such that \( g(Z^{n-1}) \subset Y^{n-1} \). Let \( B \) be a subcomplex of \( Z \) with \( g(B) \subset Y^n \). The map \( g \) is homotopic rel \( Z^{n-1} \cup B \) to a map \( g' \) with \( g'(Z) \subset Y^n \).

**Figure 654.** Illustration for Corollary 38.16 (1).

**Proof.** Let \( Z \) be a finite \( n \)-dimensional CW-complex. By Proposition 36.10 (3) the CW-complex \( Z \) is compact. It follows from Theorem 36.14 that the image of the compact set \( Z \) in a CW-complex is contained in a finite subcomplex. Therefore we can assume in both (1) and (2) that \( Y \) is in fact a finite CW-complex.

(1) Let \( g: Z \to Y \) be a map to a finite \( k \)-dimensional CW-complex \( Y \) with \( g(Z^{n-1}) \subset Y^{n-1} \). Let \( B \) be a subcomplex of \( Z \) with \( g(B) \subset Y^n \). We suppose that \( n < k \). We denote by \( \tilde{Z} \) the union of \( Z^{n-1} \) with all the \( n \)-cells of \( Z \) whose image is contained in \( Y^{k-1} \). In other words we can write \( \tilde{Z} = \tilde{Z} \cup e_1 \cup \cdots \cup e_r \) where \( e_1, \ldots, e_r \) are the \( n \)-cells such that the image is not contained in \( Y^{k-1} \). We denote by \( f_1, \ldots, f_s \) the \( k \)-cells of \( Y \). Note that by hypothesis on \( B \) the interiors of the cells \( e_1, \ldots, e_r \) are disjoint from \( B \).
In the following we apply Proposition \[38.15\] precisely \(r \cdot s\) times to get the desired homotopy. More precisely, we do the following:

(a) We apply Proposition \[38.15\] to the map

\[
h: (\hat{Z} \cup e_1 \cup \cdots \cup e_{r-1}) \cup e_r \to (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s
\]

to obtain a homotopy rel \(\hat{Z} \to Z\) to \(X\) under the map \(h_{rs}\) such that the interior of \(e_r\) does not intersect the interior of \(f_s\). Next we apply Proposition \[38.15\] to the map

\[
h_{rs}: (\hat{Z} \cup e_1 \cup \cdots \cup e_{r-2} \cup e_r) \cup e_{r-1} \to (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s.
\]

Iterating this process we obtain a homotopy rel \(\hat{Z}\) to \(X\) such that the image of the interiors of the cells \(e_1, \ldots, e_r\) does not intersect the interior of \(f_s\).

(b) Again iterating the process above we obtain a homotopy rel \(\hat{Z}\) to \(X\) such that image of the interiors of the cells \(e_1, \ldots, e_r\) does not intersect the interior of any of the \(f_i\). But that means that the image of \(Z\) lies in \(Y^{k-1}\).

(2) Let \(g: Z \to Y\) be a map to a CW-complex \(Y\) such that \(g(Z^{n-1}) \subset Y^{n-1}\) and let \(B\) be a subcomplex of \(Z\) with \(g(B) \subset Y^n\). As we pointed out in the beginning of the proof, we can assume that \(Y\) is finite-dimensional, we denote the dimension by \(k\). But then statement (2) is just an immediate consequence of applying (1) iteratively \(k - n\) times.

Now we turn to the proof of the Cellular Approximation Theorem \[38.13\].

**Proof.** Let \(X\) be a CW-complex and let \(A\) be a (possibly empty) subcomplex of \(X\). Furthermore let \(Y\) be a CW-complex. We prove the Cellular Approximation Theorem \[38.13\] only in the special case that \(X\) has finitely many cells. The general case is dealt with in [Hat02, Theorem 4.8].

Let \(g: X \to Y\) be a map.

(1) We say an \(n\)-cell \(e\) of \(X\) is \(g\)-bad if \(g(e)\) is not contained in \(Y^n\).

(2) If \(g\) is non-cellular, then we define

\[
n(g) := \text{minimal dimension of a cell that is } g\text{-bad.}
\]

If \(g\) is cellular, then we define \(n(g) := \infty\).

**Claim.** Let \(g: X \to Y\) be a non-cellular map such that the restriction of \(g\) to \(A\) is a cellular map. Then there exists a homotopy from \(g\) to a map \(g'\) rel \(A\) such that \(n(g') > n(g)\).

We write \(n = n(g)\). We apply Corollary \[38.16\] (2) to \(g: Z := X^n \to Y\) and \(B = A^n\).

We obtain a homotopy \(G\) rel \(X^{n-1} \cup A^n\) from \(g: Z = X^n \to Y\) to a map \(g': Z = X^n \to Y\) with \(g'(X^n) \subset Y^n\). We can extend this homotopy to a homotopy \(G\) on \((X^n \cup A) \times [0, 1]\) via the trivial homotopy on \(A \times [0, 1]\). Now we apply the Homotopy Extension Theorem \[38.1\] to obtain a homotopy rel \(X^n \cup A\) from \(g: X \to Y\) to a map \(g': X \to Y\) such that \(g'(X^n) \subset Y^n\). Note that by the choice of our homotopy we have \(g'|_{X^{n-1}} = g|_{X^{n-1}}\). By definition of \(n(g)\) the map \(g'|_{X^{n-1}} = g|_{X^{n-1}}\) is cellular. Thus we see that \(n(g') \geq n + 1 = n(g) + 1\).

\[628\]Note that by definition of \(n\) we have \(g(X^{n-1}) \subset Y^{n-1}\).
Finally let \( g: X \to Y \) be a non-cellular map such that the restriction of \( g \) to \( A \) is a cellular map. We apply the claim iteratively as many times as possible to obtain a sequence of maps \( g = g_1, g_2, g_3, \ldots: X \to Y \), each of which is homotopic to \( g \) rel \( A \), such that \( n(g) = n(g_1) < n(g_2) < \ldots \). Note that \( n \) can take on only finitely many values, namely \( \{0, \ldots, \dim(X), \infty\} \). This means that the sequence is finite which implies that the last map is cellular.

38.5. **Proof of Proposition 38.15 (\*)**. Before we can even think of proving Proposition 38.15 we need to introduce a few more definitions and we need to prove a rather technical lemma.

**Definition.**

1. A **closed half-space** in \( \mathbb{R}^n \) is a set of the form \( \{v \in \mathbb{R}^n | \langle v, w \rangle \geq 0\} \), for some fixed non-zero vector \( w \in \mathbb{R}^n \).
2. A **convex polyhedron** in \( \mathbb{R}^n \) is a bounded subset of \( \mathbb{R}^n \) that is the intersection of finitely many closed half-spaces.
3. A **polyhedron** in \( \mathbb{R}^n \) is the union of a finite number of convex polyhedra.
4. Given a polyhedron \( P \) a map \( f: P \to \mathbb{R}^k \) is called piecwise linear if there exists a subdivision of \( P \) into finitely many convex polyhedra \( Q_1, \ldots, Q_m \) such that the restriction of \( f \) to each \( Q_i \) is affine linear.

The following, very technical lemma, will get us around the problem of space filling curves, i.e. it will get us around the problem that we saw in Proposition 2.60 that there exist surjective continuous maps \( \overline{B^n} \to \overline{B^k} \) even if \( n < k \).

**Lemma 38.17.** Let \( W \) be a topological space and let \( \varphi: S^{k-1} \to W \) be map. Furthermore let \( g: [0, 1]^n \to Z := W \cup_{\varphi} \overline{B^k} \) be a map. Then there exists a (possibly empty) polyhedron \( K \subset [0, 1]^n \) and a map \( \tilde{g}: [0, 1]^n \to Z \) with the following properties:

1. The map \( \tilde{g} \) is homotopic to \( g \) rel \( g^{-1}(W) \).
2. We have \( \tilde{g}(K) \subset \overline{B^k} \).
3. The restriction \( \tilde{g}|_K: K \to \overline{B^k} \) is piecewise linear.
4. There exists a non-empty open subset \( U \subset \overline{B^k} \) such that \( \tilde{g}^{-1}(U) \subset K \).

---

\(^{620}\)Here the (\*) indicates once again that we do not provide the proof in the lecture. You are reading this section at your own risk.

\(^{630}\)Note that the union of zero convex polyhedra is the empty set.

\(^{631}\)A map \( f: V \to \mathbb{R}^k \) from a subset \( V \) of \( \mathbb{R}^n \) is called affine linear if there exists a \( P \in \mathbb{R}^k \) and a \( k \times n \)-matrix \( A \) such that \( f(v) = P + Av \) for all \( v \in V \).
Example. Suppose that in the setting of Lemma 38.17 there exists an open subset $U \subset B^k$ such that $g([0,1]^n) \cap U = \emptyset$. Then the empty polyhedron $K = \emptyset$ and the map $\tilde{g} = g$ already have the desired property.

Proof. Let $W$ be a topological space and let $\varphi: S^{k-1} \to W$ be map. Furthermore let $g: [0,1]^n \to Z := W \cup_{\varphi} \overline{B}^k$ be a map. We write $D_1 := \overline{B}_{\frac{1}{2}}(0) \subset B^k$ and $D_2 := \overline{B}_{\frac{1}{4}}(0) \subset B^k$. The set $g^{-1}(D_2) \subset [0,1]^n$ is closed and therefore compact by the Heine-Borel Theorem 2.20. We obtain from Proposition 2.77 that $g$ is uniformly continuous on $g^{-1}(D_2)$.

This implies that we can find an $\epsilon > 0$ with the following two properties:

(i) For any $x, y \in g^{-1}(D_2)$ with $\|x - y\| < \epsilon$ we have $\|g(x) - g(y)\| < \frac{1}{8}$.

(ii) We have

$$\epsilon < \text{distance between } g^{-1}(D_1) \text{ and } [0,1]^n \setminus g^{-1}(\hat{D}_2).$$

We divide $[0,1]^n$ into cubes such that the diameter of each cube is less than $\epsilon$. We denote by $K_1$ the union of all the cubes that meet $g^{-1}(D_1)$ and we denote by $K_2$ the union of all the cubes meeting $K_1$. By the second property of $\epsilon$ we have $K_2 \subset g^{-1}(D_2)$. We refer to Figure 657 for an illustration.

---

632 Why can't we conclude that $g$ is uniformly continuous on all of $[0,1]^n$?
633 Here recall that, according to the definition on page 175 for two non-empty subsets $A$ and $B$ of $\mathbb{R}^n$ we refer to

$$d(A, B) := \inf \{\|P - Q\| : P \in A \text{ and } Q \in B\}$$

as the distance between $A$ and $B$. If $A$ and $B$ are compact and disjoint, then it follows from Corollary 3.19 (2) that $d(A, B) > 0$. 

---

Figure 656. Illustration of Lemma 38.17

Figure 657
We need one more definition: Suppose we are given points \( P_1, \ldots, P_{n+1} \in \mathbb{R}^n \) such that the vectors \( P_2 - P_1, \ldots, P_{n+1} - P_1 \) are linearly independent. We refer to

\[
\text{convex hull of } P_1, \ldots, P_{n+1} = \left\{ \sum_{i=1}^{n+1} t_i P_i \middle| \sum_{i=1}^{n+1} t_i = 1 \right\}
\]

as a simplex in \( \mathbb{R}^n \). We will make use of the following trivial observation: if we are given \( w_1, \ldots, w_{n+1} \in \mathbb{R}^k \), then there exists a unique affine linear map \( \Phi \) with \( \Phi(P_i) = w_i \), namely the map that is given by

\[
\Phi \left( \sum_{i=1}^{n+1} t_i P_i \right) := \sum_{i=1}^{n+1} t_i w_i.
\]

We leave it to the reader to show that each cube can be subdivided into simplices. We also refer to Figure 658 for an illustration.

![Figure 658](image)

**Figure 658**

Now we subdivide all the cubes in \( K_2 \) into simplices. By the above discussion there exists a map \( h: K_2 \to \mathbb{R}^k \) that equals \( g \) on all the vertices of the simplices in the subdivision of the cubes. Furthermore we choose a map \( \psi: K_2 \to [0, 1] \) with \( \psi|_{\partial K_2} \equiv 0 \) and \( \varphi|_{K_1} \equiv 1 \).

Now we consider the homotopy

\[
F: [0, 1]^n \times [0, 1] \to Z = W \cup_{\varphi} \overline{B}^k
\]

\[
(P, t) \mapsto \begin{cases} (1 - t \cdot \psi(P)) \cdot g(P) + t \cdot \psi(P) \cdot h(P), & \text{if } P \in K_2 \\ g(P), & \text{otherwise.} \end{cases}
\]

This is a homotopy from \( g \) to a map \( \tilde{g}: [0, 1] \to Z = W \cup_{\varphi} \overline{B}^k \) that restricts to the piecewise linear map \( h \) on \( K_1 \).

**Claim.** The point \( 0 \in D_1 \) does not lie in \( \tilde{g}([0, 1]^n \setminus K_1) \).

\[\text{[Given a subset } S \text{ of } \mathbb{R}^k \text{ we defined on page 223 the convex hull of } S \text{ as the intersection of all convex subsets of } \mathbb{R}^k \text{ that contain } S. \text{ As we saw in Exercise 2.36 if } S \text{ is a finite subset of } \mathbb{R}^k, \text{ then the convex hull of } S \text{ is given by}\}

\[
\left\{ \sum_{s \in S} a_s \cdot s \middle| a_s \in [0, 1] \text{ and } \sum_{s \in S} a_s = 1 \right\}.
\]

\[\text{[Here, by “subdivide” we mean that given any cube } K \text{ there exist simplices } S_1, \ldots, S_k \text{ such that the interiors of the } S_i \text{ are disjoint and such that } K = S_1 \cup \cdots \cup S_k.\]

\[\text{[Note that it follows from the uniqueness statement above that the map } g \text{ is in fact continuous.}\]

\[\text{[Such a map can be constructed as follows: we assign the value } 1 \text{ to all vertices in } K_1 \text{ and we assign the value } 0 \text{ to all other vertices in } K_2. \text{ By the above “trivial observation” this defines a map on } K_2 \text{ with the desired property.}\]

\[\text{[Since } \varphi|_{\partial K_2} \equiv 0 \text{ we see that } F \text{ is indeed continuous.}\]
The claim is proved in two steps:

(1) On \([0,1]^n \setminus K_2\) we have \(\tilde{g} = g\). By Property (ii) of \(\epsilon\) we have \(g^{-1}(D_1) \subset K_2\). It follows that the image of \([0,1]^n \setminus K_2\) lies outside of \(D_1\).

(2) Now let \(\sigma\) be a simplex of \(K_2\) that does not lie in \(K_1\). Note that \(K_2 \subset g^{-1}(D_2)\).

It follows from Property (i) of \(\epsilon\) that \(g(\sigma)\) is contained in some ball \(B_\sigma\) of radius \(\frac{1}{8}\). Since \(g(\sigma) \subset B_\sigma\) and since \(B_\sigma\) is convex we also have \(h(\sigma) \subset B_\sigma\). Again by the convexity of \(B_\sigma\) we have \(\tilde{g}(\sigma) \subset B_\sigma\). We know that \(B_\sigma\) is not contained in \(D_1\) since \(\sigma\) contains points outside \(K_1\), hence outside \(g^{-1}(D_1)\). The radius of \(B_\sigma\) is half that of \(D_1\), so it follows that \(0\) is not in \(B_\sigma\), and hence \(0\) does not lie in \(\tilde{g}(\sigma)\). \(\square\)

Since \(\tilde{g}([0,1]^n \setminus K_1)\) is compact it follows from the claim that there exists in fact an open neighborhood \(U\) of \(0\) that does not intersect the image of \([0,1]^n \setminus K_1\). Put differently, we have \(\tilde{g}^{-1}(U) \subset K_1\). It is now straightforward to verify that \(K = K_1\), \(\tilde{g}\) and \(U\) have the desired properties.

---

**Lemma 38.18.** Let \(W\) be a topological space and let \(\varphi: S^{k-1} \to W\) be the attaching map of a \(k\)-cell. Furthermore let \(h: \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k\) be a map with \(h(S^{n-1}) \subset W\). If \(n < k\), then \(h\) is homotopic rel \(S^{n-1}\) to a map \(h'\) that misses \(B^k\).

**Proof.** Let \(W\) be a topological space and let \(\varphi: S^{k-1} \to W\) be the attaching map of a \(k\)-cell. Furthermore let \(h: \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k\) be a map with \(h(S^{n-1}) \subset W\). We suppose that \(n < k\). We have to show that \(h\) is homotopic rel \(S^{n-1}\) to a map \(h'\) that misses \(B^k\).

By Proposition 2.52 there exists a homeomorphism \(\Phi: [0,1]^n \to \overline{B}^n\). So after precomposing \(h\) with \(\Phi\) we might as well assume that the domain of \(h\) is \([0,1]^n\), i.e. that \(h\) is a map \(h: [0,1]^n \to Z := W \cup_\varphi \overline{B}^k\) with \(h(\partial[0,1]^n) \subset W\).

We pick a polyhedron \(K\), a map \(\tilde{h}: [0,1]^n \to Z\) and a non-empty open subset \(U \subset B^n\) with \(\tilde{h}^{-1}(U) \subset K\) as in the statement of Lemma 38.17. Since \(n < k\) and since \(\tilde{h}|_K: K \to \overline{B}^k\) is piecewise linear we deduce that \(\tilde{h}(K)\) cannot contain the open subset \(U\) of \(B^n\).

We pick a point \(P \in U \cup_\varphi \tilde{h}(K)\). By statement (4) of Lemma 38.17 we know that \(P\) does not lie in the image of \(\tilde{h}: [0,1]^n \to Z\).

As we pointed out on page 549 there exists a deformation retraction from \(\overline{B}^k \setminus \{P\}\) to \(S^{k-1}\). We can extend this deformation retraction via the identity map to a deformation retraction from \(Z = W \cup_\varphi (\overline{B}^k \setminus \{P\})\) to \(W\). If we compose \(\tilde{h}\) with this deformation retraction we obtain a homotopy, rel \(S^{n-1}\), from \(\tilde{h}\) to a map \(h'\) that misses \(B^k\). \(\square\)

Now we can finally provide the proof of Proposition 38.15.

**Proof of Proposition 38.15.** Let \(V\) be a CW-complex and let \(W\) be some topological space. Furthermore let \(\psi: S^{n-1} \to V^{n-1}\) be a map to the \((n-1)\)-skeleton of \(V\) and let \(\varphi: S^{k-1} \to W\) be another map. Finally let

\[ h: V \cup_\psi \overline{B}^n \to W \cup_\varphi \overline{B}^k \]

\(\text{Indeed, since } \tilde{h}|_K: K \to \overline{B}^k\text{ is piecewise linear and since } n < k\text{ we know that the image } \tilde{h}(K)\text{ is set of Lebesgue-measure zero in } B^n\text{ whereas a non-empty open subset has positive Lebesgue-measure.}
be a map with \( h(\psi(S^{n-1})) \subset W \). We suppose that \( n < k \).

We denote by \( \theta \) the obvious map \( \overline{B}^n \to V \cup \psi \overline{B}^n \), furthermore we write \( h = g \circ \theta \). By our hypothesis we have \( h(S^{n-1}) \subset W \). By Lemma 38.18 there exists a homotopy \( G \) rel \( S^{n-1} \) from \( h \) to a map \( h' : \overline{B}^n \to W \) that misses \( B^k \). The desired homotopy is now given by \( F \)\footnote{We view \( V \cup \psi \overline{B}^n \) as a CW-complex where \( V \) is a subcomplex and the image of \( \overline{B}^n \) is an \( n \)-cell. Furthermore we equip \( V \cup \psi \overline{B}^n \) with the product CW-structure. It follows from Lemma 36.8 and Lemma 36.20, applied to the subcomplexes given by \( V \times [0,1] \) and \( \theta(\overline{B}^n) \times [0,1] \), that the map \( F \) is continuous.}:

\[
F : (V \cup \psi \overline{B}^n) \times [0,1] \to W \cup \psi \overline{B}^k,
\]

\[
(P,t) \mapsto \begin{cases} 
G(Q,t), & \text{if } P = \theta(Q), \text{ for some } Q \in \overline{B}^k, \\
g(P), & \text{otherwise}.
\end{cases}
\]

\[
\square
\]

---

**Exercises for Chapter 38**

**Exercise 38.1.** Let \( X \) be a contractible CW-complex and let \( x_0 \in X \). Show that \( X \) admits a deformation retraction to the point \( x_0 \).

*Hint.* Use the Homotopy Extension Theorem 38.1

**Exercise 38.2.** We consider the map

\[
\varphi : S^1 \to S^1,
\]

\[
e^{it} \mapsto \begin{cases} 
e^{3it}, & \text{if } t \in \left[0, \frac{2\pi}{3}\right], \\
e^{-3it}, & \text{if } t \in \left[\frac{2\pi}{3}, \frac{4\pi}{3}\right], \\
e^{3it}, & \text{if } t \in \left[\frac{4\pi}{3}, 2\pi\right].
\end{cases}
\]

Put differently, \( \varphi \) wraps \( S^1 \) first around \( S^1 \) clockwise, then counter clockwise and then once again clockwise. We write \( Y = S^1 \) and we consider

\[
X := Y \cup \varphi \overline{B}^2,
\]

\[\footnote{One might be tempted to use a different approach to show that \( F \) is continuous: Namely one might want to write \((V \cup \psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup \psi \times \text{id}_{[0,1]} (\overline{B}^n \times [0,1]) \) and then argue using Lemma 38.14 (5) that the given map is continuous. But this approach is problematic since it is not clear that the two topologies on \((V \cup \psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup \psi \times \text{id}_{[0,1]} (\overline{B}^n \times [0,1]) \) agree.}

\textbf{Figure 659. Illustration for the proof of Proposition 38.15}
where we identify \( z \in \partial B^2 = S^1 \) with \( \varphi(z) \in S^1 = Y \).

(a) Show that \( X \) is homotopy equivalent to \( B^2 \).
(b) Is \( X \) homeomorphic to \( B^2 \)?

**Exercise 38.3.** Let \( X \) be a CW-complex which admits a single 0-cell. Show that every subcomplex \( Y \) of \( X \) is path-connected.

**Exercise 38.4.** Let \( X \) be a CW-complex. Use the Cellular Approximation Theorem 38.13 to give a direct proof that if \( X \) is path-connected, then its 1-skeleton \( X^1 \) is also path-connected.

*Remark.* We gave a roundabout proof of this statement in Proposition 36.10 (7).
39. Cofibrations (*)

One of the most useful properties of CW-complexes is the Homotopy Extension Theorem \[38.1\] which says that any homotopy on a subcomplex can be extended to a homotopy of the total CW-complex. In this chapter we will discuss several consequences of this property. In fact, since the “homotopy extension property” arises in many other settings we first formalize this concept by introducing the notion of a “cofibration”. Afterwards we will prove properties of cofibrations, which will in particular apply to CW-complexes. For the most part the results in this chapter are not essential for the understanding of the subsequent chapters, thus not much harm is done by initially skipping this chapter.

Throughout this chapter we will on numerous occasions make use of the notion of a mapping cylinder and of a mapping cone. Thus we start out by recalling the definition of a mapping cylinder and a mapping cone that we had initially given on pages \[697\] and page \[701\].

Definition. Let \( f : X \to Y \) be a map between topological spaces. We define the corresponding \textit{mapping cylinder} to be the topological space

\[
\text{Cyl}(f) := (\{(X \times [0, 1]) \sqcup Y\}) / \sim \quad \text{where} \quad (x, 1) \sim f(x) \text{ for all } x \in X.
\]

We refer to the maps

\[
X \xrightarrow{i} \text{Cyl}(f) \quad \text{respectively} \quad \text{Cyl}(f) \xrightarrow{r} Y
\]

\[
P \mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q, t)] \text{ with } Q \in X, t \in [0, 1], \end{cases}
\]

as the \textit{natural inclusion} respectively the \textit{natural retraction}.

![Figure 660](image)

\[
\text{Definition. Given a map } f : A \to X \text{ between topological spaces the corresponding \textit{mapping cone} is defined as}
\]

\[
\text{Cone}(f : A \to X) := (A \times [0, 1]) \sqcup X / \sim \quad \text{where} \quad (a, 0) \sim (b, 0) \text{ for all } a, b \in A \text{ and} \quad (a, 1) \sim f(a) \text{ for all } a \in A.
\]

We refer to the point \([A \times \{0\}] \in \text{Cone}(f)\) as the \textit{cone point}. We illustrate the definition for an inclusion map \(i : A \to X\) in Figure \[661\].

39.1. Cofibrations: definition and examples. Now we introduce the leading contender for our attention in this chapter.

\textsuperscript{642}Note that by Lemma \[24.8\] we know that there exists a deformation retraction \(R : \text{Cyl}(f) \times [0, 1] \to \text{Cyl}(f)\) from \(\text{Cyl}(f)\) to \(Y\), viewed as a subspace of \(\text{Cyl}(f)\), such that \(R_1 = r\).
Definition.

(1) A map $i: A \to X$ between topological spaces is called a cofibration if it has the homotopy extension property, i.e. if given any topological space $Y$ and any two maps $f: X \times \{0\} \to Y$ and $G: A \times [0,1] \to Y$ with $f(i(a),0) = G(a,0)$ for all $a \in A$ there exists a map $F: X \times [0,1] \to Y$ such that the following diagram commutes:

$$
\begin{array}{ccc}
A \times \{0\} & \longrightarrow & A \times [0,1] \\
\downarrow i & & \downarrow i \times \text{id} \\
X \times \{0\} & \leftarrow & X \times [0,1].
\end{array}
$$

We illustrate the definition in Figure 662.

(2) If $i: A \to X$ is a cofibration such that $i(A)$ is a closed subset of $X$, then we refer to $i$ as a closed cofibration.

Remark.

(1) As we will see in Lemma 39.8 in most cases of interest the map $i: A \to X$ is for all intents and purposes an inclusion. For such situations the definition of the homotopy extension property is illustrated in Figure 662.

(2) In some books what we call a cofibration is called a “Hurewicz cofibration”. Also, in some books, see e.g. [Pic92], a cofibration is defined as what we call a closed cofibration.

The following theorem gives us one of the most important examples of a cofibration.

**Theorem 39.1.** Let $X$ be a CW-complex. Given any subcomplex $A$ the corresponding inclusion map $i: A \to X$ is a closed cofibration.
Proof. The statement of the Homotopy Extension Theorem 38.1 is precisely that the inclusion $A \to X$ is a cofibration. By Lemma 36.18 (2) we know that the cofibration is in fact a closed cofibration. ■

We continue with the following fairly elementary lemma which will be proved in Exercise 39.2

**Lemma 39.2.** If $f: X \to Y$ and $g: Y \to Z$ are two (closed) cofibrations, then the composition $g \circ f: X \to Z$ is also a (closed) cofibration.

Before we give more examples of cofibrations it is convenient to add a characterization of cofibrations to our repertoire.

**Lemma 39.3.** If $i: A \to X$ is a map between two topological spaces, then the following two statements are equivalent:

1. The map $i: A \to X$ is a cofibration.
2. The map

$$s: \text{Cyl}(i) \to X \times [0, 1]$$

$$P \mapsto \begin{cases} (i(a), 1-t), & \text{if } P = [(a, t)] \text{ with } a \in A \text{ and } t \in [0, 1], \\ (P, 0), & \text{if } P \in X \end{cases}$$

admits a left-inverse, in other words, there exists a map $r: X \times [0, 1] \to \text{Cyl}(i)$ such that $r \circ s = \text{id}_{\text{Cyl}(i)}$.

If $A$ is a subset of $X$ and if $i: A \to X$ is the inclusion map, then (1) and (2) are equivalent to

3. The set $\{X \times \{0\}\} \cup (A \times [0, 1])$ is a retract of $X \times [0, 1]$.

**Example.** Let $I$ be an interval in $\mathbb{R}$ and let $P_1, \ldots, P_k$ be finitely many distinct points in $I$. In Figure 663 we show a retraction from $I \times [0, 1]$ to $(I \times \{0\}) \cup \{\{P_1, \ldots, P_k\} \times [0, 1]\}$. Together with Lemma 39.3 this shows that the inclusion $\{P_1, \ldots, P_k\} \to I$ is a cofibration.

![Figure 663](image)

Proof (*). First we prove the "(1) $\Rightarrow$ (2)"-direction. Thus we now suppose that the map $i: A \to X$ is a cofibration. We consider the inclusion map $j: X \times \{0\} \to \text{Cyl}(i)$ which is given by $j(x, 0) = x$ and we consider the map

$$G: A \times [0, 1] \to \text{Cyl}(i)$$

$$(a, s) \mapsto [(a, 1-s)].$$

\[643\] It follows from Lemma 3.44 (5) that this map is continuous.
We obtain the following diagram:

\[
\begin{array}{ccc}
A \times \{0\} & \xrightarrow{\ i \ } & X \times \{0\} \\
\downarrow & & \downarrow \\
A \times [0,1] & \xrightarrow{\ G \ } & X \times [0,1]
\end{array}
\]

One easily verifies that the black diagram commutes. Since \( i: A \to X \) is a cofibration we obtain a map \( r: X \times [0,1] \to \text{Cyl}(i) \) which makes the diagram commute. It is straightforward to verify that \( r \circ s = \text{id}_{\text{Cyl}(i)} \).

The proof of the converse, i.e. the proof of the “(2) \implies (1)”-direction is also quite straightforward. We will provide the proof in Exercise 39.3.

Now we assume that \( A \) is a subset of \( X \) and that \( i: A \to X \) is the inclusion map. We need to provide the proof for the equivalence of (2) and (3). This turns out to be quite subtle.

(a) First we assume that \( A \) is a closed subset of \( X \). Note that the image of \( \text{Cyl}(i) \) in \( X \times [0,1] \) under the map \( s \) is precisely \( (X \times \{0\}) \cup (A \times [0,1]) \). Thus we have the following commutative diagram

\[
\begin{array}{ccc}
\text{Cyl}(i) & \xrightarrow{\ s \ } & (X \times \{0\}) \cup (A \times [0,1]) \\
& \downarrow & \downarrow \\
& X \times [0,1]. &
\end{array}
\]

To show that (2) and (3) are equivalent it suffices to show that the top horizontal map is a homeomorphism. It is basically clear that the top horizontal map is a bijection. Furthermore it follows easily from Lemma 3.44 (5) that the map is continuous. Finally it follows from our hypothesis that \( A \) is a closed subset, together with Lemma 24.7 (2), that the top horizontal map is indeed a homeomorphism.

(b) The logic of (a) breaks down if \( A \) is not a closed subset. More precisely, in Lemma 24.7 (3) we saw that in general the top horizontal map is not a homeomorphism. Rather surprisingly it is nonetheless true that (2) and (3) are equivalent. This delicate argument is given in \cite{Str68}, Lemma 4 or alternatively in \cite{Hat02}, Proposition A.18.

Lemma 39.3 allows us to prove the following proposition which gives us many more examples of cofibrations.

**Proposition 39.4.** Let \( M \) be a smooth manifold.

1. For any a union \( W \) of components of \( \partial M \) the inclusion \( i: W \to M \) is a closed cofibration.
2. For any compact proper submanifold \( N \) of \( M \) the inclusion \( i: N \to M \) is a closed cofibration.

\footnote{This is also the only case we will ever need in practice.}
The proof of Proposition 39.4 relies on the following lemma.

**Lemma 39.5.** There exists a retraction

$$
\rho: [0, 1] \times [0, 1] \to (\{0\} \times [0, 1]) \cup ([0, 1] \times \{0\})
$$

that has the property that $$\rho(\{1\} \times [0, 1]) = \{(1, 0)\}.$$\[6]

**Proof.** In Figure 664 we show how such a retraction $$\rho$$ can be constructed. \[6\]

![retraction rho](image)

**Figure 664. Illustration for the proof of Lemma 39.5.**

**Sketch of a proof of Proposition 39.4.** Let $$M$$ be an $$m$$-dimensional smooth manifold. Recall that in Lemma 39.5 we saw that there exists a retraction

$$\varphi = (\varphi_1, \varphi_2): [0, 1] \times [0, 1] \to (\{0\} \times [0, 1]) \cup ([0, 1] \times \{0\})$$

that has the property that $$\varphi(\{1\} \times [0, 1]) = \{(1, 0)\}.$$

(1) Let $$W$$ be a union of components of $$\partial M$$. Our goal is to show that the inclusion

$$i: W \to M$$

is a cofibration. By the Collar Neighborhood Theorem 8.12 there exists a collar neighborhood $$[0, 1] \times W$$. We consider the map\[6\]

$$r: M \times [0, 1] \to \text{Cyl}(i) = ((W \times [0, 1]) \cup M) / \sim \text{ where } (x, 1) \sim x \text{ for } x \in W$$

$$\begin{cases}
(P, t) \mapsto (z, \varphi_1(s, t), \varphi_2(s, t)), & \text{if } P = (s, Q) \text{ with } s \in [0, 1] \text{ and } Q \in W,

P, & \text{if } P \notin [0, 1] \times W.
\end{cases}$$

(We refer to Figure 665 for an illustration of the map $$r$$.) One can easily verify that $$r$$ is a left-inverse to the map $$s: \text{Cyl}(i) \to M \times [0, 1]$$ that we had considered in Lemma 39.3 (2). Thus it follows from Lemma 39.3 that $$i: W \to M$$ is a cofibration. Finally it follows from Proposition 6.27 (3a) that $$i$$ is in fact a closed cofibration.

![retraction r](image)

**Figure 665. Illustration of the proof of Proposition 39.4 (1).**

\[6\]Recall that by definition of a collar neighborhood the set $$[0, 1] \times \partial M$$ is actually a closed subset of $$M$$. It now follows from this observation together with Lemma 8.11 and Lemma 2.35 (2) that the map $$r$$ is indeed continuous.
39. COFIBRATIONS (*)

(2) Let \( N \) be a compact proper \( n \)-dimensional submanifold of \( M \). We want to show that the inclusion \( j: N \to M \) is a cofibration. By the General Tubular Neighborhood Theorem \[10.5\] the submanifold \( N \) admits a tubular neighborhood. To simplify the discussion we will only treat the case that \( N \) admits a trivial tubular neighborhood \( \mathcal{B}^{m-n} \times N \). The general case is notationally more messy since we have to work with a trivialization of the tubular neighborhood, similar to the argument in the proof of Proposition \[10.11\]. We leave it to the doubting Thomases among the readership to deal with the general case.

We consider the map\[646\]
\[
r: M \times [0, 1] \to Cyl(j) = ((N \times [0, 1]) \sqcup M)/ \sim \text{ where } (x, 1) \sim x \text{ for } x \in N
\]
\[
(P, t) \mapsto \begin{cases} 
((z, \varphi_1(|z|, t), Q), \varphi_2(|z|, t)), & \text{if } P = (z, Q) \text{ with } z \in \mathcal{B}^{m-n} \text{ and } Q \in N, \\
\mathcal{B}^{m-n} \times N & \text{if } P \notin \mathcal{B}^{m-n} \times N.
\end{cases}
\]

(We refer to Figure 666 for an illustration of the map \( r \).) As in the proof of (1) we conclude from Lemma 39.3 that \( j: N \to M \) is a cofibration. Since \( N \) is assumed to be compact it is a closed subset by Lemma 2.17 (2).

\[\text{Figure 666. Illustration of the proof of Proposition 39.4 (2).}\]

The next proposition gives another rich source of examples of cofibrations.

**Proposition 39.6.**

1. If \( f: X \to Y \) is a map between two topological spaces, then the natural inclusion \( i: X \to Cyl(f) \) is a closed cofibration.
2. Let \( X \) be a non-empty topological space. The natural inclusion \( X \to \text{Cone}(X) \) is a closed cofibration.

Proof. Note that if \( X \) is a non-empty topological space and \( f: X \to \{\ast\} \) is the constant map, then, as we pointed out on page 698, the mapping cylinder \( Cyl(f) \) is basically the cone of \( X \). Thus we see that Statement (2) is a special case of Statement (1).

\[646\] It follows from the definition of a tubular neighborhood, see page 418 together with Lemma 2.35 (2) and Lemma 89.1 that the map \( r \) is indeed continuous.
It remains to prove Statement (1). Let \( f : X \to Y \) be a map between topological spaces. By Lemma 24.6 (4) we know that the image of \( X \) in \( \text{Cyl}(f) \) is a closed subset. Thus it remains to show that \( i : X \to \text{Cyl}(f) \) is a cofibration. By Lemma 24.6 (3) the map \( i \) is an embedding, thus we can identify \( X \) with its image in \( \text{Cyl}(f) \).

By Lemma 39.3 (3)⇒(1) it suffices to prove the following claim:

**Claim.** There is a retraction \( r \) from \( \text{Cyl}(f) \times [0, 1] \) to its subset \( (\text{Cyl}(f) \times \{0\}) \cup (X \times [0, 1]) \).

In Figure 668 we do our best to illustrate the objects involved. To construct the desired retraction \( r \) we recall that in Lemma 39.3 we saw that there exists a retraction

\[
s : [0, 1] \times [0, 1] \to (\{0\} \times [0, 1]) \cup ([0, 1] \times \{0\})
\]

that has the property that \( s(\{1\} \times [0, 1]) = \{(1, 0)\} \). Now the desired retraction is given by the map

\[
r : \text{Cyl}(f) \times [0, 1] \to (\text{Cyl}(f) \times \{0\}) \cup (X \times [0, 1])
\]

\[
P \mapsto \begin{cases} 
([x, s(t, u)]), & \text{if } P = ([x, t, u]) \text{ with } x \in X \text{ and } t, u \in [0, 1], \\
([y, 0]), & \text{if } P = ([y, u]) \text{ with } y \in Y \text{ and } u \in [0, 1].
\end{cases}
\]

We conclude this section with a proposition which says that any map \( f : X \to Y \) between topological spaces can be “replaced” by a cofibration \( X \to \text{Cyl}(f) \).

**Proposition 39.7.** Let \( f : X \to Y \) be a map between topological spaces. We denote by \( i : X \to \text{Cyl}(f) \) the natural inclusion. The natural retraction \( r : \text{Cyl}(f) \to Y \) is a homotopy equivalence and the following diagram commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{i} & \text{Cyl}(f) \\
\downarrow{f} & & \downarrow{r} \\
Y & \xleftarrow{r} & \text{Cyl}(f) \\
\end{array}
\]

By Proposition 39.6 (1) we know that the left diagonal map \( i : X \to \text{Cyl}(f) \) is a cofibration.

**Proof.** We showed in Lemma 24.8 (2a) that the natural retraction \( r : \text{Cyl}(f) \to Y \) is a homotopy equivalence. It is clear that the given diagram commutes. Thus we are done by Proposition 39.6 (1). That was quick.

\[\text{This map is continuous by Lemma 2.35 (2).}\]
39.2. **Properties of cofibrations.** The following lemma summarizes a few key properties of cofibrations.

**Lemma 39.8.** If \( i: A \to X \) is a cofibration, then the following three statements hold:

1. the map \( i: A \to X \) is injective,
2. the map \( i: A \to X \) is an embedding,
3. if \( X \) is Hausdorff, then \( i(A) \) is a closed subset of \( X \), i.e. \( i \) is a closed cofibration.

**Remark.** In Exercise 39.5 we will see that in Lemma 39.8 (3) we cannot drop the hypothesis that \( X \) is Hausdorff.

**Proof.** Let \( i: A \to X \) be a cofibration.

1. Similar to the proof of Lemma 39.3 we consider the inclusion map \( j: X \times \{0\} \to Cyl(i) \) which is given by \( j(x, 0) = x \) and we consider the map

\[
G: A \times [0, 1] \to Cyl(i) \\
(a, s) \mapsto [(a, 1 - s)].
\]

We obtain the following diagram:

\[
\begin{array}{ccc}
A \times \{0\} & \xrightarrow{i} & A \times [0, 1] \\
\downarrow{j} & & \downarrow{G} \\
X \times \{0\} & \xleftarrow{F} & X \times [0, 1].
\end{array}
\]

One easily verifies that the black diagram commutes. Since \( i \) is a cofibration we obtain a map \( F: X \times [0, 1] \to Cyl(i) \) which makes the diagram commute. Note that by design for any \( t \in (0, 1) \) the map \( G: A \times \{t\} \to Cyl(i) \) is injective. Since the diagram commutes this implies that \( i \times \text{id}_{\{t\}}: A \times \{t\} \to X \times \{t\} \) is also injective, i.e. \( i: A \to X \) is injective.

2. We continue with the argument and the notation in (1). Let \( t \in (0, 1] \). The map \( G|_{A \times \{t\}}: A \times \{t\} \to A \times \{1 - t\} \) is evidently a homeomorphism. Thus we see that

\[
(G|_{A \times \{t\}})^{-1} \circ F|_{X \times \{t\}}: i(A) \times \{t\} \to A \times \{t\}
\]

is an inverse to the map \( i \times \text{id}_{\{t\}}: A \times \{t\} \to X \times \{t\} \). This implies that the map \( i \times \text{id}_{\{t\}}: A \times \{t\} \to X \times \{t\} \) is an embedding, but this also implies that the map \( i: A \to X \) is an embedding.
(3) Note that for $x \in A$ we have $F(x, 0) = G(x, 0) = [(x, 1)] = [x]$ by construction of $F$, furthermore for $x \not\in A$ the point $[x]$ does not lie in $\text{Cyl}(i)$, thus it does not lie in the image of $F$

$$A = \{x \in X \mid F(x, 0) = [x]\} = \{\text{the points in } X \text{ on } X \to \text{Cyl}(i) \text{ and } x \mapsto [x] \text{ agree}\}.$$ 

It follows from this description of $A$, our hypothesis that $X$ is Hausdorff (which implies by (2) and Lemma 24.6 (2) that $\text{Cyl}(i)$ is also Hausdorff) and Exercise 2.30 that $A$ is indeed a closed subset of $X$. ■

The following lemma shows that inclusion maps that are cofibrations are particularly nicely behaved.

**Lemma 39.9.** Let $X$ be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i: A \to X$ the inclusion map. If $i$ is a closed cofibration, then the following three statements hold:

1. The map $\varphi: \text{Cone}(i): A \to X \to X/A$

   $$P \mapsto \begin{cases} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a, t)] \text{ with } a \in A \text{ and } t \in [0, 1] \end{cases}$$

   is a homotopy equivalence.

2. If $A$ is contractible, then the projection map $X \to X/A$ is a homotopy equivalence.

3. If $a_0 \in A$ is a point such that $\{a_0\}$ is a deformation retract of $A$, then the projection map $X \to X/A$ is a homotopy equivalence between the pointed topological spaces $(X, a_0)$ and $(X/A, [A])$.

**Remark.** The statement of Lemma 39.9 (2) is related in spirit to the statement of Proposition 38.5.

**Proof.** Let $X$ be a topological space and let $A \subset X$ be a closed subset such that the inclusion $i: A \to X$ is a cofibration.

1. Similar to the proof of Lemma 39.8 (1) we consider the following two maps:

   (a) First of all we consider the obvious inclusion map $j: X \times \{0\} \to \text{Cone}(i)$ which is given by $j(x, 0) = x$.

   (b) We consider the map

   $$G: A \times [0, 1] \to \text{Cone}(i)$$

   $$(a, s) \mapsto [(a, 1 - s)].$$

   Note that $G_1$ sends all points in $A$ to the cone point.

---

648 It follows from the ever popular Lemma 2.35 (2) and the fact that $A$ is a closed subset of $X$ that the map $\varphi$ is continuous.
We obtain the following diagram:

\[
\begin{array}{ccc}
A \times \{0\} & \xleftarrow{\delta} & A \times [0, 1] \\
\downarrow{i} & & \downarrow{G} \\
X \times \{0\} & \rightarrow & X \times [0, 1].
\end{array}
\]

One easily verifies that the diagram commutes. Since \(i\) is a cofibration we obtain a map \(F_1: X \rightarrow \text{Cone}(i)\) which makes the diagram commute. Note that the map \(F_1\) descends to a map \(\psi: X/A \rightarrow \text{Cone}(i)\). It remains to prove the following claim.

Claim. The maps \(\varphi: \text{Cone}(i) \rightarrow X/A\) and \(\psi: X/A \rightarrow \text{Cone}(i)\) are homotopy inverses of one another.

Note that \(F(A \times [0, 1]) = G(A \times [0, 1]) \subset A\). Therefore it follows from Lemma 18.21 that the map

\[
H: (X/A) \times [0, 1] \xrightarrow{([x,t]) \mapsto [F(x,t)]} (X \times [0, 1]) / (A \times [0, 1]) \xrightarrow{[(x,t)] \mapsto [F(x,t)]} X/A
\]

is continuous. It follows immediately from the definitions that \(H\) is a homotopy between \(\text{id}_{X/A}\) and \(\varphi \circ \psi\).

Conversely we consider the map

\[
H: \text{Cone}(i) \times [0, 1] \rightarrow \text{Cone}(i), \quad (P,s) \mapsto \begin{cases} F(P,s), & \text{if } P \in X, \\ [a, (1-s) \cdot t], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1]. \end{cases}
\]

One easily verifies that this is a homotopy from \(\text{id}_{\text{Cone}(i)}\) to \(\psi \circ \varphi\).

(2) We consider the following diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\varphi} & \text{Cone}(i: A \rightarrow X) \\
\downarrow{i} & & \downarrow{\varphi} \\
X/A & & \text{Cone}(i: A \rightarrow X)
\end{array}
\]

It follows immediately from the definition of \(\varphi\) that this diagram commutes. Now suppose that \(A\) is contractible. By Proposition 24.15 (1) there exists a deformation retraction \(G\) from \(\text{Cone}(i: A \rightarrow X)\) to \(X\). By statement (1) we know that \(\varphi\) is a homotopy equivalence. Thus it follows from Lemma 18.11 (1) that the map \(X \rightarrow X/A\) is a homotopy equivalence.

(3) Now assume that \(a_0 \in A\) is a point which has the property that \(\{a_0\}\) is a deformation retract of \(A\). By Proposition 24.15 (2) there exists a deformation retraction \(G\) from \(\text{Cone}(i: A \rightarrow X)\) to \(X\) such that for any \(t \in [0,1]\) we have \(G_1([(a_0,t)]) = a_0\). Also note that the homotopy equivalence \(H\) from (1) has the property that \(H(a_0,t) = [(a_0,1-t)]\). If one combines these observations with the argument in (2) it is not
difficult to see that the projection map is in fact a homotopy equivalence of the pointed topological spaces \((X, a_0)\) and \((X/A, [a_0])\).

The following corollary is quite useful.

**Corollary 39.10.** Let \(X\) be a CW-complex and let \(A \subseteq X\) be a subcomplex.

1. If \(A\) is contractible, then the projection map \(X \to X/A\) is a homotopy equivalence.
2. If \(a_0 \in A\) is a point such that \(\{a_0\}\) is a deformation retract of \(A\), then the projection map \(X \to X/A\) is a homotopy equivalence between the pointed topological spaces \((X, a_0)\) and \((X/A, [A])\).

**Remark.** Corollary 39.10 (1) is a generalization of Proposition 37.8.

**Proof.** By Theorem 39.1 we know that the inclusion \(A \to X\) is a closed cofibration. The two statements now follow immediately from the corresponding statements in Lemma 39.9.

The following proposition is a neat corollary to Corollary 39.10.

**Proposition 39.11.** Let \(X\) be a 0-connected CW-complex.

1. There exists a contractible 1-dimensional subcomplex \(T\) which contains all 0-cells.
2. Given any \(T\) as in (1) the quotient \(X/T\) is a CW-complex with precisely one 0-cell. Furthermore the projection \(X \to X/T\) is a homotopy equivalence.

**Remark.**

1. Using Proposition 37.11 it is very easy to calculate the fundamental group of a finite 0-connected CW-complex with a single 0-cell. Proposition 39.11 says in particular that given a finite 0-connected CW-complex we can always reduce the calculation of the fundamental group to the case of a finite CW-complex with a single 0-cell.
2. Let \(X\) be a 0-connected CW-complex with countably many 1-cells. Let \(x_0 \in X\) be a 0-cell. By Proposition 10.9 the inclusion \(X^1 \to X\) of the 1-skeleton induces an epimorphism \(\pi_1(X^1, x_0) \to \pi_1(X, x_0)\). Furthermore it follows from Proposition 39.11 and 20.7 that \(\pi_1(X^1, x_0)\) is a free group on a countable generating set. It follows from this discussion, together with Lemma 1.7 (2), that \(\pi_1(X, x_0)\) is countable.

\[\text{Figure 671. Illustration of Proposition 39.11}\]
39. COFIBRATIONS (*)

**Proof.** Let $X$ be a 0-connected CW-complex.

1. In Proposition 37.7 (1) we showed that the 1-skeleton $X^1$ admits a subcomplex $T$ that contains all 0-cells of $X$ and that admits a deformation retraction to $x_0$.

2. By Lemma 36.32 the quotient $X/T$ admits a CW-structure with one 0-cell. Furthermore note that it follows from Corollary 39.10 (2) that the projection map $X \to X/T$ is a homotopy equivalence between.

### 39.3. Products and cofibrations (*). In this and the following two sections we collect several technical useful results on cofibrations. As stand-alone sections these are arguably not much fun to read. Thus it is better to move on and to come back to these three sections when the results are needed.

**Proposition 39.12.**

1. If $f: A \to X$ and $g: B \to Y$ are two (closed) cofibrations, then the product map $f \times g: A \times B \to X \times Y$ is also a (closed) cofibration.

2. If $f: A \to X$ is a (closed) cofibration and if $Z$ is a topological space, then the resulting map $f \times \text{id}_Z: A \times Z \to X \times Z$ is also a (closed) cofibration.

**Example.** Let $I$ be an interval and let $P \in I$. On page 1024 we saw that the inclusion $\{P\} \to I$ is a cofibration. It follows from Proposition 39.12 that given any topological space $Z$ the inclusion $\{P\} \times Z \to I \times Z$ is a cofibration.

**Proof.** It is clear that Statement (2) is an immediate consequence of Statement (1). Thus it remains to prove Statement (1). Now let $f: A \to X$ and $g: B \to Y$ be two cofibrations.

By Lemma 39.8 we can assume that $f: A \to X$ and $g: B \to Y$ are both inclusions. Note that by Lemma 39.3 (1) $\Rightarrow$ (3) there exist retraction $r: X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1])$ and $s: Y \times [0,1] \to (Y \times \{0\}) \cup (B \times [0,1])$. We denote by $r = (r_x, r_{[0,1]})$ the coordinate functions of $r$ viewed as a map with values in $X \times [0,1]$. Similarly we define $s = (s_y, s_{[0,1]})$.

Next we consider the map

$$(X \times Y) \times [0,1] \to ((X \times Y) \times \{0\}) \cup ((A \times B) \times [0,1])$$

$$(x,y,t) \mapsto \begin{cases} (r_x(x,t), s_y(y,t)) & \text{if } x \in X \times Y \land t \in [0,1] \\ (r_{[0,1]}(x,t) + s_{[0,1]}(y,t)) & \text{if } x \in [0,1] \end{cases}$$

One can easily verify that this map is a retraction. It follows from Lemma 39.3 (3) $\Rightarrow$ (1) that $f \times g: A \times B \to X \times Y$ is indeed a cofibration.

If $f$ and $g$ are in fact closed cofibrations, then it follows from Lemma 3.9 (1) and the above that $f \times g$ is also a closed cofibration.

We continue with the following characterisation of closed cofibrations [Strø66, Strø68].

**Theorem 39.13.** Let $X$ be a topological space and let $A$ be a closed subset. The following two statements are equivalent:

1. The inclusion $i: A \to X$ is a cofibration.

2. There exists a map $\phi: X \to [0,1]$ such that $A = \phi^{-1}(\{0\})$ and there exists a homotopy $H: X \times [0,1] \to X$ rel $A$ such that $H_0 = \text{id}_X$ and such that $H(x,t) \in A$ whenever $t > \phi(x)$. 
Remark.

(1) We continue with the notation of the above Theorem 39.13. We consider the open subset $U := \phi^{-1}((0,1))$. The homotopy $H$ restricts to a homotopy $K: U \times [0,1] \to X$ rel $A$ with $K_0 = \text{id}$ and with $K_1(U) \subset A$. This almost sounds like $A$ is a deformation retract of $U$, but the given situation is somewhat looser, since $K$ can take values outside of $U$.

(2) Sometimes a topological space $X$ together with a closed subset $A$ that admit $H$ and $\phi$ as in Theorem 39.13 (2) is called a neighborhood deformation retract pair, or short, NDR-pair.

(3) Let $X$ be a topological space and let $x_0 \in X$. The pointed space $(X, x_0)$ is called well-pointed if the inclusion $\{x_0\} \to X$ is a cofibration. If $(X, x_0)$ is well-pointed, then in most practical situations the point $x_0 \in X$ is good in the sense of the definition on page 604. Nonetheless, as discussed in

https://mathoverflow.net/questions/87387/

it is not necessarily the case that $x_0$ is good.

Example. Let $M$ be a manifold. By the Collar Neighborhood Theorem 8.12 we can pick a collar neighborhood $[0,2] \times \partial M$. We consider the maps

$$
\phi: M \to [0,1] \\
P \mapsto \begin{cases} 
    s, & \text{if } P = (Q, s) \text{ with } Q \in \partial M \text{ and } t \in [0,1], \\
    1, & \text{otherwise}
\end{cases}
$$

and

$$
F: M \times [0,1] \to M \\
(P,t) \mapsto \begin{cases} 
    (Q, \frac{2(s-t)}{2-t}), & \text{if } P = (Q, s) \text{ with } Q \in \partial M \text{ and } s \in [t,2], \\
    (Q,0), & \text{if } P = (Q, s) \text{ with } Q \in \partial M \text{ and } s \in [0,t], \\
    P, & \text{otherwise.}
\end{cases}
$$

(Both maps are illustrated, to the best of the author's abilities, in Figure 673) One can easily verify that the conditions of Theorem 39.13 are satisfied. This gives basically a new proof of Proposition 39.4 (1).

Proof (*). First we deal with the "(1)⇒(2)"-direction. Thus we suppose that $i: A \to X$ is a cofibration. Note that by Lemma 39.3 (1)⇒(3) we know that there exists a retraction $r: X \times [0,1] \to (X \times \{0\}) \cup (A \times [0,1])$. We denote the two coordinate functions of $r$, viewed
as a map with values in \( X \times [0, 1] \), by \( r_X : X \times [0, 1] \to X \) and \( r_{[0,1]} : X \times [0, 1] \to [0, 1] \). We consider the following two maps:

\[
\phi : X \to [0, 1] \\
x \mapsto \max_{t \in [0,1]} |t - r_{[0,1]}(x,t)| \quad \text{and} \quad H : X \times [0, 1] \to X \\
(x,t) \mapsto r_X(x,t).
\]

Note that by definition of a retraction we have \( H_0 = \text{id}_X \).

**Claim.** The map \( \phi \) is well-defined and continuous.

First we consider the map \( \theta : X \times [0, 1] \to [0, 1] \) that is given by \( \theta(x,t) := |t - r_{[0,1]}(x,t)| \). Since \([0, 1]\) is compact and since \( \theta \) is continuous we obtain from Lemma 2.40 (2) that \( \theta \) assumes a maximum, hence \( \phi \) is well-defined.

It remains to show that \( \phi : X \to [0, 1] \) is continuous. Let \( V \) be an open subset of \([0, 1]\). By Lemma 2.5 it suffices to show that given any \( x_0 \in \phi^{-1}(V) \) there exists an open neighborhood \( U \) of \( x_0 \) with \( U \subset \phi^{-1}(V) \). First we consider the case that \( \phi(x_0) \in (0, 1) \). This implies that we can pick \( \epsilon > 0 \) such that \((\phi(x_0) - \epsilon, \phi(x_0) + \epsilon) \subset V \). Note that by definition of \( \phi \) and \( \theta \) we have \( \theta(\{x_0\} \times [0, 1]) \subset [0, \phi(x_0)] \). Since \([0, 1]\) is compact and since \([0, \phi(x_0) + \epsilon]\) is an open subset of \([0, 1]\) we obtain from Exercise 3.6 that there exists an open neighborhood \( U_1 \) of \( x_0 \) in \( X \) such that

\[
\{x_0\} \times [0, 1] \subset U_1 \times [0, 1] \subset \theta^{-1}((0, \phi(x_0) + \epsilon)).
\]

Hence, for every \( x \in U_1 \) we have \( \phi(x) \leq \phi(x_0) + \epsilon \). Next suppose we are given \( t_0 \in [0, 1] \) such that \( \theta(x_0, t_0) \in (\phi(x_0) - \epsilon, \phi(x_0) + \epsilon) \). By definition of the product topology there exists an open subset \( U_2 \subset X \) such that

\[
(x_0, t_0) \in U_2 \times \{t_0\} \subset \theta^{-1}((\phi(x_0) - \epsilon, \phi(x_0) + \epsilon)).
\]

Note that this implies that for every \( x \in U_2 \) we have \( \phi(x) \geq \phi(x_0) - \epsilon \). In particular we see that \( U_1 \cap U_2 \subset \phi^{-1}((\phi(x_0) - \epsilon, \phi(x_0) + \epsilon)) \subset V \). Basically the same argument also works if \( \phi(x_0) = 0 \) or \( \phi(x_0) = 1 \).

**Claim.** We have \( A = \phi^{-1}(0) \).

First let \( x \in A \). Since \( r \) is a retraction we know that \( r(x,t) = (x,t) \) for all \( t \in [0,1] \). This means that \( r_{[0,1]}(x,t) = t \) for all \( t \in [0,1] \). Thus we see that \( \phi(x) = 0 \). Conversely, suppose that we have \( x \in X \) with \( \phi(x) = 0 \). One easily verifies that this implies that for every \( t > 0 \) we have \( r(x,t) \in A \times [0,1] \), in other words, we have \( \{x\} \times (0, 1] \subset r^{-1}(A \times [0,1]) \).
Since \( A \times [0, 1] \) is a closed subset of \( X \times [0, 1] \) it follows from elementary arguments, see e.g. Exercise \( \Box[2.11] \) (a), that \( \{x\} \times [0, 1] \) also belongs to \( r^{-1}(A \times [0, 1]) \). But this implies that \( x \in A \).

It remains to prove the following claim.

**Claim.** Given \((x, t) \in X \times [0, 1] \) with \( t > \phi(x) \) we have \( H(x, t) \in A \).

So suppose we are given \((x, t) \in X \times [0, 1] \) with \( t > \phi(x) \). Note that this implies that \( t > \phi(x) \geq |t - r_{[0,1]}(x, t)| \). This is only possible if \( r_{[0,1]}(x, t) > 0 \). Thus we see that \( r(x, t) \in A \times [0, 1] \). This implies that \( H(x, t) \in A \). This concludes the proof of the claim and thus completes the proof of the “\((2) \Rightarrow (1)\)”-direction.

Finally we provide the proof for the “\((1) \Rightarrow (2)\)”-direction. Given \( \phi: X \to [0, 1] \) and the homotopy \( H: X \times [0, 1] \to X \) we consider the map

\[
  r: X \times [0, 1] \to (X \times \{0\}) \cup (A \times [0, 1])
  \quad (x, t) \mapsto (H(x, t), \max\{t - \phi(x), 0\}).
\]

One can easily verify that this map is indeed a retraction. Thus it follows from Lemma \( \Box[39.3] \) (3) \( \Rightarrow \) (1) that the inclusion \( i: A \to X \) is a cofibration. \( \Box \)

**Proposition 39.14.** Let \( A \subset X \) and \( B \subset Y \) be subsets of topological spaces. If the inclusion maps \( i: A \to X \) and \( j: B \to Y \) are closed cofibrations, then the inclusion map

\[
  (A \times Y) \cup (X \times B) \to X \times Y
\]

is also a closed cofibration.

**Remark.** In Exercise \( \Box[39.6] \) we will see that the conclusion of Proposition \( \Box[39.14] \) does not hold, if neither \( A \) nor \( B \) are closed subsets.

**Proof.** Since \( i \) and \( j \) are closed cofibrations we can pick maps \( \phi: X \to [0, 1] \), \( \psi: Y \to [0, 1] \) and homotopies \( G: X \times [0, 1] \to X \) and \( H: Y \times [0, 1] \to Y \) as in Theorem \( \Box[39.13] \). We consider the maps

\[
  \gamma: X \times Y \to [0, 1]
  \quad (x, y) \mapsto \min\{\phi(x), \psi(y)\}
\]

and

\[
  K: (X \times Y) \times [0, 1] \to X \times Y
  \quad ((x, y), t) \mapsto (G(x, \min\{t, \psi(y)\}), H(y, \min\{t, \phi(x)\})).
\]

It is easy to see that \( \gamma^{-1}(\{0\}) = (X \times B) \cup (A \times Y) \). Furthermore it is basically clear that \( K_0 = \text{id} \). Finally note that by construction we have \( K((x, y), t) \in (A \times Y) \cup (X \times B) \), whenever \( t > \gamma(x, y) \). Therefore it follows from Theorem \( \Box[39.13] \) that the inclusion map

\[
  (A \times X) \cup (X \times B) \to X \times Y
\]

is a closed cofibration. \( \Box \)

**Corollary 39.15.** Let \( X \) be a topological space and let \( A \subset X \) be a subset. If the inclusion \( i: A \to X \) is a closed cofibration, then the inclusion \( (X \times \{0, 1\}) \cup (A \times [0, 1]) \to X \times [0, 1] \) is also a closed cofibration.
Proof. On page 1024 we saw that the inclusion map \( \{0, 1\} \to [0, 1] \) is a cofibration. It follows from this observation together with Proposition 39.14 that the given inclusion map is a closed cofibration.

\[ X \to A \]

\[ X \times [0, 1] \]

\[ (X \times \{0, 1\}) \cup (A \times [0, 1]) \]

**Figure 674. Illustration for Corollary 39.15**

**Lemma 39.16.** Let \( i: A \to X \) be a closed cofibration. If \( i \) is a homotopy equivalence, then \( i(A) \) is a deformation retract of \( X \).

Proof. Let \( i: A \to X \) be a cofibration. By Lemma 39.8 we can assume that \( A \) is a closed subset of \( X \) and that \( i: A \to X \) is the inclusion. Let \( q: X \to A \) be a homotopy inverse of \( i \). Recall that this means that \( q \circ i = q: A \to A \) is homotopic to \( \text{id}_A \) and \( i \circ q \) is homotopic to \( \text{id}_X \).

We pick a homotopy \( F: A \times [0, 1] \to A \) from \( q \circ i = q: A \to A \) to \( \text{id}_A \). Since \( i: A \to X \) is a cofibration we can extend the map \( q: X \to A \) on \( X \) and the homotopy \( F: A \times [0, 1] \to A \) to a homotopy \( \tilde{F}: X \times [0, 1] \to A \). Note that \( \tilde{F}_1|A = F_1|A = \text{id}_A \), in other words, \( \tilde{F}_1: X \to A \) is a retraction. We write \( r := \tilde{F}_1: X \to A \subset X \).

Note that \( r: X \to X \) is homotopic to \( q = i \circ q: X \to X \) which in turn is homotopic to \( \text{id}_X \). Thus it follows from Lemma 18.4 (1) that there exists a homotopy \( G \) from \( \text{id}_X \) to \( r \).

\[ X \to A \]

\[ (x,s,t) \mapsto \begin{cases} x, & \text{if } s = 0, \\ G(r(x), 1-t), & \text{if } s = 1, \\ G(x, (1-t)s), & \text{if } x \in A, \\ G(x, s), & \text{if } t = 0. \end{cases} \]

It follows easily from the hypothesis that \( A \) is a closed subset together with Lemma 2.35 (2) that the map is continuous.

By Corollary 39.15 we know that \( (X \times \{0, 1\}) \cup (A \times [0, 1]) \to X \times [0, 1] \) is a cofibration. Thus we can extend the homotopy \( K \) to a homotopy \( \tilde{K}: (X \times [0, 1]) \times [0, 1] \to X \). The
map \( \tilde{K}_1 : X \times [0, 1] \to X \) is now a homotopy rel \( A \) from \( \text{id}_X \) to the retraction \( r \). We have thus shown that \( A \) is a deformation retract of \( X \).

**Figure 676.** Second illustration for the proof of Lemma 39.16

### 39.4. Push-outs and cofibrations (**). In this section we will consider the relationship between cofibrations and pushouts. We recall the following notation from page 732.

**Notation.** Let \( f : A \to X \) and \( g : A \to Y \) be two maps between topological spaces. We write

\[
X \cup_A Y := (X \sqcup Y) / \sim \quad \text{where } f(a) \sim g(a) \text{ for all } a \in A.
\]

We refer to \( X \cup_A Y \) as the pushout of \( f \) and \( g \).

The next proposition continues a theme that we already encountered in Lemma 3.43 and Exercise 25.11.

**Proposition 39.17.** Let \( f : A \to X \) and \( g : A \to Y \) be two maps between topological spaces. We consider the corresponding pushout diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & X \\
\downarrow{g} & & \downarrow{i} \\
Y & \xrightarrow{j} & X \cup_A Y.
\end{array}
\]

The following two statements hold:

1. If \( f \) is a (closed) cofibration, then the “opposite map” \( j : Y \to X \cup_A Y \) is also a (closed) cofibration.
2. If \( f \) is a closed cofibration and if \( f \) is a homotopy equivalence, then the “opposite map” \( j : Y \to X \cup_A Y \) is also a homotopy equivalence.

The same statements hold, by symmetry, for \( g \) and the “opposite map” \( i \).

**Example.** Let \( f : A \to Y \) be a map between topological spaces. We consider the pushout diagram

\[
\begin{array}{ccc}
A & \xrightarrow{a \mapsto (a, 0)} & A \times [0, 1] \\
\downarrow{f} & & \downarrow{i} \\
Y & \xrightarrow{j} & (A \times [0, 1]) \cup_A Y.
\end{array}
\]
By the discussion on page 1033 we know that the top horizontal map is a cofibration. Thus it follows from Proposition 39.17 that the natural inclusion \( Y \to \text{Cyl}(f: A \to Y) \) is a cofibration. Thus, together with Proposition 39.6 (1) we see that both the natural inclusions \( A \to \text{Cyl}(f: A \to Y) \) and \( Y \to \text{Cyl}(f: A \to Y) \) are cofibrations.

![Diagram](image.png)

**Figure 677**

**Proof.** Throughout the proof we assume that \( f: A \to X \) is a cofibration. By Lemma 39.8 we can assume that \( A \) is a subset of \( X \) and that \( f: A \to X \) is the inclusion.

First we want to show that \( j: Y \to X \cup_A Y \) is also a cofibration. Since \( f \) is a cofibration we know by Lemma 39.3 (1)\( \Rightarrow \) (3) that there exists a retraction

\[
r: X \times [0, 1] \to (X \times \{0\}) \cup (A \times [0, 1]).
\]

We introduce the following extra maps:

1. We denote by \( i: Y \to X \cup_A Y \) and \( j: X \to X \cup_A Y \) the two obvious maps.
2. We consider the pushout diagram

\[
\begin{array}{ccc}
Y \times \{0\} & \longrightarrow & Y \times [0, 1] \\
\downarrow g \times \text{id} & & \downarrow k \\
((X \cup_A Y) \times \{0\}) & \longrightarrow & ((X \cup_A Y) \times \{0\}) \cup (Y \times [0, 1]).
\end{array}
\]

We denote by \( k: Y \times [0, 1] \to ((X \cup_A Y) \times \{0\}) \cup (Y \times [0, 1]) \) the natural map.

Now we consider the following diagram:

\[
\begin{array}{ccc}
A \times [0, 1] & \xrightarrow{f \times \text{id}_{[0, 1]}} & X \times [0, 1] \\
\downarrow g \times \text{id}_{[0, 1]} & & \downarrow i \times \text{id}_{[0, 1]} \\
Y \times [0, 1] & \xrightarrow{j \times \text{id}_{[0, 1]}} & (X \cup_A Y) \times [0, 1] \\
& & \downarrow r \\
& & (X \times \{0\}) \cup (A \times [0, 1]) \\
& & \downarrow s \\
& & ((X \cup_A Y) \times \{0\}) \cup (Y \times [0, 1]).
\end{array}
\]

We make the following observations:

1. It follows immediately from Lemma 3.43 (3b) that we can view \( Y \times [0, 1] \) as a subset of \( (X \cup_A Y) \times [0, 1] \).
(2) The diagonal dashed map \( s \) comes from the fact, discussed on page 735, that the pushout commutes with taking products with the regionally compact topological space \([0, 1]\).

(3) It follows from (1) and (2) that we can view the map \( s \) as a retraction. Thus it follows from Lemma 39.3 that the map \( Y \to X \cup_A Y \) is indeed a cofibration.

Finally note that if \( f \) is a closed cofibration, then it follows from (1) and (2) that \( j(Y) \) is a deformation retract of \( X \cup_A Y \). By Lemma 18.14 it now suffices to show that \( j(Y) \) is a deformation retract of \( X \cup_A Y \). By Lemma 39.16 we know that there exists a deformation retraction \( G \): \( X \times [0, 1] \to X \) from \( X \) to \( A \). We consider the map

\[
H: (X \cup_A Y) \times [0, 1] \to X \cup_A Y \\
(P, t) \mapsto \begin{cases} 
   i(G(Q), t), & \text{if } P = i(Q) \text{ with } Q \in X, \\
   j(Q), & \text{if } P = j(Q) \text{ with } Q \in Y.
\end{cases}
\]

It follows from Lemma 18.23 that this map is actually continuous. Now that we put our worries regarding continuity to rest it is clear that this map is a deformation retraction from \( X \cup_A Y \) to \( j(Y) \).

The following theorem is the main result of this section.

**Theorem 39.18. (Homotopy Pushout Theorem)** Suppose we are given the following commutative diagram of maps between topological spaces:

\[
\begin{array}{ccc}
X & \xleftarrow{i} & A \\
\downarrow{\varphi_X} & & \downarrow{\varphi_A} \\
X' & \xleftarrow{i'} & A'
\end{array} \\
\begin{array}{ccc}
f & \xrightarrow{\varphi_Y} & Y \\
\downarrow & & \downarrow \\
f' & \rightarrow & Y'
\end{array}
\]

If the vertical maps are homotopy equivalences and if the maps \( i \) and \( i' \) to the left are closed cofibrations, then the induced map

\[
X \cup_A Y \to X' \cup_{A'} Y'
\]

\[
[P] \mapsto \begin{cases} 
   \varphi_X(P), & \text{if } P \in X, \\
   \varphi_Y(P), & \text{if } P \in Y
\end{cases}
\]

between the pushouts is a homotopy equivalence.

**Remark.** We outsource the proof, which follows quite closely the argument in [Rap16], to the next section. Alternative proofs are given in [BrownR68 p. 249], [BrownR06 Proposition 7.5.7] and [tD08 Proposition 5.3.4].

**Proposition 39.19.** Let \( \varphi: Y \to Y' \) be a homotopy equivalence between two topological spaces. Furthermore let \( A \) be a topological space and let \( f: A \to Y \) and \( f': A \to Y' \) be two maps such that \( \varphi \circ f \) is homotopic to \( f' \). Then there is a homotopy equivalence

\[
\text{Cone}(f: A \to Y) \to \text{Cone}(f': A \to Y')
\]
Example. Let $f_0, f_1: A \to Y$ be two maps between topological spaces. If $f_0$ and $f_1$ are homotopic, then it follows immediately from Proposition 39.19 applied to the map $\varphi = \text{id}: Y \to Y' = Y$, that the mapping cones $\text{Cone}(f: A \to Y)$ and $\text{Cone}(f': A \to Y)$ are homotopy equivalent. Note that this recovers for the most part the statement of Proposition 24.11.

Proof. Let $F: A \times [0,1] \to Y'$ be a homotopy between $\varphi \circ f$ and $f'$. We consider the following commutative diagram

\[
\begin{array}{ccc}
\text{Cone}(A) & \xleftarrow{id} & A \\
\downarrow & & \downarrow \varphi \\
\text{Cone}(A) & \xleftarrow{x \to (x,0)} & A \\
\downarrow & & \downarrow \varphi \circ f \\
\text{Cone}(A) \times [0,1] & \xleftarrow{a \to (a,0), t \to (F(a,t),t)} & A \times [0,1] \\
\downarrow & & \downarrow y \to (y,0) \\
\text{Cone}(A) & \xleftarrow{x \to (x,1)} & A \\
\downarrow & & \downarrow f' \\
\text{Cone}(A) & \xleftarrow{a \to (a,1)} & A \\
\downarrow & & \downarrow y \to (y,1) \\
X & \xrightarrow{j} & X \cup_A B.
\end{array}
\]

The vertical maps are evidently homotopy equivalences. Furthermore we know by Proposition 39.6 (2) and Proposition 39.12 that the left horizontal maps are closed cofibrations. It follows from the Homotopy Pushout Theorem 39.18 together with Lemma 18.11 (1) that the pushout on top is homotopy equivalence to the pushout at the bottom. But the pushout on top is precisely $\text{Cone}(f: A \to Y)$ and the pushout at the bottom is precisely $\text{Cone}(f': A \to Y')$.

Remark. Another typical application of the Homotopy Pushout Theorem 39.18 is given in the proof of Proposition 103.18 where we show that “handle attachments” and “cell attachments” lead to homotopy equivalent topological spaces.

39.5. Proof of Theorem 39.18 (*). In this section we provide a proof of Theorem 39.18 following the argument of [Rap16]. The least that can be said is that the proof is not for the faint of heart.

The following lemma is a key step towards the proof of Theorem 39.18.

Lemma 39.20. Let $f: A \to X$ and $g: A \to Y$ be two maps between topological spaces. We consider the corresponding pushout diagram

\[
\begin{array}{ccc}
A & \xleftarrow{s} & B \\
\downarrow & & \downarrow i \\
X & \xleftarrow{j} & X \cup_A B.
\end{array}
\]

Let $f$ be a homotopy equivalence. If $g$ is a closed cofibration, and if there exists a map $s: B \to A$ with $f \circ s = \text{id}_B$ and which is a closed cofibration, then the map “opposite to $f$”, i.e. the map $j$ is a homotopy equivalence.
Remark. Sometimes it takes a while to spot the differences to earlier results. In the similar looking Proposition 39.17 we had assumed that \( f \) is not only a homotopy equivalence but also a closed cofibration. Now we assume \( g \) is a closed cofibration and that we have the extra map \( s \) to play with.

Proof of Lemma 39.20. First note that it follows from the hypotheses that \( f \circ s = \text{id}_B \) and that \( f \) is a homotopy equivalence, together with Lemma 18.11 (1), that \( s \) is also a homotopy equivalence. We consider the following diagram:

\[
\begin{array}{ccc}
B & \xrightarrow{s} & A \\
\downarrow{g \circ s} & & \downarrow{u} \\
X & \xrightarrow{v} & P := X \cup_B A \\
\end{array}
\quad \begin{array}{ccc}
 & & B \\
\downarrow{f} & & \downarrow{g} \\
 & & X \\
\end{array}
\quad \begin{array}{ccc}
\downarrow{k} & & \downarrow{i} \\
X & \xrightarrow{j} & X \cup_A B. \\
\end{array}
\]

We make the following clarifications and observations:

1. To the top left we have a pushout square. In particular the maps \( u: A \to X \cup_B A \) and \( v: X \to X \cup_B A \) are the corresponding natural maps.
2. The map \( k: X \cup_B A \to X \) is defined via the identity on \( X \) and the map \( g \circ s \circ f \) on \( A \).
3. It follows easily from Lemma 3.43 (2) and (4) that the square to the top right is a pushout diagram.
4. The map \( l: X \cup_B A \to X \) is defined via the identity on \( X \) and the map \( g \) on \( A \).
5. It follows easily from the definitions that the diagram commutes.
6. Since \( s \) is a closed cofibration and a homotopy equivalence it follows from Proposition 39.17 (2) that the map \( v: X \to X \cup_B A \) is also a closed cofibration and a homotopy equivalence.
7. Note that \( k \circ v = \text{id}_X \) and \( l \circ v = \text{id}_X \). Since \( v \) and \( \text{id}_X \) are homotopy equivalences we obtain from Lemma 18.11 (1) that \( k \) and \( l \) are also homotopy equivalences.
8. Since \( g \circ s \) is a closed cofibration we obtain from Proposition 39.17 (1) that the map \( u \) is also a closed cofibration.

Next we consider the following two pushout diagrams:

\[
\begin{array}{ccc}
P & \xrightarrow{l} & X \\
\downarrow{p \mapsto (p,1)} & & \downarrow{t} \\
(P \times [0,1]) \cup_A [0,1]A & \xrightarrow{(P \times [0,1]) \cup_A [0,1]A \cup P X} & X \cup_A B.
\end{array}
\quad \text{and} \quad \begin{array}{ccc}
P = X \cup_B A & \xrightarrow{k} & X \\
\downarrow{\varphi(p) = (p,1)} & & \downarrow{m} \\
\text{Cyl(l)}_A & \xrightarrow{w} & \text{Cyl(l)}_A \cup P X.
\end{array}
\]

Providing the proof of the following claim is the main difficulty in the proof of the lemma. Claim. The map \( w: \text{Cyl(l)}_A \to \text{Cyl(l)}_A \cup P X \) is a homotopy equivalence.
To prove the claim we first consider the following pushout diagram:

\[
\begin{array}{c}
A \times [0, 1] \xrightarrow{(a,t) \mapsto a} A \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
P \times [0, 1] \xrightarrow{z} (P \times [0, 1]) \cup A\times[0,1] \xrightarrow{\Theta} \bigcap \xrightarrow{\text{id}} X.
\end{array}
\]

We take the resulting map $\Theta$ and use it to produce the following even more confusing pushout diagram

\[
\begin{array}{c}
P \xrightarrow{\sim} (P \times [0, 1]) \cup A\times[0,1] \xrightarrow{\Theta} \text{Cyl}(l)_A = (P \times [0, 1] \cup A\times[0,1]) \cup P \xrightarrow{\sim} X.
\end{array}
\]

We continue with the following comments:

9. We claim that the left-hand vertical map is a closed cofibration. To verify this statement we consider the following commutative diagram

\[
\begin{array}{c}
(A \times [0, 1]) \cup A\times\{0,1\} \xrightarrow{(P \times \{0, 1\})} A \cup A\times\{0,1\} \xrightarrow{\sim} P \cup_A P \xrightarrow{\sim} P. \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
P \times [0, 1] \xrightarrow{\sim} (P \times [0, 1]) \cup A\times[0,1] \xrightarrow{\Theta} \bigcap \xrightarrow{\text{id}} X.
\end{array}
\]

We make a few comments:

(a) The left top horizontal map is induced by the projection $A \times [0, 1] \to A$ and the identity on $P \times \{0, 1\}$.

(b) The left vertical map is the “obvious” map. It is a closed cofibration by the combination of Corollary 39.15 with Lemma 3.45.

(c) The middle vertical map and the bottom horizontal map are the obvious maps.

(d) We leave it to the reader to verify that the square is in fact a pushout diagram.

(e) It follows from (b) and (d) together with Proposition 39.17 that the middle vertical map is a closed cofibration.

(f) The map $P \cup_A P \rightarrow A \cup A\times\{0,1\} (P \times \{0, 1\})$ is given by sending the “left copy” of $P$ to $P \times \{0\}$ and the “right copy” of $P$ to $P \times \{1\}$. There is an obvious inverse which shows that this map is actually a homeomorphism.

(g) The map $P \rightarrow P \cup_A P$ is given by sending $P$ to the “left copy” of $P$. Since $A \to P$ is a closed cofibration we obtain again from Proposition 39.17 that the map $P \to P \cup_A P$ is a closed cofibration.

(h) It follows immediately from the definitions that the triangle to the right commutes. Thus we obtain from (e), (f) and (g) together with Lemma 39.2 that the
diagonal map is a closed cofibration. But that is precisely what we wanted to show.

(10) We claim that the left-hand vertical map \( P \to (P \times [0, 1]) \cup_{A \times [0, 1]} A \) of (I) is a homotopy equivalence. This can be seen as follows. By (9) and Lemma 39.8 we can identify \( P \) with its image under the inclusion. It follows from Lemma 18.23 that the obvious deformation retraction on \( P \times [0, 1] \) and the constant map on \( A \) give rise to a deformation retraction from \( (P \times [0, 1]) \cup_{A \times [0, 1]} A \) to the image of \( P \). Thus it follows from the elementary Lemma 18.14 that the inclusion is indeed a homotopy equivalence.

(11) We consider the pushout square in (I). It follows from (9), (10) and Proposition 39.17 (2) that the right-hand vertical map \( t \) in (I) is also closed cofibration and a homotopy equivalence.

(12) We deduce from (11) and Lemma 18.11 (1) that \( \Xi \) is a homotopy equivalence.

Next we consider the following diagram:

\[
\begin{array}{ccc}
P = X \cup_B A & \xrightarrow{k} & X \\
\downarrow \approx \quad \downarrow m & & \downarrow \Xi \\
Cyl(l)_A & \approx \downarrow \Xi & Cyl(l)_A \cup_P X \\
\downarrow \approx & & \downarrow \Xi \\
X. & & X.
\end{array}
\]

We make the following clarifications and observations:

(13) \( Cyl(l)_A \cup_P X \) is the pushout of the pushout diagram to the to top.

(14) The composition \( P \xrightarrow{\Xi} Cyl(l)_A \xrightarrow{\Xi} X \) equals the map \( l \).

(15) Since \( l \) is a homotopy equivalence and since we just saw that \( \Xi: Cyl(l)_A \to X \) is a homotopy equivalence we obtain again from Lemma 18.11 (1) that \( \varphi: P \to Cyl(l)_A \) is a homotopy equivalence.

(16) We will now argue that the map \( \varphi: P \to Cyl(l)_A \) is a closed cofibration. To do so we consider the following diagram:

\[
\begin{array}{ccc}
P & \xrightarrow{\varphi} & X \cup_A P \\
\downarrow & & \downarrow \varphi \\
(A \times [0, 1]) \cup_{A \times \{0, 1\}} (P \times \{0, 1\}) & \to & Cyl(l)_A.
\end{array}
\]

We make the following observations:

(a) The top vertical map is a closed cofibration by Proposition 39.17 and our hypothesis that \( A \to X \) is a closed cofibration.

(b) The map \( X \cup_A P \to Cyl(l)_A \) is defined by \( t \) on \( X \) and by \( \varphi \) on \( P \).

(c) The vertical map to the left is induced by the inclusions.
(d) The horizontal map on the top is induced by the projection \( A \times [0, 1] \to A \), the
obvious identification \( P \times \{0\} \to P \) and the map \( l \) on \( P = P \times \{1\} \to X \).

(e) We consider the maps
\[
(P \times [0, 1]) \cup (A \times [0, 1]) \cup (P \times \{0\}) \leftrightarrow ((P \times [0, 1]) \cup A \times [0, 1]) \cup P X
\]
which are the obvious maps on \( P \times [0, 1] \), the obvious map on \( X \) and which going
left-to-right is given by the obvious map \( P \to P \times \{0\} \) and which right-to-left is
given by the natural map \( A \to X \cup_B A = P \). These maps are well-defined and
inverses of one another, hence they are isomorphisms. These maps show that the
square is a pushout diagram.

(f) It follows from Corollary 39.15 together with Lemma 3.45 that the left vertical
map in the square is a closed fibration.

(g) It follows (f) together with Proposition 39.17 (1) that the right vertical map in
the square is also a closed fibration.

(h) By (a) and (g) the map of our desire is a composition of two closed fibrations,
hence it is itself a closed fibration by Lemma 39.2

(17) It follows from (15) and (16) together with Proposition 39.17 (2), applied the diagram
(II), that the map \( m : X \to \text{Cyl}(l)_A \cup_P X \) is a homotopy equivalence.

(18) By (7), (15) and (17) we know that \( m, k, \varphi \) are homotopy equivalences. By the
diagram (II) we have \( w \circ \varphi = m \circ k \). Thus we obtain from Lemma 18.11 (1) that \( w \)
is also a homotopy equivalence.

Finally we consider the following diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{t} & \text{Cyl}(l)_A \\
\downarrow j & \ & \downarrow \Xi \\
X \cup_A B & \xrightarrow{t'} & \text{Cyl}(l)_A \cup_P X \\
\downarrow n & \ & \downarrow j \\
X \cup_A B & \xrightarrow{id} & \text{Cyl}(l)_A \cup_P X \\
\end{array}
\]

Here are the customary clarifications and observations:

(19) Recall that the map \( t : X \to \text{Cyl}(l)_A \) is the natural inclusion.

(20) By definition of \( t \) and \( \Xi \) we have \( \Xi \circ t = \text{id}_X \).

(21) The map \( t' : X \cup_A B \to \text{Cyl}(l)_A \cup_P X \) is defined by \( w \circ t : X \to \text{Cyl}(l)_A \) and it is
defined by \( m \circ g \circ s : B \to X \). Furthermore the map \( n : \text{Cyl}(l)_A \cup_P X \to X \cup_A B \) is
defined by \( \Xi \) on \( \text{Cyl}(l)_A \) and by the natural map \( j : X \to X \cup_A B \) on \( X \).

(22) One can easily verify that \( n \circ t' = \text{id}_{X \cup_A B} \).

(23) It follows immediately from the definitions that the diagram commutes.

It follows from (20), (22) and (23) and the above commutative diagram that \( j \) is a retract
of the map \( w \), in the sense of the definition in Exercise 18.19. Since \( w \) is a homotopy
equivalence we obtain from Exercise 18.19 that \( j \) is also a homotopy equivalence. We are
done!
The next lemma is the same statement as Lemma 39.20 except that we can drop the hypothesis on the existence of $s$.

**Lemma 39.21.** Let $f: A \to X$ and $g: A \to Y$ be two maps between topological spaces. We consider the corresponding pushout diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{g} & & \downarrow{i} \\
X & \xrightarrow{j} & X \cup_A B.
\end{array}
$$

Let $f$ be a homotopy equivalence. If $g$ is a closed cofibration, then the map “opposite to $f$”, i.e. the map $j$ is a homotopy equivalence.

**Proof of Lemma 39.21.** We consider the maps

$$
\begin{array}{ccc}
A & \xrightarrow{i_f} & \text{Cyl}(f) \\
\downarrow{a \mapsto (a,0)} & & \downarrow{r} \\
\text{Cyl}(f) & \xleftarrow{s} & B
\end{array}
$$

where $i_f: A \to \text{Cyl}(f)$ and $s: B \to \text{Cyl}(f)$ are the natural inclusions and $r: \text{Cyl}(f) \to B$ is the natural retraction. We make the following observations:

1. It follows from Proposition 39.6 and the discussion on page 1039 that $i_f$ and $s$ are closed cofibrations.
2. It follows immediately from the definitions that $f = r \circ i_f$ and $r \circ s = \text{id}_B$.
3. By Lemma 24.6(3) and Lemma 24.8 we know that $r$ is a homotopy equivalence.
4. It follows from the hypothesis that $f$ is a homotopy equivalence, together with (2) and (3) and together with Lemma 18.11(1), that $i_f$ is a homotopy equivalence.

Next we consider the following diagram

$$
\begin{array}{ccc}
A & \xrightarrow{i_f} & \text{Cyl}(f) & \xleftarrow{r} & B \\
\downarrow{g} & \downarrow{\mu} & \downarrow{s} & \downarrow{\nu} & \downarrow{i} \\
X \cup_A \text{Cyl}(f) & \xrightarrow{\beta} & (X \cup_A \text{Cyl}(f)) \cup_{\text{Cyl}(f)} B & \xleftarrow{\gamma} & X \cup_A B.
\end{array}
$$

We continue with the following clarifications and observations:

5. The quadrilateral to the left is a pushout diagram. In particular $\alpha$ and $\mu$ are the natural maps of a pushout.
6. The quadrilateral in the top center is also a pushout diagram. In particular $\beta$ and $\nu$ are the natural maps of a pushout.
7. The map $\gamma$ is the natural homeomorphism given by Lemma 3.43(5).
8. It follows immediately from the definitions that the diagram commutes.
(9) We consider the quadrilateral to the left.
(a) By (1) and (4) we know that \( i_f \) is a homotopy equivalence and that it is a closed cofibration. Thus we obtain from (5) together with Proposition 39.17 (2) that the opposite map \( \alpha : X \to X \cup_A \text{Cyl}(f) \) is a homotopy equivalence.
(b) By hypothesis \( g \) is a closed cofibration, thus we obtain from (5) together with Proposition 39.17 (1) that \( \mu \) is also a closed cofibration.

(10) Next we obtain the quadrilateral in the top center. By (1), (3), (6) and (9b) we can apply Lemma 39.20 and we obtain that the map \( \beta \) is a homotopy equivalence.

(11) By (7), (9a) and (10) we know that \( \alpha, \beta \) and \( \gamma \) are homotopy equivalences. Since the diagram commutes we see that the bottom map \( j : X \to X \cup_A B \) is indeed a homotopy equivalence.

Now we can provide the proof of Theorem 39.18.

**Proof of Theorem 39.18.** We are given the following commutative diagram

\[
\begin{array}{ccc}
X & \xleftarrow{i} & A \\
\downarrow{\varphi_X} & & \downarrow{\varphi_A} \\
X' & \xleftarrow{i'} & A' \\
\end{array}
\begin{array}{c}
\xrightarrow{f} \\
\xrightarrow{f'} \\
\xrightarrow{\varphi_Y} \\
\xrightarrow{\varphi_Y'}
\end{array}
\xrightarrow{Y}
\]

where all of the vertical maps are homotopy equivalences and where the maps \( i \) and \( i' \) to the left are closed cofibrations. Recall that we need to show that the induced map

\[ \Phi : X \cup_A Y \to X' \cup_{A'} Y' \]

is a homotopy equivalence.

**Case 1.** First we assume that \( f \) and \( f' \) are homotopy equivalences. We consider the following commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{u} & X \cup_A Y \\
\downarrow{\varphi_X} & & \downarrow{\Phi} \\
X' & \xrightarrow{u'} & X' \cup_{A'} Y'
\end{array}
\]

We make the following comments:

(1) The horizontal maps \( u \) and \( u' \) are the obvious natural maps coming from the following pushout diagrams

\[
\begin{array}{ccc}
A & \xrightarrow{f} & Y \\
i & \downarrow{\simeq} & \downarrow{v} \\
X & \xrightarrow{u} & X \cup_A Y\end{array}
\quad\text{and}\quad
\begin{array}{ccc}
A' & \xrightarrow{f'} & Y' \\
i' & \downarrow{\simeq} & \downarrow{v'} \\
X' & \xrightarrow{u'} & X' \cup_{A'} Y'
\end{array}
\]

Since \( f \) and \( f' \) are homotopy equivalences and since \( i \) and \( i' \) are closed cofibrations we obtain from Lemma 39.21 applied to these two pushout diagrams, that the horizontal maps \( u \) and \( u' \) are homotopy equivalences.

(2) The left vertical map of the diagram of the claim is a homotopy equivalence by hypothesis.
(3) It follows from (1) and (2), together with Lemma 18.11 (1), that $\Phi$ is a homotopy equivalence.

Case 2. Next we assume that $f$ and $f'$ are cofibrations. We consider the following diagram:

We make the following observations and clarifications:

(1) The top square and bottom left square are the obvious pushout diagrams.

(2) The vertical map $l: X \cup_A Y \to X \cup_A Y'$ is the map induced by $\varphi_Y$. The square in the front is a pushout diagram by Lemma 3.43 (4).

(3) The square in the back is defined to be a pushout diagram.

(4) Since $i$ is a closed cofibration and $\varphi_A$ is a homotopy equivalence it follows from Lemma 39.21 applied to the pushout diagram in the back, that $k$ is a homotopy equivalence.

(5) Since $i$ is a closed cofibration we obtain, by applying Proposition 39.17 to the pushout diagram on the top, that the “opposite map” $j: Y \to X \cup_A Y$ is a closed cofibration.

(6) Since $j$ is a cofibration and since $\varphi_Y$ is homotopy equivalence we obtain again from Lemma 39.21 this time applied to the pushout diagram in front, that $l$ is a homotopy equivalence.

(7) Since $f'$ is a closed cofibration we obtain again from Proposition 39.17 that the “opposite map” $l'$ is a closed cofibration.

(8) We turn to the right part of the diagram. The map $q: X \cup_A A' \to X'$ is defined by $\varphi_X$ on $X$ and $i'$ on $A$. Furthermore the map $r: X \cup_A Y' \to X' \cup_A Y'$ is defined by $\varphi_X$ on $X'$ and id on $Y'$. Finally $s: X' \to X' \cup_A Y'$ is the natural map. One can easily verify that the right hand part of the diagram commutes.

(9) Since $\varphi_X$ and $k$ are homotopy equivalences and since $q \circ k = \varphi_X$ we obtain from Lemma 18.11 (1) that $q$ is a homotopy equivalence.

(10) As we mentioned in (2), the bottom left square is a pushout square. Furthermore it follows immediately from the definitions that the big square formed by the two squares at the bottom is also a pushout square. It follows from a fairly elementary argument, see e.g. Exercise 25.12, that the bottom right square is also a pushout square.

(11) It follows from (7), (9) and (10) together with the hard-fought Lemma 39.21 that $r$ is a homotopy equivalence.

(12) Since $\Phi = r \circ l$ we obtain from (6) and (11) that $\Phi$ is indeed a homotopy equivalence.
Case 3. Finally we deal with the case that \( f \) and \( f' \) are arbitrary maps. We consider the following diagram

\[
\begin{array}{ccc}
X & \xleftarrow{i} & A \\
\downarrow \varphi_X & \xrightarrow{\approx} & \downarrow \varphi_A \\
X' & \xleftarrow{i'} & A' \\
\end{array}
\quad \begin{array}{ccc}
A & \xrightarrow{f} & \xrightarrow{\approx} & Y \\
\downarrow \varphi_A & \xrightarrow{\approx} & \downarrow \varphi_Y \\
Cyl(f) & \xrightarrow{r} & \downarrow \varphi_Y \\
\downarrow \varphi_X & \xrightarrow{\approx} & \downarrow \varphi_Y \\
X' & \xleftarrow{i'} & A' \\
\end{array}
\quad \begin{array}{ccc}
X' & \xleftarrow{i'} \xrightarrow{j'} & \xrightarrow{\approx} & Y' \\
\downarrow q & \xrightarrow{\approx} & \downarrow q \\
Cyl(f) \cup_A A' & \xrightarrow{t} & \downarrow j' \\
\end{array}
\]

We make the following clarifications and observations:

1. The black part of the diagram is precisely the commutative diagram of our setup.
2. The top triangle is given by the usual factorization of the map \( f: A \to Y \) into the natural inclusion \( j: X \to Cyl(f) \) and the natural retraction \( r: Cyl(f) \to Y \). By Proposition \(39.6\) we know that \( j \) is a closed cofibration. Furthermore, by Lemma \(24.8\) (2a) we know that \( r \) is a homotopy equivalence.
3. The left parallelogram is defined to be the pushout of the maps \( j: A \to Cyl(f) \) and \( \varphi_A: A \to A' \).
4. Since \( j \) is a closed cofibration we obtain from (3) and Proposition \(39.17\) that the map \( j': A' \to Cyl(f) \cup_A A' \) is also a closed cofibration.
5. Since \( \varphi_A \) is a homotopy equivalence and since \( j \) is a closed cofibration we obtain from Lemma \(39.21\) that \( t \) is a homotopy equivalence.
6. The map \( q: \xrightarrow{} Cyl(f) \cup_A A' \to Y' \) is defined via \( t \) on \( Cyl(f) \) and \( f' \) on \( A' \).
7. It follows easily from the definitions that the right parallelogram commutes, i.e, we have \( q \circ t = \varphi_Y \circ r \). Since \( r, \varphi_Y \) and \( t \) are homotopy equivalences and since \( q \circ t = \varphi_Y \circ r \) we obtain from Lemma \(18.11\) (1) that \( q \) is a homotopy equivalence.

Next we consider the commutative diagram

\[
\begin{array}{ccc}
X & \xleftarrow{i} & A \\
\downarrow \varphi_X & \xrightarrow{\approx} & \downarrow \varphi_A \\
X' & \xleftarrow{i'} & A' \\
\end{array}
\quad \begin{array}{ccc}
A & \xrightarrow{j} & \xrightarrow{\approx} & Cyl(f) \\
\downarrow \varphi_A & \xrightarrow{\approx} & \downarrow t \\
Cyl(f) \cup_A A' & \xrightarrow{j'} & \downarrow \varphi_Y \\
\end{array}
\]

Here we just make a single observation:

8. By (2) and (4) and by hypothesis we know that all horizontal maps are closed cofibrations. Furthermore by hypothesis and (5) we know that all vertical maps are homotopy equivalences. Thus we obtain from Case 2 that the induced map

\[
\Xi: X \cup_A Cyl(f) \to X' \cup_{A'} (Cyl(f) \cup_A A')
\]

is a homotopy equivalence.
We move on to consider the following diagram:

\[
\begin{array}{c}
\xymatrix{
X \cup_A \text{Cyl}(f) & \ar[l]_{\mu} \ar[d]^\cong & \ar[r]^\cong \ar[d]^\cong & \ar[l]_{\nu} X' \cup_A' (\text{Cyl}(f) \cup_A A') \ar[d]^\cong \\
X' \cup_A \text{Cyl}(f) & \ar[l]_{\gamma} \ar[d]^\cong & \ar[r]^\cong \ar[d]^\cong & \ar[l]_{\beta} \text{Cyl}(f) \cup_A A' \ar[d]^\cong \\
\ar[r]^\cong & \ar[r]^\cong & \ar[r]^\cong & \ar[r]^\cong & Y \ar[d]^\cong \\
& & & & Y'.
\end{array}
\]

We make the following clarifications and observations:

(9) The lower diagonal map \( \mu \) is the natural homeomorphism that is provided by Lemma 3.43 (5).

(10) The horizontal map \( \alpha \) at the top left and the diagonal map \( \beta \) are the natural maps coming from pushouts. The vertical map \( \nu \) to the left is induced by \( \varphi_X \) and the horizontal map \( \gamma \) at the bottom left map is induced by \( i' \). One can easily verify that the diagram commutes.

(11) Recall that by hypothesis \( i: A \to X \) and \( i': A' \to X' \) are closed cofibrations. Thus we obtain from Proposition 39.1 that the maps \( \alpha \) and \( \beta \) are closed cofibrations. Since \( \gamma = \mu \circ \beta \) and since \( \mu \) is a homeomorphism we see that \( \gamma \) is also a closed cofibration.

Finally we consider the following diagram:

\[
\begin{array}{c}
\xymatrix{
(X \cup_A \text{Cyl}(f)) \cup_{\text{Cyl}(f)} Y & \ar[d]^\cong \ar[r] & (X' \cup_A \text{Cyl}(f)) \cup_{\text{Cyl}(f) \cup_A A'} Y'' \\
X \cup_A Y & \ar[r]^\cong \ar[d]^\cong & X' \cup_A Y'.
\end{array}
\]

As usual we cannot be refrained from making comments.

(12) The top horizontal map is induced by \( \nu \) and \( \varphi_Y \).

(13) By (5), (8), (9) and our hypothesis we know that all the vertical maps in the diagram (*) are homotopy equivalences. Furthermore by (2) and (7) we know that the right horizontal maps of (*) are homotopy equivalences. Thus we obtain from Case 1 that the top horizontal map in our present diagram is a homotopy equivalence.

(14) The vertical maps are the natural homeomorphism provided by Lemma 3.43 (5).

(15) One can easily verify that the diagram commutes. Since the top horizontal map is a homotopy equivalence and since the vertical maps are homeomorphisms we see that the bottom horizontal map \( \Phi \) is also a homotopy equivalence. And that had been our goal since page 1040.

This concludes our discussion of closed cofibrations. More information on closed cofibrations can be found in [D08, Chapter 5], [BrownR06, Chapter 7], [May99a, Chapter 6] and [Pic92, Chapter 2.3].
Exercises for Chapter 39

Exercise 39.1. Solve the following problems “by hand”, i.e. without making use of any of above results. For example you should not use Lemma 39.8.

(a) Let $A = [a, b]$ be a compact interval and let $X = \mathbb{R}$. Show that the inclusion $i: A \to X$ is a cofibration.

(b) Let $A = \mathbb{R} \setminus \{0\}$ and $X = \mathbb{R}$. Show that the inclusion $i: A \to X$ is not a cofibration.

(c) Let $A = (-1, 1)$ and $X = \mathbb{R}$. Show that the inclusion $i: A \to X$ is not a cofibration.

Exercise 39.2. Let $f: X \to Y$ and $g: Y \to Z$ be two (closed) cofibrations. Show that $g \circ f: X \to Z$ is a (closed) cofibration.

Exercise 39.3. Prove the “(2) $\Rightarrow$ (1)”-direction of Lemma 39.3.

Exercise 39.4. Given an example of a topological space $X$ and a non-empty subset $A$ such that the map $\text{Cone}(i: A \to X) \to X/A$ given in Lemma 39.9 (1) is not a homotopy equivalence.

Exercise 39.5. Let $X = \{x, y\}$ be a set with two elements and the trivial topology furthermore let $A = \{x\}$. Show that the inclusion $A \to X$ is a cofibration.

Remark. This is an example of a cofibration that is not closed.

Exercise 39.6. Let $X = \{a, b\}$ be the topological space with two elements $a$ and $b$ and where the open sets are precisely $\emptyset, \{a\}, X$. We set $A := \{a\}$.

(a) Show that the inclusion $A \to X$ is a cofibration.

(b) Show that the inclusion $(X \times A) \cup (A \times X) \to X \times X$ is not a cofibration.

Remark. This exercise shows that the conclusion of Proposition 39.14 does not hold if neither $A$ nor $B$ are closed subsets.

Exercise 39.7. Let $i: A \to X$ be a closed cofibration. Show that the induced map $\text{Cone}(A) \to \text{Cone}(X)$ is also a cofibration.

Hint. Make sense of the following diagram and use it as a guideline:

$$
\begin{array}{cccccc}
A \times \{0\} & \longrightarrow & X \times \{0\} & \longrightarrow & \{\ast\} \\
\downarrow & & \downarrow & & \downarrow \\
A \times [0, 1] & \longrightarrow & (X \times \{0\}) \cup_{A \times \{0\}} (A \times [0, 1]) & \longrightarrow & \text{cone}(A) = \ast \cup_{A \times \{0\}} (A \times [0, 1]) \\
\downarrow & & \downarrow & & \downarrow \\
X \times [0, 1] & \longrightarrow & \text{Cone}(X).
\end{array}
$$
Part VI

Singular Homology
40. Higher homotopy groups: a primer

After these rather technical chapters on CW-complexes we now return to our original goal, namely trying to distinguish topological spaces. Using the fundamental group we had established several non-trivial results, for example we proved that

1. $S^1$ and $S^k$ with $k \geq 2$ are not homeomorphic,
2. $\mathbb{R}^2$ and $\mathbb{R}^n$ with $n \geq 3$ are not homeomorphic,
3. surfaces of different genus are not homeomorphic,
4. we showed that $S^1$ is not a deformation retract of $\overline{B}^2$,
5. the trefoil is not isotopic to the trivial knot.

On the other hand there are still many even rather elementary questions we cannot answer. For example at the moment we cannot show that for $k \neq l$ with $k, l \geq 2$ the spheres $S^k$ and $S^l$ are not homeomorphic and we cannot show that for $k \neq l$ with $k, l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic. Also, the somewhat mysterious lens spaces $L(p,q)$ still evaded our attempts at distinguishing them for a given $p$.

The problem with fundamental groups is that we only probe a topological space $X$ with loops. The natural idea is now to go from using maps $S^1 \to X$ to studying maps $S^n \to X$ for $n \geq 2$. As we will see, this idea leads us naturally to the definition of the “higher homotopy groups” of a topological space.

40.1. Definition of the higher homotopy groups.

**Notation.** Throughout this chapter we write $I = [0,1]$ for the unit interval. Given $n \in \mathbb{N}$ we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$ and we denote, as usual, by $\partial I^n$ its boundary as a subset of $\mathbb{R}^n$.

Now let $X$ be a topological space and let $x_0 \in X$. With the definitions from page 571 we can write

$$\pi_1(X, x_0) = \text{homotopy classes of maps } (I, \partial I) \to (X, x_0).$$

This definition can be easily generalized to higher dimensions:

**Definition.** Given a pointed topological space $(X, x_0)$ and $n \in \mathbb{N}_0$ we define

$$\pi_n(X, x_0) = \text{homotopy classes of maps } (I^n, \partial I^n) \to (X, x_0).$$

For $n \geq 1$ we refer to $\pi_n(X, x_0)$ as the $n$-th homotopy group.

**Figure 678.** Illustration of an element in $\pi_2(S^2 \vee S^1, x_0)$.

**Remark.** This definition makes in particular sense for $n = 0$, we can thus consider $\pi_0(X, x_0)$. In Section 2.9 we had already defined $\pi_0(X)$ as the set of path-components
of $X$. In fact it is straightforward to see that the map

$$\pi_0(X, x_0) \rightarrow \pi_0(X)$$

$$[\gamma: I^0 = \{0\} \rightarrow X] \mapsto \text{path-component of } X \text{ that contains } \gamma(0)$$

is a bijection.

Note that $\pi_n(X, x_0)$ is a priori only a set. So to justify the name "homotopy group" we need to define a group structure on $\pi_n(X, x_0)$ which for $n = 1$ agrees with our previous definition of the group structure. Here is what we do:

**Definition.** Let $(X, x_0)$ be a pointed topological space and let $n \geq 1$. Furthermore let $f, g: (I^n, \partial I^n) \rightarrow (X, x_0)$ be two maps. We define

$$f * g: (I^n, \partial I^n) \rightarrow (X, x_0)$$

$$(x_1, \ldots, x_n) \mapsto \begin{cases} f(2x_1, \ldots, 2x_n), & \text{if } (x_1, \ldots, x_n) \in [0, \frac{1}{2}]^n, \\ g(2x_1 - 1, \ldots, 2x_n - 1), & \text{if } (x_1, \ldots, x_n) \in [\frac{1}{2}, 1]^n, \\ x_0, & \text{otherwise.} \end{cases}$$

This map is illustrated in Figure 679. Applying Lemma 14.3 several times one sees that this map is indeed continuous.

![Figure 679](image_url)

It is straightforward to see that the homotopy class of $f * g$ only depends on the homotopy classes of $f$ and $g$. This leads us to the following definition:

**Definition.** Let $(X, x_0)$ be a pointed topological space and let $n \geq 1$. We define

$$\pi_n(X, x_0) \times \pi_n(X, x_0) \rightarrow \pi_n(X, x_0)$$

$$([f], [g]) \mapsto [f] \cdot [g] := [f * g].$$

Note that for $n = 1$ this is precisely the same definition of the product structure that we had we already introduced in Chapter 14.2

Now we can formulate the following proposition:

---

650 For mysterious reasons in all figures of this chapter the origin $(0, 0)$ is in the top left corner and the point $(1, 1)$ is the vertex at the bottom right.
**Proposition 40.1.** Let \((X, x_0)\) be a pointed topological space and let \(n \geq 1\). The following two statements hold:

1. The map
   \[
   \pi_n(X, x_0) \times \pi_n(X, x_0) \rightarrow \pi_n(X, x_0)
   \]
   \[
   ([f], [g]) \mapsto [f \cdot g] := [f * g]
   \]
   defines a group structure on \(\pi_n(X, x_0)\).

2. Given a map \(f: (I^n, \partial I^n) \rightarrow (X, x_0)\) the inverse of \([f] \in \pi_n(X, x_0)\) is represented by the map \(f \circ \Phi: (I^n, \partial I^n) \rightarrow (X, x_0)\) where \(\Phi: I^n \rightarrow I^n\) is the homeomorphism given by \(\Phi(x_1, x_2, \ldots, x_n) = (1 - x_1, x_2, \ldots, x_n)\).

As we will see, the proof of Proposition 40.1 is very similar to the proof of Proposition 14.4 and the proof of Proposition 14.6. To deal with the technical differences between the case \(n = 1\) and the general case we need a few more definitions and one lemma.

**Definition.**

1. A **cuboid** is any subset of \(\mathbb{R}^n\) of the form \([c_1, d_1] \times \cdots \times [c_n, d_n]\).
2. We say a cuboid \([c_1, d_1] \times \cdots \times [c_n, d_n]\) is **non-degenerate** if for all \(i = 1, \ldots, n\) we have \(d_i > c_i\).

Let \(X\) be a topological space, let \(x_0 \in X\) and let \(f: I^n \rightarrow X\) be a map.

3. We say a cuboid \(A \subset I^n\) is **boundary-trivial** if \(f\) sends all points on the boundary \(\partial A\) of \(A\) to \(x_0\).

4. Let \(A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n\) be a boundary-trivial cuboid and furthermore let \(C = [c_1, d_1] \times \cdots \times [c_n, d_n]\) be a non-degenerate cuboid that is contained in \(A\). We define
   \[
   f(A, C): I^n \rightarrow X
   \]
   \[
   x = (x_1, \ldots, x_n) \mapsto \begin{cases} 
   f(x), & \text{if } x \notin A, \\
   x_0, & \text{if } x \in A \setminus C, \\
   f\left(a_1 + \left(x_1 - c_1\right) \frac{b_1 - a_1}{d_1 - c_1}, \ldots, a_n + \left(x_n - c_n\right) \frac{b_n - a_n}{d_n - c_n}\right) & \text{if } x \in C.
   \end{cases}
   \]

By applying Lemma 14.3 several times one can easily verify that this map is continuous.

The definition of \(f(A, C)\) is sketched in Figure 680.

**Lemma 40.2.** Let \((X, x_0)\) be a pointed topological space and let \(f: (I^n, \partial I^n) \rightarrow (X, x_0)\) be a map. Furthermore let \(A \subset I^n\) be a boundary-trivial cuboid and let \(C\) be a non-degenerate...
cuboid that is contained in \( A \). Then the maps \( f \) and \( f(A, C) \) from \( (I^n, \partial I^n) \) to \( (X, x_0) \) are homotopic.

**Proof** (\(* \)). Let \( f: (I^n, \partial I^n) \rightarrow (X, x_0) \) be a map, let \( A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n \) be a boundary-trivial cuboid and let \( C = [c_1, d_1] \times \cdots \times [c_n, d_n] \) be a non-degenerate cuboid that is contained in \( A \). For \( t \in [0, 1] \) we write

\[
o_t = [a_1(1-t) + c_1t, b_1(1-t) + d_1t] \times \cdots \times [a_n(1-t) + c_n t, b_n(1-t) + d_n t].
\]

Note that \( C_0 = A \) and \( C_1 = C \). It is now straightforward to see that the map

\[
I^n \times [0,1] \rightarrow X
\]

\[
(x,t) \mapsto f(A, C_t)(x)
\]

is a homotopy between \( f \) and \( f(A, C) \). \( \blacksquare \)

Now we can provide the proof of Proposition 40.1

**Proof of Proposition 40.1** The neutral element of the product structure is given by the equivalence class of the constant map

\[
c_{x_0}: I^n \rightarrow X
\]

\[
x \mapsto x_0.
\]

Indeed, it follows immediately from Lemma 40.2 applied to \( A = [0,1]^n \) and \( C = [0, \frac{1}{2}]^n \), that given any map \( f: (I^n, \partial I^n) \rightarrow (X, x_0) \) we have \( f \ast c_{x_0} \simeq f \). Basically the same argument shows also that \( c_{x_0} \ast f \simeq f \).

![Diagram](image.png)

**Figure 681**

Now consider three maps \( f, g, h: (I^n, \partial I^n) \rightarrow (X, x_0) \). By applying Lemma 40.2 several times one can easily show that \( (f \ast g) \ast h \simeq f \ast (g \ast h) \), see e.g. Figure 682. This proves that the multiplication on \( \pi_n(X, x_0) \) is associative.

Now we turn to the most interesting question, namely finding the inverse of a given element in \( \pi_n(X, x_0) \). Thus suppose we are given a map \( f: (I^n, \partial I^n) \rightarrow (X, x_0) \). We consider the map

\[
\overline{f}: I^n \rightarrow X
\]

\[
(x_1, \ldots, x_n) \mapsto f(1 - x_1, x_2, \ldots, x_n).
\]
We claim that \([f] \cdot \overline{f} = [f \circ \overline{f}] = [c_{x_0}]\). Thus we need to show that \(f \circ \overline{f}\) is homotopic to \(c_{x_0}\). It follows from Lemma 40.2 that \(f \circ \overline{f}\) is homotopic to the map

\[
\begin{align*}
  h: (I^n, \partial I^n) &\to (X, x_0) \\
  (x_1, \ldots, x_n) &\mapsto \begin{cases} 
    f(2x_1, x_2, \ldots, x_n), & \text{if } x_1 \in [0, \frac{1}{2}], \\
    \overline{f}(2x_1 - 1, x_2, \ldots, x_n), & \text{if } x_1 \in \left[\frac{1}{2}, 1\right], \\
    f(2-2x_1, x_2, \ldots, x_n), & \text{if } x_1 \in \left(\frac{1}{2}, 1 - \frac{1}{2}\right), \\
    x_0, & \text{otherwise}
  \end{cases}
\end{align*}
\]

Thus it suffices to show that \(h\) is homotopic to \(c_{x_0}\). It is in fact straightforward to see that the map

\[
H: I^n \times [0, 1] \to X \\
(x_1, \ldots, x_n, t) \mapsto \begin{cases} 
    f(2(x_1 - \frac{1}{2}), x_2, \ldots, x_n), & \text{if } x_1 \in \left[\frac{1}{2}, \frac{1}{2}\right], \\
    f(2 - 2(x_1 + \frac{1}{2}), x_2, \ldots, x_n), & \text{if } x_1 \in \left(\frac{1}{2}, 1 - \frac{1}{2}\right), \\
    x_0, & \text{otherwise}
  \end{cases}
\]

is a homotopy from \(h\) to \(c_{x_0}\). We refer to Figure 683 for an illustration of the argument. Basically the same argument also shows that \([\overline{f}] \cdot [f] = [f \circ \overline{f}] = [c_{x_0}]\). We have thus verified both statements of the proposition. 

\[\text{Figure 682}\]

\[\text{Figure 683}\]

---

651 This map is continuous by Lemma 14.3.

652 Even for \(n = 1\) this homotopy is different from the homotopy used in Proposition 14.6 (3). What is that?
**Example.** There is one non-empty topological space for which we can immediately compute the higher homotopy groups, namely the topological space consisting of a single point $P$. In this case the only map $I^n \to \{P\}$ is the constant map, hence we see that $\pi_n(\{P\}) = 0$ for any $n \geq 1$.

The higher homotopy groups $\pi_n(X,x_0)$ seem even more complicated than the fundamental group. Surprisingly at least their algebraic structure is much simpler.

**Proposition 40.3.** For any pointed topological space $(X,x_0)$ and any $n \geq 2$ the homotopy group $\pi_n(X,x_0)$ is abelian.

**Remark.** The higher homotopy groups were initially introduced by Eduard Čech in 1932 [Čech32]. Since it was quickly noticed that they are abelian it was initially assumed that higher homotopy groups are of little interest. This perception changed soon afterwards.

**Proof.** Suppose we are given two maps $f, g : (I^n, \partial I^n) \to (X,x_0)$. We have to show that $f * g$ is homotopic to $g * f$. The homotopy is described in Figure 684 for $n = 2$. It is straightforward to write down an explicit homotopy between $f * g$ and $g * f$ by composing four instances of the homotopy provided by Lemma 40.2. We leave the details to the reader.

![Figure 684](image-url)

**40.2. Alternative descriptions of homotopy groups.** In this short section we present several alternative points of views regarding elements in homotopy groups. In the following let $n \in \mathbb{N}$.

1. We denote by $\Phi : (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from page 126.
2. We write $* = (0, \ldots, 0, 1) \in S^n$. We denote by $\Psi : (\overline{B}^n/S^{n-1}, [S^{n-1}]) \to (S^n, *)$ the homeomorphism from page 182.

Now let $X$ be a topological space and let $x_0 \in X$. The above homeomorphisms $\Phi$ and $\Psi$, together with Lemma 3.24, define bijections

- (homotopy classes) of maps $(I^n, \partial I^n) \to (X,x_0)$
- (homotopy classes) of maps $(\overline{B}^n, S^{n-1}) \to (X,x_0)$
- (homotopy classes) of maps $(\overline{B}^n/S^{n-1}, [S^{n-1}]) \to (X,x_0)$
- (homotopy classes) of maps $(S^n, *) \to (X,x_0)$.

The four equivalences combined say that we can view elements in $\pi_n(X,x_0)$ as homotopy classes of maps $(S^n, *) \to (X,x_0)$. This point of view is perhaps closest to our visual
approach to thinking about topological spaces. But as we have seen above, for technical purposes it is often much easier to work with the maps \((I^n, \partial I^n) \to (X, x_0)\).

**Remark.** It is visually most natural to work with the last point of view, namely to think of elements in \(\pi_n(X, x_0)\) as homotopy classes of maps \((S^n, \ast) \to (X, x_0)\). Unfortunately with this definition it is a little less clear how the group structure on \(\pi_n(X, x_0)\) is defined. To visualize the group structure we need to work a little:

1. First note that the homeomorphism \(\Phi: (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})\) descends to a homeomorphism \(\overline{\Phi}: I/\partial I^n \to \overline{B}^n/S^{n-1}\).
2. We consider the homeomorphism \(\Theta := \overline{\Phi}^{-1} \circ \Psi^{-1}: S^n \to I^n/\partial I^n\). Note that it identifies the North Pole \((0, \ldots, 0, 1)\) with the point \([\partial I^n]\).
3. We write \(K := \{ (x_1, \ldots, x_n) \in I^n \mid x_1 = \frac{1}{2} \}\).

In Figure 685 we show \(K\) and its journey through the maps \(\Phi\) and \(\Psi\).

![Figure 685](image)

(4) We denote by \(S^n_1 \vee S^n_2\) the wedge of two copies of \(S^n\) along the point \(\ast \in S^n\).

(5) We refer to the map

\[ S^n \xrightarrow{\Theta} I^n/\partial I^n \to I^n/(\partial I^n \cup K) \to S^n_1 \vee S^n_2 \]

\[ [x_1, \ldots, x_n] \mapsto \begin{cases} \Theta^{-1}(\{2x_1, x_2, \ldots, x_n\}) & \text{if } x_1 \in [0, \frac{1}{2}], \\ \Theta^{-1}(\{2x_1 - 1, x_2, \ldots, x_n\}) & \text{if } x_1 \in [\frac{1}{2}, 1] \end{cases} \]

as the pinching map.

(6) It follows basically immediately from the definitions that the group structure on \(\pi_n(X, x_0)\) is given as follows:

\[ \pi_n(X, x_0) \times \pi_n(X, x_0) \to \pi_n(X, x_0) \]

\[ ([f_1: S^n \to X], [f_2: S^n \to X]) \mapsto [S^n \to S^n_1 \vee S^n_2 \xrightarrow{f_1 \vee f_2} X]. \]

In Figure 686 we sketch the pinching map and we sketch the corresponding definition of the group structure on \(\pi_n(X, x_0)\).

We conclude this section with the following lemma that can be viewed as a generalization of Lemma 14.1

---

653 It follows easily from Lemma 2.35 (2') that this map is continuous.

654 The meticulous reader will notice that it is perhaps not completely clear how the maps \(f\) and \(g\) are defined on the two smaller spheres.
Lemma 40.4. Let $X$ be a topological space, let $x_0 \in X$ and let $n \geq 1$. Furthermore let $f: (S^n, *) \to (X, x_0)$ be a map. Then the following statements are equivalent:

1. the map $f: S^n \to X$ is homotopic to a constant map,
2. there exists a map $F: \overline{B}^{n+1} \to X$ so that $F|_{S^n} = f$,
3. $f$ represents the trivial element in $\pi_n(X, x_0)$.

Proof (*). The equivalence of (2) and (3) is proved in a similar way as Lemma 40.1. We leave it to the reader to make the fairly straightforward modifications.

We turn to the proof that (3) implies (2). This is basically obvious. Indeed, the fact that $f$ represents the trivial element in $\pi_n(X, x_0)$ means that there exists a homotopy of maps of pairs $(S^n, *) \to (X, x_0)$ from $f$ to the constant map. But this means in particular that $f$ is homotopic to the constant map $c_{x_0}$.

Finally suppose that (1) holds. This means that we assume that there exists a homotopy $H: S^n \times [0, 1] \to X$ with $H_0 = f$ and $H_1 = c_{x_0}$. This time we do not assume that $H(*, t) = *$ for all $\in [0, 1]$. We consider the map

$$F: \overline{B}^{n+1} \to X$$

$$P \mapsto \begin{cases} H(Q, 2 - 2t), & \text{if } P = Q \cdot t \text{ with } Q \in S^n \text{ and } t \in [1, \frac{1}{2}], \\ x_0, & \text{otherwise.} \end{cases}$$

It follows from Lemma 2.35 (2) that this map is indeed continuous. By construction we have $F|_{S^n} = f$. Thus we see that (2) is satisfied. This concludes the proof that all three statements are equivalent.

Figure 686. Illustration for the proof of Lemma 40.4.
40.3. **Properties and basic calculations of higher homotopy groups.** Now we want to understand some of the basic properties of higher homotopy groups. Perhaps not surprisingly, many of the basic statements about the fundamental group can be easily generalized to the setup of higher homotopy groups.

For example the following proposition can be viewed as a generalization of Proposition [14.11]

**Proposition 40.5.** Let $X$ be a topological space, let $x_0$ and $x_1$ be two points in $X$ and let $\gamma: [0, 1] \to X$ be a path from $x_0$ to $x_1$. Given a map $f: (I^n, \partial I^n) \to (X, x_1)$ we consider the map $f^{\gamma}$

$$f^{\gamma}: (I^n, \partial I^n) \to (X, x_0)$$

$$(t_1, \ldots, t_n) \mapsto \begin{cases} f(2t_1 - \frac{1}{2}, \ldots, 2t_n - \frac{1}{2}), & \text{if } (t_1, \ldots, t_n) \in \left[\frac{1}{4}, \frac{3}{4}\right]^n, \\ \gamma(t), & \text{if } (t_1, \ldots, t_n) \in \partial\left(\left[\frac{1}{4}, \frac{3}{4}\right]^n\right) \text{ for } t \in [0, 1]. \end{cases}$$

The definition of $f^{\gamma}$ is illustrated in Figure 688. The map $\gamma_*: \pi_n(X, x_1) \to \pi_n(X, x_0)$ $[f] \mapsto [f^{\gamma}]$ is well-defined and it is a group isomorphism.

**Remark.** If $X$ is a path-connected topological space and if we are only interested in the isomorphism type of the $n$-th homotopy group of $X$, then sometimes we use this proposition as an excuse to just write $\pi_n(X)$, i.e. we suppress the base point from the notation.

**Proof.** Let $X$ be a topological space, let $x_0$ and $x_1$ be two points in $X$ and let $\gamma: [0, 1] \to X$ be a path from $x_0$ to $x_1$. We need to prove the following claim.

**Claim.**

1. The map $\Phi: \pi_n(X, x_1) \to \pi_n(X, x_0)$ given by $[f] \mapsto [f^{\gamma}]$ is well-defined,
2. the map $\Phi$ is a bijection, and
3. the map $\Phi$ is a group homomorphism.

---

655If we view elements in $\pi_1(X, x_1)$ as represented by maps $(S^1, *) \to (X, x_1)$, what does the corresponding map $\pi_1(X, x_1) \to \pi_1(X, x_0)$ look like?

656Using Lemma 2.35 (2) one can easily verify that the map is continuous.
We quickly discuss the three statements of the claim:

1. This statement can be verified easily by hand.
2. As usual we denote by $\gamma$ the path given by $\gamma(t) = \gamma(1-t)$. It is straightforward to verify that the map $\Psi: \pi_n(X, x_0) \to \pi_n(X, x_1)$ given by $[g] \mapsto [f\gamma]$ is an inverse to $\Phi$.
3. Now let $f, g: (I^n, \partial I^n) \to (X, x_0)$ be maps. We need to show that $f^\gamma * g^\gamma$ is homotopic to $(f * g)^\gamma$. (These two maps are illustrated in Figure 689.) It should be clear that verifying this statement is elementary, in the sense that one can write down an explicit homotopy. On the other hand it should also be clear that writing down an explicit homotopy is supremely painful and highly non-instructive. Thus we will skip this step and leave it to the eager reader to fill in the details. ■

![Figure 689. Illustration of the proof of Proposition 40.5.](image)

Next we will see that higher homotopy groups are functorial.

**Definition.** Let $f: X \to Y$ be a map between two topological spaces, let $n \in \mathbb{N}$ and let $x_0 \in X$. We write $y_0 = f(x_0)$. The map

$$f_*: \pi_n(X, x_0) \to \pi_n(Y, y_0)$$

$$[\sigma: (I^n, \partial I^n) \to (X, x_0)] \mapsto [f \circ \sigma: (I^n, \partial I^n) \to (X, x_0) \overset{f}{\to} (Y, y_0)]$$

is well-defined map and it is a group homomorphism for every $n \geq 1$\footnote{Both statements follow basically immediately from the definitions.}. As usual we say that $f_*$ is the map induced by $f$.

The following proposition is straightforward generalization of Proposition 15.6.

**Proposition 40.6.** Let $n \geq 1$. Recall that we denote by $\mathcal{PTop}$ the category of pointed topological spaces and that we denote by $\mathcal{Gr}$ be the category of groups. Then

$$\text{Ob}(\mathcal{PTop}) \to \text{Ob}(\mathcal{Gr})$$

$$(X, x_0) \mapsto \pi_n(X, x_0)$$

together with the maps

$$\text{Mor}(\mathcal{PTop}) \to \text{Mor}(\mathcal{Gr})$$

$$(f: (X, x_0) \to (Y, y_0)) \mapsto (f_*: \pi_n(X, x_0) \to \pi_n(Y, y_0))$$

is a covariant functor.
Proof. It follows immediately from the definitions that
\[ \text{id}_* = \text{id} \quad \text{for all pointed pairs} \ (X, x_0), \]
and that
\[ (g \circ f)_* = g_* \circ f_* \quad \text{for all maps} \ f : (X, x_0) \to (Y, y_0) \text{ and } g : (Y, y_0) \to (Z, z_0). \]
But this is exactly what we need to show. \(\blacksquare\)

We continue with the following fairly elementary but useful proposition.

**Proposition 40.7.** Let \( n \geq 1 \).

(1) Let \( f, g : X \to Y \) be two maps between topological spaces and let \( x_0 \in X \). If \( f \) and \( g \) are homotopic, then
\[ f_* : \pi_n(X, x_0) \to \pi_n(Y, f(x_0)) \]
is an isomorphism \iff \[ f_* : \pi_n(X, x_0) \to \pi_n(Y, g(x_0)) \]
is an isomorphism.

The analogous statement holds if we replace “isomorphism” by “epimorphism” or “monomorphism”.

(2) Let \( f : X \to Y \) be a map between topological spaces and let \( x_0 \in X \) be a point. If \( f \) is a homotopy equivalence, then
\[ f_* : \pi_n(X, x_0) \to \pi_n(Y, f(x_0)) \]
is an isomorphism.

(3) If \( X \) is a contractible topological space, then the following two statements hold:

(a) For any base point \( x_0 \in X \) we have \( \pi_n(X, x_0) = 0 \).

(b) Any map \( f : S^n \to X \) can be extended to a map \( \overline{B}^{n+1} \to X \).

(4) Let \( (X, x_0) \) be a pointed topological space. If we denote by \( Y \) the component of \( X \) that contains \( x_0 \) and if we denote by \( i : Y \to X \) the inclusion map, then the map
\[ i_* : \pi_n(Y, x_0) \to \pi_n(X, x_0) \]
is an isomorphism.

Proof.

(1) This statement is proved basically the same way as Proposition [18.16] (1). We leave it to the reader to make the necessary changes to the argument.

(2) As in the case of Proposition [18.16] one can easily deduce Statement (2) from Statement (1).

(3) Let \( X \) be a contractible topological space.

(a) By definition of “contractible” the topological space \( X \) is homotopy equivalent to a topological space consisting of a single point \( \{*\} \). Evidently \( \pi_n(\{*\}, *) = 0 \), which by (2) implies that \( \pi_n(X, x_0) = 0 \) for some base point \( x_0 \). In Lemma [18.13] we saw that a contractible topological space is path-connected. Thus it follows from Proposition [40.5] that \( \pi_n(X, x_0) = 0 \) for any base point \( x_0 \).

(b) This statement is proved basically the same way as Lemma [14.1] For completeness’ sake we carry out the argument. So let \( f : S^n \to X \) be a map. We pick a base point \( * \) for \( S^n \) and we set \( x_0 := f(*) \). By (a) we know that \( \pi_n(X, x_0) = 0 \). We take the point of view from page [1060]. Thus we can view \([f]\) as an element
in \( \pi_n(X, x_0) = 0 \). By definition \([f] = 0\) means that there exists a homotopy \( F: S^n \times [0, 1] \to X \) such that \( F(p, 0) = f(p) \) for all \( p \in S^n \), that \( F(p, 1) = x_0 \) for all \( p \in S^n \) and that \( F(*, t) = x_0 \) for all \( t \in [0, 1] \). We consider the map

\[
\overline{B}^{n+1} \to X \\
\begin{align*}
 r \cdot v & \mapsto F(v, (1 - r))
\end{align*}
\]

where we write a point in \( \overline{B}^{n+1} \) as \( r \cdot v \) with \( r \in [0, 1] \) and \( v \in S^n \). It follows from Lemma 3.25 (2) that this map is indeed continuous. Clearly this is the desired extension.

(c) This statement is an easy consequence of Lemma 2.70 and the fact that \( I^n \) is path-connected. ■

**Example.** The topological space \( \mathbb{R}^n \) is homotopy equivalent to a point \( P \). Thus it follows from Proposition [40.7] (2) and the discussion on page 1059 that \( \pi_k(\mathbb{R}^n) \cong \pi_k(P) \cong 0 \). Exactly the same way, using the discussion on page 548, one can show that all the higher homotopy groups of convex subsets of \( \mathbb{R}^n \) vanish, e.g. we have \( \pi_k(B^n) = \pi_k(B^n) = 0 \).

The following proposition is the high-dimensional analogue of Proposition 16.20.

**Proposition 40.8.** Let \( A \) and \( B \) be two topological spaces and let \( a_0 \in A \) and \( b_0 \in B \). We consider the inclusion maps

\[
i: A \to A \times B \\
a \mapsto (a, b_0)
\]

and \( j: B \to A \times B \)

\[
b \mapsto (a_0, b)
\]

and we consider the projection maps

\[
p: A \times B \to A \\
(a, b) \mapsto a
\]

and \( q: A \times B \to B \)

\[
(b) \mapsto b.
\]

(1) The maps

\[
\Phi: \pi_n(A, a_0) \times \pi_n(B, b_0) \to \pi_n(A \times B, (a_0, b_0)) \\
(x, y) \mapsto i_\ast(x) \cdot j_\ast(y)
\]

and

\[
\Psi: \pi_n(A \times B, (a_0, b_0)) \to \pi_n(A, a_0) \times \pi_n(B, b_0) \\
z \mapsto (p_\ast(z), q_\ast(z))
\]

are both homomorphisms and they are inverses of one another, in particular both are isomorphisms.

(2) The map \( \Phi \) agrees with the map

\[
\Theta: \pi_n(A, a_0) \times \pi_n(B, b_0) \to \pi_n(A \times B, (a_0, b_0)) \\
([f: (S^n, *) \to (A, a_0)], [g: (S^n, *) \to (B, b_0)]) \mapsto \left[ (S^n, *) \to (A \times B, (a_0, b_0)) \right] z \mapsto (f(z), g(z))
\]

In particular we obtain from (1) that \( \Theta \) is a homomorphism.

---

\(^{658}\)In fact in this case it follows immediately from Proposition 40.3 and Lemma 16.19 that \( \Phi \) is a homomorphism.
Proposition 40.9.

(1) Let \( X \) be a CW-complex and let \( k \in \mathbb{N}_0 \). As usual we denote by \( X^k \) the \( k \)-skeleton of \( X \). Let \( x_0 \in X^k \). The following two statements hold:

(a) For \( j = 1, \ldots, k-1 \) the inclusion induced map \( \pi_j(X^k, x_0) \to \pi_j(X, x_0) \) is an isomorphism.

(b) The inclusion induced map \( \pi_k(X^k, x_0) \to \pi_k(X, x_0) \) is an epimorphism.

(2) Let \( X \) be a CW-complex with a single 0-cell \( x_0 \) and let \( n \in \mathbb{N} \). If \( X \) has no cells in dimensions \( 1, \ldots, n \), then \( \pi_n(X, x_0) = 0 \) for \( k = 1, \ldots, n \).

Note that the above proposition is a generalization of Corollary 37.14.

Proof.

(1) Let \( X \) be a CW-complex and let \( x_0 \in X^k \). We denote by \( i: X^k \to X \) the inclusion. We take the point of view from page 1060, i.e., we view elements of \( \pi_j(X, x_0) \) as homotopy classes of maps \( (S^j, \ast) \to (X, x_0) \). As on page 935, we consider the \( j \)-sphere \( S^j \) as a CW-complex with one 0-cell \( \ast \) and one \( j \)-cell.

(a) First we show that for \( j = 1, \ldots, k \) the map \( i_*: \pi_j(X^k, x_0) \to \pi_j(X, x_0) \) is an epimorphism.

Let \( [g] \in \pi_j(X, x_0) \) be some element. In other words, we are given a map \( g: (S^j, \ast) \to (X, x_0) \) is a map. By the Cellular Approximation Theorem \ref{cellular_approximation}, we can assume that \( g \) is a homotopy of maps \( (S^j, \ast) \to (X, x_0) \) of pairs of topological spaces. Thus we see that \( [g] = [\tilde{g}] \in \pi_j(X, x_0) \).

Since \( \tilde{g} \) is cellular, we know that \( \tilde{g}(S^j) \) lies in the \( j \)-skeleton of \( X \). Since \( j \leq k \) we see in particular that \( \tilde{g}(S^j) \) is contained in \( X^k \). In other words, \( \tilde{g} \) is a map \( (S^k, \ast) \to (X^k, x_0) \). This shows that \( [g] = [\tilde{g}] = [i \circ \tilde{g}] = i_*([\tilde{g}]) \) lies in the image of \( \pi_j(X^k, x_0) \).

(b) Now we show that for \( j = 1, \ldots, k-1 \) the map \( i_*: \pi_j(X^k, x_0) \to \pi_j(X, x_0) \) is a monomorphism. So suppose that we are given \( f_0, f_1 \in \pi_j(X^k, x_0) \) with \( i_*([f_0]) = i_*([f_1]) \). By the Cellular Approximation Theorem \ref{cellular_approximation}, we can assume that the maps \( f_0, f_1: (S^j, \ast) \to (X^k, x_0) \) are cellular. The fact that \( i_*([f_0]) = i_*([f_1]) \) means that there exists a homotopy \( H: S^j \times [0,1] \to X \) with \( H_0 = f_0 \) and \( H_1 = f_1 \). This time we apply the Cellular Approximation Theorem \ref{cellular_approximation} to the map \( H: S^j \times [0,1] \to X \) and the subcomplex \( (S^j \times \{0\}) \cup (S^j \times \{1\}) \) and we obtain a cellular map \( \tilde{H}: S^j \times [0,1] \to X \) such that \( \tilde{H}_0 = H_0 = f_0 \) and \( \tilde{H}_1 = H_1 = f_1 \). Since \( \tilde{H} \) is cellular it takes values in the \((j+1)\)-skeleton of \( X \times [0,1] \). Since \( j < k \)
we see in particular that \( \tilde{H} \) takes values in \( X^k \times [0, 1] \). But this means that we can use \( \tilde{H} \) to show that \( [f_0] = [f_1] \in \pi_k(X^k, x_0) \).

(2) Let \( n \in \mathbb{N} \). Let \( X \) be a CW-complex with a single 0-cell \( x_0 \) and which has no cells in dimensions \( 1, \ldots, n \). Let \( k \in \{1, \ldots, n\} \). By hypothesis the \( k \)-skeleton of \( X \) equals \( \{x_0\} \). By (1a) we know that the map \( \pi_k(\{x_0\}, x_0) \to \pi_k(X, x_0) \) is an epimorphism. But the former group is evidently trivial, hence \( \pi_k(X, x_0) \) is trivial as well.

In Proposition 14.14 we saw that \( \pi_1(S^n) = 0 \) for \( n \geq 2 \). Now we can prove the analogous statement for higher homotopy groups. Now we obtain, basically for free, the following much more general proposition.

**Proposition 40.10.** Let \( n \in \mathbb{N} \). For any \( k \in \{1, \ldots, n-1\} \) we have

\[
\pi_k(S^n) = 0.
\]

**Proof.**

(1) Again, as on page 935 we consider the \( n \)-sphere \( S^n \) as a CW-complex with one 0-cell and one \( n \)-cell. With this CW-structure it follows immediately from Proposition 40.9 that \( \pi_k(S^n) = 0 \) for \( k = 1, \ldots, n-1 \).

(2) An alternative approach to proving Proposition 40.10 is given by the point of view taken in Exercise 9.1 where we used the Whitney Approximation Theorem 9.3 and Proposition 6.62 to show that for an \( n \geq 2 \) we have \( \pi_1(S^n) = 0 \).

The following proposition is also a straightforward generalization from the setting of fundamental groups to the setting of higher homotopy groups. The proof is almost verbatim the same as the proof of Proposition 37.3 and of Proposition 25.7.

**Proposition 40.11.** Let \( X \) be a topological space and let \( X_1 \subset X_2 \subset X_3 \subset \ldots \) be a sequence of subsets such that \( X = \bigcup_{i \in \mathbb{N}} X_i \) and such that one of the following three conditions holds:

(1) every compact subset of \( X \) is already contained in one of the \( X_i \), or
(2) each \( X_i \) is open in \( X \), or
(3) \( X \) is a CW-complex and each \( X_i \) is a subcomplex.

Then for any \( w \in X_1 \) and any \( n \in \mathbb{N} \) the inclusion induced maps \( \pi_n(X_i, w) \to \pi_n(X, w) \) induce an isomorphism

\[
\pi_n(X, w) = \lim_{i \to \infty} \pi_n(X_i, w).
\]

In Lemma 36.4 we already saw that \( S^\infty \) is contractible, thus we know by that all homotopy groups are trivial. But it is also illuminating to apply Proposition 40.11 to obtain this result.

**Corollary 40.12.** For every \( n \in \mathbb{N} \) we have \( \pi_n(S^\infty) = 0 \).
Proof. We equip $S^\infty$ and all spheres $S^k$, $k \in \mathbb{N}$ with the CW-complex structure that we defined on page 942. We have

\[
\pi_n(S^\infty) = \pi_n\left( \bigcup_{k \in \mathbb{N}} S^k \right) = \lim_{\rightarrow} \pi_n(S^k) = 0.
\]

\[\blacksquare\]

40.4. Covering spaces and higher homotopy groups. One of the main tools in studying fundamental groups was to study the relationship between the fundamental group of a topological space and coverings of the given topological space. Perhaps somewhat surprisingly, for $n \geq 2$ we have a completely different relationship between the $n$-th homotopy group and coverings.

Proposition 40.13. Let $p: (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces. Let $n \geq 2$. Then the following two statements hold:

1. The map $p_*: \pi_n(X,x_0) \to \pi_n(B,b_0)$ is an isomorphism.

2. The map

\[
\pi_n(B,b_0) \to \pi_n(X,x_0) \quad f: (S^n,*) \to (B,b_0) \mapsto [\text{unique lift of } f \text{ to a map } (S^n,*) \to (X,x_0)]
\]

is well-defined and it is the inverse to $p_*$. 

Before we provide the proof of Proposition 40.13 let us first state an immediate, and very useful, corollary to Proposition 40.13 and let us give a few examples.

Corollary 40.14. Let $X$ be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Given any $n \geq 2$ the universal covering $p: \widetilde{X} \to X$ induces an isomorphism

\[p_*: \pi_n(\text{universal covering } \widetilde{X} \text{ of } X) \cong \pi_n(X).
\]

Now we present some examples for Corollary 40.14. We will consider a few more examples after the proof of Proposition 40.13.

Examples.

1. Let $k \in \mathbb{N}$ and $n \geq 2$. We have

\[
\pi_n((S^1)^k) = \pi_n(\mathbb{R}^k/\mathbb{Z}^k) \xrightarrow{\cong} \pi_n(\mathbb{R}^k) \uparrow 0.
\]

Proposition 40.13 page 1065

In particular we see that all of the higher homotopy groups of $S^1$ and the torus $S^1 \times S^1$ vanish.

---

\[659\] Here we take the point of view from page 1060 where we saw that we view the elements of $\pi_n(B,b_0)$ as homotopy classes of maps $(S^n,*) \to (B,b_0)$.

\[660\] In Corollary 29.9 we showed that every topological space $X$ that is path-connected, locally path-connected and semi-locally simply connected admits a universal covering $p: \widetilde{X} \to X$, i.e. a covering such that $\widetilde{X}$ is simply connected.
(2) We consider $X = S^1 \vee S^2$. On page 836 we had determined its universal covering $\tilde{X}$. For convenience we picture it again in Figure 690. It follows from Proposition 40.13 that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\pi_2(\tilde{X})$. At the moment we cannot determine $\pi_2(X)$, but since $\tilde{X}$ has “infinitely many spheres” one might expect $\pi_2(\tilde{X})$ to be pretty big.

\[ \begin{array}{c}
\tilde{X} \\
\xrightarrow{p} \\
X = S^1 \vee S^2
\end{array} \]

\textbf{Figure 690}

(3) One of our goals is still to complete the classification of lens spaces, in particular we would like to answer Question 16.7. So let $L(p, q)$ and $L(p, r)$ be two lens spaces. Then for any $n \geq 2$ we have

$$
\pi_n(L(p, q)) \xleftarrow{\cong} \pi_n(S^3) \xrightarrow{\cong} \pi_n(L(p, r)).
$$

Proposition 40.13

We do not know the higher homotopy groups of $S^3$, but this argument shows that higher homotopy groups are useless for distinguishing lens spaces.

\textbf{Proof of Proposition 40.13}. Let $p: (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces and furthermore let $n \geq 2$. Our goal is to construct an inverse to the map $p_*: \pi_n(X, x_0) \to \pi_n(B, b_0)$.

We saw on page 1060 that we can think of elements in $\pi_n(B, b_0)$ as homotopy classes of maps $(S^n, \ast) \to (B, b_0)$. Thus let $f: (S^n, \ast) \to (B, b_0)$ be given. We are in the following setting:\footnote{In Proposition 29.2 we need that the sphere $S^n$ is of path-connected and locally path-connected, but there are no hypotheses on $B$ or $X$.}

\[ \begin{array}{c}
(X, x_0) \\
\xrightarrow{p} \\
(B, b_0)
\end{array} \]

$$(S^n, \ast) \xrightarrow{f} (B, b_0).$$

Furthermore it follows again from Proposition 29.2 applied to $Z = S^n \times [0, 1]$, that the lifts of two homotopic maps $(S^n, \ast) \to (B, b_0)$ are two homotopic maps $(S^n, \ast) \to (X, x_0)$.

Summarizing we just constructed a map

$$
\lambda: \pi_n(B, b_0) \to \pi_n(X, x_0)
$$

$$
[f] \mapsto [\tilde{f}].
$$

\footnote{Here there is a little hidden subtlety: if $F: S^n \times [0, 1] \to B$ is a homotopy between two maps $f, g: (S^n, \ast) \to (B, b_0)$, then we can lift $f, g$ to maps $\tilde{f}, \tilde{g}: (S^n, \ast) \to (X, x_0)$. Furthermore we can apply Proposition 29.2 to lift $F$ to a map $\tilde{F}: S^n \times [0, 1] \to X$ such that $\tilde{F}(*, 0) = x_0$. We still need to show that $\tilde{F}(*, t) = x_0$ for all $t \in [0, 1]$. We know that for every $t \in [0, 1]$ we have $\tilde{F}(*, t) \in p^{-1}(b_0)$. By Lemma 16.3 the preimage $p^{-1}(b_0)$ is discrete. Since $[0, 1]$ is connected it follows that the map $p: [0, 1] \to p^{-1}(b_0)$ is constant by Lemma 2.61. But since it takes the value $x_0$ for $t = 0$ it takes the value $x_0$ for all $t \in [0, 1]$.}
Now we have to show that $\lambda$ is an inverse to $p_*$. First of all, given any $[f] \in \pi_n(B, b_0)$ we have
\[(p_\ast \circ \lambda)([f]) = p_\ast([\widetilde{f}]) = [p \circ \widetilde{f}] = [f].\]
Now let $[g] \in \pi_n(X, x_0)$. We then have
\[(\lambda \circ p_\ast)([g]) = \lambda([p \circ g]) = [g],\]
since $g$ is the unique lift of $p \circ g$ to $x_0$. \hfill \blacksquare

Now we give a few more applications of Proposition [40.13].

Examples.

(1) Let $\Sigma$ be a surface of genus $\geq 2$. In Theorem [33.9] we have seen that there exists a covering $p: \mathbb{D} \to \Sigma$ where $\mathbb{D} = B_1(0) \subset \mathbb{C}$. Since $\mathbb{D}$ is convex it follows from Proposition [40.13] and the discussion on page 1065 that $\pi_n(\Sigma) \cong \pi_n(\mathbb{D}) = 0$ for all $n \geq 2$.

Together with the example on page 1068 we have now shown that the higher homotopy groups of every surface of genus $\geq 1$ vanish.

(2) Let $\Sigma$ be a surface of genus $\geq 1$ and let $f: \Sigma \to \Sigma$ be a self-homeomorphism. We denote by $\text{Tor}(\Sigma, f)$ the mapping torus that we introduced on page 711. For $n \geq 2$ we have
\[
\pi_n(\text{Tor}(\Sigma, f)) \cong \pi_n(\Sigma \times \mathbb{R}) \cong \pi_n(\Sigma) = 0.
\]
by Lemma [24.26] Proposition [40.7] previous example

and Proposition [40.13]

Lemma 40.15. Let $X$ be a 1-dimensional CW-complex and let $x_0 \in X$ be base point. Then $\pi_n(X, x_0) = 0$ for every $n \geq 2$.

Sketch of proof. Let $X$ be a 1-dimensional CW-complex, let $x_0 \in X$ and let $n \geq 2$. We first assume that $X$ is finite and connected. We write $k = 1 - \chi(X)$. We have
\[
\pi_n(X) \cong \pi_n\left(\bigvee_{i=1}^{k} S^1\right) \cong \pi_n\left(\text{universal covering of } \bigvee_{i=1}^{k} S^1\right) \cong \lim \pi_n(\text{trees } T_i) = \lim 0 = 0.
\]
Proposition [37.8] (2) and Proposition [40.13] Proposition [40.11] and Figure 691 Proposition [40.29] and Proposition [40.7]

universal covering of $S^1 \vee S^1$

$S^1 \vee S^1$

union of an ascending sequence of trees $\{T_i\}_{i \in \mathbb{N}}$

Figure 691
Now suppose that $X$ is an arbitrary 1-dimensional CW-complex. Let $[f] \in \pi_n(X, x_0)$. It follows from Theorem 36.14 that the image of $f$ lies in a finite connected subcomplex $Y$ of $X$. But by the above discussion $[f] = 0 \in \pi_n(Y, x_0)$, hence, by functoriality of $\pi_n$, we also have $[f] = 0 \in \pi_n(X, x_0)$.

The discussion of $\pi_2(S^1 \vee S^2)$ on page 1069 strongly suggests that even simple topological spaces can have surprisingly large higher homotopy groups. This raises the following anxious question, which after these examples is no longer totally absurd.

**Question 40.16.** Are the homotopy groups of a countable CW-complex countable?

**Remark.** On page 1032 we saw that at least the fundamental of a countable CW-complex is countable.

We will answer this question in Proposition 85.19.

40.5. **Are there any higher homotopy groups that are non-trivial?** We have now computed lots of higher homotopy groups, but so far the results have been rather dull, all the groups we have computed so far are trivial.

So are there any higher homotopy groups that are non-trivial? A natural candidate for a non-trivial group is surely $\pi_n(S^n)$. The following question naturally arises:

**Question 40.17.** Let $n \geq 2$. Does the identity map $\text{id}: S^n \to S^n$ define a non-trivial element in the homotopy group $\pi_n(S^n, \ast)$?

We can also ask, what are the higher homotopy groups of spheres, i.e. what can we say about $\pi_k(S^n)$ for $k > n$? On page 1068 we saw that all these groups are trivial for $n = 1$. But what happens for $n > 1$? Can the higher homotopy groups of spheres be non-trivial?

To construct our first example of a potentially interesting map from a higher-dimensional to a lower-dimensional sphere we recall that on page 197 we gave an identification $\mathbb{C}P^1 = S^2$. We consider the following map which is usually referred to as the *Hopf map*:

$$H: S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\} \to S^2 = \mathbb{C}P^1 \quad (z_1, z_2) \mapsto [z_1 : z_2].$$

The homotopy class of $H$ defines an element in $\pi_3(S^2)$.

**Question 40.18.** Does the Hopf map $H: S^3 \to S^2$ represent a non-trivial element in the homotopy group $\pi_3(S^2)$?

**Remark.** The definition of the Hopf map is very elegant, but unfortunately we pay for the elegance by loosing any intuition for what the map looks like. So how are supposed to think about the Hopf map? A straightforward calculation shows that for each $P \in S^2$ the preimage $H^{-1}(\{P\})$ is a circle. Furthermore, if we use the explicit homeomorphism from Lemma 2.44 to make the identification of $S^3$ with $\mathbb{R}^3 \cup \{\infty\}$ then we can make the following observations:

1. the circle $S^1 \times \{0\}$ corresponds to the points $(z, 0) \in S^3$, in particular the circle gets sent to the point $[1 : 0] \in \mathbb{C}P^1$.

Heinz Hopf (1894-1971) was a German mathematician.
(2) the circle that is given by the $z$-axis together with $\infty$ corresponds to the points $(0, z) \in S^3$, in particular the circle gets sent to the point $[0 : 1] \in \mathbb{C}P^1$.

Next recall that Lemma 27.1 we gave an explicit identification

$$\left( S^1 \times \mathbb{B}^2 \right) \cup_{S^1 \times S^1} \left( \mathbb{B}^2 \times S^1 \right) \cong S^3.$$ 

It follows from the definition of this identification that on the torus $S^1 \times S^1$ the “diagonal circle” $\{(z, z) | z \in S^1\}$ is the preimage of the point $[1 : 1] \in \mathbb{C}P^1$. In Figure 692 we show the preimages of $H$ for some points in $\mathbb{C}P^2 = S^2$.

We introduce one more construction of maps that represent potentially non-trivial elements in homotopy groups of spheres.

**Definition.**

1. Let $X$ be a topological space. Recall that on page 694 we defined the suspension of $X$ to be the topological space

$$\Sigma(X) := (X \times [-1, 1])/\sim$$

where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point. We refer to the point $[X \times \{1\}]$ as the *North Pole* of $\Sigma(X)$.

2. Given a map $f : X \to Y$ between topological spaces we denote by

$$\Sigma(f) : \Sigma(X) \to \Sigma(Y)$$

$$[(x, t)] \mapsto [(f(x), t)]$$

the suspension of $f$.

---

Note that in Lemma 27.2 we saw that the corresponding smooth embedding $S^1 \times \mathbb{B}^2 \to S^3$ is essential given by the standard smooth embedding.
Remark. Let \( n \in \mathbb{N}_0 \). Recall that on page 695 we wrote down an explicit homeomorphism \( \Sigma(S^n) \to S^{n+1} \) that sends the North Pole of \( \Sigma(S^n) \) to the North Pole \((0, \ldots, 0, 1)\) of \( S^{n+1} \). We will use this homeomorphism to identify \( \Sigma(S^n) \) with \( S^{n+1} \).

Now we have the following elementary lemma.

**Lemma 40.19.** Let \( k \in \mathbb{N}_0 \).

1. Let \((X, x_0)\) be a pointed topological space. We denote by \(*\) the North Pole of \( \Sigma(X) \).
   The map
   \[
   \pi_k(X, x_0) \to \pi_{k+1}(\Sigma(X), *)
   \]
   \[
   [f: S^k \to X] \mapsto \left[ \Sigma(f): \Sigma(S^k) = S^{k+1} \to \Sigma(X) \right]
   \]
   is a well-defined group homomorphism. We refer to it as the suspension homomorphism.

2. Let \( n \in \mathbb{N}_0 \). We denote by \(*\) the North Pole of \( S^n \) and \( S^{n+1} \). The map
   \[
   \pi_k(S^n, *) \to \pi_{k+1}(S^{n+1}, *)
   \]
   \[
   [f: S^k \to S^n] \mapsto \left[ \Sigma(f): \Sigma(S^k) = S^{k+1} \to \Sigma(S^n) = S^{n+1} \right]
   \]
   is a well-defined group homomorphism. We refer to it also as the suspension homomorphism.

**Proof.**

1. It follows from Lemma 24.4 (4) that this map is well-defined. We leave it the task of verifying that the map is in fact a group homomorphism as a somewhat challenging exercise to the reader. Alternatively we refer to [Hilt53, Theorem 2.1] for a proof.

2. This statement follows immediately from (1).

---

We conclude this chapter with the following question:

**Question 40.20.** Let \( H: S^3 \to S^2 \) be the Hopf map. Is the image of \([H] \in \pi_3(S^2)\) under the iterated suspension homomorphisms \( \pi_3(S^2, x_0) \to \pi_{3+k}(S^{2+k}, x_1) \) non-trivial?

Unfortunately at the moment we do not have the tools to answer any of the above questions. In general it is very hard to compute higher homotopy groups as there are few computational techniques that can be used to show that higher homotopy groups are non-zero. One of the key problems is that there is no analogue to the Seifert–van Kampen Theorem 22.1. We will get to know a few techniques to compute higher homotopy groups of spheres, but we will cover these only in much later chapter, since the calculations will require the use of singular homology groups. But even then we will only be able to determine some homotopy groups of spheres. The results we obtain are summarized in Chapter 118. But note that the full computation of homotopy groups of spheres is still an open problem.

This sorry state of affairs means that as of right now we cannot use higher homotopy groups to distinguish any of the topological spaces that we could not distinguish already.

---

\(^{665}\)In an earlier version of these it was written that “it is straightforward to see that the map is well-defined”. If one traces through the ancestry of Lemma 24.4 (4) one realizes that this lemma is, despite appearances, by no means obvious.
using the fundamental group. In particular we still cannot show that for \( k \neq l \) the topological spaces \( \mathbb{R}^k \) and \( \mathbb{R}^l \) are not homeomorphic. We will only be able to do so after developing a new tool, namely the singular homology groups, in the coming sections.

Exercises for Chapter 40

Exercise 40.1. Let \( X \) be a topological space, let \( x_0 \in X \) and let \( f : (I^n, \partial I^n) \to (X, x_0) \) be a map with \( n \geq 1 \). We consider the map
\[
\tilde{f} : I^n \to X \\
(x_1, \ldots, x_n) \mapsto f(1 - x_1, 1 - x_2, \ldots, 1 - x_n).
\]

Is \( \tilde{f} \in \pi_n(X, x_0) \) the inverse of \( [f] \in \pi_n(X, x_0) \)?

Exercise 40.2. Let \( k \leq l \) be natural numbers, let \( f : S^k \to S^l \) be a map and let \( x_0 \in S^k \). Show that for any \( i \in \mathbb{N} \) the map \( f_* : \pi_i(S^k, x_0) \to \pi_i(S^l, f(x_0)) \) is the trivial map.

Hint. Use Proposition 40.10

Exercise 40.3. In this exercise you can assume that we already know that \( \pi_3(S^2) \cong \mathbb{Z} \). Show that there exists an epimorphism \( \pi_3(S^1 \lor S^2) \to \mathbb{Z}^3 \oplus \mathbb{Z}_4 \).

Exercise 40.4. Let \( n \in \mathbb{N} \) and let \( K \) be a non-empty compact subset of \( \mathbb{R}^n \). Let \( r \in \mathbb{R} \) such that \( r > \sup\{\|P\| \mid P \in K\} \). Show that for any \( k \in \mathbb{N} \) the inclusion induced map \( \pi_k(S^n_r - 1(0)) \to \pi_k(\mathbb{R}^n \setminus K) \) is a monomorphism.

\[
\begin{array}{c}
K \\
\rightarrow \pi_1(S^n_r - 1(0))
\end{array}
\]

Figure 694. Illustration of Exercise 40.4

Exercise 40.5. We consider the pseudocircle, i.e. we consider the slightly weird topological space \( X = \{A, B, C, D\} \) from page 107. Show that \( \pi_n(X, A) = 0 \) for any \( n \geq 2 \).

Hint. Find a convenient covering of \( X \).

Exercise 40.6. Let \( (X, x_0) \) be a topological space. We denote by \( \Sigma(X) \) the suspension of \( X \) and we denote by \( * \) the North Pole of \( \Sigma(X) \). Is the suspension homomorphism
\[
\pi_1(X_0, x_0) \to \pi_2(\Sigma(X), *)
\]
that we introduced in Lemma 40.19 necessarily a monomorphism?

41. The homology groups of a topological space

One of our main goals is to show that for \( m \neq n \) the spheres \( S^m \) and \( S^n \) are not homeomorphic. We have seen that for most cases fundamental groups are of no use. Furthermore, it might be that in principle higher homotopy groups can distinguish such spheres, but since we cannot compute higher homotopy groups, those are of no use either. So we need a new approach to finding invariants that can distinguish spheres.
In this chapter we want to introduce a new functor from the category of topological spaces to an algebraic category, more precisely, we will introduce a functor from the category of topological spaces to the category of abelian groups.

41.1. **Singular chains.**

**Definition.** Let \( n \in \mathbb{N}_0 \).

1. Given \( k \) points \( P_1, \ldots, P_k \) in \( \mathbb{R}^n \) such that \( P_2 - P_1, \ldots, P_k - P_1 \) are linearly independent we refer to the convex hull of \( P_1, \ldots, P_k \) as a **\( k \)-simplex**.

2. Given \( n \in \mathbb{N}_0 \) we refer to the convex hull of the standard basis vectors \( e_1, \ldots, e_{n+1} \) of \( \mathbb{R}^{n+1} \), i.e. to

\[
\Delta^n := \{(x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \mid x_0 + \cdots + x_n = 1 \text{ and } x_i \geq 0 \text{ for all } i = 0, \ldots, n \}
\]

as the **standard \( n \)-simplex**.

3. Given the standard \( n \)-simplex \( \Delta^n \) we define its boundary as

\[
\partial \Delta^n := \bigcup_{i=0}^{n} \{(t_0, \ldots, t_n) \in \Delta^n \mid t_i = 0 \}.
\]

4. Finally we write

\[
\hat{\Delta}^n := \Delta^n \setminus \partial \Delta^n.
\]

Sometimes it will be helpful to view \( \hat{\Delta}^n \) as a smooth manifold where a smooth atlas for \( \hat{\Delta}^n \) is given by projection to the first \( n \) coordinates. We equip the smooth manifold \( \hat{\Delta}^n \) with the orientation where for each \( P \in \hat{\Delta}^n \) a basis \( v_1, \ldots, v_n \) of \( V_P \hat{\Delta}^n \) is positive if the vectors \( \{(1, \ldots, 1), v_1, \ldots, v_n\} \) are a positive basis for \( \mathbb{R}^{n+1} \).

**Example.** The standard 0-simplex \( \Delta^0 \) is just the point \( \{1\} \in \mathbb{R} \), the standard 1-simplex \( \Delta^1 \) equals the segment in \( \mathbb{R}^2 \) from \((1,0)\) to \((0,1)\) and the standard 2-simplex \( \Delta^2 \) is the triangle in \( \mathbb{R}^3 \) spanned by the vertices \((1,0,0)\), \((0,1,0)\) and \((0,0,1)\). We refer to Figure 695 for an illustration of the standard simplices in dimension 0, 1 and 2 and for an illustration of the boundary of the standard 2-simplex.

![Figure 695](image)

For the record we state the following elementary lemma.

---

\footnote{In Exercise 2.36 (a) we showed that the standard \( n \)-simplex \( \Delta^n \) is the convex hull of \( e_i \in \mathbb{R}^{n+1} \), \( i = 1, \ldots, n + 1 \). In particular the standard \( n \)-simplex is an \( n \)-simplex.}

\footnote{The definition of the “boundary” of the standard \( n \)-simplex \( \Delta^n \) is the “obvious one”. Nonetheless note that if we had taken the original definition of the boundary of a subset \( A \) in some subspace \( X \) as introduced on page 92 and applied it to \( \Delta^n \subset \mathbb{R}^{n+1} \), then the boundary of \( \Delta^n \) in \( \mathbb{R}^{n+1} \) would be all of \( \Delta^n \).}
Lemma 41.1. Let \( n \in \mathbb{N} \).

1. Every \( n \)-simplex, in particular the standard \( n \)-simplex \( \Delta^n \), is compact.

We set

\[
\Delta_n := \left\{ (x_1, \ldots, x_n) \in [0, 1]^n \mid \sum_{i=1}^n x_i \in [0, 1] \right\}
\]

and refer to it as the planar \( n \)-simplex. The following statements hold:

2. The maps

\[
\Phi: \Delta^n \to \Delta_n \quad \text{and} \quad \Psi: \Delta_n \to \Delta^n
\]

are homeomorphisms that are inverses of one another.

3. The map

\[
\Delta^n \xrightarrow{\Phi} \Delta_n \xrightarrow{\text{the homeomorphism } \Xi \text{ obtained from Proposition 2.53 (2)}} B^n
\]

applied to \( \Delta_n \) and \( Q = \left( \frac{1}{n+1}, \ldots, \frac{1}{n+1} \right) \) is a homeomorphism that restricts to a homeomorphism from \( \partial \Delta^n \) to the sphere \( S^{n-1} \).

Proof.

1. We had proved this statement in Exercise 2.36 (b). Of course it is not difficult to prove the statement “from scratch”.

2. Note that \( \Phi \) extends “by the same formula” to a map \( \mathbb{R}^{n+1} \to \mathbb{R}^n \) which is evidently continuous. Hence the restriction to \( \Delta^n \) is also continuous. Now that this is settled we see that the remaining statements are basically trivial.

3. This statement follows easily from (1) and Proposition 2.53 (2). ■

Definition. An \( r \)-dimensional face of the standard \( n \)-simplex is defined as a subset of the form

\[
\{(t_0, \ldots, t_n) \in \Delta^n \mid t_{d_1} = t_{d_2} = \cdots = t_{d_{n-r}} = 0\},
\]

where \( d_1 < d_2 < \cdots < d_{n-r} \in \{0, \ldots, n\} \) are fixed. We illustrate the definition in Figure 697 on the left.

Remark.
41. THE HOMOLOGY GROUPS OF A TOPOLOGICAL SPACE 1077

(1) The boundary \( \partial \Delta^n \) of the standard \( n \)-simplex is the union of all \((n - 1)\)-dimensional faces of \( \Delta^n \).

(2) Every \( r \)-dimensional face of \( \Delta^r \) is homeomorphic to the standard \( r \)-simplex. For later we fix homeomorphism in the case of \((n - 1)\)-dimensional faces. More precisely, for \( j \in \{0, \ldots, n\} \) we consider the map

\[
i_j^n: \Delta^{n-1} \to \Delta^n
\]

\[
(t_0, \ldots, t_{n-1}) \mapsto (t_0, \ldots, t_{j-1}, 0, t_j, \ldots, t_{n-1}).
\]

This map is sometimes called the \( j \)-th face map. It is straightforward to see that these face maps are homeomorphisms. The face maps \( i_0^1, i_1^1, i_2^1: \Delta^1 \to \Delta^2 \) are illustrated in Figure 697 on the right.

The first idea for the definition of homology groups is now the following. In the definition of the fundamental group \( \pi_1(X, x_0) \) we had considered all maps \( f: [0, 1] \to X \) with the extra condition \( f(0) = f(1) = x_0 \). Using this extra condition we could concatenate loops to eventually end up with a group structure. Now given \( n \in \mathbb{N}_0 \) we want to consider all maps from \( \Delta^n \) to \( X \) with no extra condition on the boundary. This time there is no reasonable way how two such maps can be composed to give a new map. Since we nonetheless want the notion of a group we turn the set of all maps \( \Delta^n \to X \) into a group by “brute force”, i.e. by considering the free abelian group generated by these maps.

This leads us to the following definition.

**Definition.** Let \( X \) be a topological space and let \( n \in \mathbb{N}_0 \).

1. A **singular \( n \)-simplex** is a map \( \sigma: \Delta^n \to X \).
2. We define

\[
C_n(X) := \text{free abelian group generated by the set of singular } n\text{-simplices in } X.
\]

For \( n \in \mathbb{Z}_{<0} \) we set \( C_n(X) = 0 \).

3. We refer to an element in \( C_n(X) \) as a **singular \( n \)-chain in } X \).

**Remark.** In principle, given a map \( \sigma: \Delta^n \to X \) to some topological space \( X \) we need to show that this map is actually continuous. If one really feels compelled to give an argument, then often it is more convenient to show the equivalent statement that the map \( \sigma \circ \Psi: \Delta_n \to X \) is continuous, where \( \Psi: \Delta_n \to \Delta^n \) is the homeomorphism given in Lemma 41.1 (1).

**Examples.**
(1) For \( n = 0 \) a singular \( n \)-simplex is a map from \( \Delta^0 \) to \( X \). Such a map is uniquely determined by the corresponding point in \( X \). Therefore frequently we will identify singular 0-simplices with points in \( X \).

(2) For points \( z_0, \ldots, z_k \in \mathbb{R}^n \) we consider the map

\[
[z_0, \ldots, z_k]: \Delta^k \to \mathbb{R}^n \quad (t_0, \ldots, t_k) \mapsto \sum_{j=0}^k t_j \cdot z_j.
\]

The map \([z_0, \ldots, z_k]\) thus sends the standard \( k \)-simplex \( \Delta^k \) to the simplex spanned by \( z_0, \ldots, z_k \) in \( \mathbb{R}^n \). Put differently, \([z_0, \ldots, z_k]\) is a singular \( k \)-simplex in \( \mathbb{R}^n \).

Remark. Let \( X \) be a topological space. By the discussion on page 580 we can view every element in \( C_n(X) \), i.e. every singular \( n \)-chain, as a linear combination \( a_1 \sigma_1 + \cdots + a_k \sigma_k \) where \( a_1, \ldots, a_k \in \mathbb{Z} \) and where \( \sigma_1, \ldots, \sigma_k \) are singular \( n \)-simplices.

Now let \( f: X \to Y \) be a map between topological spaces. For each \( n \) we consider

\[
f_*: C_n(X) \to C_n(Y) \quad \sum_{i=1}^k a_i \cdot \sigma_i \mapsto \sum_{i=1}^k a_i \cdot (f \circ \sigma_i).
\]

It is easy to verify that \( X \mapsto C_n(X) \) and \( f \mapsto f_* \) defines a functor from the category of topological spaces to the category of abelian groups.

Have we made any progress towards our goal of distinguishing topological spaces? Not really. For example, if \( X \) is a smooth manifold of dimension \( \geq 1 \), then given any \( n \in \mathbb{N}_0 \) there exist uncountably many maps \( \Delta^n \to X \), i.e. the group \( C_n(X) \) is a free abelian group with uncountably many generators. Such groups are totally useless for distinguishing non-homeomorphic topological spaces.

41.2. Definition of the homology groups of a topological space. Before we give the definition of homology groups it is perhaps helpful to recall the definition of de Rham cohomology.

Let \( M \) be a smooth manifold. We write

\[
\Omega^n(M) := \{ \text{smooth } n \text{-forms on } M \}.
\]

The isomorphism type of this vector space is an invariant of the diffeomorphism type of the smooth manifold \( M \), but it is rather useless, since for \( 1 \leq n \leq \dim(M) \) this is a vector space of uncountable dimension. To cut \( \Omega^n(M) \) into something much smaller we defined linear maps \( d_n: \Omega^n(M) \to \Omega^{n+1}(M) \) with \( d_{n+1} \circ d_n = 0 \). Finally we defined the \( n \)-th de Rham cohomology group of \( M \) as

\[
H^n_{dR}(M) := \ker(d_n: \Omega^n(M) \to \Omega^{n+1}(M))/\text{im}(d_{n-1}: \Omega^{n-1}(M) \to \Omega^n(M)).
\]

We are now in a similar situation: to a topological space \( X \) we associated the free abelian group \( C_n(X) \) which is “too big”. The idea now is to introduce a “differential” as for the case of differential forms. But in this case there is no good way to associate to a map \( \Delta^n \to X \) a new map \( \Delta^{n+1} \to X \). But by restricting the map \( \Delta^n \to X \) to each

\footnote{Using Lemma 41.1 (2) one can easily show that this map is continuous.}
of the \((n - 1)\)-dimensional faces of \(\Delta^n\) which are, as we have seen, homeomorphic to the standard \((n - 1)\)-simplex, we can associate to a singular \(n\)-simplex \(\sigma: \Delta^n \to X\) a sum of singular \((n - 1)\)-simplices, i.e. a singular \((n - 1)\)-chain. To do this we will use the maps \(i^n_k: \Delta^{n-1} \to \Delta^n, k = 0, \ldots, n\) from page \(1077\) to identify the standard \((n - 1)\)-simplex with the \((n - 1)\)-dimensional faces of \(\Delta^n\). Now we can define

\[
\widetilde{\partial}_n \sigma := \sum_{j=0}^{n} \sigma \circ i^n_j.
\]

By Lemma \([19,1]\) this defines a map \(\widetilde{\partial}_n: C_n(X) \to C_{n-1}(X)\). But it is quite straightforward to see that for this definition the composition of the maps \(\widetilde{\partial}_n: C_n(X) \to C_{n-1}(X)\) and \(\widetilde{\partial}_{n-1}: C_{n-1}(X) \to C_{n-2}(X)\) is not zero\(^{669}\). But we can rectify this problem by cleverly introducing signs. This leads us to the following definition.

**Definition.** Let \(X\) be a topological space and let \(\sigma: \Delta^n \to X\) be a singular \(n\)-simplex. The boundary \(\partial_n \sigma \in C_{n-1}(X)\) of \(\sigma\) is defined as

\[
\partial_n \sigma := \sum_{j=0}^{n} (-1)^j \cdot \sigma \circ i^n_j.
\]

By Lemma \([19,1]\) the map \(\sigma \mapsto \partial_n \sigma\) extends uniquely to a linear map

\[
\partial_n: C_n(X) \to C_{n-1}(X)
\]

\[
\sum_{i=1}^{k} a_i \sigma_i \mapsto \sum_{i=1}^{k} a_i \cdot \partial \sigma_i,
\]

which we refer to as the \(n\)-th boundary map. If it is clear with what dimension we are working with, then we just write \(\partial\) instead of \(\partial_n\).

**Examples.**

1. For any singular 1-simplex \(\sigma: \Delta^1 \to X\) we have\(^{660}\)

\[
\partial \sigma = (-1)^0 \cdot \sigma \circ i^1_0 + (-1)^1 \cdot \sigma \circ i^1_1 = \sigma(0, 1) - \sigma(1, 0).
\]

Put differently, a singular 1-simplex can be viewed as a map \(\sigma\) from the “interval” \(\Delta^1\) to \(X\). The boundary of \(\sigma\) is thus the “endpoint” \(\sigma(0, 1)\) “minus” the “starting point” \(\sigma(1, 0)\). Here we view points in \(X\) again as singular 0-simplices. We sketch the definition of a singular 1-simplex in Figure \(698\).

2. In Figure \(699\) we sketch the boundary of a singular 2-simplex.

As promised, these boundary maps have the following fundamental property:

**Proposition 41.2.** Let \(X\) be a topological space. For any \(n \in \mathbb{N}_0\) the composition

\[
\partial_{n-1} \circ \partial_n: C_n(X) \to C_{n-2}(X)
\]

is the zero map.

\(^{660}\)Indeed, let \(S\) be a set and let \(\mathbb{Z}^{(S)}\) be the free abelian group generated by \(S\). We define \(\epsilon: \mathbb{Z}^{(S)} \to \mathbb{Z}\) to be the linear map that assigns to each \(s \in S\) the value 1. It follows easily from the definitions that for any \(\sigma: \Delta^n \to X\) we have \(\epsilon(\partial_n \sigma) = n + 1\) and \(\epsilon((\partial_{n-1} \circ \partial_n)(\sigma)) = n \cdot (n + 1)\).

\(^{669}\)Here we again use the convention that given a point \(x \in X\) we denote by \(x\) also the corresponding singular 0-simplex.
Proof. It suffices to show that $\partial_{n-1}(\partial_n(\sigma)) = 0$ for every singular $n$-simplex $\sigma: \Delta^n \to X$. Thus let $\sigma: \Delta^n \to X$ be a singular $n$-simplex. Then it follows immediately from the definitions that

$$
\partial_{n-1}(\partial_n(\sigma)) = \partial_{n-1}\left( \sum_{j=0}^{n} (-1)^j \cdot \sigma \circ i_j^n \right) = \sum_{k=0}^{n-1} (-1)^k \cdot \sum_{j=0}^{n} (-1)^j \cdot (\sigma \circ i_j^n) \circ i_k^{n-1}
$$

$$
= \sum_{0=k<j \leq n} (-1)^{k+j} \cdot \sigma \circ (i_j^n \circ i_k^{n-1}) + \sum_{0=j \leq k \leq n-1} (-1)^{k+j} \cdot \sigma \circ (i_j^n \circ i_k^{n-1}) =: (*) .
$$

Now we want to show that each expression $\sigma \circ (i_j^n \circ i_k^{n-1})$ appears precisely twice, but with opposite signs. From the definitions it follows easily that for $j \leq k$ we have\(^\text{67}\)

$$
i_j^n \circ i_k^{n-1} = i_k^{n+1} \circ i_j^n .
$$

\(^{67}\)Indeed, if $j \leq k$, then the zero-entries of $(i_j^n \circ i_k^{n-1})(t_0, \ldots, t_{n-1})$ are the entries $j$ and $k+1$. 

Figure 698. Boundary of a singular 1-simplex.

Figure 699. Boundary of a singular 2-simplex.
Now we continue with the above calculation:

\[
(\ast) = \sum_{0=k<j\leq n} (-1)^{k+j} \cdot \sigma \circ (i^n_j \circ i^{n-1}_k) + \sum_{0=j\leq k\leq n-1} (-1)^{k+j} \cdot \sigma \circ (i^n_k \circ i^{n-1}_j)
\]

above calculation of \(i^n_j \circ i^{n-1}_k\)

\[
= \sum_{0=k<j\leq n} (-1)^{k+j} \cdot \sigma \circ (i^n_j \circ i^{n-1}_k) + \sum_{0<j\leq l\leq n} (-1)^{l+j-1} \cdot \sigma \circ (i^n_l \circ i^{n-1}_j) = 0.
\]

substitution \(l = k + 1\) all summands left and right cancel

The following is arguably the most important definition of algebraic topology.

**Definition.** Let \(X\) be a topological space and let \(n \in \mathbb{N}_0\). We define the \(n\)-th singular homology group of \(X\) as the quotient group:

\[
H_n(X) := \frac{\ker(\partial_n : C_n(X) \to C_{n-1}(X))}{\text{im}(\partial_{n+1} : C_{n+1}(X) \to C_n(X))}.
\]

For \(n \in \mathbb{Z}_{<0}\) we extend this definition to \(H_n(X) := 0\). Throughout the lecture notes we will mostly shorten the name "singular homology" to "homology".

One of the key goals of this course is to develop tools for computing homology groups of topological spaces. In particular we want to compute the homology groups for all spheres. In the subsequent discussions it is helpful to introduce a few more definitions.

**Definition.** Let \(X\) be a topological space.

1. We say \(c \in C_n(X)\) is a singular \(n\)-cycle, or short \(n\)-cycle, if \(\partial c = 0\).
2. If \(c\) is an \(n\)-cycle, then we refer to \([c] \in H_n(X)\) as the homology class of \(c\).
3. We say two singular \(n\)-chains \(c\) and \(d\) are homologous if there exists a singular \((n+1)\)-chain \(e\) with \(\partial e = c - d\). In particular, if \(c\) and \(d\) are cycles, then they are homologous if they represent the same homology class.
4. An \(n\)-cycle \(c\) is called null-homologous, if \([c] = 0 \in H_n(X)\).
5. Given a singular 1-simplex \(\sigma : \Delta^1 \to X\) we denote by \(\overline{\sigma}\) the singular 1-simplex that is given by \(\overline{\sigma}(t, 1-t) = \sigma(1-t, t)\). Put differently, \(\overline{\sigma}\) is given by reversing the orientation of \(\sigma\).

**Example.** In Figure 700 we show that torus \(T = ([0, 1] \times [0, 1]) / \sim\) together with two singular 1-simplices \(c\) and \(d\) and together with two singular 2-simplices \(\alpha\) and \(\beta\). It follows easily from the definitions that \(c\) and \(d\) are 1-cycles. It is a good exercise to verify that \(\alpha - \beta\) is a 2-cycle. With our present knowledge it is impossible though to determine whether these cycles represent non-trivial homology classes.

The following lemma will be proved in Exercises 41.2 and 41.4.
Lemma 41.3. Let $X$ be a topological space and let $\sigma: \Delta^1 \rightarrow X$ be a singular 1-simplex.

(1) If $\sigma$ is a constant map, then $\sigma$ is null-homologous.

(2) The singular 1-chains $-\sigma$ and $\sigma$ are homologous.

(3) Let $s \in (0, 1)$ and consider the singular 1-simplices

$$\alpha: \Delta^1 \rightarrow X \quad \text{and} \quad \beta: \Delta^1 \rightarrow X,$$

$$(t, 1-t) \mapsto \sigma(st, 1-st) \quad \text{and} \quad (t, 1-t) \mapsto \sigma(s+t(1-s), 1-(s+t(1-s))).$$

Then the singular 1-chains $\sigma$ and $\alpha + \beta$ are homologous.

The second part of the lemma says that for a singular 1-simplex the geometric operation of reversing the orientation is (up to the boundary of a simplicial 2-chain) the same as algebraically inverting the sign. Furthermore, the third part of the lemma says that for a singular 1-simplex (again up to the boundary of a simplicial 2-chain) it does not make a difference whether or not we split the singular 1-simplex into two singular 1-simplices.

Examples.

(1) We consider Figure 702. We see three singular chains on the torus, and it is straightforward to show that all three singular chains are cycles. Now the question arises, which of these cycles are in fact null-homologous. In Figure 703 we see that the first cycle $a-b+c$ in Figure 702 is the boundary of a singular 2-simplex $D$. One can easily see that the second cycle, $a+b+c$ in Figure 702, is not the boundary of a singular 2-simplex. On the other hand by Lemma 41.3 we know that $b+\bar{b}$ is a null-homologous cycle, i.e. there exists an $E \in C_2(X)$ such that $b+\bar{b} = \partial E \in C_1(X)$. 

\textbf{Figure 700}

\begin{figure}[h]
\centering
\includegraphics[scale=0.5]{figure700.png}
\caption{Example of Lemma 41.3}
\end{figure}

\textbf{Figure 701. Illustration of Lemma 41.3}

\begin{figure}[h]
\centering
\includegraphics[scale=0.5]{figure701.png}
\caption{Examples of singular chains}
\end{figure}
Thus it follows that
\[ a + b + c = a + \partial E - b + c = a - b + c + \partial E = \partial D + \partial E = \partial(D + E), \]
i.e. \( a + b + c \) is null-homologous.

It is not clear whether the third cycle in Figure 702 is the boundary of a 2-dimensional singular chain. We will see later that this not the case. But it will take us quite some time to develop the techniques which will allow us to prove this statement.

(2) In Figure 704 we show the torus \( T = ([0, 1] \times [0, 1])/\sim \) and two singular simplices \( \alpha: \Delta^2 \to T \) and \( \beta: \Delta^2 \to T \) that are given by affine linear maps. It is straightforward to verify that \( \alpha - \beta \) is a cycle, hence it represents an element in \( H_2(T) \). We will see later on page 1083 whether or not this element is zero in \( H_2(T) \).

---

674 More precisely, \( \alpha \) is the unique affine linear map with \( \alpha(1, 0, 0) = [(0, 0)] \), \( \alpha(0, 1, 0) = [(1, 0)] \) and \( \alpha(0, 0, 1) = [(1, 1)] \) whereas \( \beta \) is the unique affine linear map with \( \beta(1, 0, 0) = [(0, 0)] \), \( \beta(0, 1, 0) = [(0, 1)] \) and \( \beta(0, 0, 1) = [(1, 1)] \).
In Exercise 41.6 we will try to generalize the approach taken for the torus to other 2-dimensional smooth manifolds, namely the sphere, the Klein bottle and the projective space \( \mathbb{R}P^2 \).

41.3. **First calculations of homology groups.** Given a topological space the corresponding homology groups are defined as the quotient of two abelian groups which in general will be infinitely generated. Somewhat surprisingly we will see in the coming chapters that the homology groups are nonetheless very frequently finitely generated abelian groups.

We start out our computations of homology groups with the 0-th homology of a path-connected topological space. The key to the calculation is the following definition.

**Definition.** Given a topological space \( X \) we refer to the map 

\[
\epsilon_X : C_0(X) \to \mathbb{Z}
\]

\[
\sum_{i=1}^{k} a_i \sigma_i \mapsto \sum_{i=1}^{k} a_i
\]

as the **augmentation map**.

The following lemma shows that the augmentation map is a neat addition to the singular chain complex of a topological space.

**Lemma 41.4.** Let \( X \) be a topological space.

1. The map \( \epsilon_X \circ \partial_1 : C_1(X) \to \mathbb{Z} \) is the zero map.
2. The map

\[
\epsilon_X : H_0(X) \to \mathbb{Z}
\]

\[
[\sigma] \mapsto [\epsilon_X(\sigma)]
\]

is well-defined. In the following we refer to this map also as the augmentation map.

**Proof.** Let \( X \) be a topological space.

1. Let \( c = \sum_{i=1}^{n} b_i \sigma_i \in C_1(X) \). We calculate that

\[
\epsilon(\partial_1(c)) = \epsilon\left( \sum_{i=1}^{n} b_i \cdot \partial_1(\sigma_i) \right) = \epsilon\left( \sum_{i=1}^{n} b_i \cdot \sigma_i(0,1) - b_i \cdot \sigma_i(1,0) \right) = \sum_{i=1}^{n} b_i - \sum_{i=1}^{n} b_i = 0
\]

for every singular 1-simplex \( \sigma \) we have \( \partial \sigma = \sigma(0,1) - \sigma(1,0) \), see page 1079

2. Note that

\[
H_0(X) = \ker(\partial_0 : C_0(X) \to C_{-1}(X)) / \im(\partial_1 : C_1(X) \to C_0(X))
\]

\[
= C_0(X) / \im(\partial_1 : C_1(X) \to C_0(X))
\]

\[
\uparrow
\]

since \( C_{-1}(X) = 0 \)

Thus we see that Statement (2) is an immediate consequence of Statement (1). \( \blacksquare \)

Now we can formulate the following proposition.
Proposition 41.5. Let $X$ be a path-connected non-empty topological space and let $P$ be a point in $X$. Then the augmentation map
\[ \epsilon = \epsilon_X : H_0(X) \to \mathbb{Z} \]
is a natural isomorphism where the inverse is given by the map
\[ \iota : \mathbb{Z} \to H_0(X) \quad n \mapsto n \cdot [P]. \]

Proof. Let $X$ be a non-empty path-connected topological space. Let $P$ be a point in $X$. It is clear that $\epsilon \circ \iota = \text{id}_\mathbb{Z}$, in particular the homomorphism $\epsilon$ is surjective. It remains to show that $\epsilon$ is injective.

Thus let $c \in C_0(X)$ with $\epsilon(c) = 0$. By definition of $C_0(X)$ we can find points $Q_1, \ldots, Q_k$ in $X$ and $a_1, \ldots, a_k \in \mathbb{Z}$ such that $c = \sum_{i=1}^k a_i \cdot Q_i$. We choose a point $P$ in $X$. Since $X$ is path-connected we can find, for $i = 1, \ldots, k$, a path from $P$ to $Q_i$. Put differently, for each $i = 1, \ldots, k$ we can find a singular 1-simplex $\sigma_i$ with $\partial \sigma_i = Q_i - P$. Then we have
\[
\partial \left( \sum_{i=1}^k a_i \sigma_i \right) = \sum_{i=1}^k a_i \partial \sigma_i = \sum_{i=1}^k a_i (Q_i - P) = \sum_{i=1}^k a_i Q_i - \left( \sum_{i=1}^k a_i \right) \cdot P = \sum_{i=1}^k a_i Q_i.
\]

This implies that $[c] = 0 \in H_0(X)$. Thus we have shown that $\epsilon$ is injective.

The proof of the following lemma is Exercise 41.3.

Lemma 41.6. Let $X$ be a topological space which consists of a single point. Then the following holds
\[ H_n(X) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases} \]

The calculation of $H_0(X)$ in Proposition 41.5 and the calculation of the homology of a point in Lemma 41.6 are the only calculations of homology groups of path-connected topological spaces that one can do “by hand”. For all other topological spaces we will need to work significantly harder.

41.4. Algebraic chain complexes. Before we continue with the discussion of homology groups it is convenient to introduce several algebraic definitions. The following definitions are just the obvious algebraic abstractions of the definitions that we had already introduced.

Definition.
(1) An (algebraic) chain complex \((C_*, \partial_*)\) is a sequence

\[
\ldots \rightarrow C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \ldots C_1 \xrightarrow{\partial_1} C_0 \rightarrow 0
\]

of maps between abelian groups\(^{675}\) such that for every \(i \in \mathbb{N}\) we have \(\partial_{i-1} \circ \partial_i = 0\). As before we introduce the convention that \(C_n = 0\) for \(n \in \mathbb{Z}_{<0}\).

(2) We define the \(n\)-th homology group of the chain complex precisely the same way as we defined the homology of a topological space, namely we set

\[
H_n(C) := \ker(\partial_n : C_n \rightarrow C_{n-1}) / \text{im}(\partial_{n+1} : C_{n+1} \rightarrow C_n).
\]

(3) As before we refer to elements in the kernel of \(\partial_n : C_n \rightarrow C_{n-1}\) as cycles. Furthermore, we say that a cycle \(z \in C_n\) is null-homologous if \([z] = 0\) \(\in H_n(C)\).

On some occasions we will need the following generalization:

(4) A generalized (algebraic) chain complex \((C_*, \partial_*)\) is a sequence

\[
\ldots \rightarrow C_3 \xrightarrow{\partial_3} C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \xrightarrow{\partial_0} C_{-1} \xrightarrow{\partial_{-1}} C_{-2} \rightarrow \ldots
\]

of maps between abelian groups such that for every \(i \in \mathbb{Z}\) we have \(\partial_{i-1} \circ \partial_i = 0\). Basically all present and future definitions and results for chain complexes also make sense for generalized chain complexes. In most cases we will not explicitly state the generalization to generalized chain complex.

Now we introduce a new notion, namely the notion of a chain map between chain complexes.

**Definition.** A chain map \(f : C_* \rightarrow D_*\) between two chain complexes\(^{676}\) consists of a family \(\{f_n : C_n \rightarrow D_n\}_{n \in \mathbb{N}_0}\) of maps such that for each \(n\) the following equality holds:\(^{677}\)

\[
f_{n-1} \circ \partial_n = \partial_n \circ f_n.
\]

Put differently the maps \(f_n\) have the property that the following diagram commutes:

\[
\begin{array}{ccc}
\ldots & \xrightarrow{\partial} & C_{n+1} & \xrightarrow{\partial_{n+1}} & C_n & \xrightarrow{\partial_n} & C_{n-1} & \xrightarrow{\partial_{n-1}} & \ldots \\
\downarrow{f_{n+1}} & & \downarrow{f_n} & & \downarrow{f_{n-1}} & & \uparrow{f_{n-1}} & & \uparrow{f_n} & & \downarrow{f_{n+1}} & & \ldots
\end{array}
\]

**Remark.** On many occasions we will use the elementary observation that the composition of two chain maps \(f : C_* \rightarrow D_*\) and \(g : D_* \rightarrow E_*\) defines a chain map \(g \circ f : C_* \rightarrow E_*\).

Now we can prove the following lemma:

\(^{675}\)It is perhaps worth pointing out that we do not assume that the chain groups \(C_*\) are free abelian groups.

\(^{676}\)As usual we suppress bits from the notation which are understood from the context. In this instance we suppress the notation for the boundary maps in the chain complexes. Put differently, instead of saying “let \((C_*, \partial_*)\) be a chain complex” we say simply “let \(C_*\) be a chain complex”.

\(^{677}\)More precisely, for any \(c \in C\) we have \(f_{n-1}(\partial_n(c)) = \partial_n(f_n(c))\) where on the left-hand side we consider the boundary map \(C_n \rightarrow C_{n-1}\), and on the right-hand side we consider the boundary map \(D_n \rightarrow D_{n-1}\) which we also denote by \(\partial_n\). Usually it is obvious from the context which boundary map we consider.
Lemma 41.7. Let $f: C_* \to D_*$ be a chain map between chain complexes $C_*$ and $D_*$. Then the map

$$f_*: H_n(C_*) \to H_n(D_*)$$

is well-defined.

In the following we refer to the map $f_*: H_n(C) \to H_n(D)$ as the \textit{induced map on homology}.

\textbf{Proof.} Let $c \in C_n$ be a cycle. First we have to show that $f_n(c)$ is again a cycle. Indeed we have

$$\partial_n(f_n(c)) = f_{n-1}(\partial_n c) = f_n(0) = 0.$$  

\textit{definition of a chain map since $c$ is a cycle}

Now let $c, d \in C_n$ be two cycles which represent the same element in $H_n(C)$. We have to show that $[f_n(c)] = [f_n(d)]$. Indeed we have

$$[f_n(c)] - [f_n(d)] = [f_n(c-d)] = [f_n(\partial_n+1(e))] = [\partial_n+1(f_{n+1}(e))] = 0 \in H_n(D).$$

\textit{since $c,d$ are homologous there exists an $e \in C_{n+1}$ with $\partial_{n+1}e = c-d$}

We can state the above results more formally. To do so it is convenient to introduce the following definition.

\textbf{Definition.} We refer to category $\mathcal{CnCplx}$ that is given by

\textit{Ob}(\mathcal{C}n\mathcal{C}plx) := \text{all chain complexes},

and with morphisms

\textit{Mor}(C_*, D_*) := \text{all chain maps from $C_*$ to $D_*$},

with the obvious composition of morphisms as the \textit{category of chain complexes}.

The following lemma follows easily from Lemma 41.7 and from the definitions:

\textbf{Lemma 41.8.} For each $n \in \mathbb{N}_0$ the maps

$$C_* \mapsto H_n(C_*)$$

and

$$(f: C_* \to D_*) \mapsto (f_*: H_n(C_*) \to H_n(D_*))$$

define a functor from the category $\mathcal{CnCplx}$ of chain complexes to the category $\mathcal{AbGr}$ of abelian groups.

41.5. \textbf{The functoriality of homology groups.} Let $f: X \to Y$ be a map between topological spaces. We already saw on page 1078 that for each $n \in \mathbb{N}_0$ the map $f$ induces a map

$$f_*: C_n(X) \to C_n(Y),$$

$$\sum_{i=1}^k a_i \cdot \sigma_i \mapsto \sum_{i=1}^k a_i \cdot f \circ \sigma_i.$$  

Now we can formulate the following lemma:
Lemma 41.9.

(1) Let \( f: X \to Y \) be a map between topological spaces and let \( n \in \mathbb{N}_0 \). For every \( c \in C_n(X) \) we have
\[
f_*(\partial c) = \partial_n(f_*(c)) \in C_n(Y).
\]
In particular \( f_*: C_*(X) \to C_*(Y) \) is a chain map.

(2) The maps

\[
topological space X \mapsto C_*(X)
\]

and
\[
(f: X \to Y) \mapsto (f_*: C_*(X) \to C_*(Y))
\]

define a functor from the category Top of topological spaces to the category \( \text{ChCplx} \) of chain complexes.

Proof.

(1) Let \( f: X \to Y \) be a map between topological spaces and let \( \sigma: \Delta^n \to X \) be a singular \( n \)-simplex. We have
\[
f_*(\partial \sigma) = f_* \left( \sum_{j=0}^{n} (-1)^j \cdot \sigma \circ i^n_j \right) = \sum_{j=0}^{n} (-1)^j \cdot (f \circ \sigma) \circ i^n_j = \partial(f_* \sigma).
\]

Since the singular \( n \)-simplices generate \( C_*(X) \) we obtain the desired equality for all singular \( n \)-chains. By definition this means that \( f_*: C_*(X) \to C_*(Y) \) is a chain map.

(2) The second statement is an almost immediate consequence of the first statement. ■

In particular, using Lemma 41.7 we immediately obtain the following lemma.

Lemma 41.10. Let \( f: X \to Y \) be a map between topological spaces. Then the map
\[
f_*: H_n(X) \to H_n(Y)
\]
\[
[\sum_{i=1}^{k} a_i \cdot \sigma_i] \mapsto [\sum_{i=1}^{k} a_i \cdot (f \circ \sigma_i)]
\]
is well-defined.

Example. Let \( f: X \to Y \) be a map between two topological spaces. It follows immediately from the definitions that the following diagram commutes
\[
\begin{array}{ccc}
H_0(X) & \xrightarrow{f_*} & H_0(Y) \\
\epsilon_X & \searrow & \nearrow \epsilon_Y \\
\mathbb{Z} & & \mathbb{Z}
\end{array}
\]

where the maps \( \epsilon_X \) and \( \epsilon_Y \) denote the augmentation maps. In particular, if \( X \) and \( Y \) are path-connected topological spaces, then it follows easily from Proposition 41.5 that the map \( f_*: H_0(X) \to H_0(Y) \) is an isomorphism. Furthermore, if \( X = Y \), i.e. if \( f \) is a self-map on a path-connected topological space \( X \), then \( f_* \) is in fact the identity on \( H_0(X) \).

The combination of Lemmas 41.9 and 41.8 now gives us the following lemma.
Lemma 41.11. For each \( n \in \mathbb{N}_0 \) the map

\[ X \mapsto H_n(X) \]

together with the map

\[ (f: X \to Y) \mapsto \left( f_*: H_n(X) \to H_n(Y) \right) \]

\[ \sum_{i=1}^{k} a_i \cdot \sigma_i \mapsto \sum_{i=1}^{k} a_i \cdot (f \circ \sigma_i) \]

defines a functor from the category of topological spaces to the category of abelian groups.

Example. Let \( X \) and \( Y \) be non-empty topological spaces. Let \( f: X \to Y \) be a map. We suppose that \( f \) is constant, i.e. we suppose that there exists a \( y \in Y \) such that \( f(X) = \{y\} \). We denote by \( i: \{y\} \to Y \) the inclusion. Let \( n \in \mathbb{N} \). We consider the commutative diagram

\[ \begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow f & & \downarrow f \\
\{y\} & \xrightarrow{i} & H_n(Y)
\end{array} \]

which gives rise to the commutative diagram

\[ \begin{array}{ccc}
H_n(X) & \xrightarrow{f_*} & H_n(Y) \\
\downarrow i_* & & \downarrow i_* \\
H_n(\{y\}) & & H_n(Y).
\end{array} \]

By Lemma 41.6 we know that \( H_n(\{y\}) = 0 \). Thus we see that \( f_*: H_n(X) \to H_n(Y) \) factors through the trivial group, i.e. the map is the trivial map. On many occasions we will make use of this observation without referring to this discussion.

41.6. Direct products and direct sums (*). In this short section we recall the definition of the direct product and the direct sum of a family of abelian groups.

Definition. Let \( G_i, i \in I \) be a family of abelian groups. We define the direct product as

\[ \prod_{i \in I} G_i := \left\{ \text{all maps } g: I \to \bigcup_{i \in I} G_i \text{ such that for all } i \in I \text{ we have } g(i) \in G_i \right\}. \]

Given such a map we usually write \( g_i := g(i) \) for \( i \in I \) and we denote such a map by \( \{g_i\}_{i \in I} \). The direct product is again a group with respect to the group structure

\[ \prod_{i \in I} G_i \times \prod_{i \in I} G_i \to \prod_{i \in I} G_i \]

\[ ((a_i)_{i \in I}, (b_i)_{i \in I}) \mapsto (a_i + b_i)_{i \in I}. \]

Furthermore we consider the direct sum

\[ \bigoplus_{i \in I} G_i := \left\{ (g_i)_{i \in I} \in \prod_{i \in I} G_i \mid \text{there exists only finitely many } i \in I \text{ with } g_i \neq e \right\}. \]

The same way one can also define the direct product respectively the direct sum of rings, algebras, vector spaces, modules and so on.

Example. Let \( I = \mathbb{N} \) and for each \( i \in I = \mathbb{N} \) we pick \( G_i = \mathbb{R} \). Then

\[ \prod_{i \in \mathbb{N}} \mathbb{R} = \text{ all real-valued sequences } i \mapsto a_i \]

and

\[ \bigoplus_{i \in \mathbb{N}} \mathbb{R} = \text{ all real-valued sequences with only finitely many non-zero terms.} \]
In general the direct product is “significantly larger” than the direct sum. For example the direct product \( \prod_{i \in \mathbb{N}} \mathbb{Z} \) is uncountable while the direct sum \( \bigoplus_{i \in \mathbb{N}} \mathbb{Z} \) is countable.

**Convention.** Let \( \{ G_i \}_{i \in I} \) be family of abelian groups.

1. For some element \( g_j \in G_j \), following the discussion on page \( 580 \) we sometimes denote by \( g_j \) also the element in \( \bigoplus_{i \in I} G_i \) that is given by \( i \mapsto 0 \) if \( i \neq j \) and \( j \mapsto g_j \). In particular we can view each \( G_j \) as a subgroup of \( \bigoplus_{i \in I} G_i \).

2. Given \( i_1, \ldots, i_l \in I \) and \( g_{i_j} \in G_{i_j} \) we can use (1) to consider the corresponding element

\[
g_{i_1} + \cdots + g_{i_l} \in \bigoplus_{i \in I} G_i.
\]

It follows immediately from the definitions that any element of \( \bigoplus_{i \in I} G_i \) is of that form.

Finally we introduce the following notation.

**Notation.**

(I) Let \( \{ G_i \}_{i \in I} \) be a family of abelian groups and let \( H \) be an abelian group. Furthermore let \( \{ \varphi_i : G_i \rightarrow H \}_{i \in I} \) be a family of homomorphisms. We refer to

\[
\bigoplus_{i \in I} \varphi_i : \bigoplus_{i \in I} G_i \rightarrow H
\]

\[
g_{i_1} + \cdots + g_{i_l} \mapsto \sum_{i \in I} \varphi_i(g_{i_i})
\]

as the *direct sum of the homomorphisms* \( \{ \varphi_i \}_{i \in I} \).

(II) Let \( G \) be an abelian group, let \( \{ H_i \}_{i \in I} \) be a *finite* family of abelian groups and let \( \{ \varphi_i : G \rightarrow H_i \}_{i \in I} \) be a family of homomorphisms. We refer to

\[
\bigoplus_{i \in I} \varphi_i : G \rightarrow \bigoplus_{i \in I} H_i
\]

\[
g \mapsto \sum_{i \in I} \varphi_i(g)
\]

also as the *direct sum of the family of homomorphisms* \( \{ \varphi \}_{i \in I} \).

(III) Let \( \{ \varphi_i : G_i \rightarrow H_i \}_{i \in I} \) be a *finite* family of homomorphisms between abelian groups. We refer to

\[
\bigoplus_{i \in I} \varphi_i : \bigoplus_{i \in I} G_i \rightarrow \bigoplus_{i \in I} H_i
\]

\[
\sum_{i \in I} g_i \mapsto \sum_{i \in I} \varphi_i(g_i)
\]

also as the *direct sum of the homomorphisms* \( \{ \varphi_i \}_{i \in I} \).

The notation is arguably somewhat ambiguous. But usually it should be clear from the context what we precisely mean when we write \( \bigoplus_{i \in I} \varphi_i \). Sometimes, in desperation, we will refer to \( \bigoplus_{i \in I} \varphi_i \) a direct sum of type (I), (II) or (III).

\[678\text{Why is that the case?}\]
41. THE HOMOLOGY GROUPS OF A TOPOLOGICAL SPACE 1091

For reference we jot down the following lemma which follows immediately from the definitions.

**Lemma 41.12.** (*) Let $I$ be a finite set and let $\{\varphi_i: G_i \to H_i\}_{i \in I}$ be a family of homomorphisms between abelian groups.

1. Let $F$ be an abelian group and let $\{\alpha_i: F_i \to G_i\}_{i \in I}$ be a family of homomorphisms. Then
   $$(\bigoplus_{i \in I} \varphi_i) \circ (\bigoplus_{i \in I} \alpha_i) = \bigoplus_{i \in I} \alpha_i \circ \varphi_i: F \to \bigoplus_{i \in I} G_i.$$  

2. Let $\{\alpha_i: F_i \to G_i\}_{i \in I}$ be another family of homomorphisms between abelian groups. Then
   $$(\bigoplus_{i \in I} \varphi_i) \circ (\bigoplus_{i \in I} \alpha_i) = \bigoplus_{i \in I} \alpha_i \circ \varphi_i: F \to \bigoplus_{i \in I} G_i.$$  

41.7. The homology groups of a direct sum. Now we return to the study of chain complexes. Let $C_\ast$ and $D_\ast$ be two chain complexes. The same way as we introduced the direct sum of abelian groups we can also define the direct sum of chain complexes. The following lemma says that homology commutes with direct sums and direct products. The proof is a standard exercise in homological algebra, which oddly enough nobody ever feels like doing, see [Weib94, p. 5].

**Lemma 41.13.** If $\{C_a\}_{a \in A}$ is a family of chain complexes, then the obvious inclusion maps $C_a \to \bigoplus_{a \in A} C_a$ and $C_a \to \prod_{a \in A} C_a$ induce isomorphisms

$$\bigoplus_{a \in A} H_n(C_a) \xrightarrow{\cong} H_n \left( \bigoplus_{a \in A} C_a \right) \quad \text{and} \quad \prod_{a \in A} H_n(C_a) \xrightarrow{\cong} H_n \left( \prod_{a \in A} C_a \right).$$

Now we can formulate and prove the following lemma.

**Lemma 41.14.** Let $X$ be a topological space with path-components $\{X_a\}_{a \in A}$. Given $a \in A$ we denote by $i_a: X_a \to X$ the inclusion map. Then the map

$$\bigoplus_{a \in A} i_a^\ast: \bigoplus_{a \in A} C_\ast(X_a) \to C_\ast(X)$$

is an isomorphism of chain complexes. In particular for each $n \in \mathbb{N}_0$ the map

$$\bigoplus_{a \in A} i_a^\ast: \bigoplus_{a \in A} H_n(X_a) \to H_n(X)$$

is an isomorphism.

The lemma says in particular that the homology groups of a topological space $X$ are the direct sum of the homology groups of the path-components of $X$. Put differently, this shows that in most cases it suffices to consider the homology groups of path-connected topological spaces.

**Examples.**

1. One of our goals is to calculate the homology groups of the spheres. Now we can calculate the homology groups of the 0-dimensional sphere $S^0 = \{\pm 1\}$. More precisely,
by Lemmas 41.6 and 41.14 we have
\[ H_n(S^0) \cong \begin{cases} \mathbb{Z}^2, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases} \]

Later in the proof of Proposition 43.4 we will cleverly reduce the computation of the homology groups of all other spheres to this calculation.

(2) Let \( X \) be a topological space and let \( \{U_a\}_{a \in A} \) be a family of disjoint open subsets of \( X \). It follows fairly easily from Lemma 41.14 together with Lemma 2.68 (4) and (5) that the map
\[ \bigoplus a \in A i_a : \bigoplus a \in A H_n(U_a) \to H_n \left( \bigcup_{a \in A} U_a \right) \]
is an isomorphism.

**Proof.** Evidently the standard simplex \( \Delta^n \) is path-connected. Thus it follows from Lemma 2.70 that the image of a map \( \sigma: \Delta^n \to X \) is contained in a path-component \( X_a \). This shows that
\[ \bigsqcup a \in A \text{singular } n\text{-simplices in } X_a = \text{singular } n\text{-simplices in } X. \]

It follows that the map
\[ \bigoplus a \in A i_a : \bigoplus a \in A C_n(X_a) \to C_n(X) \]
\[ \left( \sum_{i=1}^k c_i(\sigma: \Delta^n \to X_{a_i}) \right) \mapsto \left( \sum_{i=1}^k c_i(\sigma: \Delta^n \to X_{a_i}) \right) \]
is an isomorphism of free abelian groups. From the definitions it follows immediately that this a chain map. The second statement of the lemma now follows from Lemma 41.13.  

The following corollary is an immediate consequence of Proposition 41.5 and Lemma 41.13.

**Corollary 41.15.** Let \( X \) be a topological space. As on page 135 we denote by \( \pi_0(X) \) the set of path-components of \( X \). Then
\[ H_0(X) \cong \mathbb{Z}^{(\pi_0(X))}. \]
In particular, if \( X \) consists of \( n \) path-components with \( n \in \mathbb{N}_0 \), then
\[ H_0(X) \cong \mathbb{Z}^n. \]

**Exercises for Chapter 41**

**Exercise 41.1.** Let \( n \in \mathbb{N} \). As in Lemma 41.1 we consider
\[ \Delta_n := \left\{ (x_1, \ldots, x_n) \in [0,1]^n \mid \sum_{i=1}^n x_i \in [0,1] \right\} \subset \mathbb{R}^n. \]

We denote by \( \Phi: \Delta^n \to \Delta_n \) the obvious projection map. We pick any \( P \in \Delta_n \). Next we consider the maps
\[ f_P: \Delta_n \to \mathbb{R}^n \]
\[ (x_1, \ldots, x_n) \mapsto \frac{(x_1, \ldots, x_n) - P}{x_1 \cdots x_n (1 - x_1 - \cdots - x_n)} \]
and
\[ g: \mathbb{R}^n \to B^n \]
\[ (x_1, \ldots, x_n) \mapsto \frac{x_1^2 + \cdots + x_n^2}{1 + x_1^2 + \cdots + x_n^2} \cdot (x_1, \ldots, x_n) \]
Note that \( f_P \) is defined in such a way that it sends rays emanating from \( P \) to rays emanating from the origin.

(a) Show that \( f_P: \overset{\circ}{\Delta}_n \to \mathbb{R}^n \) is an orientation-preserving diffeomorphism.

(b) Show that \( g: \mathbb{R}^n \to B^n \) is an orientation-preserving diffeomorphism.

Note that for the most part we had solved this problem on page 295.

(c) Show that \( g \circ f_P: \overset{\circ}{\Delta}_n \to B^n \) extends to a homeomorphism \( \Theta: \Delta_n \to \overline{B}^n \).

(d) Let \( \Xi: \Delta_n \to \overline{B}^n \) be the homeomorphism obtained from Proposition 2.53(2) applied to \( P \). Show that \( \Theta \) and \( \Xi \) are homotopic rel \( P \).

Remark. The composition \( \Psi \circ \Phi: \Delta^n \to \overline{B}^n \) is now a homeomorphism such that the restriction \( \overset{\circ}{\Delta}_n \to B^n \) is a diffeomorphism. Furthermore this diffeomorphism is orientation-preserving if and only if \( n \) is even. Here we use the definitions on page 1075 to view \( \overset{\circ}{\Delta}_n \) as an oriented smooth manifold.

Exercise 41.2.

(a) Let \( X \) be a topological space and let \( x \in X \). For each \( n \in \mathbb{N}_0 \) denote by \( \sigma_n \) the singular \( n \)-simplex \( \sigma_n: \Delta^n \to X \) which is defined by \( \sigma_n(P) = x \) for all \( P \in \Delta^n \). Determine \( \partial \sigma_n \in C_{n-1}(X) \).

(b) Let \( X \) be a topological space and let \( \sigma: \Delta^1 \to X \) be a singular 1-simplex. Show that if \( \sigma \) is a constant map, then \( \sigma \) is null-homologous.

Exercise 41.3. Let \( X \) be a topological space which consists of a single point. Show that the following holds:

\[
H_n(X) \cong \begin{cases} 
\mathbb{Z}, & \text{if } n = 0, \\
0, & \text{if } n \neq 0.
\end{cases}
\]

Exercise 41.4.

(a) Let \( X \) be a topological space and let \( \sigma: \Delta^1 \to X \) be a singular 1-simplex. We consider the singular 1-simplices

\[
\sigma_1: \Delta^1 \to X \quad (t, 1-t) \mapsto \sigma\left(\frac{1}{2}t, 1 - \frac{1}{2}t\right) \quad \text{and} \quad \sigma_2: \Delta^1 \to X \quad (t, 1-t) \mapsto (\frac{1}{2} + \frac{1}{2}t, \frac{1}{2} - \frac{1}{2}t).
\]

Show that \( \sigma \) and \( \sigma_1 + \sigma_2 \) are homologous.

(b) Let \( X \) be a topological space and let \( \sigma: \Delta^1 \to X \) be a singular 1-simplex. We consider the singular 1-simplex

\[
\tau: \Delta^1 \to X \quad (t, 1-t) \mapsto \sigma(1 - t, t).
\]

Show that \( \sigma + \tau \) is a 1-cycle and that this 1-cycle is null-homologous.
We refer to Figure 701 for an illustration of the definitions.

**Exercise 41.5.** Let $\Sigma = E_8 / \sim$ be the surface of genus 2. Provide an example of a 2-cycle $\sum_{i=1}^{m} a_i \cdot \sigma_i \in C_2(\Sigma)$ with the following three properties:

1. At least one $a_i$ is non-zero.
2. The images of the singular 2-simplices cover the whole surface.
3. The images of the singular 2-simplices overlap only in “1-dimensional” subsets.

**Remark.** Note that on page 1083 we provided an example of such a 2-cycle for the torus $\Sigma = ([0,1] \times [0,1]) / \sim$.

![Figure 707. Illustration of Exercise 41.5](image)

**Exercise 41.6.**

(a) Try to find “interesting” elements in the following homology groups:
   (i) $H_2(S^2)$,
   (ii) $H_2(\text{surface } \Sigma \text{ of genus 2})$,
   (iii) $H_2(\text{Klein bottle } K)$ and
   (iv) $H_2(\mathbb{RP}^2)$.
   More precisely, try to find 2-cycles which have the properties (1), (2) and (3) from Exercise 41.5.

(b) Make a guess for which surfaces you expect $H_2$ to be zero and for which it is non-zero.

**Exercise 41.7.** Let $n \in \mathbb{N}$.

(a) Provide an example of an $n$-cycle $\sum_{i=1}^{m} a_i \cdot \sigma_i \in C_n(S^n)$ which has the properties (1), (2) and (3) from Exercise 41.5.

(b) Make an educated guess what the homology groups of $S^n$ might be.

**Exercise 41.8.** Provide an example of a chain complex $(C_\ast, \partial_\ast)$ such that all $C_\ast$ are finitely generated free abelian groups and such that $H_i(C_\ast) = 0$ for all even $i \in \mathbb{N}_0$ and such that $H_i(C_\ast) = \mathbb{Z}_2$ for all odd $i \in \mathbb{N}_0$.

**Exercise 41.9.**

(a) Determine the isomorphism types of the homology groups of the chain complex

$$0 \to C_1 = \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 3 & 7 \\ 4 & 2 \end{pmatrix}} C_0 = \mathbb{Z}^2 \to 0.$$
(b) Determine the isomorphism types of the homology groups of the chain complex

\[ 0 \to C_2 = \mathbb{Z}^2 \xrightarrow{(2, 4)} C_1 = \mathbb{Z}^2 \xrightarrow{(-2, 1)} C_0 = \mathbb{Z} \to 0. \]

(Why is this a chain complex?)

Exercise 41.10. Given a topological space \( X \) and \( n \in \mathbb{N}_0 \) we consider the map

\[ \epsilon : C_n(X) \to \mathbb{Z}, \quad \sum_{i=1}^k a_i \sigma_i \mapsto \sum_{i=1}^k a_i. \]

(a) Show that the following diagram commutes

\[ \cdots \to C_3(X) \xrightarrow{\partial_3} C_2(X) \xrightarrow{\partial_2} C_1(X) \xrightarrow{\partial_1} C_2(X) \xrightarrow{\partial_0} 0 \]

\[ \cdots \xrightarrow{id} \mathbb{Z} \xrightarrow{\epsilon} 0 \xrightarrow{id} \mathbb{Z} \xrightarrow{\epsilon} 0 \xrightarrow{\epsilon} 0. \]

(b) Show that if \( n \) is even, then for every cycle \( \sigma \in C_n(X) \) we have \( \epsilon(\sigma) = 0 \).

Exercise 41.11. Let \( f : C \to B \) be a homomorphism between abelian groups and let \( A \) be a subgroup of \( B \) with the following two properties:

1. We have \( f(C) \cap A = 0 \).
2. The subgroups \( f(C) \) and \( A \) generate \( B \).

Show that the map

\[ A \to \text{coker}(f) = B/\text{im}(f), \quad a \mapsto [a] \]

is an isomorphism.

Exercise 41.12. Suppose we are chain complex of the following form

\[ D_* = \cdots \to C_{k+2} \xrightarrow{\partial_{k+2}} A_{k+1} \oplus B_{k+1} \xrightarrow{\partial_{k+1}} A_k \oplus B_k \xrightarrow{\partial_k} C_{k-1} \to \cdots \]

Given \( m \in \{k, k+1\} \) we denote by \( i_m : A_m \to A_m \oplus B_m \) and \( j_m : B_m \to A_m \oplus B_m \) the natural inclusions and we denote by \( p_m : A_m \oplus B_m \to A_m \) and \( q_m : A_m \oplus B_m \to B_m \) the natural projections. We suppose that \( p_k \circ \partial_{k+1} \circ i_{k+1} : A_{k+1} \to A_k \) is an isomorphism. Show that we can “cancel” \( A_{k+1} \) and \( A_k \) from the exact sequence without changing the isomorphism type of the homology groups. More precisely, consider the following chain complex:

\[ \tilde{D}_* = \cdots \to C_{k+2} \xrightarrow{p_{k+1} \circ \partial_{k+2}} B_{k+1} \xrightarrow{q_k \circ \partial_{k+1} \circ j_{k+1}} B_k \xrightarrow{\partial_k \circ j_k} C_{k-1} \to \cdots \]

Show that for each \( i \in \mathbb{N}_0 \) there exists an isomorphism \( H_i(D_*) \to H_i(\tilde{D}_*) \).

Remark. This implies in particular that \( D_* \) is acyclic if and only if \( \tilde{D}_* \) is acyclic.
42. Homology and homotopies

It was not overly difficult to introduce the homology groups of a topological space. We also proved several straightforward properties of homology groups. But so far we are unable to calculate any interesting homology group. In this section we will show in particular that homotopy equivalent topological spaces have isomorphic homology groups. That does not yet lead to the calculation of non-trivial homology groups, but this result will play an important role in the calculation of the homology groups of spheres that we will give in Proposition 43.4.

42.1. Chain homotopies. In this section we introduce a criterion that ensures that two chain maps \( f, g : C_* \to D_* \) induce the same maps on the corresponding homology groups.

**Definition.** Let \( f, g : C_* \to D_* \) be chain maps between chain complexes \( C_* \) and \( D_* \). A chain homotopy \( P = \{ P_n \}_{n \in \mathbb{N}_0} \) between \( f \) and \( g \) consists of family \( \{ P_n : C_n \to D_{n+1} \}_{n \in \mathbb{N}_0} \) such that for each \( n \in \mathbb{N}_0 \) we have

\[
\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n = f_n - g_n.
\]

If there exists a chain homotopy between chain maps \( f \) and \( g \), then we say that \( f \) and \( g \) are chain homotopic and we write \( f \simeq g \).

For the definition of a chain homotopy and the subsequent discussion of chain homotopies it is sometimes helpful to keep in mind the following diagram that combines all objects involved in the definition:

- The following basic lemma will be proved in Exercise 42.1.

**Lemma 42.1.** Let \( C_* \) and \( D_* \) be two chain complexes.

1. Chain homotopy defines an equivalence relation on the set of all chain maps from \( C_* \) to \( D_* \). In particular, if \( f, g, h : C_* \to D_* \) are chain maps with \( f \simeq g \) and \( g \simeq h \), then \( f \simeq h \).
2. Let \( f, g : C_* \to D_* \) be chain maps, and let \( e : B_* \to C_* \) and \( h : D_* \to E_* \) be two other chain maps. Then

\[
f \simeq g \implies f \circ e \simeq g \circ e \quad \text{and} \quad h \circ f \simeq h \circ g.
\]

Now we can formulate the following lemma.

**Lemma 42.2.** Let \( f, g : C_* \to D_* \) be two chain maps between chain complexes. If \( f \) and \( g \) are chain homotopic, then \( f_* = g_* : \mathbb{H}_n(C) \to \mathbb{H}_n(D) \) for all \( n \in \mathbb{N}_0 \).
42. HOMOLOGY AND HOMOTOPIES

Proof. Let \( P = \{P_n\}_{n \in \mathbb{N}_0} \) be a chain homotopy between \( f \) and \( g \). Then for any cycle \( z \in C_n \) we get the equalities
\[
f(z) - g(z) = (f - g)(z) = (\partial_{n+1}P_n + P_{n-1}\partial_n)(z) = (\partial_{n+1}P_n)(z) + P_{n-1}\partial_nz = \partial P_nz,
\]
i.e. \( f(z) \) and \( g(z) \) are homologous.

Definition. Let \( C_* \) and \( D_* \) be two chain complexes.

(1) A chain map \( f: C_* \to D_* \) is called a chain homotopy equivalence between \( C_* \) and \( D_* \), if it admits a chain homotopy inverse, i.e. a chain map \( g: D_* \to C_* \) with \( g \circ f \simeq \text{id}_{C_*} \) and \( f \circ g \simeq \text{id}_{D_*} \).

(2) If there exists a chain homotopy equivalence between \( C_* \) and \( D_* \), then we say that the chain complexes \( C_* \) and \( D_* \) are chain homotopy equivalent and we write \( C_* \simeq D_* \).

Remark. It is again straightforward to show that “homotopy equivalence” of chain complexes is indeed an equivalence relation.

For later we record the following straightforward corollary to Lemma 42.2.

Corollary 42.3. If \( f: C_* \to D_* \) is a chain homotopy equivalence between chain complexes, then the induced maps \( f_*: H_n(C) \to H_n(D) \) are isomorphisms.

We also record the following useful little lemma.

Lemma 42.4. Let \( (C_*, \partial) \) be a chain complex. If there exist “diagonal” maps \( P_n \), \( n \in \mathbb{Z}_{\geq -1} \), to obtain a diagram\(\:\begin{array}{cccccccc}
\ldots & \longrightarrow & C_3 & \underset{\partial_3}{\longrightarrow} & C_2 & \underset{\partial_2}{\longrightarrow} & C_1 & \underset{\partial_1}{\longrightarrow} & C_0 & \overset{\partial_0}{\longrightarrow} & 0 \\
\ldots & \longrightarrow & C_3 & \overset{P_3}{\longrightarrow} & C_2 & \overset{P_2}{\longrightarrow} & C_1 & \overset{P_1}{\longrightarrow} & C_0 & \overset{P_0}{\longrightarrow} & 0
\end{array}\)\(\]
such that for every \( n \in \mathbb{N}_0 \) we have the equality
\[
\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n = \text{id}_{C_n},
\]
then all homology groups of \( (C_*, \partial) \) vanish.

Proof (*). Let \( D_* \) be the zero chain complex and for each \( n \in \mathbb{N}_0 \) let \( f_n: C_n \to D_n = 0 \) be the trivial map. Since the homology groups of \( D_* \) it suffices, by Corollary 42.3, to show that \( f_* \) is a chain homotopy equivalence. For each \( n \in \mathbb{N}_0 \) let \( g_n: D_n \to C_n \) be the trivial map. Evidently \( f_n \circ g_n = \text{id}_{D_n} \). Thus it remains to show that \( g_* \circ f_* \simeq \text{id}_{C_*} \). In other words we need to show that \( 0 \simeq \text{id}_{C_*} \). But that is exactly what the maps \( P_n \) do.

42.2. Homology and homotopic maps. The name chain homotopy introduced in the previous section suggests that this concept is related to the notion of a homotopy between two topological spaces. As we will see shortly, this is indeed the case. For the reader’s

\[\text{The diagram has no particular role, except that it shows the domain and the target of the maps } P_n \text{ and that it is convenient for keeping track of the various maps.}\]
convenience we recall that if \( f, g : X \to Y \) are two maps between topological spaces, then a homotopy between the maps \( f \) and \( g \) is a map
\[
F : X \times [0, 1] \to Y,
\]
such that
\[
F(x, 0) = f(x) \text{ and } F(x, 1) = g(x) \text{ for all } x \in X.
\]
If there exists a homotopy between \( f \) and \( g \), then we say that \( f \) and \( g \) are homotopic and we write \( f \simeq g \).

**Proposition 42.5.** Let \( X \) and \( Y \) be two topological spaces and let \( f, g : X \to Y \) be two maps. If \( f \) and \( g \) are homotopic, then the following hold:

1. the induced maps \( f_* \) and \( g_* \) from \( C_*(X) \) to \( C_*(Y) \) are chain homotopic,
2. for each \( n \in \mathbb{N}_0 \) we have \( f_* = g_* : H_n(X) \to H_n(Y) \).

**Remark.** The proposition can be stated more succinctly as follows:
\[
f \simeq g : X \to Y \implies f_* \simeq g_* : C_*(X) \to C_*(Y) \implies f_* = g_* : H_*(X) \to H_*(Y).
\]

We start out with a discussion of the key idea behind the proof of Proposition 42.5. Afterwards we will fill in the details. So let \( f, g : X \to Y \) be two maps between topological spaces and let \( F : X \times [0, 1] \to Y \) be a homotopy between the maps \( f \) and \( g \). Our goal is to find a chain homotopy between \( f_* \) and \( g_* \). Thus let \( \sigma : \Delta^n \to X \) be a singular \( n \)-simplex. We need to find \( P(\sigma) \in C_{n+1}(Y) \) and \( P(\partial \sigma) \in C_n(Y) \) such that
\[
\partial P(\sigma) = -P(\partial \sigma) + f_* (\sigma) - g_* (\sigma).
\]
Note that \( F \circ (\sigma \times \text{id}_{[0,1]}) \) defines a map \( \Delta^n \times [0,1] \to Y \). Now we can rewrite the above desired equality as follows:
\[
\partial P(\sigma) = -P(\partial \sigma) + \frac{\text{map } F \circ (\sigma \times \text{id}_{[0,1]})}{=\Delta^n} \text{ restricted to } \Delta^n \times \{0\} - \frac{\text{map } F \circ (\sigma \times \text{id}_{[0,1]})}{=\Delta^n} \text{ restricted to } \Delta^n \times \{1\}.
\]
To get an idea we consider Figure 708. We make the following trivial observation: we have
\[
\partial (\Delta^n \times [0,1]) = \partial \Delta^n \times [0,1] \cup \Delta^n \times \{0\} \cup \Delta^n \times \{1\}.
\]
Comparing the desired equality of maps and the equality of sets suggests that each map \( P_k : C_k(X) \to C_{k+1}(Y) \) should take the role of replacing a singular \( k \)-simplex \( \mu : \Delta^k \to X \) by the map \( F \circ (\mu \times \text{id}_{[0,1]}) : \Delta^k \times [0,1] \to Y \). This is a good idea, but the problem is that \( \Delta^k \times [0,1] \) is not a \( (k+1) \)-simplex. The idea now is to write \( \Delta^k \times [0,1] \) as the union of \( (k+1) \)-simplices. In Figure 709 we see for example that we can view \( \Delta^1 \times [0,1] \) as the union of the triangles with the vertices \( v_0, w_0, w_1 \) respectively \( v_0, v_1, w_1 \).

To generalize this observation we have to introduce some more notation.

**Notation.** Let \( n \in \mathbb{N}_0 \).

1. For \( i = 0, \ldots, n \) we write
\[
v_i := (0, \ldots, 1, 0, \ldots, 0) \times \{0\} \in \mathbb{R}^{n+1} \times \{0\},
\]
and
\[
w_i := (0, \ldots, 1, 0, \ldots, 0) \times \{1\} \in \mathbb{R}^{n+1} \times \{1\}.
\]
The points \(v_0, \ldots, v_n\) thus span the simplex \(\Delta^n \times 0\) and the points \(w_0, \ldots, w_n\) span the simplex \(\Delta^n \times 1\). Furthermore for each \(i\) the points \(v_0, \ldots, v_i, w_i, \ldots, w_n\) span an \((n+1)\)-simplex that is a subset of \(\Delta^n \times [0, 1]\).\(^{680}\)

(2) For \(a_0, \ldots, a_k \in \Delta^n \times [0, 1]\) we consider, as on page 1078, the map

\[
[a_0, \ldots, a_k] : \Delta^k \rightarrow \Delta^n \times [0, 1] \\
(\lambda_0, \ldots, \lambda_k) \mapsto \sum_{j=0}^k \lambda_j a_j.
\]

The map \([a_0, \ldots, a_k]\) thus sends the standard \(k\)-simplex \(\Delta^k\) to the simplex spanned by \(a_0, \ldots, a_k\) in \(\Delta^n \times [0, 1]\).

(3) We define

\[
\Omega_n := \sum_{j=0}^n (-1)^j \cdot \left[ v_0, \ldots, v_j, w_j, \ldots, w_n \right] \in C_{n+1}(\Delta^n \times [0, 1]).
\]

\(^{680}\)It is a straightforward exercise to show that the union of these \((n+1)\)-dimensional simplices is precisely \(\Delta^n \times [0, 1]\). We will not make use of this fact.
In the following lemma we compute the boundary of $\Omega_n \in C_{n+1}(\Delta^n \times [0,1])$. The statement might not be particularly visually appealing, but it will turn out to be very useful.

**Lemma 42.6.** Let $n \in \mathbb{N}_0$. Given $t \in \{0, 1\}$ we write

$$\eta_t : \Delta^n \rightarrow \Delta^n \times [0,1]$$

$$x \mapsto (x, t).$$

With this notation we have

$$\partial_{n+1}(\Omega_n) + \sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \text{id}_{[0,1]})* (\Omega_{n-1}) = \eta_1 - \eta_0 \in C_n(\Delta^n \times [0,1]).$$

**Proof.** The proof of the lemma is basically an elementary, albeit slightly confusing calculation. First note that

$$\partial \Omega_n = \partial \left( \sum_{j=0}^{n} (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, w_n] \right)$$

$$= \sum_{k=0}^{n+1} (-1)^k \cdot \sum_{j=0}^{n} (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, w_n] \circ i_k^{n+1}.$$ 

It is straightforward to see that for any $k \in \{0, \ldots, n+1\}$ we have\(^{581}\)

$$[v_0, \ldots, v_j, w_j, \ldots, w_n] \circ i_k^{n+1} = \begin{cases} [v_0, \ldots, \hat{v}_k, \ldots, v_j, w_j, \ldots, w_n], & \text{if } k \leq j, \\ [v_0, \ldots, v_j, w_j, \ldots, \hat{w}_{k-1}, \ldots, w_n], & \text{if } k > j. \end{cases}$$

Thus it follows that\(^{582}\)

$$\partial \Omega_n = \sum_{0 \leq k \leq j \leq n} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, \hat{v}_k, \ldots, v_j, w_j, \ldots, w_n]$$

$$+ \sum_{n+1 \geq k > j \geq 0} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, \hat{w}_{k-1}, \ldots, w_n].$$

\(^{581}\)The first case, $k \leq j$ is slightly easier: one has to figure out, where the $h$-th vertex $e_h$ of the standard $n$-simplex gets sent to. If $h < k$, then $i_k^{n+1}$ sends the $h$-th vertex again to the $h$-th vertex, and $[v_0, \ldots, v_j, w_j, \ldots, w_n]$ sends this vertex to $v_h$. If $h \geq k$, then $i_k^{n+1}$ sends the $h$-th vertex again to the $(h+1)$-th vertex, and $[v_0, \ldots, v_j, w_j, \ldots, w_n]$ sends this vertex to $v_{h+1}$. If $k \leq j$ this corresponds just to the map $[v_0, \ldots, \hat{v}_k, \ldots, v_j, w_j, \ldots, w_n].$

The second case, $k > j$ is proved precisely the same way.

\(^{582}\)Here we use the usual notation that $\hat{v}_k$ means that we do not plug in $\hat{v}_k$, the same applies to $\hat{w}_{k-1}$. 
Now we split the first sum into the cases \( k = j \) and \( k < j \) and we split the second sum into the cases \( k = j + 1 \) and \( k > j + 1 \). This leads us to the following equality:

\[
\partial \Omega_n = \sum_{k=0}^{n} (-1)^{2k} \cdot [v_0, \ldots, v_{k-1}, w_k, \ldots, w_n] \\
+ \sum_{k=1}^{n+1} (-1)^{2k+1} \cdot [v_0, \ldots, v_{k-1}, w_k, \ldots, w_n] \\
+ \sum_{0 \leq k < j \leq n} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, \hat{v_k}, \ldots, v_j, w_j, \ldots, w_n] \\
+ \sum_{n+1 \geq k > j + 1 \geq 1} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, \hat{w_{k-1}}, \ldots, w_n].
\]

Next we consider the first two sums. The summands cancel each other, except for the summands for \( k = 0 \) and \( k = n + 1 \). Thus we obtain that

\[
\partial \Omega_n = [w_0, \ldots, w_n] - [v_0, \ldots, v_n] \\
+ \sum_{0 \leq k < j \leq n} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, \hat{v_k}, \ldots, v_j, w_j, \ldots, w_n] \\
+ \sum_{n+1 \geq k > j + 1 \geq 1} (-1)^k \cdot (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, \hat{w_{k-1}}, \ldots, w_n].
\]

The first summand is just \( \eta_1 \) and the second is \( -\eta_0 \). It remains to show that the remaining summand corresponds to the remaining term in the formula. Thus we continue our proof with the discussion of the one term in the statement of the lemma that we have not studied yet. We have

\[
\sum_{j=0}^{n} (-1)^j \cdot (i^n_j \times \text{id}_{[0,1]})_\ast(\Omega_{n-1}) = \sum_{r=0}^{n} \sum_{s=0}^{n-1} (-1)^r \cdot (-1)^s \cdot (i^n_r \times \text{id}_{[0,1]}) \circ [v_0, \ldots, v_s, w_s, \ldots, w_{n-1}].
\]

It follows from an elementary (but arguably confusing) argument, using only the definitions, that we have the following equalities of maps \( \Delta^n \to \Delta^{n} \times [0,1] \):

\[
(i^n_r \times \text{id}_{[0,1]}) \circ [v_0, \ldots, v_s, w_s, \ldots, w_{n-1}] = \begin{cases} 
[v_0, \ldots, v_{s+1}, w_{s+1}, \ldots, w_n], & \text{if } r \leq s, \\
[v_0, \ldots, v_s, w_s, \ldots, w_{r+1}, \ldots, w_n], & \text{if } r > s.
\end{cases}
\]

Thus we see that

\[
\sum_{j=0}^{n} (-1)^j \cdot (i^n_j \times \text{id}_{[0,1]})_\ast(\Omega_{n-1}) = \sum_{0 \leq r \leq s \leq n-1} (-1)^r \cdot (-1)^s \cdot [v_0, \ldots, \hat{v_r}, \ldots, v_{s+1}, w_{s+1}, \ldots, w_n] \\
+ \sum_{n \geq r > s \geq 0} (-1)^r \cdot (-1)^s \cdot [v_0, \ldots, v_s, w_s, \ldots, \hat{w_{r+1}}, \ldots, w_n].
\]

\[\text{Here } v_0, \ldots, v_{n-1}, w_0, \ldots, w_{n-1} \text{ are now, unfortunately somewhat confusingly, the corresponding vertices of } \Delta^{n-1} \times [0,1].\]
In the first term we perform the substitutions \( r = k \) and \( s = j - 1 \) and in the second term we perform the substitutions \( r = k - 1, s = j \). We obtain the following equality:

\[
\sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \text{id}_{[0,1]})_*(\Omega_{n-1}) = \sum_{0 \leq k \leq j \leq n-1} (-1)^{j-1} \cdot (-1)^k \cdot [v_0, \ldots, \tilde{v}_k, \ldots, v_j, w_j, \ldots, w_n] + \sum_{n \geq k-1 > j \geq 0} (-1)^j \cdot (-1)^{k-1} \cdot [v_0, \ldots, v_j, w_j, \ldots, \tilde{w}_k, \ldots, w_n].
\]

We see immediately that these terms are just the negatives of the corresponding terms in the above equation (*).

The following lemma implies in particular the first statement of Proposition 42.3. The second statement of Proposition 42.5 regarding the induced maps on homology follows immediately from the first statement together with Lemma 42.2. In other words, the following lemma completes the proof of Proposition 42.5.

**Lemma 42.7.** Let \( X \) be a topological space and let \( F: X \times [0,1] \to X \) be a homotopy from a map \( f \) to a map \( g \). Given any \( n \in \mathbb{N}_0 \) we define

\[
P_n: C_n(X) \to C_{n+1}(Y)
\]

to be the map that is induced by

\[
(\sigma: \Delta^n \to X) \mapsto (F \circ (\sigma \times \text{id}_{[0,1]}))_*(\Omega_n).
\]

Then for any \( n \in \mathbb{N}_0 \) we have

\[
\partial P_n + P_{n-1} \partial = g_* - f_*
\]
as maps from \( C_n(X) \) to \( C_n(Y) \).

**Proof.** Let \( X \) be a topological space and let \( F: X \times [0,1] \to X \) be a homotopy from a map \( f \) to a map \( g \). Furthermore let \( \sigma: \Delta^n \to X \) be a singular \( k \)-simplex. Then

\[
(\partial P_n + P_{n-1} \partial)(\sigma) = \partial(P_n(\sigma)) + P_{n-1} \left( \sum_{j=0}^{n} (-1)^j \cdot \sigma \circ i_j^n \right) = \partial(P_n(\sigma)) + \sum_{j=0}^{n} (-1)^j \cdot P_{n-1}(\sigma \circ i_j^n)
\]

\[
= \partial((F \circ (\sigma \times \text{id}_{[0,1]}))_*(\Omega_n)) + \sum_{j=0}^{n} (-1)^j \cdot (F \circ (\sigma \circ i_j^n \times \text{id}_{[0,1]}))_*(\Omega_{n-1})
\]

\[
= (F \circ (\sigma \times \text{id}_{[0,1]}))_*(\partial(\Omega_n)) + \sum_{j=0}^{n} (-1)^j \cdot (i_j^n \times \text{id}_{[0,1]})_*(\Omega_{n-1})
\]

\[
\uparrow \quad \text{by Lemma 41.9 (1) and since } (\sigma \times \text{id}) \circ (i_j^n \times \text{id}) = (\sigma \circ i_j^n) \times \text{id}
\]

\[
\uparrow \quad = (F \circ (\sigma \times \text{id}_{[0,1]}))_*(\eta_1 - \eta_0) = f \circ \sigma - g \circ \sigma = g_*(\sigma) - f_*(\sigma).
\]

We recall the following definition from page 546.

**Definition.** Let \( X \) and \( Y \) be topological spaces.

1. A map \( f: X \to Y \) is a homotopy equivalence between \( X \) and \( Y \), if there exists a homotopy inverse to \( f \), i.e. if there exists a continuous map \( g: Y \to X \) with \( g \circ f \simeq \text{id}_X \) and \( f \circ g \simeq \text{id}_Y \).
(2) If there exists a homotopy equivalence between \( X \) and \( Y \), then we say that the topological spaces \( X \) and \( Y \) are homotopy equivalent and we write \( X \simeq Y \).

(3) We say \( X \) is contractible, if \( X \) is homotopy equivalent to \( \{ \ast \} \), i.e. if \( X \) is homotopy equivalent to a topological space which consists of precisely one point.

Now we obtain the following corollary to Proposition 42.5. This corollary mirrors the fact, proved in Propositions \( \boxed{18.16} \) (2) and \( \boxed{40.7} \) (2), that homotopy equivalences induce isomorphisms of fundamental groups and higher homotopy groups.

**Corollary 42.8.** Let \( X \) and \( Y \) be topological spaces and let \( n \in \mathbb{N}_0 \).

1. If \( f : X \to Y \) is a homotopy equivalence (e.g. a homeomorphism), then the induced map \( f_* : H_n(X) \to H_n(Y) \) is an isomorphism.
2. If \( X \) and \( Y \) are homotopy equivalent, then \( H_n(X) \cong H_n(Y) \).
3. If \( X \) is contractible, then \( H_0(X) \cong \mathbb{Z} \) and \( H_n(X) = 0 \) for \( n \geq 1 \).
4. If \( X \) is a deformation retract of \( Y \), then the inclusion induced map \( H_n(X) \to H_n(Y) \) is an isomorphism.

**Proof.**

1. Let \( f : X \to Y \) be a homotopy equivalence and let \( g : Y \to X \) be a homotopy inverse of \( f \), i.e. \( g \) is a map such that \( f \circ g \simeq \text{id}_Y \) and \( g \circ f \simeq \text{id}_X \). It follows from Proposition 42.5 and the functoriality of homology that \( f_* \circ g_* = (f \circ g)_* = \text{id}_{H_n(Y)} \) and similarly \( g_* \circ f_* = \text{id}_{H_n(X)} \). But that means precisely that \( f_* : H_n(X) \to H_n(Y) \) is an isomorphism.

2. This statement follows immediately from (1).

3. This statement follows immediately from (2) and Lemma 41.6.

4. This statement follows immediately from (1) and Lemma 18.14.

**Examples.**

1. On page 348 we saw that every convex subset of \( \mathbb{R}^n \), e.g. the open disk \( B^n \), the closed disk \( \overline{B}^n \), any simplex or \( \mathbb{R}^n \), is contractible. Thus it follows from Corollary 42.8, that

   \[
   H_i(\text{convex subset of } \mathbb{R}^n) \cong H_i(B^n) \cong H_i(\overline{B}^n) \cong H_i(\mathbb{R}^n) \cong \begin{cases} 
   \mathbb{Z}, & \text{if } i = 0, \\
   0, & \text{if } i > 0.
   \end{cases}
   \]

2. In Exercise 42.2 we will use Corollary 42.8 to show that if \( A \) is a compact convex subset of \( \mathbb{R}^n \) and if \( x \) is a point in the interior of \( A \), then the inclusion \( \mathbb{R}^n \setminus A \to \mathbb{R}^n \setminus \{x\} \) induces isomorphisms \( H_i(\mathbb{R}^n \setminus A) \to H_i(\mathbb{R}^n \setminus \{x\}) \) for all \( i \).

**Remark.** Given a map \( f : X \to Y \) between topological spaces we denote by \([f]\) the homotopy equivalence class of \( f \), and we denote by \([X, Y]\) the set of equivalence classes of maps from \( X \) to \( Y \). As we pointed out on page 544,

\[
\text{Ob}(\text{HomTop}) := \text{all topological spaces}, \\
\text{Mor}(X, Y) := [X, Y]
\]

together with the composition

\[
\text{Mor}(X, Y) \times \text{Mor}(Y, Z) \to \text{Mor}(X, Z) \\
([f], [g]) \mapsto [g \circ f]
\]
defines a category \textit{HomTop}, called the \textit{homotopy category}. Proposition 42.5 thus says that for each \( n \in \mathbb{N}_0 \) the maps

\[
X \mapsto H_n(X)
\]

and

\[
[f] \mapsto f_* : H_n(X) \to H_n(Y)
\]

define a functor from the category \textit{HomTop} to the category \textit{AbGr} of abelian groups. In particular we now have the following commutative diagram of categories and functors:

\[
\begin{array}{ccc}
\text{category Top of topological spaces} & \xrightarrow{X \mapsto X} & \text{homotopy category HomTop} \\
& X \mapsto H_n(X) & \\
& & X \mapsto H_n(X)
\end{array}
\]

\[
\begin{array}{ccc}
\text{category AbGr of abelian groups} & \xleftarrow{X \mapsto X} & \text{category AbGr of abelian groups}.
\end{array}
\]

\textbf{Exercises for Chapter 42}

\textbf{Exercise 42.1.} Let \( C_* \) and \( D_* \) be two chain complexes.

(a) Show that chain homotopy defines an equivalence relation on the set of all chain maps from \( C_* \) to \( D_* \).

(b) Let \( f, g : C_* \to D_* \) be chain maps, and let \( e : B_* \to C_* \) and \( h : D_* \to E_* \) be two other chain maps. Show that if \( f \simeq g \), then \( f \circ e \simeq g \circ e \) and \( h \circ f \simeq h \circ g \).

\textbf{Exercise 42.2.} Let \( A \) be a compact convex subset of \( \mathbb{R}^n \) and let \( x \in A \) be a point. Show that the inclusion \( \mathbb{R}^n \setminus A \to \mathbb{R}^n \setminus \{x\} \) induces isomorphisms \( H_i(\mathbb{R}^n \setminus A) \to H_i(\mathbb{R}^n \setminus \{x\}) \) for all \( i \).

\textit{Hint.} Use Exercise 18.13

\textbf{Exercise 42.3.} Let \( X = S^1 \) and let \( Y = \overline{B}^2 \times S^1 \). We consider the map \( f : X \to Y \) shown in Figure 710. Show that for every \( i \in \mathbb{N} \) the induced map \( f_* : H_i(X) \to H_i(Y) \) is the zero map.

\textit{Figure 710. Illustration of Exercise 42.3}
43. The Excision Theorem

In this section, given a topological space $X$ and a “good” subset $A$ we will relate the homology groups of $X$, $A$ and the quotient space $X/A$ via a long exact sequence. We will use this long exact sequence to fulfill our dream of calculating the homology groups of all spheres. Unfortunately it will take a very long time to prove the existence of this long exact sequence.

43.1. Reduced homology groups. In this section we introduce the reduced homology groups of a topological space. These are a minute but at times surprisingly useful variation on the usual homology groups.

**Definition.** Let $X$ be a topological space. By Lemma 41.4 (1) we know that the following is a generalized chain complex

$$
\ldots \xrightarrow{\partial_3} C_2(X) \xrightarrow{\partial_2} C_1(X) \xrightarrow{\partial_1} C_0(X) \xrightarrow{\epsilon} \mathbb{Z} \to 0.
$$

We introduce the following three definitions.

1. We refer to this chain complex as the augmented chain complex $\tilde{C}_*(X)$ of $X$.
2. Given $n \in \mathbb{Z}_{\geq -1}$ we define the $n$-th reduced homology group $\tilde{H}_n(X)$ of $X$ to be the $n$-th homology group of the augmented chain complex.
3. If $f: X \to Y$ is a map between topological spaces we denote by $f_*: \tilde{C}_*(X) \to \tilde{C}_*(Y)$ the map that is the usual map on $C_n(X) = C_n(X)$ for $n \geq 0$ and that is the identity on the final $\mathbb{Z}$-term.

The following elementary lemma summarizes a few properties of reduced homology groups.

**Lemma 43.1.**

1. Given a topological space $X$ we have

$$
\tilde{H}_{-1}(X) = \begin{cases} 0, & \text{if } X \neq \emptyset; \\ \mathbb{Z}, & \text{if } X = \emptyset. 
\end{cases}
$$

2. If $f: X \to Y$ is a map between two topological spaces, then the induced maps $f_*: \tilde{C}_*(X) \to \tilde{C}_*(Y)$ are chain maps. In particular we see that for each $n \in \mathbb{Z}_{\geq -1}$ we get a well-defined induced map $f_*: \tilde{H}_n(X) \to \tilde{H}_n(Y)$.

3. For every $n \in \mathbb{Z}_{\geq -1}$ the maps

$$
X \mapsto \tilde{H}_n(X) \\
(f: X \to Y) \mapsto (f_*: \tilde{H}_n(X) \to \tilde{H}_n(Y))
$$

---

684 Recall that a generalized chain complex is like a chain complex, but we also allow non-zero groups in negative degrees.
define a functor from the category of topological spaces to the category of abelian groups.

(3) For each \( n \in \mathbb{Z}_{\geq -1} \) the maps

\[
\varpi : \tilde{H}_n(X) \to H_n(X)
\]

\[ [\sigma] \mapsto [\sigma] \]

are well-defined. Furthermore they define a natural transformation from the functor \( X \mapsto \tilde{H}_n(X) \) to the functor \( X \mapsto H_n(X) \).

(4) For every topological space \( X \) the following statements hold:

(a) Given any point \( P \in X \) the map

\[
\tilde{H}_0(X) \oplus \mathbb{Z} \to H_0(X)
\]

\[ [\sigma] \oplus n \mapsto [\sigma] + [n \cdot P] \]

is an isomorphism.

(b) For every \( n \geq 1 \) the natural map \( \varpi : \tilde{H}_n(X) \to H_n(X) \) is the identity.

(5) If \( X \) is a topological space with \( n \in \mathbb{N} \) path-components, then \( \tilde{H}_0(X) \cong \mathbb{Z}^n \). In particular \( X \) is path-connected if and only if \( \tilde{H}_0(X) = 0 \).

(6) The statements of Corollary 42.8 (1), (2) and (4) also hold the same way for reduced homology groups and the corresponding induced maps. For example, if \( X \) is a deformation retract of some topological space \( Y \), then the inclusion induced maps \( \tilde{H}_k(X) \to \tilde{H}_k(Y) \) are isomorphisms for all \( k \in \mathbb{Z}_{\geq -1} \).

(7) If \( X \) is a contractible topological space, then \( \tilde{H}_k(X) = 0 \) for all \( k \in \mathbb{Z}_{\geq -1} \).

The lemma shows in particular that reduced homology groups are almost the same as the usual homology groups. So it might sound slightly silly to introduce them. But we will see that on several occasions reduced homology groups make it easier to formulate some statements.

Remark.

(1) If \( X \) is a non-empty topological space, then it follows from Lemma 43.1 (4) that we have isomorphisms

\[
H_n(X) \cong \begin{cases} 
\tilde{H}_0(X) \oplus \mathbb{Z}, & \text{if } n = 0, \\
\tilde{H}_n(X), & \text{if } n \neq 0.
\end{cases}
\]

Furthermore, by Lemma 43.1 (3) we know that for \( n \geq 1 \) the isomorphism is natural. On other hand for \( n = 0 \) the isomorphism depends on the choice of a point.

(2) In Lemma 43.2 we will formulate a useful variation on Lemma 43.1 (3).

(3) By Lemma 43.1 (7) we know for any \( k \in \mathbb{N}_0 \) and any \( n \in \mathbb{Z}_{\geq -1} \) we have

\[
\tilde{H}_n(\Delta^k) = \tilde{H}_n(B^k) = \tilde{H}_n(B^n) = \tilde{H}_n(\mathbb{R}^k) = 0.
\]

\[\text{This calculation shows that in almost all cases we can ignore } \tilde{H}_{-1}(X). \text{ Nonetheless, some formulas later on become cleaner if we take into account that } \tilde{H}_{-1}(\emptyset) = \mathbb{Z}.\]
43. THE EXCISION THEOREM

(4) We will often use Lemma 43.1 without explicitly mentioning it. For example we will refer to earlier results about homology groups and state the corresponding results for reduced homology groups.

**Proof.**

(0) First let \( X \) be a non-empty topological space. It follows immediately from the definitions that the augmentation map \( \epsilon \) is an epimorphism which entails that \( \tilde{H}_{n-1}(X) = 0 \). The fact that \( \tilde{H}_{-1}(\emptyset) = \mathbb{Z} \) is clear.

(1) Let \( f : X \to Y \) be a map between two topological spaces. It is a straightforward consequence of the definition of the augmentation maps that the following diagram commutes:

\[
\begin{array}{ccc}
C_0(X) & \xrightarrow{f_*} & C_0(Y) \\
\downarrow \epsilon & & \downarrow \epsilon \\
\mathbb{Z} & & \mathbb{Z}
\end{array}
\]

It follows almost immediately from the fact that this diagram commutes that the induced maps \( f_* : \tilde{C}_*(X) \to \tilde{C}_*(Y) \) are chain maps. Furthermore we obtain from Lemma 43.7 that we get induced maps on reduced homology.

(2) This statement is basically obvious.

(3) This statement follows easily from the definitions.

(4) Let \( X \) be a topological space. By the definition of \( \tilde{H}_n(X) \) we only have to deal with the case \( n = 0 \). Let \( P \in X \) be a point. It is straightforward to show that the maps

\[
\begin{align*}
\tilde{H}_0(X) \oplus \mathbb{Z} & \to H_0(X) \\
[\sigma] \oplus n & \mapsto [\sigma] + [n \cdot P]
\end{align*}
\]

\[
\begin{align*}
H_0(X) & \to \tilde{H}_0(X) \oplus \mathbb{Z} \\
[\sigma] & \mapsto [\sigma - \epsilon_X(\sigma) \cdot P] + \epsilon_X(\sigma)
\end{align*}
\]

are inverses of one another. In particular both maps are isomorphisms.

(5) This statement follows immediately from (1), Corollary 43.15 and Lemma 19.8 (4).

(6) This statement is proved exactly the same way as Corollary 42.8.

(7) This final statement follows immediately from (5) and (6).

►

43.2. **Long exact sequences.** We need two more definitions before we can formulate one of the key theorems of homology theory.

**Definition.** Let \( X \) be a topological space and let \( A \subset X \) be a subset. We say \( A \) is **good** if \( A \) is closed and if there exists an open neighborhood \( U \) of \( A \) in \( X \) such that \( A \) is a deformation retract of \( U \).

![Figure 711. Illustration of a good subset.](image)

**Remark.** Our definition of a good subset is the same as on [Hat02, p. 114], except that we do not demand that a good subset is non-empty.
Examples.

(1) Let $x \in X$ be a point. Basically by definition the subset $\{x\} \subset X$ is good in the above sense if and only the point is good in the sense of the definition on page 604.

(2) The sphere $S^{n-1}$ is a good subset of the closed ball $B^n$. Indeed, it is clear that $S^{n-1}$ is a closed subset. Furthermore, if we consider the open neighborhood $U = B^n \setminus \{0\}$, then a deformation retraction is given by the map

$$((B^n \setminus \{0\}) \times [0, 1]) \rightarrow B^n \setminus \{0\}$$

$$(x, t) \mapsto \left(1 - t \cdot \frac{1-\|x\|}{\|x\|}\right) \cdot x.$$

(3) We can generalize the second example: It follows easily from Proposition 6.27 (3) and the Collar Neighborhood Theorem 8.12 that every boundary component of a smooth manifold is good.

(4) Finally it follows from Lemma 36.18 (2) and Proposition 36.10 (8a) that every subcomplex $A$ of a CW-complex $X$ is good.

The following definition might be familiar from earlier algebra courses.

**Definition.** A sequence of group homomorphisms

$$
\ldots \rightarrow A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \rightarrow \ldots
$$

is called **exact**, if for each $n$ we have

$$\ker(f_n) = \text{im}(f_{n+1}).$$

**Example.** Let $A$ and $B$ be abelian groups. The sequence

$$0 \rightarrow A \xrightarrow{a \mapsto (a,0)} A \oplus B \xrightarrow{(a,b) \mapsto b} B \rightarrow 0$$

is easily seen to be exact.

**Remark.** We collect a few basic statements about exact sequences which we will use frequently.

(1) In any exact sequence the composition of two consecutive maps is necessarily zero.

(2) We have the following equivalences of statements:

- the sequence $0 \rightarrow A \xrightarrow{f} B$ is exact $\iff f$ is injective
- the sequence $A \xrightarrow{f} B \rightarrow 0$ is exact $\iff f$ is surjective
- the sequence $0 \rightarrow A \xrightarrow{f} B \rightarrow 0$ is exact $\iff f$ is an isomorphism.

(3) Sometimes we also use the following observations:

- the sequence $0 \rightarrow A \rightarrow B \xrightarrow{f} C$ is exact $\implies A \cong \ker(f)$
- the sequence $A \xrightarrow{f} B \rightarrow C \rightarrow 0$ is exact $\implies C \cong \text{coker}(f)$.

The following lemma gives us the first slightly interesting example of an exact sequence.
Lemma 43.2. If $X$ is a non-empty topological space, then the natural sequence

$$0 \to \tilde{H}_0(X) \xrightarrow{\kappa} H_0(X) \xrightarrow{\text{augmentation map } \epsilon_X} \mathbb{Z} \to 0$$

is exact.

Proof. Let $P \in X$ be a point. We consider the following diagram:

$$
\begin{array}{ccc}
0 & \to & \tilde{H}_0(X) \\
\downarrow & & \downarrow \kappa \\
\tilde{H}_0(X) & \to & H_0(X) \xrightarrow{\epsilon_X} \mathbb{Z} \to 0
\end{array}
$$

We make the following observations:

1. It follows immediately from the definitions that the diagram commutes.
2. By Lemma 43.1 (4) we know that the vertical map is an isomorphism.
3. The “bottom sequence” via $\tilde{H}_0(X) \oplus \mathbb{Z}$ is precisely of the form of the above example, i.e. this sequence is exact.
4. It follows easily from the above that the original sequence is also exact. ■

Now we can formulate the following theorem.

Theorem 43.3. Let $X$ be a topological space and let $A \subset X$ be a good subset. We denote by $i: A \to X$ the inclusion map and we denote by $p: X \to X/A$ the projection map. For each $n \in \mathbb{N}_0$ there exists a natural homomorphism $\partial: \tilde{H}_n(X/A) \to \tilde{H}_{n-1}(A)$ such that the sequence

$$\ldots \xrightarrow{p_*} \tilde{H}_{n+1}(X/A) \xrightarrow{\partial} \tilde{H}_n(X/A) \xrightarrow{p_*} \tilde{H}_n(X) \xrightarrow{i_*} \tilde{H}_{n-1}(A) \xrightarrow{\partial} \ldots$$

is exact.

Example. In Figure 712 we show a topological space $X$ together with a good subset $A$ and we show the inclusion map $i: A \to X$ and the projection $p: X \to X/A$. Theorem 43.3 relates the (reduced) homology groups of $A$, $X$ and $X/A$ in a mysterious way.

Remark.

(1) In Exercise 43.18 we will see that in general the conclusion of Theorem 43.3 does not hold, if we do not assume that $A$ is a good subset.

---

686 The most common situation is that $X$ is a CW-complex and that $A$ is a subcomplex.

687 Here natural means the following: If $f: (X, A) \to (Y, B)$ is a map between pairs of topological spaces and if $A$ and $B$ are good subsets, then the following diagram commutes:

$$
\begin{array}{ccc}
\tilde{H}_n(X/A) & \xrightarrow{\partial} & \tilde{H}_{n-1}(A) \\
\downarrow f_* & & \downarrow f_* \\
\tilde{H}_n(Y/B) & \xrightarrow{\partial} & \tilde{H}_{n-1}(B).
\end{array}
$$
(2) If $A$ is non-empty, then it follows from Lemma 43.1 that the last term that is possibly non-zero is $\tilde{H}_0(X/A)$.

It will take a while to prove Theorem 43.3. Therefore we will first consider several applications which will convince us that proving Theorem 43.3 is worth the effort.

43.3. The homology groups of spheres. Using Theorem 43.3 we can now determine the homology groups of spheres and we get a nice and satisfactory result.

**Proposition 43.4.** For each $n \in \mathbb{Z}_{\geq 1}$ we have

$$\tilde{H}_k(S^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

**Remark.**

(1) Put differently, the combination of Lemma 43.1 and Proposition 43.4 says that for any $n > 0$ we have

$$H_k(S^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0 \text{ or } k = n, \text{ and} \\ 0, & \text{if } k \neq 0, n. \end{cases}$$

Furthermore we have

$$H_k(S^0) \cong \begin{cases} \mathbb{Z}^2, & \text{if } k = 0, \text{ and} \\ 0, & \text{if } k \neq 0. \end{cases}$$

(2) Note that the statement of Proposition 43.4 is in marked contrast to the situation for higher homotopy groups. As formulated in Question 40.18 we have the strong suspicion that $\pi_3(S^2) \neq 0$.

By Proposition 6.26 we know that for $k \neq l$ the spheres $S^k$ and $S^l$ are not diffeomorphic. The following corollary is a serious upgrade of this fact.

**Corollary 43.5.** For $k \neq l$ the spheres $S^k$ and $S^l$ are not homeomorphic.

So we have finally managed to distinguish spheres of different dimensions. Our initial idea had been to use higher homotopy groups to prove that result. Even though the definition of higher homotopy groups is arguably much more natural than the definition of homology groups, it turns out that the latter groups are significantly easier to compute.

**Proof of Proposition 43.4 assuming Theorem 43.3.** We prove the proposition by induction on $n$. First note that for $n = -1$ we have $S^{n} = S^{-1} = \emptyset$, thus the statement follows immediately from Lemma 43.1 (0).

To readers who prefer $S^0$ as a starting point we point out that $S^0$ consists of precisely two points. Thus the promised isomorphisms follow from Lemmas 41.6, 41.14, and 43.1.
Now we suppose that the statement of the proposition holds for \( n - 1 \). We want to determine the reduced homology of \( S^n \). On page 182 we remarked that \( S^n \) is homeomorphic to \( \overline{B^n} / S^{n-1} \). We had just seen on page 1108 that \( S^{n-1} \) is a good subset of \( \overline{B^n} \). Therefore we can apply Theorem 43.3 to \( X = \overline{B^n} \) and the closed subset \( S = S^{n-1} \) and we obtain the following exact sequence

\[
\ldots \longrightarrow \widetilde{H}_{k+1}(\overline{B^n}) \xrightarrow{p_*} \widetilde{H}_{k+1}(\overline{B^n} / S^{n-1}) \xrightarrow{\partial} \widetilde{H}_k(\overline{B^n}) \xrightarrow{i_*} \widetilde{H}_k(\overline{B^n}) \xrightarrow{p_*} \widetilde{H}_k(\overline{B^n} / S^{n-1}) \xrightarrow{\partial} \widetilde{H}_{k-1}(\overline{B^n}) \xrightarrow{i_*} \ldots
\]

From the induction hypothesis, from the homeomorphism \( S^n \cong \overline{B^n} / S^{n-1} \) and from the fact that \( \widetilde{H}_i(\overline{B^n}) = 0 \) for all \( i \) (obtained on page 1106) we now see that the above long exact sequence gives rise to the following exact sequence:

\[
\ldots \longrightarrow 0 \xrightarrow{p_*} \widetilde{H}_{k+1}(S^n) \xrightarrow{\partial} \widetilde{H}_k(S^n) \xrightarrow{\partial} \widetilde{H}_{k-1}(S^{n-1}) \xrightarrow{i_*} \ldots
\]

In particular we obtain for each \( k \) an exact sequence

\[
0 \longrightarrow \widetilde{H}_{k+1}(S^n) \xrightarrow{\partial} \widetilde{H}_k(S^{n-1}) \longrightarrow 0.
\]

But this means that the maps \( \partial \) are isomorphisms, and using our induction hypothesis we obtain the desired result that

\[
\widetilde{H}_k(S^n) = \widetilde{H}_{k-1}(S^{n-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } k - 1 = n - 1, \text{ i.e. if } k = n \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}
\]

In Lemma 2.59 we had used elementary arguments to show that \( \mathbb{R} \) is not homeomorphic to \( \mathbb{R}^2 \). Furthermore, in Lemma 18.17 we had used the fundamental group to prove that \( \mathbb{R}^2 \) is not homeomorphic to \( \mathbb{R}^n \) for \( n \geq 3 \). Now we can finally show that for any \( k \neq l \) the topological spaces \( \mathbb{R}^k \) and \( \mathbb{R}^l \) are not homeomorphic.

**Proposition 43.6.** For any \( k \neq l \) the topological spaces \( \mathbb{R}^k \) and \( \mathbb{R}^l \) are not homeomorphic.

**Proof.** Clearly we only have to deal with the case \( k, l \geq 1 \). Let \( k, l \in \mathbb{N} \) and suppose there exists a homeomorphism \( f : \mathbb{R}^k \to \mathbb{R}^l \). Then we obtain that

\[
\begin{align*}
\mathbb{Z} & \cong \widetilde{H}_{k-1}(S^{k-1}) \cong \widetilde{H}_{k-1}(\mathbb{R}^k \setminus \{0\}) \xrightarrow{f_*} \widetilde{H}_{k-1}(\mathbb{R}^l \setminus \{f(0)\}) \cong \widetilde{H}_{k-1}(S^{l-1}).
\end{align*}
\]

Proposition 43.4 gives us the following proposition.

So we have \( \widetilde{H}_{k-1}(S^{l-1}) \cong \mathbb{Z} \). But by Proposition 43.4 that is only possible if \( k = l \).
**Proposition 43.7.** For every \( n \in \mathbb{N} \) the sphere \( S^{n-1} = \partial B^n \) is not a retract of the closed ball \( B^n \).

**Remark.** I found the following amusing description of Proposition 43.7 online: “Suppose a shark jumps into a shoal of fish (a kind of big ball). The small fishes start escaping in all directions towards the border of the shoal, where the fishes stand still. Yet they escape with a certain disposition to follow a continuous flow, as they usually do, since everybody tends to follow its neighborhoods. But since there is no continuous retraction to the boundary, somebody doesn’t know where to go, and stay there for a moment, much to the shark’s satisfaction. There is also a 2D version, with a wolf entering into a herd of sheep.”

**Proof.** Suppose there exists a retraction \( r : B^n \to S^{n-1} \). We denote by \( i : S^{n-1} \to B^n \) the inclusion map. We consider the following diagram

\[
\begin{array}{ccc}
\tilde{H}_{n-1}(\mathbb{S}^n) & \xrightarrow{(r \circ i)_*} & \tilde{H}_{n-1}(S^{n-1}) \\
i_* & & (r \circ i)_* & & r_* \\
\end{array}
\]

This diagram commutes since it follows from the functoriality of the homology groups that \( r_* \circ i_* = (r \circ i)_* \). Since \( r \) is a retraction it follows that \( r \circ i = \text{id}_{S^{n-1}} \), i.e. \( (r \circ i)_* = (\text{id}_{S^{n-1}})_* \) is the identity map on \( \tilde{H}_{n-1}(S^{n-1}) \) which, by Proposition 43.4, is isomorphic to \( \mathbb{Z} \). The lower map is thus an isomorphism, but the upper map factorizes through the trivial group, i.e. the composition of \( i_* \) and \( r_* \) cannot be an isomorphism of \( \mathbb{Z} \). Thus we have obtained a contradiction.

**Theorem 43.8. (Brouwer Fixed Point Theorem)** Every map \( f : B^n \to B^n \) admits a fixed point, i.e. for every map \( f : B^n \to B^n \) there exists a point \( x \in B^n \) such that \( f(x) = x \).

**Proof.** Suppose there exists a map \( f : B^n \to B^n \) without a fixed point. Since \( f \) admits no fixed points there exists for each \( x \) precisely one ray which starts at \( f(x) \) and which goes through \( x \). We consider the following map which is illustrated in Figure 713:

\[
\Phi : B^n \to B^n \\
x \mapsto \text{the intersection point of } S^{n-1} \text{ with the uniquely determined ray from } f(x) \text{ to } x.
\]

---

689 Luitzen Brouwer (1881-1966) was a Dutch mathematician.
690 How can one prove the statement for \( n = 1 \) using elementary methods from real analysis?
It is elementary to show that $\Phi$ is continuous. It is evident that $\Phi(x) = x$ for all $x \in S^{n-1}$ and that $\Phi(x) \in S^{n-1}$ for all $x \in S^{n-1}$. The map $\Phi$ is thus a retraction from $\overline{B^n}$ to $S^{n-1}$. But according to Proposition 43.7 this not possible. Thus we have obtained a contradiction. 

The Brouwer Fixed Point Theorem pops up many times in mathematics. For example we can use it to prove the following theorem in linear algebra.

**Theorem 43.9. (Perron-Frobenius Theorem)** Let $A = (a_{ij})$ be an $n \times n$-real matrix. If all entries are positive, then $A$ has a positive eigenvalue $\lambda$ with an eigenvector $v$ such that all entries of $v$ are non-negative.

**Remark.** There are more precise statements one can prove about matrices with positive entries we refer to [Meyr00] Section 8.2 and also to

https://en.wikipedia.org/wiki/Perron-Frobenius_theorem

for details. Supposedly the Perron-Frobenius Theorem and some of the more refined results mentioned in [Meyr00] Section 8.2 play a major role in Google’s algorithm, see e.g.

for more information.

**Proof.** We consider the convex set

$$T := \{(t_1, \ldots, t_n) \in [0, 1]^n \mid \sum_{i=1}^n t_i = 1\}.$$  

This set is just the standard $(n-1)$-simplex endowed with a different name. We saw in Lemma 41.1 that it is homeomorphic to $B^{n-1}$. It follows immediately from this observation and from the Brouwer Fixed Point Theorem 43.8 that any self-map $f: T \to T$ has a fixed point.

---

\[^{[69]}\text{Here is the precise argument: given } x \in \overline{B^n} \text{ the ray } r_x \text{ emanating from } x \text{ and through } f(x) \text{ is given by } r + x(t) = x + t(f(x) - x) \text{ for } t \in \mathbb{R}_{\geq 0}. \text{ For any } x \text{ there exists a unique } t_x \geq 0 \text{ with } \|r_x(t_x)\| = 1, \text{ and } \Phi(x) = r_x(t_x). \text{ It suffices to show that } x \mapsto t_x \text{ is continuous. One can determine } t_x \text{ through the quadratic equation} \\
1 = \|r_x(t_x)\|^2 = \langle r_x(t_x), r_x(t_x) \rangle = 2 \langle x, f(x) - x \rangle + \|f(x) - x\|^2 = \langle x + t_x(f(x) - x), x + t_x(f(x) - x) \rangle \\
\text{and the quadratic formula for polynomials of degree two which is continuous in the coefficients.} \]
Let $A = (a_{ij})$ be an $n \times n$-real matrix such that all entries are positive. We consider the map 

$$f : T \rightarrow T$$

$$v = (v_1, \ldots, v_n) \mapsto \frac{Av}{|Av|}.$$ 

Note that this map is defined since our hypothesis that all $a_{ij}$ are positive and the fact that all entries of $v$ are non-negative and that at least one entry of $v$ is positive imply that $Av \neq 0$. As we had just discussed above, the map $f : T \rightarrow T$ has a fixed point $v \in T$. But this means that $Av = |Av| \cdot v$. Put differently, we have just shown that $v$ is an eigenvector to the positive eigenvalue $|Av|$.

We conclude this discussion of the Brouwer Fixed Point Theorem with two applications outside of mathematics:

1. The board game “Hex” was invented in 1942 by Piet Hein\footnote{Piet Hein (1905-1996) was a Danish mathematician.} and it was re-invented in 1948 by John Nash\footnote{John Nash (1928-2015) was an American mathematician who was awarded the Nobel prize in economics in 1994. The movie “a beautiful mind” was based on his struggles with schizophrenia.}. The game is illustrated in Figure 714 and an online version can be found at 

http://www.lutanho.net/play/hex.html

David Gale \cite{Gal79} showed in 1979 that the statement that the board game “Hex” cannot end in a draw, is equivalent to the Brouwer Fixed Point Theorem. We also refer to \cite{Gh14, p. 102} for a discussion of Hex and the Brouwer Fixed Point Theorem.

![11 \times 11 Hex gameboard showing a winning configuration for Blue](image)

**Figure 714**

2. The Brouwer Fixed Point Theorem can also be used to show the existence of a “Nash equilibrium” in game theory. We refer to the following website for more information:

https://en.wikipedia.org/wiki/Nash_equilibrium

43.4. **Basic homological algebra.** Now that we have made use of Theorem 43.3 we also need to provide a proof of Theorem 43.3. In this chapter we will first develop several algebraic methods which later on will be used in the proof of the existence of the exact sequence of Theorem 43.3.
Definition. A short exact sequence is an exact sequence of the form
\[ 0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0, \]
which consists of at most three non-trivial groups. A short exact sequence of chain complexes
\[ 0 \rightarrow A_n \xrightarrow{i} B_n \xrightarrow{p} C_n \rightarrow 0 \]
consists of chain complexes \( A_n, B_n, C_n \) and chain maps \( i: A_n \to B_n \) and \( p: B_n \to C_n \) such that for each \( n \) the maps
\[ 0 \rightarrow A_n \xrightarrow{i} B_n \xrightarrow{p} C_n \rightarrow 0 \]
form a short exact sequence.

Remark. Throughout the subsequent discussion in the following pages it is helpful to keep in mind the following commutative diagram of short exact sequences:

Now suppose that we are given such a short exact sequence of chain complexes. We will define a map
\[ \partial_n: H_n(C) \to H_{n-1}(A) \]
as follows:

1. Let \( z \in H_n(C) \).
2. We pick \( c \in C_n \) with \( z = [c] \).
3. By the surjectivity of \( p \) we have \( c = p(b) \) for some \( b \in B_n \).
4. We have
\[ p(\partial b) = \partial p(b) = \partial c = 0. \]
   since the diagram commutes since \( c \) is a cycle
5. Since the second horizontal row in the above diagram is exact it follows immediately from (4) that \( \partial b = i(a) \) for some uniquely determined \( a \in A_{n-1} \).
6. We put \( \partial_n(z) := [a] \).

We refer to this map \( \partial_n: H_n(C) \to H_{n-1}(A) \) as the connecting homomorphism.

The following lemma summarizes two of the key properties of the connecting homomorphisms.

Lemma 43.10.
(1) Let $0 \to A_* \to B_* \to C_* \to 0$ be a short exact sequence of chain complexes. The connecting homomorphism $\partial_n: H_n(C) \to H_{n-1}(A)$ is well-defined and it is indeed a homomorphism.

Remark. Let us explain why we say that the connecting homomorphism is “natural”. Let $\mathcal{S}$ be the category of short exact sequences of chain complexes where the morphisms are chain maps. Lemma 43.10 (2) says given any $n \in \mathbb{N}_0$ the connecting homomorphism $\partial_n: H_n(C) \to H_{n-1}(A)$ is a natural transformation from the functor $(A_* \to B_* \to C_*) \mapsto H_n(C)$ to the functor $(A_* \to B_* \to C_*) \mapsto H_{n-1}(A)$.

The proof of this lemma and the following proposition are done by a “diagram chase”. This means that one needs to keep the commutative diagram on page [1115] in mind and one has to use on several occasions that the vertical maps are chain maps and that the horizontal sequences are exact. In both cases the proofs are quite elementary.

Proof.

The proof below is elementary but not very readable. It is much easier to prove the lemma on your own than to try to read the proof.

For the undeterred reader we now provide the fully gory details.

(1) We start out with the following claim.

Claim. The map

$$\partial_n: H_n(C) \to H_{n-1}(A)$$

is well-defined.

Let $z \in H_n(C)$. We denote by $c$, $b$ and $a$ the elements as in the definition of $\partial_n$. We need to show that the element $a$ is indeed a cycle and that the definition of $\partial_n([c])$ does not depend on the choices of $c$ and $b$. 
The proofs of these two statements is not particularly difficult and it is done via “diagram chasing”. First we note that

\[ i(\partial a) = \partial i(a) = \partial(\partial b) = 0. \]

since the diagram commutes

Since \( i \) is injective we obtain that \( \partial a = 0 \), i.e. \( a \) is indeed a cycle. Now we show that the homology class \([a]\) depends only on the homology class \([c]\).

(a) If we choose a different element in \( B_n \), then it follows from the fact that the horizontal sequences are exact that this element would be of the form \( b + i(a') \) for some \( a' \in A_n \). But then we obtain the following equality:

\[ \partial(b + i(a')) = \partial b + \partial(i(a')) = \partial b + i(\partial a') = i(a + \partial a'). \]

Since \([a] = [a + \partial a'] \in H_{n-1}(A)\) this does not change the homology class.

(b) If we picked an other representative for \([c]\), then this representative would be of the form \( c + \partial c' \) for some \( c' \in C_{n+1} \). Since the map \( p: B_n \to C_n \) is an epimorphism there exists a \( b' \in B_{n+1} \) with \( p(b') = c' \). It follows that

\[ p(b + \partial b') = p(b) + p(\partial b') = c + \partial p(b') = c + \partial c'. \]

\[ \text{since the diagram commutes} \]

Since \( \partial(b + \partial b') = \partial b \) we see that we have ended up with the same element in \( B_{n-1} \) as before.

**Claim.** The map

\[ \partial_n: H_n(C) \to H_{n-1}(A) \]

is a homomorphism.

Thus let \([c_1]\) and \([c_2]\) be given. For \( j = 1, 2 \) we choose \( b_j \) as in this definition of \( \partial_n \), and we denote by \( a_j \) the uniquely determined element with \( i(a_j) = \partial b_j \). Then we also have \( p(b_1 + b_2) = c_1 + c_2 \) and \( i(a_1 + a_2) = i(a_1) + i(a_2) = \partial b_1 + \partial b_2 = \partial(b_1 + b_2) \).

It follows that

\[ \partial_n([c_1 + c_2]) = [a_1 + a_2] = [a_1] + [a_2] = \partial_n([c_1]) + \partial_n([c_2]). \]

(2) The second statement follows easily from the definitions. We leave the verification of the details to the reader.

Now we can formulate the following proposition which explains the name “connecting homomorphism”.

**Proposition 43.11.**

(1) Let

\[ 0 \to A_* \overset{i}{\to} B_* \overset{p}{\to} C_* \to 0 \]
be a short exact sequence of chain complexes. Then the sequence
\[ \ldots \to H_n(A) \xrightarrow{i_*} H_n(B) \xrightarrow{p_*} H_n(C) \xrightarrow{\partial} H_{n-1}(A) \xrightarrow{i_*} H_{n-1}(B) \xrightarrow{p_*} \ldots \]

is exact.

(2) The connecting homomorphism is natural. More precisely, let
\[
\begin{array}{c}
0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} C_* \to 0 \\
\downarrow^a \downarrow^b \downarrow^c
\end{array}
\]

be a commutative diagram of chain maps where the horizontal sequences are exact. Then the following diagram commutes:
\[
\begin{array}{c}
\ldots \to H_n(A) \xrightarrow{i_*} H_n(B) \xrightarrow{p_*} H_n(C) \xrightarrow{\partial} H_{n-1}(A) \xrightarrow{i_*} \ldots \\
\downarrow^{a_*} \downarrow^{b_*} \downarrow^{c_*} \downarrow^{a_*}
\end{array}
\]

The fact that the square to the right commutes is just in plain words the statement that the connecting homomorphism is natural.

In the following we refer to the exact sequence of Proposition \text{43.11} as the as long exact sequence in homology corresponding to the short exact sequence of chain complexes.

**Proof of Proposition \text{43.11}**. First note that Statement (2) is an immediate consequence of Lemma \text{43.10}. We included the statement for the convenience of the reader. Thus let us turn to the actual meat, namely Statement (1).

The proof below is elementary but not very readable. It is much easier to prove the proposition on your own than to try to read the proof.

Let
\[
0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} C_* \to 0
\]
be a short exact sequence of chain complexes. Then the sequence
\[
\ldots \to H_n(A) \xrightarrow{i_*} H_n(B) \xrightarrow{p_*} H_n(C) \xrightarrow{\partial} H_{n-1}(A) \xrightarrow{i_*} H_{n-1}(B) \xrightarrow{p_*} \ldots
\]
is exact. We examine the exactness at the three groups $H_{n-1}(A)$, $H_n(B)$ and $H_n(C)$. Put differently, at each of the three groups we want to show the following two statements:

(1) the image of the map to the left is contained in the image of the map to the right, or equivalently, the composition of the map to the left and the map to the right is zero,

(2) the kernel of the map to the right is contained in the image of the map to the left.

Now we perform these steps:

(A) First let $[c] \in H_n(C)$. We want to show that $i(\partial[c]) = 0$. We choose $b$ with $p(b) = c$ and denote by $a \in A_{n-1}$ the element with $i(a) = \partial b$. Then we have
\[
\downarrow^i \uparrow^i \downarrow^i ([a]) = \partial b = 0 \in H_{n-1}(B).
\]

definition of $\partial$: $H_n(C) \to H_{n-1}(A)$
Now let \([a] \in \ker(i_\ast). Then \(i(a) = \partial b\) for some \(b \in B_n\). It follows immediately from the definitions that \(\partial[p(b)] = [a]\).

(B) From \(p \circ i = 0\) it follows that \(p_\ast \circ i_\ast = 0\), i.e. \(\text{im}(i_\ast) \subset \ker(p_\ast)\).

Conversely let \(b \in \ker(p_\ast). Then \(p(b) = \partial c\) for some \(c \in C_{n+1}\). Since \(p\) is surjective, there exists a \(b' \in B_{n+1}\) with \(p(b') = c\). From the commutativity it follows that \(p(\partial b') = \partial p(b') = \partial c = p(b)\). Thus it follows that \(p(b - \partial b') = 0\), i.e. \(b - \partial b' = i(a)\) for some \(a \in A_n\). But then it follows that \([b] = [b - \partial b'] = [i(a)] \in \ker(i_\ast)\).

(C) Let \([b] \in H_n(B)\). We have to show that \(\partial(p_\ast([b])) = 0\). In the definition of \(\partial p_\ast([b])\) we choose some \(b \in B\). Since \(\partial b = 0\) it follows immediately that \(\partial p_\ast([b]) = 0\).

Finally let \([c] \in \ker(\partial; H_n(C) \to H_{n-1}(A))\). We choose \(b \in B_n\) with \(p(b) = c\). Then there exists a uniquely determined \(a \in A_{n-1}\) with \(i(a) = \partial b\). Since we have \([a] = \partial[c] = 0 \in H_{n-1}(A)\) there exists an \(a' \in A_n\) with \(\partial a' = a\). Then it follows that

\[
\partial(b - i(a')) = \partial b - \partial i(a') = \partial b - i(\partial a') = \partial b - i(a) = 0,
\]

i.e. \(b - i(a')\) is a cycle. On the other hand we have \(p(b - i(a')) = p(b) - (p \circ i)(a') = p(b)\).

Thus we see that \(p_\ast([b - i(a')]) = [c]\). We have thus shown that \(\ker(\partial) \subset \text{im}(p_\ast)\).

Thus we have proved the claim and therefore we have also completed the proof of the proposition.

The proof of the following lemma is also done via “diagram chasing”. We will provide the proof in Exercise 43.6.

**Lemma 43.12. (Five Lemma)** Let

\[
\begin{array}{cccccc}
A & \overset{i}{\rightarrow} & B & \overset{j}{\rightarrow} & C & \overset{k}{\rightarrow} & D & \overset{l}{\rightarrow} & E \\
\downarrow a & \cong & \downarrow b & \cong & \downarrow c & \cong & \downarrow d & \cong & \downarrow e \\
A' & \overset{i'}{\rightarrow} & B' & \overset{j'}{\rightarrow} & C' & \overset{k'}{\rightarrow} & D' & \overset{l'}{\rightarrow} & E'
\end{array}
\]

be a diagram of groups (here for once we do not suppose that the groups are abelian) such that the horizontal sequences are exact and such that every squares commute (if all the groups are abelian, then it suffices that the squares commute up to a sign). If \(i\) is surjective, if \(b\) and \(d\) are isomorphisms, and if \(e\) is injective, then \(c\) is an isomorphism.\(^{694}\)

43.5. **Relative homology groups.** In this section we will introduce the relative homology groups which will play an important role in the proof of Theorem 43.3 and also in the remainder of this course.

**Definition.** Let \((X, A)\) be a pair of topological spaces. We view each chain group \(C_n(A)\) as a subgroup of \(C_n(X)\). Thus we can define

\[
C_n(X, A) := C_n(X)/C_n(A)
\]

\(^{694}\)In many applications it suffices to remember the following slightly weaker statement: if the two vertical maps on the left and right are isomorphisms, then the middle map is also an isomorphism.
and we consider the boundary map

\[
\partial_n : C_n(X, A) \rightarrow C_{n-1}(X, A)
\]

\[
[c] \mapsto [\partial_n c].
\]

We refer to

\[
\ldots C_{n+1}(X, A) \xrightarrow{\partial_{n+1}} C_n(X, A) \xrightarrow{\partial_n} C_{n-1}(X, A) \xrightarrow{\partial_{n-1}} \ldots
\]

as the chain complex of the pair \((X, A)\). Given any \(n \in \mathbb{N}_0\) we define the \(n\)-th relative homology group of \((X, A)\) as follows:

\[
H_n(X, A) := H_n(C_*(X, A)).
\]

**Remark.** Let \((X, A)\) be a pair of topological spaces and let \(n \in \mathbb{N}_0\). We write

\[
S := \{ \sigma : \Delta^n \rightarrow X \mid \text{im}(\sigma) \cap (X \setminus A) \neq \emptyset \},
\]

i.e. \(S\) denotes the set of all singular \(n\)-simplices of \(X\) that are not completely contained in \(A\). Then it is straightforward to show that the map

\[
\mathbb{Z}^S \rightarrow C_n(X, A)
\]

\[
\sum_{i=1}^n n_i \sigma_i \mapsto \left[ \sum_{i=1}^n n_i \sigma_i \right]
\]

is an isomorphism. In particular we see that \(C_n(X, A)\) is a free abelian group.

**Examples.**

1. If \(A = \emptyset\), then for all \(n \in \mathbb{N}_0\) we have \(C_n(\emptyset) = 0\) and \(C_n(X, \emptyset) = C_n(X)\), i.e. we have \(H_n(X, \emptyset) = H_n(X)\). In the following we will freely go back and forth between the notations \(H_n(X, \emptyset)\) and \(H_n(X)\).

2. If \(X\) is a path-connected topological space and if \(A\) is non-empty, then \(H_0(X, A) = 0\). Indeed, let \(P \in X\) be a point. We pick a point \(Q \in A\). Since \(X\) is path-connected we can pick a map \(\sigma : \Delta^1 \rightarrow X\) such that \(\sigma(0, 1) = P\) and \(\sigma(1, 0) = Q\). As discussed on page 1079 in \(C_*(X, A)\) we have \(\partial \sigma = P - Q\), but since \(Q = 0 \in C_0(X, A)\) we have \(\partial \sigma = P\), which shows that \(P = 0 \in H_0(X, A)\). But this clearly implies that \(H_0(X, A) = 0\). We refer to Figure 715 for an illustration.

\[\text{Figure 715}\]

---

\textsuperscript{695}Recall that according to the definition on page 477 this means that \(X\) is a topological space and \(A \subset X\) is a subset.

\textsuperscript{696}The map \(\partial_n\) is well-defined, since for any \(c \in C_n(A) \subset C_n(X)\) the boundary \(\partial c\) lies obviously in \(C_{n-1}(A) \subset C_{n-1}(X)\).

\textsuperscript{697}Since \(\partial_{n-1} \circ \partial_n : C_n(X) \rightarrow C_{n-2}(X)\) is the zero map it follows immediately that the composition \(\partial_{n-1} \circ \partial_n : C_n(X, A) \rightarrow C_{n-2}(X, A)\) is also the zero map.
(3) Whereas it is often difficult to write down singular cycles in absolute chain complexes $C_*(X)$, it can be surprisingly easy to write down singular cycles in a relative chain complex $C_*(X, A)$. Indeed, given any map $\sigma: \Delta^n \to X$ with $\sigma(\partial\Delta^n) \subset A$ we have

$$\partial_n(\sigma) = \sum_{j=0}^n (-1)^j \cdot \sigma \circ i^n_j = 0 \in C_{n-1}(X, A) = C_{n-1}(X)/C_{n-1}(A).$$

Thus $\sigma$ defines a cycle in the chain complex $C_n(X, A)$. As an example we consider $X = \mathbb{R}^2$ and $A = B_1(-2) \cup B_1(2)$. Let $\sigma: \Delta^1 \to X$ be a singular 1-simplex with $\sigma(0,1) \in B_1(2)$ and $\sigma(1,0) \in B_1(-2)$. (We refer to Figure 7.16 for an illustration.) It follows from the above discussion that $\sigma$ is a cycle in $C_*(X, A)$. Later, on page 1126 we will see whether or not $[\sigma] \in H_1(X, A)$ is non-trivial.

Definition.

(1) Recall that we refer to the category that is given by

$$\text{Ob}(\text{PairTop}) := \text{all pairs of topological spaces},$$

$$\text{Mor}((X, A), (Y, B)) := \text{all continuous maps } f: X \to A \text{ with } f(A) \subset B$$

with the usual composition of maps as the category of pairs of topological spaces.

(2) Let $f: (X, A) \to (Y, B)$ be a map of pairs of topological spaces, i.e. a map $f: X \to Y$ with $f(A) \subset B$. Then $f$ induces maps

$$f_*: H_n(X, A) \to H_n(Y, B) \quad \left[\sum_{j=1}^n a_j \sigma_j\right] \mapsto \left[\sum_{j=1}^n a_j (f \circ \sigma_j)\right].$$

It is straightforward to show that these maps are well-defined.

The following lemma follows almost immediately from the definitions.

Lemma 43.13. For each $n \in \mathbb{N}_0$ the maps

$$(X, A) \to H_n(X, A)$$

$$(f: (X, A) \to (Y, B)) \mapsto (f_*: H_n(X, A) \to H_n(Y, B))$$

define a covariant functor from the category PairTop of pairs of topological spaces to the category $\text{AbGr}$ of abelian groups.

Remark. If $(Y, B)$ is a pair of topological spaces and if $X \subset Y$ and $A \subset B$, then we have the obvious inclusion map $(X, A) \to (Y, B)$ and we therefore obtain the induced maps $H_n(X, A) \to H_n(Y, B)$ in relative homology. If it is clear from the context that we are
dealing with such an inclusion induced map, then on many occasions we will not explicitly point out that we are working with the inclusion induced maps.

Next we study the interaction between ordinary homology, relative homology and reduced homology. We introduce the following notation.

**Notation.** Let $X$ be a topological space, let $A \subset X$ and let $n \in \mathbb{N}_0$. We introduce the following maps:

$$
\begin{align*}
H_n(X) \xrightarrow{=} H_n(X, \varnothing) & \xrightarrow{=} H_n(X, A) \\
\tilde{H}_n(X) \xrightarrow{\varkappa} H_n(X) & \xrightarrow{=} H_n(X, A),
\end{align*}
$$

**Lemma 43.14.** Let $X$ be a topological space and let $n \in \mathbb{N}_0$. The following statements hold:

1. Let $A \subset X$. The maps $\pi_{X,A}$ and $\varkappa_{X,A}$ are natural in the sense that if we are given a map $f: (X, A) \to (Y, B)$ of pairs of topological spaces then the following diagrams commute:

$$
\begin{align*}
H_n(X) & \xrightarrow{f_*} H_n(Y) \xleftarrow{\pi_{X,Y,B}} \\
H_n(X, A) & \xrightarrow{f_*} H_n(Y, B)
\end{align*}
$$

2. For each $x_0 \in X$ the map $\varkappa_{X,\{x_0\}}: \tilde{H}_n(X) \to H_n(X, \{x_0\})$ is a natural isomorphism.

**Proof.**

1. The first statement follows immediately from the definitions.
2. We will provide the proof of this statement in Exercise 43.13.

Before we can state the next proposition we need to introduce the notion of a triple of topological spaces which is defined in almost the same fashion as a pair of topological spaces.

**Definition.**

1. A *triple of topological spaces* is a triple $(X, B, A)$ where $X$ is a topological space and $A \subset B \subset X$ are subsets.
2. A map $f: (X, B, A) \to (X', B', A')$ between triples of topological spaces is a continuous map $f: X \to X'$ such that $f(B) \subset B'$ and $f(A) \subset A'$. 
Proposition 43.15. Let \( X \) be a topological space and let \( A \subset B \subset X \) be two subsets. We denote by \( i: (B, A) \to (X, A) \) and by \( p: (X, A) \to (X, B) \) the obvious maps.

1. For each \( n \in \mathbb{N}_0 \) the map
\[
\partial_n: H_n(X, B) \to H_{n-1}(B, A)
\]

is well-defined.

2. We consider the category of triples of topological spaces\(^{[a]}\). The maps \( \partial_n \) from (1) define a natural transformation from the functor \( (X, B, A) \to H_n(X, B) \) to the functor \( (X, B, A) \to H_{n-1}(B, A) \). In down-to-earth language this means that for a map \( f: (X, A, B) \to (\tilde{X}, \tilde{A}, \tilde{B}) \) of triples of topological spaces the following diagram commutes:
\[
\begin{array}{ccc}
H_n(X, B) & \xrightarrow{\partial_n} & H_{n-1}(B, A) \\
\downarrow{f_*} & & \downarrow{f_*} \\
H_n(\tilde{X}, \tilde{B}) & \xrightarrow{\partial_n} & H_{n-1}(\tilde{B}, \tilde{A})
\end{array}
\]

In particular the following diagram commutes:
\[
\begin{array}{ccccccc}
\cdots & \to & H_n(B, A) & \xrightarrow{f_*} & H_n(X, A) & \xrightarrow{f_*} & H_n(X, B) & \xrightarrow{\partial} & H_{n-1}(B, A) & \to & \cdots \\
\downarrow{f_*} & & \downarrow{f_*} & & \downarrow{f_*} & & \downarrow{f_*} & & \downarrow{f_*} & & \downarrow{f_*} \\
\cdots & \to & H_n(\tilde{B}, \tilde{A}) & \xrightarrow{f_*} & H_n(\tilde{X}, \tilde{A}) & \xrightarrow{f_*} & H_n(\tilde{X}, \tilde{B}) & \xrightarrow{\partial} & H_{n-1}(\tilde{B}, \tilde{A}) & \to & \cdots
\end{array}
\]

3. The maps
\[
\begin{array}{ccc}
\cdots & \to & H_n(B, A) & \xrightarrow{i_*} & H_n(X, A) & \xrightarrow{p_*} & H_n(X, B) & \xrightarrow{\partial_n} & H_{n-1}(B, A) & \to & \cdots
\end{array}
\]

form an exact sequence.

The long exact sequence of Proposition 43.15 (2) is sometimes called the long exact sequence of the triple \( (X, B, A) \) and we refer to \( \partial_n \) as the connecting homomorphism of the triple \( (X, B, A) \).

Proof. It follows immediately from the definitions and the third isomorphism theorem\(^{[b]}\) that
\[
0 \to C_*(B, A) \xrightarrow{i_*} C_*(X, A) \xrightarrow{p_*} C_*(X, B) \to 0
\]
is a short exact sequence of chain complexes.

\(^{[a]}\)The fact that here the symbol “\( \partial_n \)” denotes the boundary map of singular chains and the desired map \( H_n(X, B) \to H_{n-1}(B, A) \) is an unfortunate problem in our choice of notation.

\(^{[b]}\)Here we use that every homology class in \( H_n(X, B) \) admits by definition a representative in the quotient \( C_n(X, B) = C_n(X) / C_n(B) \), so it can be represented by a singular \( n \)-chain in \( X \).

\(^{[c]}\)It should be clear from the definitions preceding the definition what the objects and morphisms of this category are.

\(^{[d]}\)The third isomorphism theorem in group theory implies that we have a natural isomorphism \( (C_*(X) / C_*(A)) / (C_*(B) / C_*(A)) \cong C_*(X) / C_*(B) \).
Claim. The maps $\partial_n$ introduced in Statement (1) of the propositions are precisely the connecting homomorphisms, as defined on page 1115 of the above short exact sequence of chain complexes. In particular the maps $\partial_n$ are well-defined.

The claim follows basically immediately from the definitions. But for completeness’ sake we give some details. We consider the following commutative diagram

\[
\begin{array}{ccccccccc}
0 & \rightarrow & C_n(B, A) & \rightarrow & C_n(X, A) & \rightarrow & C_n(X, B) & \rightarrow & 0 \\
\downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} & & \downarrow{\partial} \\
0 & \rightarrow & C_{n-1}(B, A) & \rightarrow & C_{n-1}(X, A) & \rightarrow & C_{n-1}(X, B) & \rightarrow & 0.
\end{array}
\]

Let $z \in H_n(X, A)$. Now we will determine the image of $z$ under the connecting homomorphism $H_n(X, B) \rightarrow H_{n-1}(B, A)$ which during the proof of the claim we denote by $\partial^c$.

We pick a representative $\sum_{j=1}^k a_j \cdot \sigma_j : \Delta^n \rightarrow X$ in $C_n(X)$. Note that $\sum_{j=1}^k a_j \cdot \sigma_j : \Delta^n \rightarrow X$ also defines an element in $C_n(X, A)$. We then take the boundary of the above singular $n$-chain under the boundary map $\partial_n : C_n(X, A) \rightarrow C_{n-1}(X, A)$ and we end up with the singular $n$-chain $\sum_{j=1}^k a_j \cdot \partial \sigma_j \in C_{n-1}(X, A)$. As we have seen in the proof of Lemma 43.10 this singular $n$-chain lies in fact in $C_{n-1}(B, A) \subset C_{n-1}(X, A)$. The homology class thereof is by definition precisely $\partial^c(z) \in H_{n-1}(B, A)$. Summarizing we have shown that

\[
\partial^c(z) = \left[ \sum_{j=1}^k a_j \cdot \partial \sigma_j \right].
\]

This shows that the map defined in (1) agrees with $\partial^c$. ■

Statement (2) of the lemma is an easy consequence of Lemma 43.10. The fact that the stated sequence of homology groups is exact is now an immediate consequence of Proposition 43.11. ■

For convenience we record two important special cases of Proposition 43.15 in the following corollary.

**Corollary 43.16.**

1. Let $X$ be a topological space and let $B \subset X$ be a subset. The connecting homomorphism of Proposition 43.15 applied to $A = \emptyset$ gives rise to a long exact sequence

\[
\ldots \rightarrow H_n(B) \rightarrow H_n(X) \rightarrow H_n(X, B) \rightarrow H_{n-1}(B) \rightarrow \ldots
\]

Furthermore, for $n = 1$ the connecting homomorphism $\partial : H_1(X, B) \rightarrow H_0(B)$ takes values in $\tilde{H}_0(B)$ and we obtain a long exact sequence

\[
\ldots \rightarrow \tilde{H}_n(B) \rightarrow \tilde{H}_n(X) \rightarrow \tilde{H}_n(X, B) \rightarrow \tilde{H}_{n-1}(B) \rightarrow \ldots
\]

2. The connecting homomorphisms in (1) are natural. In particular, given a map $f : (X, A) \rightarrow (Y, B)$ between pairs of topological spaces we obtain a commutative
By Corollary 42.8 (3) together with Lemma 41.14 we have the excision theorem applied to $(X,B,A)$.

First note that the statement regarding unreduced homology follows from Proposition [43.15](1) applied to $A = \emptyset$. Now we turn to the statement regarding reduced homology. This statement follows basically immediately from the unreduced case together with Lemma [43.1](4) and Lemma [43.2](2). We leave it to the reader to fill in the dull details for the reduced case.

**Remark.** Let $(X,B,A)$ be a triple of topological spaces. Then $(X,B,\emptyset) \to (X,B,A)$ is a map between triples of topological spaces and by the naturality of the long exact sequence we obtain the following commutative diagram

\[
\begin{array}{ccccccccc}
\ldots & \longrightarrow & H_n(B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X,B) & \longrightarrow & H_{n-1}(B) & \longrightarrow & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\ldots & \longrightarrow & H_n(B,A) & \longrightarrow & H_n(X,A) & \longrightarrow & H_n(X,B) & \longrightarrow & H_{n-1}(B,A) & \longrightarrow & \ldots \\
\end{array}
\]

The analogous statement also holds for reduced homology groups.

**Proof.** First note that the statement regarding unreduced homology follows from Proposition [43.15](1) applied to $A = \emptyset$. Now we turn to the statement regarding reduced homology. This statement follows basically immediately from the unreduced case together with Lemma [43.1](4) and Lemma [43.2](2). We leave it to the reader to fill in the dull details for the reduced case.

**Example.** Let $X$ be a topological space. Furthermore let $x_0 \in X$ be a point. We denote by $i: \{x_0\} \to X$ the inclusion map. By Corollary [43.16](1) we have a long exact sequence

\[
\begin{align*}
\{x_0\} & \longrightarrow H_1(X) \\
i_* & \longrightarrow H_1(X) \to H_1(X,\{x_0\}) \\
& \longrightarrow H_0(X) \to H_0(X,\{x_0\}) \to 0.
\end{align*}
\]

We obtain from that the map $i_*: H_0(\{x_0\}) \to H_0(X)$ is a monomorphism. Together with Lemma [41.6](1) we see that for each $n \in \mathbb{N}$ the map $H_n(X) \to H_n(X,\{x_0\})$ is an isomorphism.

We move on to a more elaborate example.

**Example.** We let $X = \mathbb{R}^2$ and $A = B_1^2(\emptyset) \cup B_1^2(2)$. We want to determine the relative homology groups of $(X,A)$. We denote by $i: A \to X$ the inclusion map. By Corollary [43.16](1) we have a long exact sequence

\[
\begin{align*}
H_2(X) & \to H_2(X,A) \to H_1(A) \\
i_* & \to H_1(X) \to H_1(X,A) \to H_0(A) \to H_0(X) \to H_0(X,A) \to 0.
\end{align*}
\]

By Corollary [42.8](1) together with Lemma [41.14](2) we have $H_i(X) = H_i(\mathbb{R}^2) = 0$ and also $H_i(A) = H_i(B_1(\emptyset)) \oplus H_i(B_1(2)) = 0$ for $i \geq 1$. Thus we see from the above long exact

\[
\begin{align*}
H_i(X) & = H_i(A) \\
& \oplus H_i(B_1(\emptyset)) \oplus H_i(B_1(2)) = 0
\end{align*}
\]

Note that if $B$ is non-empty, then it follows from Lemma [43.1](0) that $\tilde{H}_{n-1}(B) = 0$. Thus the last possibly non-zero term is $H_0(X,B)$. On the other hand, if $B = \emptyset$, then we have $H_{n-1}(B) = H_{n-1}(\emptyset) = \mathbb{Z}$, and if $X = \emptyset$, then we have $\tilde{H}_{n-1}(X) = \tilde{H}_{n-1}(\emptyset) = \mathbb{Z}$. If $B = \emptyset$ the sequence is understood to continue with $H_0(B,\emptyset) \to H_{-1}(\emptyset) \to H_{-1}(X)$. 

---

\[\text{Note to editor:} \]
sequence that \( H_i(X, A) = 0 \) for \( i \geq 2 \). We denote by \( \epsilon : H_0(\mathbb{R}^2) \to \mathbb{Z} \) the augmentation map that is an isomorphism by Proposition [41.5]. Similarly we denote by \( \mu_1 : H_0(B_1(-2)) \to \mathbb{Z} \) and \( \mu_2 : H_0(B_1(2)) \to \mathbb{Z} \) the isomorphisms that are given by the augmentation maps. We obtain the following commutative diagram

\[
\begin{array}{cccccccc}
0 & \longrightarrow & H_1(X, A) & \xrightarrow{\partial} & H_0(A) & \xrightarrow{i_*} & H_0(X) & \longrightarrow & H_0(X, A) & \longrightarrow & 0 \\
\phantom{=} & \downarrow & \mu_1 \oplus \mu_2 \downarrow & \cong & \cong & \downarrow & = & \downarrow & = \\
0 & \longrightarrow & H_1(X, A) & \longrightarrow & \mathbb{Z}^2 & \longrightarrow & \mathbb{Z} & \longrightarrow & H_0(X, A) & \longrightarrow & 0.
\end{array}
\]

We want to determine the matrix representing the homomorphism \( \mathbb{Z}^2 \to \mathbb{Z} \) at the bottom. We do so in the following claim.

**Claim.** The homomorphism \( \epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1} : \mathbb{Z}^2 \to \mathbb{Z} \) is given by the matrix \((1, 1)\).

We pick a point \( P \in B_1(-2) \) and we pick a point \( Q \in B_1(2) \). It follows from Proposition [41.5] and Lemma [41.14] that the map

\[
\Psi : \mathbb{Z}^2 \to H_0(A) = H_0(B_1(-2)) \oplus H_0(B_1(2))
\]

\[
(m, n) \mapsto [m \cdot P + n \cdot Q]
\]

is the inverse to \( \mu_1 \oplus \mu_2 \). Now it is easy to verify that \( \epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1} = \epsilon \circ i_* \circ \Psi \) applied to \((1, 0)\) and \((0, 1)\) gives in both cases the value 1. So the map is described by the matrix \((1, 1)\). \( \square \)

Since the top sequence in the above commutative diagram is exact and since the vertical maps are isomorphisms we see that the bottom sequence is also exact. It is now straightforward to see that

\[
H_1(X, A) \cong \ker (\mathbb{Z}^2 \xrightarrow{(1, 1)} \mathbb{Z}) \cong \mathbb{Z} \quad \text{and} \quad H_0(X, A) \cong \text{coker} (\mathbb{Z}^2 \xrightarrow{(1, 1)} \mathbb{Z}) \cong 0.
\]

Now we return to the situation of the example on page 1121. Let \( \sigma : \Delta^1 \to X \) be a singular 1-simplex with \( \sigma(0, 1) \in B_1(2) \) and \( \sigma(1, 0) \in B_1(-2) \). We have

\[
((\mu_1 \oplus \mu_2) \circ \partial)[\sigma] = ((\mu_1 \oplus \mu_2)([\partial \sigma]) = (\mu_1 \oplus \mu_2)([\sigma(0, 1)] - [\sigma(1, 0)]) = (1, -1).
\]

Since \((1, -1)\) is a generator of the kernel of \( \mathbb{Z}^2 \xrightarrow{(1, 1)} \mathbb{Z} \) we see that \([\sigma]\) is in fact a generator of \( H_1(X, A) \cong \mathbb{Z} \). In particular it is non-zero.

Recall that, as defined on page 571, we say that two maps \( f, g : (X, A) \to (Y, B) \) between pairs of topological spaces are homotopic, if there exists a map \( F : X \times [0, 1] \to Y \) such that \( F(x, 0) = f(x) \) and \( F(x, 1) = g(x) \) for all \( x \in X \), and \( F(a, t) \in B \) for all \( a \in A \) and all \( t \in [0, 1] \). The following proposition extends Proposition [42.5] to the relative case.

**Proposition 43.17.** Let \( f, g : (X, A) \to (Y, B) \) be two maps between pairs of topological spaces. If \( f \) and \( g \) are homotopic, then the maps \( f_* , g_* : C_*(X, A) \to C_*(Y, B) \) are chain homotopic, in particular for every \( n \in \mathbb{N}_0 \) we have

\[
f_* = g_* : H_n(X, A) \to H_n(Y, B).
\]
Proof. Let \( f, g : (X, A) \to (Y, B) \) be two homotopic maps between pairs of topological spaces. To prove the proposition we have to look again at the proof of Proposition 42.5. In that proof we explicitly constructed a chain \( P_n : C_n(X) \to C_{n+1}(Y), \ n \in \mathbb{N}_0 \) between the maps \( f_* \) and \( g_* \) from \( C_*(X) \) to \( C_*(Y) \). It follows immediately from the definition of the chain homotopy that it has the property that \( C_n(A) \) gets sent to \( C_{n+1}(B) \). In particular the chain homotopy descends to maps \( Q_n : C_n(X, A) \to C_{n+1}(Y, B) \) which then form a chain homotopy between the maps \( f_* \) and \( g_* \) from \( C_*(X, A) \) to \( C_*(Y, B) \). It now follows immediately from Lemma 42.2 that \( f_* = g_* : H_n(X, A) \to H_n(Y, B) \). □

We conclude this section with the following result that can be viewed as a generalization of Corollary 42.8 to the relative setting.

Corollary 43.18.

(1) If \( f : (X, A) \to (Y, B) \) is a homotopy equivalence of pairs of topological spaces, then for every \( n \in \mathbb{N}_0 \) the induced map \( f_* : H_n(X, A) \to H_n(Y, B) \) is an isomorphism.

(2) Let \( X \) be a topological space.

(a) Let \( A \subset B \) be subsets of \( X \). If \( A \) is a deformation retract of \( B \), then for every \( n \in \mathbb{N}_0 \) the inclusion induced map \( H_n(X, A) \to H_n(X, B) \) is an isomorphism.

(b) If \( A \) is a deformation retract of \( X \), then \( H_n(X, A) = 0 \) for all \( n \in \mathbb{N}_0 \).

(c) Let \( A \subset Y \) be subsets of \( X \). If \( Y \) is a deformation retract of \( X \), then for every \( n \in \mathbb{N}_0 \) the inclusion induced map \( H_n(Y, A) \to H_n(X, A) \) is an isomorphism.

Proof. Let \( X \) be a topological space.

(1) We deduce this statement from Proposition 43.17 the same way we deduced Corollary 42.8 from Proposition 42.5.

(2) (a) Let \( A \subset B \) be a deformation retract of \( B \). As we mentioned on page 571, the inclusion map \( (X, A) \to (X, B) \) is a homotopy equivalence of pairs of topological spaces. Thus the desired statement follows from (1).

(b) This statement follows from Statement (a) applied to \( B = X \) and the trivial observation that \( H_n(X, X) = 0 \) for all \( n \in \mathbb{N}_0 \).

(c) Let \( A \subset Y \) be subsets of \( X \). If \( Y \) is a deformation retract of \( X \), then we saw already on page 571 that the inclusion map \( (Y, A) \to (X, A) \) is a homotopy equivalence of pairs of topological spaces. Thus the desired statement follows again from (1). □

The statement of Corollary 43.16 looks already very similar to the statement of Theorem 43.3 that we actually want to prove. Now we “only” have to find the connection between the groups \( H_n(X, A) \) and \( H_n(X/A) \). The notations already look very similar, and they do so for good reasons, since in both cases “one ignores what lies in \( A \)”. Nonetheless, proving the precise relationship will still require some substantial piece of work.

43.6. The Excision Theorem. The key step in finding the connection between the groups \( H_n(X, A) \) and \( H_n(X/A) \) is given by the following Excision Theorem 43.19.

\(^{703}\text{We refer to page 571 for the definition.}\)
**Theorem 43.19. (Excision Theorem)** Let \( X \) be a topological space and let \( Z \subset A \subset X \) be subsets such that the closure of \( Z \) is contained in the interior of \( A \). Then the inclusion \( (X \setminus Z, A \setminus Z) \to (X, A) \) induces for each \( n \in \mathbb{N}_0 \) an isomorphism

\[
H_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} H_n(X, A).
\]

The theorem thus says in particular that if we are given a pair of topological spaces \((X, A)\) and if we excise \( \lbrack 0 \rbrack \) a subset \( Z \) from the interior of \( A \), then this does not affect the relative homology groups.

\[
\xymatrix{ X \ar@/^/[r] & X \setminus Z \ar@/^/[l] \\
A \ar@/^/[u] & A \setminus Z \ar@/^/[u] \\
Z \ar@/^/[u] & Z \ar@/^/[u]
}
\]

Figure 717. Illustration of the Excision Theorem \([43.19]\).

On many occasions we will need the following variation on the Excision Theorem \([43.19]\).

**Theorem 43.20. (Excision Theorem)** Let \( X \) be a topological space.

1. Let \( K \) be a subset of \( X \) and let \( U \) be a neighborhood of the closure of \( K \). Then the inclusion \( (U, U \setminus K) \to (X, X \setminus K) \) induces for each \( n \in \mathbb{N}_0 \) an isomorphism

\[
H_n(U, U \setminus K) \xrightarrow{\cong} H_n(X, X \setminus K).
\]

2. The hypotheses of (1) are satisfied if \( X \) is Hausdorff (e.g. if \( X \) is a topological manifold) and if \( K \) is a compact subset that is contained in an open set \( U \).

\[
\xymatrix{ X \ar@/^/[r] & X \setminus K \\
U \ar@/^/[u] & U \setminus K \ar@/^/[u]
}
\]

Figure 718. Illustration of the Excision Theorem \([43.20]\).

**Proof of Theorem 43.20 assuming Theorem 43.19**

1. We have

\[
H_n(U, U \setminus K) = H_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} H_n(X, A) = H_n(X, X \setminus K).
\]

set \( A := X \setminus K \) and \( Z := X \setminus U \) since \( U \) is a neighborhood of the closure of \( K \) we see that the closure of \( Z \) is contained in the interior of \( A \), thus we can apply the Excision Theorem \([43.19]\).

2. If \( X \) is Hausdorff and if \( K \) is a compact subset that is contained in an open set \( U \), then it follows from Lemma \([2.17]\) (2) that \( K \) is also a closed subset, hence we have \( \overline{K} \subset U \).

\( \lbrack 0 \rbrack \) The verb “to excise” means to cut out, or in German “ausschneiden”.

---

\( \lbrack 0 \rbrack \)
Before we turn to the proof of the Excision Theorem 43.19 we first want to show that we can now relate the relative homology groups of a pair \((X, A)\) to the homology groups of the quotient space \(X/A\), assuming \(A \subset X\) is good. To do so we need the following definition.

**Definition.** Let \(X\) be a topological space and let \(A \subset X\) be a \(\text{705}\) subset. We denote by \(p: (X, A) \to (X/A, A/A)\) the obvious projection map. For each \(n \in \mathbb{N}_0\) we define

\[
\begin{align*}
H_n(X, A) &\xrightarrow{p_*} H_n(X/A, A/A) \xleftarrow{\sim \text{ from Lemma 43.14}} \tilde{H}_n(X/A).
\end{align*}
\]

The following lemma summarizes two properties of the maps \(\iota_0\).

**Lemma 43.21.** (*)

1. Let \(X\) be a topological space and let \(A \subset X\) be a subset. We denote by \(p: X \to X/A\) the projection. The following diagram commutes:\(\text{706}\)

\[
\begin{array}{ccc}
H_k(X, A) & \xrightarrow{\sim} & \tilde{H}_k(X) \\
\xrightarrow{\iota_0} & \xrightarrow{p_*} & \xrightarrow{\iota_0} \\
\tilde{H}_k(X) & \xrightarrow{p_*} & \tilde{H}_k(X/A).
\end{array}
\]

2. We denote by \(\text{PairTop}\) the category of pairs of topological spaces that we introduced on page 477. Furthermore as usual we denote by \(\text{AbGr}\) the category of abelian groups. The above maps \(\iota_0\) define a natural transformation from the functor

\[
\begin{array}{ccc}
\text{PairTop} & \to & \text{AbGr} \\
(X, A) & \mapsto & H_n(X, A)
\end{array}
\]

**Proof (\text{\textbullet})**.

1. We consider the following diagram

\[
\begin{array}{ccc}
H_k(X, A) & \xrightarrow{\sim} & \tilde{H}_k(X) \\
\xrightarrow{p_*} & \xrightarrow{\iota_0} & \xrightarrow{p_*} \\
\tilde{H}_k(X/A, A/A) & \xleftarrow{\sim \text{ from Lemma 43.14}} & \tilde{H}_k(X/A).
\end{array}
\]

It follows immediately from the definitions that all three regions of the diagram commute. This observation gives us the desired statement.

2. This statement follows basically immediately from the definitions. \text{\textbullet}

The following proposition is much more interesting than the previous lemma.

---

\(\text{705}\) Note that the definition also makes sense if \(A\) is the empty set.

\(\text{706}\) The left diagonal map is the composition of the natural map \(\tilde{H}_k(X) \to H_k(X)\) from \text{Lemma 43.1} with the natural map \(H_k(X) \to H_k(\tilde{X}, A)\).
Proposition 43.22. Let \( X \) be a topological space and let \( A \subset X \) be a subset and let \( n \in \mathbb{N}_0 \). If \( A \) is good, then the natural homomorphism \( H_n(X, A) \to \tilde{H}_n(X/A) \) is an isomorphism.

Remark. In Corollary 46.17 we will show the analogue of Proposition 43.22 under the slightly different hypothesis that the inclusion map \( i : A \to X \) is a closed cofibration.

Example. Let \( X \) be a topological space, let \( A \subset X \) be a subset and let \( n \in \mathbb{N}_0 \). For better or worse the natural homomorphism \( H_n(X, A) \to \tilde{H}_n(X/A) \) is in general not an isomorphism. In fact in general the two groups \( H_n(X, A) \) and \( \tilde{H}_n(X/A) \) are not even abstractly isomorphic.

For example consider \( X = [0, 1] \) and \( A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\} \). In Exercise 25.1 we showed that the quotient space \( X/A \) is homeomorphic to the Hawaiian earrings. (See Figure 719 for an illustration.) In Exercise 43.17 we will prove the following two statements:

1. The group \( H_1(X, A) \) is countable.
2. The group \( H_1(X/A) \) is uncountable.

![Figure 719](Hawaiian_earrings_X)

Proof of Proposition 43.22 assuming the Excision Theorem 43.19. Let \( X \) be a topological space, let \( A \subset X \) be a good subset and let \( n \in \mathbb{N}_0 \).

First we need to get the annoying case that \( A = \emptyset \) out of the way. Note that the map \( (X, \emptyset) \to (X/\emptyset, \emptyset/\emptyset) \) is easily seen to be a homeomorphism of pairs of topological spaces. Thus it remains to show that the map \( \varpi : \tilde{H}_n(X/\emptyset) \to H_n(X, \emptyset) \) is an isomorphism. It follows immediately from Lemma 43.1 (4) and Corollary 43.16 that the only dimension one needs to worry about for a second is \( n = 0 \). In this case we have the following diagram:

\[
\begin{array}{c}
0 \\
\downarrow \\
H_0(\emptyset/\emptyset) \\
\downarrow \\
\tilde{H}_0(X/\emptyset) \xrightarrow{\varpi} H_0(X/\emptyset) \xrightarrow{\epsilon} \mathbb{Z} \xrightarrow{\epsilon} 0 \\
\downarrow \\
H_0(X/\emptyset, \emptyset/\emptyset) \\
\downarrow \\
0.
\end{array}
\]

It follows from Lemma 43.2 and Corollary 43.16 that the horizontal and the vertical sequences are both exact. The diagonal map on the top right is easily seen to be an isomorphism. Some mild diagram chasing, see Exercise 43.10, now shows that the diagonal map on bottom the is also an isomorphism.
Now we turn to the much more interesting case that $A \neq \emptyset$. We make the following simple preparations:

1. Since $A$ is good we can pick an open neighborhood $U$ of $A$ in $X$ such that $A$ is a deformation retract of $U$.
2. We denote by $p: X \to X/A$ the projection map.
3. We denote by $q: X \setminus A \to X \setminus A/A$ the restriction of $p$ to $X \setminus A$. For completeness’ sake we point out that it follows from Lemma 2.30 that $q$ is continuous.

Now we consider the following diagram

$$
\begin{array}{ccc}
H_n(X, A) & \to & H_n(X, U) \\
\downarrow p_* & & \downarrow p_* \\
H_n(X/A, A/A) & \to & H_n(X/A, U/A)
\end{array}
\quad 
\begin{array}{ccc}
\leftrightarrow & & \leftrightarrow \\
\downarrow q_* & & \downarrow q_* \\
H_n(X \setminus A, U \setminus A/A) & \leftrightarrow & H_n(X \setminus A, U \setminus A/A)
\end{array}
$$

here all the horizontal maps are induced by inclusions of pairs of topological spaces. It follows easily from the definitions that the diagram commutes. It follows from our hypothesis that $A$ is closed, together with the slightly obscure but rather elementary Lemma 3.29 that the map $q: (X \setminus A, U \setminus A) \to (X/A \setminus A/A, U/A \setminus A/A)$ is a homeomorphism of pairs of topological spaces. We obtain from this observation that the vertical map on the right is an isomorphism. Our actual goal is to show that the vertical map on the left is an isomorphism. This follows from the commutativity of the above diagram and from the following claim:

Claim. All horizontal maps are isomorphisms.

We distinguish three different situations:

1. It follows from the Excision Theorem 43.19 that both the top horizontal and the bottom horizontal map on the right-hand side are isomorphisms.
2. Since $A$ is deformation retract of $U$ we obtain from Corollary 43.18 that the top left horizontal map is an isomorphism.
3. Recall that $A$ is a deformation retract of $U$. It follows from Corollary 18.22 that $A/A$ is a deformation retract of $U/A$707. As in (2) we now see that the bottom-left horizontal map is an isomorphism.

\[\square\]

**Figure 720.** Illustration for the proof of Proposition 43.22

**Proof of Theorem 43.3 assuming the Excision Theorem 43.19** Let $X$ be a topological space and let $A \subset X$ be a good subset. We denote by $i: A \to X$ the inclusion and

---

707 The diligent reader who checks the statements we refer to will not fail to notice, that Corollary 18.22 rests eventually on the not-so-trivial Theorem 5.16. It is all too often overlooked (see e.g. earlier version of these notes) that Corollary 18.22 is required and that it is non-trivial.
we denote by \( q: X \to X/A \) the projection map. We consider the following diagram:

\[
\ldots \to \tilde{H}_n(A) \xrightarrow{i_*} \tilde{H}_n(X) \xrightarrow{\tilde{r}_{X,A}} \tilde{H}_n(X,A) \xrightarrow{\partial} \tilde{H}_{n-1}(A) \to \tilde{H}_{n-1}(X) \xrightarrow{i_*} \ldots
\]

We make the following comments and observations:

1. The horizontal sequence is the long exact sequence coming from Corollary \[43.16\].
2. The vertical map is the natural homomorphism that we defined on page \[1129\]. By Lemma \[43.21\] (1) we know that the triangle commutes.
3. Since \( A \) is good we obtain from Proposition \[43.22\] that the vertical map \( i_0 \) is an isomorphism.

Now we consider the maps \( \tilde{\partial} := i_0^{-1} \circ \partial: \tilde{H}_n(X/A) \to \tilde{H}_{n-1}(A) \). Since \( i_0 \) and \( \partial \) are natural we see that the maps \( i_0^{-1} \circ \partial \) are also natural. By the above sequence

\[
\ldots \to \tilde{H}_n(A) \xrightarrow{i_*} \tilde{H}_n(X) \xrightarrow{q_*} \tilde{H}_n(X/A) \xrightarrow{\tilde{\partial}} \tilde{H}_{n-1}(A) \to \tilde{H}_{n-1}(X) \xrightarrow{i_*} \ldots
\]

is exact.

43.7. **The proof of the Excision Theorem \[43.19\]: the idea.** We are still not done with the proof of Theorem \[43.3\] since we still have to prove the Excision Theorem \[43.19\]. In this section we want to come up with the idea for the proof of the Excision Theorem \[43.19\].

The full details of the proof will then be given in the following section.

Thus let \( X \) be a topological space and let \( Z \subset A \subset X \) be two subsets such that the closure of \( Z \) is contained in the interior of \( A \). Our goal is to show that the inclusion \( (X \setminus Z, A \setminus Z) \to (X, A) \) induces for every \( n \in \mathbb{N}_0 \) an isomorphism

\[
H_n(X \setminus Z, A \setminus Z) \to H_n(X, A).
\]

Let us attempt to prove that the map \( H_n(X \setminus Z, A \setminus Z) \to H_n(X, A) \) is surjective. We take an element in \( H_n(X, A) \) and we choose a representative \( a_1\sigma_1 + \cdots + a_r\sigma_r \) where \( \sigma_i: \Delta^n \to X \), \( i = 1, \ldots, r \) are singular \( n \)-simplices in \( X \).

We make the following two basic observations:

1. If the singular \( n \)-simplices \( \sigma_1, \ldots, \sigma_r \) lie in \( X \setminus Z \), then \( [a_1\sigma_1 + \cdots + a_r\sigma_r] \) evidently lies in the image of the inclusion induced map \( H_n(X \setminus Z, A \setminus Z) \to H_n(X, A) \).
2. If a singular \( n \)-simplex lies entirely in \( A \), then it represents the zero element in the quotient group \( C_n(X, A) = C_n(X)/C_n(A) \).

The combination of these two observations proves the following lemma.

**Lemma 43.23.** Let \( X \) be a topological space and let \( Z \subset A \) be two subsets of \( X \). Let \( c = a_1\sigma_1 + \cdots + a_r\sigma_r \) be a cycle in \( X \) such that each \( \sigma_i \) lies entirely in \( A \) or it lies entirely in \( X \setminus Z \). Then \( [c] \) lies in the image of \( H_n(X \setminus Z, A \setminus Z) \to H_n(X, A) \).

\[708\]Given a topological space \( X \) and a subset \( A \) we say that a singular simplex \( \sigma: \Delta^n \to X \) lies in \( A \) if the image of \( \sigma \) lies in \( A \).
Unfortunately not every cycle in $C_n(X)$ satisfies the hypothesis of the lemma. But we will see in the next section that we can subdivide each singular simplex into smaller singular simplices that lie entirely in $A$ or lie entirely in $X \setminus Z$.

![Diagram: singular 1-simplex $\sigma$ in $X$ and subdivision of $\sigma$ such that each new singular simplex lies in $A$ or in $X \setminus Z$]

**Figure 721.** Illustration of the key idea of the proof of the Excision Theorem 43.19.

43.8. **The proof of the Excision Theorem 43.19** **the full details.** In this chapter we will now turn the vague idea of the last section into a rigorous proof of the Excision Theorem 43.19. This will take a surprisingly long time.

First we introduce a few definitions.

**Definition.** Let again $X$ be a topological space.

1. On page 89 we defined a *cover* of $X$ to be a family $\{U_i\}_{i \in I}$ of subsets of $X$ such that $X = \bigcup_{i \in I} U_i$.

2. We say a cover $\{U_i\}_{i \in I}$ is *comfortable* if $X = \bigcup_{i \in I} \overset{\circ}{U}_i$, i.e., if the interiors of the $U_i$ also form a cover of $X$.

We move straight to the next definition.

**Definition.** Let again $X$ be a topological space. Given a comfortable cover $\mathcal{U} = \{U_i\}_{i \in I}$ we consider the following subgroup of $C_n(X)$:

$$C^d_n(X) := \left\{ \sum_{j=1}^k a_j \sigma_j : \text{for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \right\}.$$  

It follows quite easily from the definitions that the restriction of the usual boundary map $\partial_n : C_n(X) \xrightarrow{\partial} C_{n-1}(X)$ to $C^d_n(X)$ restricts to a map $\partial_n : C^d_n(X) \xrightarrow{\partial} C^d_{n-1}(X)$. Since this map is the restriction of the usual boundary map it follows in particular that the composition $\partial_n \circ \partial_{n+1} : C^d_{n+1}(X) \xrightarrow{\partial} C^d_{n-1}(X)$ is the zero map. Thus we can define

$$H^d_n(X) := \text{ker} (\partial_n : C^d_n(X) \to C^d_{n-1}(X)) / \text{im} (\partial_{n+1} : C^d_{n+1}(X) \to C^d_n(X)).$$

The homology groups $H^d_n(X)$ are thus defined by singular chains which are “small” in the sense that the image of each singular simplex lies in some $U_i$.

The following proposition says that we can determine the homology of a topological space through such “small” singular chains. As we will see later on many occasions, this proposition is at the heart of many methods for computing homology groups.
Proposition 43.24. Let $X$ be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be a comfortable cover of $X$. Then the inclusion map
\[ C^d_* (X) \to C_* (X) \]
induces for every $n \in \mathbb{N}_0$ an isomorphism
\[ H^n_d (X) \cong H_n (X). \]

Remark. In fact a stronger statement holds: the inclusion map $C^d_* (X) \to C_* (X)$ is in fact a chain homotopy equivalence. Later, in Section 49.1 we will show that this stronger statement follows in fact from Proposition 43.24 and a purely algebraic argument. Alternatively one can fight one’s way through the proof of Proposition 43.24 and upgrade the proof to this stronger statement. This approach is for example pursued in [Hat02 Proposition 2.21]. The disadvantage is that it makes the proof even more complicated than it already is.

The idea of the proof of Proposition 43.24 is the one we already described in the previous section. We want to replace systematically each singular $n$-simplex $\sigma : \Delta^n \to X$ by a singular $n$-chain of the form $\sum_{j=1}^r a_j \cdot \sigma_j$ such that the image of each singular simplex $\sigma_j$ lies in some $U_i \in \mathcal{U}$. As we have seen before in Lemma 41.3 in the 1-dimensional case, an appropriate subdividing procedure does not change the homology class. The systematic approach we are going to use is given by “barycentric subdivision”. The key idea is sketched in Figure 722 for the case $n = 2$.

![Figure 722. Barycentric decomposition of a singular 2-simplex.](image)

Before we can execute this idea we have to introduce a few more definitions.

1. Given $n \in \mathbb{N}_0$ we denote by $B_n := (\frac{1}{n+1}, \ldots, \frac{1}{n+1}) \in \Delta^n$ the barycenter\(^{709}\) of the standard $n$-simplex $\Delta^n$.

---

\(^{709}\)The word “barycenter” comes from the Greek word “barys” which means heavy. In physics the barycenter of an object is the center of mass, in our case the barycenter of the standard $n$-simplex is the center of mass if we view $\Delta^n$ as a physical object of uniform density.
(2) Given a singular $l$-simplex $\mu: \Delta^l \to \Delta^n$ we consider the singular $(l + 1)$-simplex $c_{l+1}(\mu): \Delta^{l+1} \to \Delta^n$ which is defined as the composition of the (inverses) of the following two maps:

$$c_{l+1}(\mu): \Delta^{l+1} \leftarrow \left(\Delta^l \times [0, 1]\right)/\Delta^l \times \{1\} \to \Delta^n$$

Pictorially speaking the singular $(l+1)$-simplex $c_{l+1}(\mu)$ thus corresponds to the “cone” which is given by the singular $l$-simplex $\mu$ and the barycenter $B_n$. By Lemma 19.1 this map $\mu \to c_{l+1}(\mu)$ defines a linear map $C_l(\Delta^n) \to C_{l+1}(\Delta^n)$ that we also denote by $c_{l+1}$ and which we call the $(l+1)$-st cone map.

![Illustration of the cone map.](image)

Figure 7.23. Illustration of the cone map.

(3) For $n = 0, 1, 2, 3, \ldots$ we now inductively do the following:

(a) we define an element $\chi_n \in C_n(\Delta^n)$, and

(b) for each topological space $X$ we define a homomorphism $u_n: C_n(X) \to C_n(X)$.

We do this inductive procedure as follows:

(i) We set $\chi_0 = \text{id}: \Delta^0 \to \Delta^0$ and for each topological space $X$ we define $u_0$ to be the identity on $C_0(X)$.

(ii) Now suppose $\chi_{n-1} \in C_{n-1}(\Delta^{n-1})$ and that furthermore all the homomorphisms $u_{n-1}: C_{n-1}(X) \to C_{n-1}(X)$ are already defined. Then we define

$$\chi_n := (-1)^n \cdot c_n(u_{n-1}(\partial_{\text{id}}\Delta^n)) \in C_n(\Delta^n).$$

Furthermore, for each topological space $X$ we define

$$u_n: C_n(X) \to C_n(X)$$

$$\sum_{i=1}^r a_i \cdot (\sigma_i: \Delta^n \to X) \mapsto \sum_{i=1}^r a_i \cdot (\sigma_i)_* (\chi_n) \in C_n(\Delta^n)$$

the map $\sigma_i: \Delta^l \to X$ induces a map $(\sigma_i)_*: C_n(\Delta^l) \to C_n(X)$.
Note that with this notation we have $u_n(\text{id}_{\Delta^n}) = \chi_n$. The map $u_n$ is illustrated for $n = 1$ in Figure 724. For $n = 2$ we already gave a more schematic sketch in Figure 722 without considering signs and orientations.

The definition of $\chi_1$ is illustrated in Figure 724.

\[ \begin{array}{c}
\Delta^1 \quad \Delta^0 \\
\uparrow \sigma = \text{id} \quad \uparrow \quad \mapsto \quad - ( + c_1(\sigma((0, 1))) - c_1(\sigma((1, 0))) ) \quad -c_1(u_0(\partial \sigma)) = -c_1(\partial \sigma)
\end{array} \]

**Figure 724.** Illustration of the definition of first subdivision map.

Before we can continue we need to prove several technical lemmas about the subdivision maps.

**Lemma 43.25.** Let $X$ be a topological space. The maps $u_n : C_n(X) \to C_n(X)$, $n \in \mathbb{N}_0$, form a chain map from the chain complex $(C_*(X), \partial)$ to itself.

The statement of Lemma 43.25 is equivalent to the statement that for any singular $n$-simplex $\sigma$ in $X$ we have

$$ u_{n-1}(\partial \sigma) = \partial(u_n(\sigma)). $$

Put differently, Lemma 43.25 says that it does not make a difference whether we first take the boundary and then subdivide, or whether we first subdivide and then take the boundary. This statement is sketched in Figure 725. The picture is quite convincing.

**Figure 725.** Illustration of Lemma 43.25.
Proof of Lemma 43.25 (*).  We adopt the following notation and we make the following remarks:

1. We denote the barycenter of $\Delta^n$ by $b$.
2. As on page 1078, given points $x_0, \ldots, x_k \in \Delta^n$ we denote by $[x_0, \ldots, x_k]$ the singular $k$-chain $\Delta^k \to \Delta^n$ that is given by $\sum_{i=0}^k t_i x_i$,

we refer to such a singular $k$-simplex as a linear singular simplex.
3. We denote by $C_k^{\text{lin}}(\Delta^n)$ the subgroup of $C_k(\Delta^n)$ generated by all the linear singular $k$-simplices. Note that the boundary map $\partial: C_k(\Delta^n) \to C_{k-1}(\Delta^n)$ restricts to a boundary map $\partial: C_k^{\text{lin}}(\Delta^n) \to C_{k-1}^{\text{lin}}(\Delta^n)$.
4. For $x_0, \ldots, x_k \in \Delta^n$ we write $[x_0, \ldots, \hat{x}_i, \ldots, x_k] := [x_0, \ldots, x_{i-1}, x_{i+1}, \ldots, x_k]$.

The proof of the lemma will be broken into three claims.

Claim. For any $\mu \in C_k^{\text{lin}}(\Delta^n)$ we have

$$\partial(c_{k+1}(\mu)) = c_k(\partial\mu) + (-1)^{k+1} \cdot \mu \in C_k(\Delta^n).$$

We illustrate the claim in Figure 726. To prove the claim we first note that for any choice of points $x_0, \ldots, x_{l-1} \in \Delta^n$ we have by definition of $c_l$ that

$$c_l([x_0, \ldots, x_{l-1}]) = [x_0, \ldots, x_{l-1}, b].$$

\footnote{We will not do this proof in the lectures. The proof is somewhat lengthy but straightforward. The cleverness hereby does not lie in the proof, but in the cleverly chosen definitions, which turn the verification into a simple calculation.}

\footnote{It is straightforward to show that this map does indeed take values in $\Delta^n$.}
It now follows that for any $w_0, \ldots, w_k \in \Delta^n$ we have the following equality in $C_k(\Delta^n)$:

by the above equality

$$\partial(c_{k+1}([w_0, \ldots, w_k])) = \partial([w_0, \ldots, w_k, b])$$

$$= \sum_{j=0}^{k} (-1)^{j} \cdot [w_0, \ldots, \hat{w_j}, \ldots, w_k, b] + (-1)^{k+1} \cdot [w_0, \ldots, w_k]$$

definition of $\partial$ and by the above equality

$$\downarrow = c_k(\partial([w_0, \ldots, w_k])) + (-1)^{k+1} \cdot [w_0, \ldots, w_k].$$

The claim immediately follows from this equality.

**Claim.** For any $n \in \mathbb{N}_0$ and any $\nu \in C_n^{\text{lin}}(\Delta^n)$ we have

$$\partial u_n(\nu) = u_{n-1}(\partial \nu).$$

We will prove this claim by induction on $n$. The case $n = 0$ is trivial. So now suppose we have already shown the case $n - 1$. It suffices to show the claim for all linear singular $n$-simplices. So let $\nu: \Delta^n \rightarrow \Delta^n$ be a linear singular $n$-simplex. We then have

definition of $u_n$ and $\chi_n$, see page 1135 since $\partial \circ \nu = \nu \circ \partial$

$$\partial u_n(\nu) = \partial(\nu_*(\chi_n)) = (-1)^n \cdot \partial(\nu_*(c_n(u_{n-1}(\partial(\Delta^n))))) = (-1)^n \cdot \nu_*(\partial(c_n(u_{n-1}(\partial(\Delta^n)))))$$

$$= (-1)^n \cdot \nu_*(c_{n-1}(\partial(u_{n-1}(\partial(\Delta^n)))) + (-1)^n \cdot u_{n-1}(\partial(\nu)(\Delta^n))$$

we can apply the previous claim since $\mu := u_{n-1}(\partial(\Delta^n)) \in C_{n-1}^{\text{lin}}(\Delta^n)$

$$= (-1)^n \cdot \nu_*(c_{n-1}(u_{n-2}(\partial(\Delta^n)))) + \nu_*(u_{n-1}(\partial(\Delta^n)))$$

by induction hypothesis we have $\partial u_{n-1}(\rho) = u_{n-2}(\partial(\rho))$ for $\rho \in C_{n-1}^{\text{lin}}(\Delta^n)$, applied here to $\rho = \partial(\Delta^n)$

$$= u_{n-1}(\nu_*(\partial(\Delta^n))) = u_{n-1}(\partial \nu).$$

Lemma 43.26 applied to $f = \nu$ by definition

The following claim is just a reformulation of the statement of the lemma.

**Claim.** For any singular $n$-simplex $\sigma$ in $X$ we have $u_{n-1}(\partial \sigma) = \partial(u_n(\sigma))$.

So let $\sigma: \Delta^n \rightarrow X$ be a singular $n$-simplex in $X$. Then we have

Lemma 43.26 applied to $f = \sigma$ since $\sigma_*$ is a chain map

$$\partial(u_n(\sigma)) = \partial(u_n(\sigma_*(\Delta^n))) = \partial(\sigma_*(u_n(\Delta^n))) = \sigma_*(\partial(u_n(\Delta^n)))$$

$$= \sigma_*(u_{n-1}(\partial(\Delta^n))) = u_{n-1}(\sigma_*(\partial(\Delta^n))) = u_{n-1}(\partial(\sigma_*(\Delta^n))) = u_{n-1}(\partial \sigma).$$

by the previous claim Lemma 43.26 applied to $f = \sigma$ since $\sigma_*$ is a chain map

We continue with a refreshingly straightforward lemma.

**Lemma 43.26.** The maps $u_n: C_n(X) \rightarrow C_n(X)$ are natural in particular for any map $f: X \rightarrow Y$ between topological spaces and any $n \in \mathbb{N}_0$ we have

$$f_* \circ u_n = u_n \circ f_*: C_n(X) \rightarrow C_n(Y).$$
As we will see, Lemma [43.26] follows immediately from the definitions.

**Proof (\#).** Let \(\sigma: \Delta^n \to X\) be a singular \(n\)-simplex. Then
\[
f_* (u_n (\sigma)) = f_* (\sigma_* (\chi_n)) = (f \circ \sigma)_* (\chi_n) = u_n (f_* (\sigma)).
\]
by definition of \(u_n (\sigma)\) since \((f \circ \sigma)_* = f_* \circ \sigma_*\) by definition of \(u_n (f_* (\sigma))\)

Since the desired equality holds for all generators of \(C_n (X)\) it also holds for all of \(C_n (X)\). ■

The proof of the next lemma is again rather involved.

**Lemma 43.27.** Let \(X\) be a topological space. The chain maps
\[u_n : C_n (X) \to C_n (X)\]
are chain homotopic to the identity.

**Proof (\#).** Showing that the chain maps \((u_n)_{n \in \mathbb{N}}\) are chain homotopic to the identity requires us to find maps \(P_n : C_n (X) \to C_{n+1} (X), n \in \mathbb{N}_0\) such that for each \(n \in \mathbb{N}_0\) the following equality holds:
\[\partial_{n+1} \circ P_n = -P_{n-1} \circ \partial_n + u_n - \text{id} .\]
First we consider the case that \(X\) is a convex subset of some \(\mathbb{R}^m\). Recall that we defined \(C_{-1} (X) = 0\), accordingly we define \(P_{-1} : C_{-1} (X) \to C_0 (X)\) to be the zero map. Let us suppose that we have already found maps \(P_{-1}, \ldots, P_{n-1}\) with the desired properties.

We want to define the next map \(P_n : C_n (X) \to C_{n+1} (X)\). This map has to have the property that for each singular \(n\)-simplex \(\sigma\) we have
\[\partial_{n+1} (P_n (\sigma)) = -(P_{n-1} \circ \partial_n (\sigma)) + (u_n - \text{id})(\sigma) .\]
Put differently, to define \(P_n (\sigma)\) we have to find a singular \((n+1)\)-chain \(E_\sigma \in C_{n+1} (X)\) with
\[\partial E_\sigma = -(P_{n-1} \circ \partial)(\sigma) + (u_n - \text{id})(\sigma) ,\]
so that we can then define \(P_n (\sigma) := E_\sigma\). Thus let \(\sigma: \Delta^n \to X\) be a singular \(n\)-simplex.

(1) For \(n = 0\) we have
\[
\left( P_{-1} \circ \partial_0 + u_0 - \text{id} \right)(\sigma) = 0 \in C_0 (X) ,
\]
and we put \(E_\sigma := 0 \in C_1 (X)\).

\[\text{Let us explain in what sense these maps deserve to be called “natural”. Given } n \in \mathbb{N}_0 \text{ we consider the functor } C_* \text{ from the category Top of topological spaces to the category ChCplx of chain complexes which is given by}
\]
\[\text{topological space } X \mapsto C_* (X) \text{ and}
\]
\[\left( f : X \to Y \right) \mapsto \left( f_* : C_* (X) \to C_* (Y) \right) .\]
Given a topological space \(X\) we denote by \(\Phi_X : C_* (X) \to C_* (X)\) the map that is given by the \(n\)-th subdivision map that we defined on page [1135]. Lemmas [43.25] and [43.26] say that these maps define a natural transformation from the functor \(C_*\) to itself.
(2) Now suppose that \( n > 0 \). Since \( X \) is convex we know from the discussion on page \( \text{103} \) that \( H_n(X) = 0 \). Therefore to show that an element \( c \in C_n(X) \) is the boundary of some element in \( C_{n+1}(X) \) it suffices to show that \( \partial c = 0 \). In our specific situation we calculate

by Lemma \( \text{43.25} \) the subdivision maps form a chain map, i.e. \( \partial \circ u_n = u_{n-1} \circ \partial \)

\[
\partial \left( (-P_{n-1} \partial_n + u_n - \text{id}) (\sigma) \right) = -\partial P_{n-1} \partial \sigma + u_{n-1} \partial \sigma - \partial \sigma
= \underbrace{(-\partial P_{n-1} + u_{n-1} - \text{id})(\partial \sigma)}_{= P_{n-2} \partial^2} = 0.
\]

As we had just remarked, this implies that there exists an \( E_\sigma \in C_{n+1}(X) \) with \( \partial(E_\sigma) = (P_{n-1} \partial_n - u_{n-1} - \text{id})(\sigma) \).

Now we denote by \( P_n: \ C_n(X) \to C_{n+1}(X) \) the map which assigns to each singular \( n \)-simplex \( \sigma \) the element \( E_\sigma \in C_{n+1}(X) \). Then it follows from the definition of \( E_\sigma \) that

\[
\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n = u_n - \text{id}
\]
as maps \( C_n(X) \to C_n(X) \). This concludes the proof of Lemma \( \text{43.27} \) if \( X \) is a convex subset of some \( \mathbb{R}^m \).

Now we deal with the general case. So let \( X \) be a topological space. We consider

\[
P_n: \ C_n(X) \to C_{n+1}(X)
\]

\[
\sum_{l=1}^{r} a_l \cdot (\sigma_l: \Delta^n \to X) \mapsto \sum_{l=1}^{r} a_l \cdot (\sigma_l)_* (P_n(\text{id}_{\Delta^n})).
\]

It is straightforward to see that this is a chain homotopy from the subdivision map to the identity map.

\[\square\]

**Remark.** Later on, in Chapter \( \text{80.7} \) we will generalize the idea behind the proof of Lemma \( \text{43.27} \) to prove the Acyclic Model Theorems.

**Definition.** Given a topological space \( X \) and \( m \in \mathbb{N}_0 \) we denote by \( u_m \) the \( m \)-fold composition of \( u: \ C_n(X) \to C_n(X) \).

**Lemma 43.28.** For each topological space \( X \) and every \( m \in \mathbb{N} \) the maps \( \{u_m\}_{n \geq 0} \) form a chain map \( C_*(X) \to C_*(X) \) that is chain homotopic to the identity.

**Proof.** Recall that in Lemma \( \text{43.25} \) we already saw that the maps \( \{u_n\}_{n \geq 0} \) form a chain map \( C_*(X) \to C_*(X) \). As we remarked on page \( \text{1086} \) the composition of chain maps is again a chain map. Thus for any \( m \in \mathbb{N}_0 \) the maps \( \{u_m\}_{n \geq 0} \) are also chain maps.

By Lemma \( \text{43.27} \) we have \( u_\ast \simeq \text{id} \). By Lemma \( \text{42.1} \)(2) this implies \( u_2 \simeq u_\ast \), and by Lemma \( \text{42.1} \)(1) this implies \( u_1 \simeq \text{id} \). An induction argument now shows that \( u_m \simeq \text{id} \) for all \( m \).

\[\square\]

**Definition.** Given a singular chain \( c \) we can write it uniquely as \( c = a_1 \sigma_1 + \cdots + a_s \sigma_s \) with \( a_1, \ldots, a_s \in \mathbb{Z} \setminus \{0\} \) and where the \( \sigma_i \) are pairwise different. We then say \( \sigma_1, \ldots, \sigma_s \) are the pieces of \( c \).
43. THE EXCISION THEOREM

If $\sigma: \Delta^n \to X$ is a singular $n$-simplex, then the pieces of $u_n(\sigma)$ are evidently “smaller” than the pieces of $\sigma$, and by iteratively applying $u_n$ one can hope to make the resulting pieces “arbitrary small”. In the following two lemmas we will make it precise what we mean by “arbitrary small”. Before we formulate the first lemma we need to recall and introduce several definitions.

Definition.

(1) Given a bounded subset $A$ of $\mathbb{R}^{n+1}$ the diameter is defined as
\[
\text{diam}(A) := \sup \{ \|a - b\| \mid a, b \in A \} \in \mathbb{R}_{\geq 0}.
\]
(2) Given a singular simple $\sigma: \Delta^n \to X$ we denote by $|\sigma|$ the image of $\sigma$.

Now we can formulate the following lemma.

Lemma 43.29. For any $x_0, \ldots, x_k \in \mathbb{R}^n$ and any piece $\tau$ of $u_k([x_0, \ldots, x_k])$ we have
\[
\text{diam}(|\tau|) \leq \frac{n}{n+1} \cdot \text{diam}([x_0, \ldots, x_k]).
\]

![Illustration of Lemma 43.29](image)

**Figure 727.** Illustration of Lemma 43.29.

In the proof of Lemma 43.29 we will need the following elementary geometric lemma.

Lemma 43.30. Let $y_0, \ldots, y_k \in \mathbb{R}^n$.

(1) We have the equality
\[
\text{diam}([y_0, \ldots, y_k]) = \max \{ \|y_i - y_j\| \mid i, j = 1, \ldots, k \}.
\]
(2) We denote by $b = \frac{1}{k} \sum_{i=0}^k y_i$ the barycenter of $y_0, \ldots, y_k$. Then for any $i = 0, \ldots, k$ we have
\[
\|y_i - b\| \leq \text{diam}([y_0, \ldots, y_k]).
\]

**Proof of Lemma 43.30.**

(1) The inequality “$\geq$” follows immediately from the definitions and the observation that each $y_i$ lies in
\[
[y_0, \ldots, y_k] = \left\{ \sum_{i=0}^k t_i \cdot y_i \mid t_i \in [0, 1] \text{ and } \sum_{i=0}^k t_i = 1 \right\}.
\]

We turn to the proof of the reverse inequality “$\leq$”. So we pick $a, b \in [y_0, \ldots, y_k]$.

By definition we can write $a = \sum_{i=0}^k s_i y_i$ and $b = \sum_{i=0}^k t_i y_i$ with $s_i, t_i \in [0, 1]$ and such that

---

\[713\] Recall the definition on page 1078 of the map $[x_0, \ldots, x_k]: \Delta^k \to \mathbb{R}^n$.

\[714\] Here “elementary” means that the statement and the proof are basically high school level mathematics which does not mean that the proofs are entirely obvious.
\[
\sum_{i=0}^{k} s_i = \sum_{i=0}^{k} t_i = 1. \quad \text{We then have}
\]

since \( \sum_{i=0}^{k} t_i = 1 \)

\[
\|a - b\| = \left\| \sum_{i=0}^{k} t_i y_i \right\| = \left\| \sum_{i=0}^{k} t_i (a - t_i y_i) \right\| \leq \sum_{i=0}^{k} \|t_i (a - t_i y_i)\| \leq \sum_{i=0}^{k} \|a - t_i y_i\|
\]

since \( \sum_{i=0}^{k} t_i = 1 \) \quad \text{same argument applied to} \quad a = \sum_{j=0}^{k} s_j y_j

(2) We denote by \( b_i \) the barycenter of \( y_0, \ldots, \hat{y}_i, \ldots, y_k \), i.e.

\[
b_i = \frac{1}{k} \sum_{j \neq i} y_j.
\]

We then have

\[
b = \frac{1}{k+1} y_i + \frac{k}{k+1} b_i.
\]

It follows that

\[
\|b - y_i\| = \left\| \frac{1}{k+1} y_i + \frac{k}{k+1} b_i - y_i \right\| = \left\| \frac{k}{k+1} b_i - \frac{k}{k+1} y_i \right\| = \frac{k}{k+1} \|b_i - y_i\| \leq \frac{k}{k+1} \cdot \text{diam}([y_0, \ldots, y_k]).
\]

Thus we have obtained the desired inequality. \[\Box\]

Now we are ready to provide the proof of Lemma 43.29.

**Proof of Lemma 43.29** (\( * \)). We need to show that for any \( x_0, \ldots, x_k \in \mathbb{R}^n \) and any piece \( \tau \) of \( u_k([x_0, \ldots, x_k]) \) we have

\[
\text{diam}(|\tau|) \leq \frac{n}{n+1} \cdot \text{diam}([x_0, \ldots, x_k]).
\]

We prove the claim by induction on \( k \). For \( k = 0 \) all the diameters are zero, so the inequality holds trivially. Now suppose that the claim holds for \( k - 1 \). Let \( x_0, \ldots, x_k \in \Delta^n \) and denote by \( b = \frac{1}{k} \sum_{i=0}^{k} x_i \) the barycenter of \( x_0, \ldots, x_k \). We denote by \( \sigma_1, \ldots, \sigma_r \) the pieces of \( \partial [x_0, \ldots, x_k] \).

Now let \( \tau \) be a piece of \( u_k([x_0, \ldots, x_k]) \). By the definition of the subdivision map given on page 1135 we see that \( |\tau| = [w_0, \ldots, w_{k-1}, b] \) where \( [w_0, \ldots, w_{k-1}] \) is a piece of \( u_{k-1}(\sigma_s) \) for some \( s \in \{1, \ldots, r\} \). By Lemma 43.30 (1) it now suffices to prove the following claim.

**Claim.**

1. For any \( i, j = 0, \ldots, k - 1 \) we have \( \|w_i - w_j\| \leq \frac{k}{k+1} \cdot \text{diam}([x_0, \ldots, x_k]). \)
2. For any \( i = 0, \ldots, k - 1 \) we have \( \|w_i - b\| \leq \frac{k}{k+1} \cdot \text{diam}([x_0, \ldots, x_k]). \)

\[715\] Why does it not say that the number of pieces is \( k + 1 \)?
Now we provide a proof of these two inequalities. First let \( i, j \in \{0, \ldots, k - 1\} \). Then
\[
\|w_i - w_j\| \leq \text{diam}([w_0, \ldots, w_{k-1}]) \leq \frac{k-1}{k} \cdot \text{diam}(\sigma_s) \leq \frac{k}{k+1} \cdot \text{diam}([x_0, \ldots, x_k]).
\]

\[
\text{induction hypothesis applied to } \sigma_s
\]

Now let \( i \in \{0, \ldots, k - 1\} \). We then have
\[
\|w_i - b\| \leq \frac{k}{k+1} \cdot \text{diam}([w_0, \ldots, w_{k-1}]) \leq \frac{k}{k+1} \cdot \text{diam}([x_0, \ldots, x_k])
\]

\[\text{Lemma } 43.30 (2)\]

\[\text{since } [w_0, \ldots, w_{k-1}] \subset [x_0, \ldots, x_k] \]

\[\square\]

\[\text{Figure 728. Illustration of the proof of Lemma } 43.29\]

\[\text{Lemma 43.31. Let } X \text{ be a topological space and let } U = \{U_i\}_{i \in I} \text{ be an open cover of } X. \text{ For every singular } n\text{-simplex } \sigma: \Delta^n \to X \text{ there exists an } m \text{ such that } u_n^m(\sigma) \text{ lies in } C_n^d(X).\]

\[\text{Proof. Let } X \text{ be a topological space and let } U = \{U_i\}_{i \in I} \text{ be an open cover of } X \text{ and let } \sigma: \Delta^n \to X \text{ be a singular } n\text{-simplex. By the Lebesgue Lemma 2.75 there exists a } \delta > 0 \text{ such that for any subset } A \text{ of } \Delta^n \text{ with diameter } \text{diam}(A) < \delta \text{ there exists an } i \in I \text{ such that } A \subset \sigma^{-1}(U_i).\]

\[\text{We pick an } m \in \mathbb{N} \text{ such that } \left(\frac{n}{n+1}\right)^m < \delta. \text{ We have}\]

\[\text{Lemma } 43.26 \quad \text{by Lemma } 43.29 \text{ and } \left(\frac{n}{n+1}\right)^m < \delta\]

\[u_n^m(\sigma) = u_n^m(\sigma_*(\text{id}_{\Delta^n})) = \sigma_*(u_n^m(\text{id}_{\Delta^n})) = \sigma_*(\text{simplicial chain such that the image has diameter less than } \delta)\]

\[= \sigma_*(\text{simplicial chain such that the image of each piece lies in some } \sigma^{-1}(U_i)),\]

\[\text{by definition of } \delta\]

But this means precisely that \( u_n^m(\sigma) \in C_n^d(X) \).

\[\square\]

Now we can prove Proposition 43.24.

\[\text{Proof of Proposition } 43.24. \text{ Let } X \text{ be a topological space and let } U = \{U_i\}_{i \in I} \text{ be an open cover of } X. \text{ We want to show that the inclusion map } \iota: C_n^d(X) \to C_n(X) \text{ induces for each } n \text{ an isomorphism}\]

\[\iota_*: H_n^d(X) \xrightarrow{\sim} H_n(X).\]

\[\text{We first show that the map } \iota_*: H_n^d(X) \xrightarrow{\sim} H_n(X) \text{ is surjective. Let } z \in H_n(X) \text{ be given. We choose a cycle } c = \sum_{j=1}^n a_j \sigma_j \in C_n(X) \text{ which represents } z \in H_n(X). \text{ It follows from}\]

Lemma 43.31 applied to the singular $n$-simplices $\sigma_1, \ldots, \sigma_r$, that there exists an $m \in \mathbb{N}$ such that $u_n^m(c) \in C_n^d(X)$. By Lemma 43.28 the maps $\{u_n^m\}_{n \in \mathbb{N}_0}$ form a chain map that is chain homotopic to the identity. By definition this means that there exists a chain homotopy $P_k : C_k(X) \to C_{k+1}(X)$, $k \in \mathbb{N}_0$. Thus we obtain that

$$z = [c] = \begin{bmatrix} w_n^m(c) - P_{n-1} \partial(c) - \partial_{n+1} P_n(c) \end{bmatrix} = \begin{bmatrix} w_n^m(c) - \partial_{n+1} P_n(c) \end{bmatrix} = \begin{bmatrix} [w_n^m(c)] \end{bmatrix}.$$ 

Thus we have shown that $\iota_* : H_n^d(X) \cong H_n(X)$ is surjective.

The argument that the map $\iota_* : H_n^d(X) \cong H_n(X)$ is injective is very similar. Indeed, let $[c] \in H_n^d(X)$ be an element such that $[c] = 0 \in H_n(X)$. This means that there exists an $e \in C_{n+1}(X)$ with $\partial e = c$. From Lemma 43.31 it follows, as above, that there exists an $m \in \mathbb{N}$ with $u_n^m(e) \in C_{n+1}^d(X)$. We again choose a chain homotopy $\{P_k\}_{k \in \mathbb{N}_0}$ between the chain maps $\{u_k^m\}_{k \in \mathbb{N}_0}$ and id. Then we have

$$c = \partial e = \partial(u_{n+1}^m(e) - P_{n+1}^m(e) - P_n \partial e) = \partial u_{n+1}^m(e) - \partial P_n(e).$$

Thus we have shown that $c$ is indeed the boundary of an $(n+1)$-dimensional singular chain, in $C_{n+1}^d(X)$ i.e. $[c] = 0 \in H_n^d(X)$. Put differently, we have now proved that $\iota_* : H_n^d(X) \cong H_n(X)$ is injective.

Using Proposition 43.24 we can now prove the Excision Theorem 43.19.

**Proof of the Excision Theorem 43.19** Let $X$ be a topological space. Furthermore let $Z \subset A \subset X$ be subsets such that the closure of $Z$ is contained in the interior of $A$. We have to show that the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X \setminus Z, A \setminus Z) \cong H_n(X, A).$$

We put $B := X \setminus Z$. Note that $A \cap B = A \setminus Z$. It follows from our hypothesis on $Z$ and $A$ that $X$ is the union of the interiors of $A$ and $B$, put differently, the two sets $\{A, B\}$ is a cover of $X$.

For each $n$ we consider the following commutative diagram of abelian groups:

$$\begin{array}{cccccc}
0 & \longrightarrow & C_n(A) & \longrightarrow & C_n^{(A,B)}(X) & \longrightarrow & C_n^{(A,B)}(X)/C_n(A) & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & C_n(A) & \longrightarrow & C_n(X) & \longrightarrow & C_n(X, A) & \longrightarrow & 0.
\end{array}$$

---

\[\text{Here we use the definition from page 1133 which in this context says that} \]

$$C_n^{(A,B)}(X) := \{\sigma + \tau | \sigma \in C_n(A) \text{ and } \tau \in C_n(B)\}.$$
Note that by definition the horizontal sequences are in fact short exact sequences of chain complexes. We first make the observation that it follows immediately from the definition of \( C^{(A,B)}_n(X) \) that the inclusion
\[
C_n(B) \to C^{(A,B)}_n(X)
\]
induces a chain map
\[
C_n(B, A \cap B) \to C^{(A,B)}_n(X) / C_n(A)
\]
that is in fact an isomorphism. Thus in the above diagram we can replace the chain complex \( C^{(A,B)}_n(X) / C_n(A) \) by \( C_n(B, A \cap B) = C_n(X \setminus Z, A \setminus Z) \).

Now we consider the long exact sequence of homology groups arising from the above short exact sequences of chain complexes. By Proposition 43.11 we obtain the following commutative diagram where the horizontal sequences are exact:
\[
\cdots \to H_n(A) \to H^{(A,B)}_n(X) \to H_n(B, A \cap B) \xrightarrow{\partial} H_{n-1}(A) \to H^{(A,B)}_{n-1}(X) \to \cdots
\]
\[
\downarrow = \downarrow \downarrow \downarrow = \downarrow \downarrow \downarrow
\]
\[
\cdots \to H_n(A) \to H_n(X) \to H_n(X, A) \xrightarrow{\partial} H_{n-1}(A) \to H_{n-1}(X) \to \cdots
\]
From Proposition 43.24 it follows that the second and fifth vertical map are isomorphisms. Since the first and fourth map are evidently isomorphisms it now follows from the Five Lemma 43.12 that the middle map is also an isomorphism.

\[\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure729}
\caption{Illustration for the proof of the Excision Theorem 43.19}
\end{figure}\]

Exercises for Chapter 43

Exercise 43.1. Let \( X \) be a non-empty topological space. By Lemma 43.1 (4) we know that there exists an isomorphism \( H_0(X) \xrightarrow{\approx} \tilde{H}_0(X) \oplus \mathbb{Z} \). Show that there is no natural isomorphism \( H_0(X) \xrightarrow{\cong} \tilde{H}_0(X) \oplus \mathbb{Z} \). More precisely, show that it is not possible to assign to each non-empty topological space \( X \) an isomorphism \( \Phi_X : H_0(X) \xrightarrow{\cong} \tilde{H}_0(X) \oplus \mathbb{Z} \) such that for any map \( f : X \to Y \) between non-empty topological spaces the following diagram commutes:
\[
\begin{array}{ccc}
H_0(X) & \xrightarrow{\Phi_X} & \tilde{H}_0(X) \oplus \mathbb{Z} \\
\downarrow{f_*} & & \downarrow{f_* \oplus \text{id}_{\mathbb{Z}}} \\
H_0(Y) & \xrightarrow{\Phi_Y} & \tilde{H}_0(Y) \oplus \mathbb{Z}.
\end{array}
\]

Hint. Let \( X \) be the discrete topological space consisting of two points. If such a natural isomorphism \( \Phi_X \) did exist, what should the map \( \Phi_X \) do?
Exercise 43.2. Let 
\[
\mathbb{Z} \xrightarrow{f} B \xrightarrow{g} \mathbb{Z} \oplus \mathbb{Z}_6 \to 0
\]
be an exact sequence, i.e. we know that \(g \circ f = 0\), we know that \(\text{im}(f) = \ker(g)\) and we know that \(g\) is an epimorphism. What are the possible isomorphism types of the group \(B\)?

Exercise 43.3. We consider the following commutative diagram of homomorphisms between abelian groups:

\[
\begin{array}{cccccc}
0 & \to & A & \to & B & \to & C & \to & 0 \\
\downarrow & & \downarrow a & & \downarrow b & & \downarrow c & & \downarrow \\
0 & \to & A' & \to & B' & \to & C' & \to & 0
\end{array}
\]

We suppose that the horizontal sequences are exact and that the maps \(a\) and \(c\) to the left and right are the zero map. Does it follow that the middle map \(b\) is also the zero map?

Exercise 43.4. Let \(X\) be a topological space with \(\tilde{H}_0(X) \cong \mathbb{Z}\).

(a) Show that given any \(\epsilon \in \{-1, 0, 1\}\) there exists a map \(f : X \to X\) such that the induced map \(f_*\) on \(\tilde{H}_0(X)\) is given by multiplication by \(\epsilon\).

(b) Show that given any map \(f : X \to X\) the induced map \(f_*\) on \(\tilde{H}_0(X)\) is given by multiplication by some \(\epsilon \in \{-1, 0, 1\}\).

Exercise 43.5. Determine the homology groups of \(S^2 \vee S^1\).

Exercise 43.6.

(a) Let

\[
\begin{array}{cccccc}
A & \xrightarrow{i} & B & \xrightarrow{j} & C & \xrightarrow{k} & D & \xrightarrow{l} & E \\
\downarrow a & & \downarrow b & & \downarrow c & & \downarrow d & & \downarrow e \\
A' & \xrightarrow{i'} & B' & \xrightarrow{j'} & C' & \xrightarrow{k'} & D' & \xrightarrow{l'} & E'
\end{array}
\]

be a commutative diagram such that the horizontal sequences are exact. Show that if \(a\) is surjective, if \(b\) and \(d\) are isomorphisms, and if \(e\) is injective, then \(c\) is an isomorphism.

(b) Does the statement in (a) also hold, if \(a\) injective and if \(e\) is surjective?

Exercise 43.7. Let \(M\) be the Möbius band. Determine the relative homology groups of the pair \((M, \partial M)\).

Exercise 43.8. Give examples of two contractible subspaces \(A\) and \(B\) of \(\mathbb{R}^2\) such that \(H_1(A \cup B)\) is infinitely generated.

Exercise 43.9. Let

\[
\begin{array}{cccccc}
0 & \to & A_* & \xrightarrow{\varphi} & B_* & \xrightarrow{\psi} & C_* & \to & 0 \\
\downarrow a & & \downarrow b & & \downarrow c & & \downarrow \\
0 & \to & A'_* & \xrightarrow{\varphi'} & B'_* & \xrightarrow{\psi'} & C'_* & \to & 0
\end{array}
\]
be a commutative diagram of homomorphisms between abelian groups. Show that there exists an exact sequence

\[ 0 \longrightarrow \ker(a) \xrightarrow{\varphi} \ker(b) \xrightarrow{\psi} \ker(c) \xrightarrow{\phi'} \coker(a) \xrightarrow{\psi'} \coker(b) \xrightarrow{\psi'} \coker(c) \longrightarrow 0. \]

This statement is sometimes referred to as the “Snake Lemma”.

**Hint.** Try to prove the statement with as little effort as possible.

**Exercise 43.10.** We consider the following diagram of homomorphisms between abelian groups:

\[
\begin{array}{ccccccccc}
0 & 
\downarrow & M & 
\downarrow^\mu & 
\downarrow^{\beta \circ \mu} & 
\downarrow & N & 
\downarrow & 0. \\
0 & 
\longrightarrow & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & 
\longrightarrow & 0 \\
\end{array}
\]

We suppose that the horizontal and the vertical sequences are exact.

(a) Show that $\beta \circ \mu$ is a monomorphism if and only if $\nu \circ \alpha$ is a monomorphism.

(b) Show that $\beta \circ \mu$ is an epimorphism if and only if $\nu \circ \alpha$ is an epimorphism.

**Exercise 43.11.** We consider the following commutative diagram:

\[
\begin{array}{ccccccccc}
\text{ker}(\beta) & 
\downarrow & 
0 & 
\longrightarrow & A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & 
\longrightarrow & 0 \\
\end{array}
\]

Evidently we assume that the horizontal sequences are exact. Furthermore we assume that $\alpha: A \to A'$ and $\beta: B \to B'$ are epimorphisms. Show that $\gamma: C \to C'$ is an isomorphism.
Exercise 43.12. For readers who really really enjoy diagram chases we have the following problem on offer. Suppose we are given the following commutative diagram of
\[
\begin{array}{ccc}
0 & \to & A_* \to B_* \xrightarrow{h_B} C_* \to 0 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
0 & \to & D_* \xrightarrow{h_D} E_* \xrightarrow{v_B} F_* \to 0 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
0 & \to & G_* \to H_* \to J_* \to 0 \\
\end{array}
\]
where the vertical and horizontal sequences are exact. We suppose that the chain complex $H_*$ is acyclic, i.e. we suppose that homology groups of $H_*$ vanish. Show that for any $k \in \mathbb{N}_0$ the following diagram commutes up to a minus sign:
\[
\begin{array}{ccc}
H_k(D_*) & \xrightarrow{v_{D_*}} & H_k(G_*) \\
\downarrow & \cong & \downarrow & \cong \\
H_k(E) & \xrightarrow{v_{B_*}} & H_k(B) \xrightarrow{h_{B_*}} H_k(C).
\end{array}
\]

Exercise 43.13. Let $X$ be a topological space, let $x_0 \in X$ be a point and let $n \in \mathbb{N}_0$. Show that the map
\[
\widetilde{H}_n(X) \xrightarrow{\sim} H_n(X) \xrightarrow{\sim} H_n(X, \emptyset) \xrightarrow{\sim} H_n(X, \{x_0\})
\]
is an isomorphism.

Exercise 43.14. We say that a map $f : \mathbb{R}^n \to \mathbb{R}^n$ has bounded displacement if there exists a $C \in \mathbb{R}$ such that for any $x \in \mathbb{R}^n$ we have $\|x - f(x)\| \leq C$. Show that any map $f : \mathbb{R}^n \to \mathbb{R}^n$ of bounded displacement is onto.

*Hint.* Use the Brouwer Fixed Point Theorem.

Exercise 43.15. Let $(X, A)$ be a pair of topological spaces. Suppose there exists a deformation retraction $r : X \times [0, 1] \to X$ from $X$ to some subset $Y = r_1(X)$. We write $B = r_1(A)$. Show that the inclusion induced maps $H_k(Y, B) \to H_k(X, A)$ are isomorphisms.

\[\text{Figure 730. Illustration of Exercise 43.15}\]

Exercise 43.16. Let $X_0 \subset X_1 \subset X_2 \subset \cdots \subset X_m$ be a nested sequence of topological spaces.
Suppose that for each \( k = 0, \ldots, m - 1 \) we have \( H_n(X_{k+1}, X_k) = 0 \) for all \( n \in \mathbb{N}_0 \).

(a) Let \( n \in \mathbb{N}_0 \). Suppose that for each \( k = 0, \ldots, m - 1 \) we have \( H_n(X_{k+1}, X_k) = 0 \). Does it also follow that \( H_n(x, x_0) = 0 \)?

Exercise 43.17. We consider \( X = [0, 1] \) and \( A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\} \). Prove the following two statements:

(a) The group \( H_1(X, A) \) is countable.
(b) The group \( H_1(X/A) \) is uncountable. For psychological reasons it might be convenient to recall that in Exercise 25.11 we showed that the quotient space \( X/A \) is homeomorphic to the Hawaiian earrings.

Remark. The homology groups of the Hawaiian earrings are computed in [EKa00]. In particular it is shown that the higher homology groups \( H_i(X/A) \) are zero for \( i \geq 2 \), which is not clear at all, see e.g. [BaM62].

Exercise 43.18. Give an example of a topological space \( X \) and some non-empty subset \( A \) for which there is no exact sequence of the form

\[
\cdots \to \tilde{H}_{n+1}(X/A) \to \tilde{H}_n(A) \to \tilde{H}_n(X) \xrightarrow{i^*} \tilde{H}_n(X/A) \to \cdots
\]

where \( i: A \to X \) is the inclusion and \( p: X \to X/A \) is the projection.

Remark. You might want to consult your calculations from Exercise 43.17.

Exercise 43.19. Let \( X \) be a non-empty bounded subset of \( \mathbb{R}^n \). We pick an \( r \in \mathbb{R}_{>0} \) such that \( X \) is contained in the bounded \( n \)-ball \( B_r \) of radius \( r \). We consider the map

\[
f: S^{n-1} \to \mathbb{R}^n \setminus X
\]

\[
x \mapsto 2r \cdot x.
\]

Show that the induced map \( f_*: H_{n-1}(S^{n-1}) \to H_{n-1}(\mathbb{R}^n \setminus X) \) is a monomorphism.

Figure 731. Illustration of Exercise 43.19.

Exercise 43.20. Show that for \( k \geq 1 \) the wedge \( S^k \vee S^k \) is not a topological manifold.

Exercise 43.21. Compute the homology groups of the quotient of \( S^2 \) obtained by identifying the North Pole \( N \) and the South Pole \( S \) to a point. We refer to Figure 732 for an illustration.

Exercise 43.22. Let \( T = S^1 \times S^1 \) be the torus. We consider the subset \( A := S^1 \times \{1\} \).

(a) Show that \( T/A \) is homeomorphic to the topological space \( S^2/(S \cup N) \) considered in Exercise 43.21.
(b) Compute the homology groups of the torus.
identify North and South Pole and we obtain

\textbf{Figure 7.32}

(c) Bonus question: How far can you push the above approach if we start out with the Klein bottle instead of the torus?

\textit{Remark.} We will soon see a more conceptual, less ad hoc, approach to calculating the homology groups of the torus.
44. APPLICATIONS AND VARIATIONS OF THE EXCISION THEOREM

As the title of this chapter suggests, in this chapter we will consider some applications of the Excision Theorem 43.19 and we will state and prove several variations thereof.

In particular we will prove several statements on the topology of topological manifolds which extend the results obtain in Section 6.7 from the setting of smooth manifolds to the more general context of topological manifolds. We will also use the opportunity to state a few other results on topological manifolds. At the end of the chapter we will introduce the double of a manifold. This construction makes sense, and is of interest, for smooth and for topological manifolds.

The chapter does not contain any real surprises. The overall message is that the statement of the Excision Theorem 43.19 holds in several convenient alternative settings and that many of the statements which we know and love about the topology of smooth manifolds also hold for topological manifolds. These variations and generalizations of earlier results are non-trivial, but most readers will have a hard time building up enthusiasm for these results. Thus it might be best to have a quick glimpse at the results and then move on to the next section.

44.1. THE LOCAL HOMOLOGY GROUPS OF A TOPOLOGICAL SPACE. We start out with the following definition which at first glance might look somewhat artificial.

**Definition.** Given a topological space \( X \) and a point \( x_0 \in X \) the relative homology group \( H_n(X, X \setminus \{x_0\}) \) is called the \( n \)-th local homology group of \( X \) at the point \( x_0 \).

The main goal of this section is to calculate the local homology groups of topological manifolds and to draw several consequences from this calculation. At this point it is helpful to recall the definition on page 261 of charts of type (i) and (ii) of a topological manifold. For the reader’s convenience we illustrate the definitions in Figure 733. We also recall that on page 262 we said that a point \( x \) on a topological manifold is a boundary point if \( x \) does not admit a chart of type (i).

![Figure 733](image)

The following lemma calculates the local homology groups of topological manifolds.

**Lemma 44.1.** Let \( M \) be a \( k \)-dimensional topological manifold.

1. Every point on \( X \) admits either a chart of type (i) or it admits a chart of type (ii).
2. Given any point \( P \in M \), any \( l \in \mathbb{N}_0 \) and any neighborhood \( U \) of \( P \) we have

\[
H_l(U, U \setminus \{P\}) \xrightarrow{\sim} H_l(M, M \setminus \{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and if } l = k, \\ 0, & \text{otherwise.} \end{cases}
\]

*induced by the inclusion \((U, U \setminus \{P\}) \to (M, M \setminus \{P\})*)
Proof. Let \( P \) be a point on a \( k \)-dimensional topological manifold \( M \). We start out with the following claim.

**Claim.** We have the following isomorphisms:

\[
H_l(U, U \setminus \{P\}) \xrightarrow{\cong} H_l(M, M \setminus \{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \text{ admits a chart of type (i) and if } l = k, \\ 0, & \text{if } P \text{ admits a chart of type (ii) or if } l \neq k. \end{cases}
\]

First we consider the case that \( P \) admits a chart of type (i). It follows easily from the definition of an open subset of \( \mathbb{R}^k \) that we can pick a chart \( \Phi: U \to B^k \) for \( P \) with \( \Phi(P) = 0 \). We then have the following isomorphisms:

\[
\text{isomorphism since } \Phi \text{ is a homeomorphism} \quad \xrightarrow{\Phi^*} \quad \text{isomorphism by the long exact sequence} \quad \text{isomorphism since } S^{k-1} \text{ is homotopy equivalent to } B^k \setminus \{0\}
\]

The desired statement now follows from the calculation of the reduced homology groups of spheres given in Proposition 43.4.

Now we consider the case that \( P \) admits a chart of type (ii). Similar to the above we can pick a chart \( \Phi: U \to B^k_{\geq 0} := B^k \cap H_k \) for \( P \) with \( \Phi(P) = 0 \). By arguments that are very similar to the ones used above we see that we have the following isomorphisms:

\[
\text{isomorphism by the Excision Theorem } 43.20 \quad \xrightarrow{\Phi^*} \quad \text{sequence in reduced homology} \quad \text{one can easily show that } B^k_{\geq 0} \text{ is contractible, hence its reduced homology vanishes by Lemma 43.1} \quad \Box
\]

The topology of topological manifolds. With the results from Chapter 43 we can now generalize Proposition 6.27 from the case of smooth manifolds to the more general setting of topological manifolds.

**Proposition 44.2.** Let \( X \) be an \( n \)-dimensional topological manifold. The following statements hold:

1. Every point on \( X \) admits either a chart of type (i) or it admits a chart of type (ii).
2. If \( F \) is equipped with a smooth atlas, i.e. if we view \( F \) as a smooth manifold, then the boundary of \( F \) as a topological manifold agrees with the boundary of \( F \) viewed as a topological manifold.
The boundary $\partial X$ is an $(n-1)$-dimensional topological manifold with empty boundary, i.e. we have $\partial(\partial X) = \emptyset$.

(4) (a) Any union of components of $\partial X$ is a closed subset of $X$. In particular $\partial X$ itself is a closed subset of $X$.

(b) If $X$ is compact, then $\partial X$ is also compact.

(5) If $\partial X$ is non-empty, then $X \setminus \partial X$ is non-compact.

(6) If $N \subset X$ is a proper $k$-dimensional submanifold, then we have $N \cap \partial X = \partial N$ and $N \cap \partial X = \partial N$ is a proper $(k-1)$-dimensional submanifold of $\partial X$.

(7) Let $M$ be an $m$-dimensional topological manifold with possibly non-empty boundary and let $N$ be an $n$-dimensional topological manifold with empty boundary. Then $M \times N$ is an $(m+n)$-dimensional topological manifold with $\partial(M \times N) = \partial M \times N$.

Example. It follows from Proposition 44.2 and the examples of charts for $B^n$ given on page 264 that the boundary of the $n$-dimensional topological manifold is indeed $S^{n-1}$. We had suspected this for a long time, but only recently did we acquire the tools for providing a proof.

Remark.

(1) For 2-dimensional topological manifolds we had proved some of the statements of Proposition 44.2 in Proposition 18.18.

(2) In Proposition 80.9 we will generalize Proposition 44.2 to the setting that both $M$ and $N$ have non-empty boundary.

(3) Let $M$ and $N$ be two connected $n$-dimensional topological manifolds with empty boundary. If $M \times [0, 1]$ is homeomorphic to $N \times [0, 1]$, then evidently the corresponding boundaries are also homeomorphic. It follows from Proposition 44.2 (7) that $\partial(M \times [0, 1]) = M \times \{0, 1\}$ and $\partial(N \times [0, 1]) = N \times \{0, 1\}$. Since $M$ and $N$ are connected we obtain easily from the above that $M$ and $N$ are homeomorphic. Even though this sounds quite reasonable, very similar sounding statements can easily be wrong. For example there exists a 3-dimensional topological manifold $W$ (called the Whitehead manifold) which is non-compact and has no boundary, which is not homeomorphic to $\mathbb{R}^3$ but such that $W \times \mathbb{R}$ is homeomorphic to $\mathbb{R}^3 \times \mathbb{R} = \mathbb{R}^4$. We refer to [Kir89, p. 87] and [AnR65] for details.

Proof. Let $X$ be an $n$-dimensional topological manifold.

(1) This statement is precisely the statement of Lemma 44.1 (1). The only reason why we wrote down the statement again is to preserve the analogy with Proposition 6.27.

(2) Verbatim the same argument as in the 2-dimensional setting, see the proof of Proposition 18.18 (2) on page 556, shows how to deduce this statement from Statement (1).

(3) First note that it follows from Lemma 2.12 and from Lemma 6.1 (2) that $\partial X$ is Hausdorff and second-countable. Now it remains to show that $\partial X$ admits an $(n-1)$-dimensional atlas. Let $P \in \partial X$. By definition of $\partial X$ there exists a chart $\Phi: U \to V$ of type (ii) for $X$ with $P \in U$. Note that $\Phi$ is a chart of type (ii) precisely for the
points in $\Phi^{-1}(\partial H_n)$. Also note that it follows from (1) and the definition of $\partial X$ that $\Phi^{-1}(\partial H_n) = \partial X \cap U$. In other words, under the obvious identification $\partial H_n = \mathbb{R}^{n-1}$ we see that $\Phi$ restricts to an $(n - 1)$-dimensional chart of type (i) for the topological space $\partial X$. This shows that $\partial X$ is an $(n - 1)$-dimensional topological manifold with empty boundary.

(4) This statement is precisely the content of Lemma 6.7.
(5) The proof of this statement is verbatim the same as the proof of the corresponding statement for smooth manifolds, see Proposition 6.27 (4).
(6) This statement follows reasonably easily from (1) and the various definitions. We leave it to the reader to fill in the details.
(7) In Proposition 6.5 we already showed that $M \times N$ is an $(m + n)$-dimensional topological manifold. As in the proof of Proposition 6.5 we obtain from (1) that $\partial(M \times N) = \partial M \times N$. □

Let $X$ be a topological manifold and let $Y$ be a submanifold. It follows almost immediately from the definitions that $Y$ is a topological manifold in its own right. In particular it makes sense to consider its boundary $\partial Y$ and in particular it makes sense to introduce the following definition which can be viewed as a generalization of the definition on page 283.

**Definition.** Let $X$ be a topological manifold and let $Y$ be a submanifold. We write

$$\partial_0 Y := \partial Y \setminus \partial X \quad \text{and} \quad \partial_1 Y := \partial Y \cap \partial X.$$ 

here $\partial Y$ denotes the boundary of $Y$ viewed as a topological manifold.

The definition is illustrated in Figure 734.

![Figure 734](diagram.png)

The next proposition gives us some results on the boundary of submanifolds. It can be viewed as a generalization of Lemma 6.28 and as an analogue of Proposition 6.30.

**Proposition 44.3.** Let $X$ be an $m$-dimensional topological manifold and let $Y$ be an $n$-dimensional submanifold. We assume that $Y$ is a closed subset of $X$. (In most applications $Y$ will be compact).

1. $\partial_0 Y$ and $\partial_1 Y$ are disjoint and each of them is a union of components of $\partial Y$.
2. If $Y$ is a proper submanifold, then $\partial Y = \partial_1 Y = Y \cap \partial X$.
3. If $Y$ is of codimension zero, then the interior $\tilde{Y}$ of $Y$ as a subset of $X$ agrees with $Y \setminus \partial_0 Y$. In particular $Y \setminus \partial_0 Y$ is an open subset of $X$. 

(4) Suppose that $Y$ is of codimension zero and that $Y$ is compact.

(a) The set $Z := X \setminus \hat{Y}$ is also an $n$-dimensional submanifold of $X$ and we have $Y \cap Z = \partial_0 Y = \partial_0 Z$.
(b) If $X$ and $\partial Y$ are connected, then $Z = X \setminus \hat{Y}$ is also connected.
(c) If $X$ is compact, then $Z = X \setminus \hat{Y}$ is also compact.

Proof. The proposition follows easily from making the obvious modifications to the proofs of Lemma 6.28 and Proposition 6.30. The biggest change is that we need to replace Proposition 6.27 by Proposition 44.4. We leave it to the reader to fill in the details.

We conclude this section with the following proposition which is the generalization of Proposition 6.26 from smooth manifolds to topological manifolds.

Proposition 44.4. Let $M$ be an $m$-dimensional non-empty topological manifold and let $N$ be an $n$-dimensional topological manifold. If $M$ is homeomorphic to an open subset of $N$ (e.g. if $M$ is homeomorphic to $N$), then $m = n$.

It follows in particular from Proposition 44.4 that the dimension of a non-empty topological manifold is well-defined.

Proof. By the remark on page 272 it suffices to consider the case that we are given a homeomorphism $f: M \rightarrow N$ between a non-empty $m$-dimensional topological manifold $M$ and a topological manifold $N$. By Proposition 44.2 (5) we know that $M \setminus \partial M$ is non-empty. In particular we can find a point $P \in M \setminus \partial M$. Then

$$Z \cong H_m(M, M \setminus \{P\}) \xrightarrow{\cong} H_m(N, N \setminus \{f(P)\})$$

Lemma 44.1 since $f$ is a homeomorphism.

It now follows from Lemma 44.1 that $N$ is also $m$-dimensional.

44.3. The Topological Collar Neighborhood Theorem. In the next section we will consider some useful variations on the Excision Theorem 43.19 for topological manifolds. To prove these results we will make use of the following following theorem which is an analogue of the Collar Neighborhood Theorem 8.12 for topological manifolds.

Theorem 44.5. (Topological Collar Neighborhood Theorem) Given any topological manifold $M$ there exists a map $\Phi: [0, 1] \times \partial M \rightarrow M$ with the following four properties:

1. The map $\Phi$ is an embedding.
2. The image of $[0, 1] \times \partial M$ is an open subset of $M$.
3. For every $P \in \partial M$ we have $\Phi(0, P) = P$.
4. The image of $[0, 1] \times \partial M$ is a closed subset of $M$.

Remark.

1. In the compact case the Topological Collar Neighborhood Theorem 44.5 is also proved in [Vic94, Theorem Appendix II.7] and [Hat02, p. 253]. The general case, where $M$ is also allowed to be non-compact, is also proved in [BrownM62, Theorem 3] and [Arm70, Theorem 1]. Note that [Arm70, Theorem 1] has a few refinements which could be useful in some applications.
(2) In Exercise 89.1 we will prove a variation on the Topological Collar Neighborhood Theorem 44.5 for the case that $M$ is a codimension-zero submanifold with corner of some other topological manifold.

Proof of Theorem 44.5 For compact $M$. We consider $M$ with an “external collar” attached, i.e. we consider $W := M \cup_{\partial M = \{0\} \times \partial M} ([0, 1] \times \partial M)$. Let us assume for a second that we have found a homeomorphism $F: M \to W$ with $F(\partial M) = \{1\} \times \partial M$. In this fortunate setting one can verify easily, say using Lemma 3.43, that the map

$$
\Phi: [0, 1] \times \partial M \to M \\
(t, x) \mapsto F^{-1}([(1 - t, x)])
$$

has all the desired properties. Thus it remains to show that such an $F$ actually exists.

We start out our search for such $F$ with the following claim.

Claim. There exist compact subsets $K_1, \ldots, K_m \subset \partial M$, embeddings $\Phi_i: K_i \times [-1, 0] \to M$ and maps $f_i: \partial M \to [0, 1]$ such that the following are satisfied:

1. For each $i \in \{1, \ldots, m\}$ we have $\Phi_i^{-1}(\partial M) = K_i \times \{0\}$.
2. For each $i \in \{1, \ldots, m\}$ we have $\text{supp}(f_i) \subset K_i$.
3. We have $f_1 + \cdots + f_m = 1$ on all of $\partial M$.

It follows from the definition of $\partial M$, together with Proposition 44.2 (1), that for each $x \in \partial M$ there exists an open neighborhood $U_x$ of $x$ and an embedding $\Phi_x: [-1, 0] \times U_x \to M$ with $\Phi_x^{-1}(\partial M) = \{0\} \times U_x$. For each $x$ we can and will pick a compact neighborhood $K_x$ with $K_x \subset U_x$. Since $M$ is compact we know by Proposition 44.2 (4b) that $\partial M$ is also compact. Evidently the interiors of the $K_x$ cover all of $\partial M$. Since $\partial M$ is compact we see that there exist $x_1, \ldots, x_m \in \partial M$ such that $\partial M$ is covered by the interiors of the $K_{x_i}$. Finally note that it follows from Proposition 2.81 together with Lemma 2.78 that there exist maps $f_1, \ldots, f_m: \partial M \to [0, 1]$ such that for each $i \in \{1, \ldots, m\}$ we have $\text{supp}(f_i) \subset K_{x_i}$ and such that $f_1 + \cdots + f_m = 1$. Renaming $K_{x_i}$ and $\Phi_{x_i}$ as $K_i$ and $\Phi_i$ we obtain the desired result.

Next, for $i = 0, \ldots, m$ we set $g_i := f_1 + \cdots + f_i$ and we set

$$
W_i := M \cup_{\partial M = \{0\} \times \partial M} \{(t, x) \mid x \in \partial M \text{ and } t \in [0, g_i(x)]\}.
$$

By Lemma 3.43 (2d) we know that $W_0$ is homeomorphic to $M$ and evidently $W_m = W$.

Claim. For $i = 1, \ldots, m$ there exists a homeomorphism $F_i: W_{i-1} \to W_i$.\[
\text{Figure 735. First illustration for the proof of Theorem 44.5.}\]
Let $i \in \{1, \ldots, m\}$. We consider the map

$$\Theta: [-1, 1] \times K_i \rightarrow W$$

$$(t, x) \mapsto \begin{cases} \Phi_i((t, x)], & \text{if } t \in [-1, 0], \\ (t, x], & \text{if } t \in [0, 1]. \end{cases}$$

It follows fairly easily from Lemma 3.43, Lemma 3.45 and Proposition 2.43 (2) that this map is a closed embedding. To simplify the notation we identify $[-1, 1] \times K_i$ with its image in $W$. The desired homeomorphism $W_{i-1} \rightarrow W_i$ is now given by “stretching horizontally” along $[-1, 1] \times K_i$. More precisely, we consider the map

$$F_i: W_{i-1} \rightarrow W_i$$

$$x \mapsto \begin{cases} x, & \text{if } x \not\in [-1, 1] \times K_i \\ x + \frac{1+y_i(y)}{1+y_{i-1}(y)}(t+1, y), & \text{if } x = (t, y) \in [-1, 1] \times K_i. \end{cases}$$

It follows easily from the fact that $\text{supp}(f_i) \subset K_i$, Lemma 3.8 (2b) and Lemma 2.35 that this map is continuous and it follows from Proposition 2.43 (2) that this map is in fact a homeomorphism.

It is now clear that $F := F_m \circ \cdots \circ F_1: M \rightarrow W$ is a homeomorphism which has the feature that $F(\partial M) = \{1\} \times \partial M$. 

**Figure 736. Second illustration for the proof of Theorem 44.5.**

**Proof of the Topological Collar Neighborhood Theorem 44.5.** Now let $M$ be any topological manifold. The proof of the Topological Collar Neighborhood Theorem 44.5 in this setting is not that different from the compact case. For space and time reasons we only sketch the argument.

It follows from the fact that $\partial M$ is in particular second-countable together with Theorem 6.57 that there exists an infinite sequence $K_1, K_2, \ldots$ of compact subsets, embeddings $\Phi_i: K_i \times [-1, 0] \rightarrow M$ and maps $f_i: \partial M \rightarrow [0, 1]$ such that beyond the aforementioned Statements (1), (2) and (3) the following extra condition is satisfied:

(4) For each $x \in \partial M$ there exists an open neighborhood $V$ such that there exist only finitely many $i \in \mathbb{N}$ with $\text{supp}(f_i) \cap U \neq \emptyset$.

As in the previous argument we now define functions $g_1, g_2, \ldots$, subsets $W_1, W_2, \ldots$ and homeomorphisms $F_i: W_{i-1} \rightarrow W_i$. It follows from (4) that the map

$$F: M \rightarrow W$$

$$x \mapsto (F_k \circ \cdots \circ F_1)(x) \quad \text{if } f_i(x) = 0 \text{ for } i \geq k$$
is well-defined and continuous. In fact using Proposition 2.45 it is straightforward to see that $F$ is actually a homeomorphism. Furthermore, note that by construction we again have $F(\partial M) = \{1\} \times \partial M$. Thus, as in the proof of the compact case, we are done. ■

The following uniqueness statement for collar neighborhoods is almost verbatim the same as the statement of Proposition 8.13.

**Proposition 44.6.** Let $M$ be a topological manifold and let $f_0, f_1 : [0, 1] \times \partial M \to M$ be two embeddings that are the identity map on $\{0\} \times \partial M = \partial M$. If $\partial M$ is compact, then there exists an isotopy $H : M \times [0, 1] \to M$ rel $\partial M$ from $H_0 = \text{id}_M$ to a homeomorphism $\Phi = H_1 : M \to M$ with $\Phi \circ f_0 = f_1$. In particular $\Phi$ restricts to a homeomorphism $\Phi : f_0([0, 1] \times \partial M) \to f_1([0, 1] \times \partial M)$.

**Proof.** The proof is sketched in [KS69, Essay I, Theorem A.1]. The proof is also given in [Arm70, Theorem 2].

**Convention.** Suppose we are given a topological manifold $M$ with compact boundary $\partial M$. We pick a map $\Phi : [0, 1] \times \partial M \to M$ as in the conclusion of the Topological Collar Neighborhood Theorem 44.5. Usually we identify $[0, 1] \times \partial M$ with the image in $M$ under the map $\Phi$ and we just refer to $[0, 1] \times \partial M$ as a “collar neighborhood of $\partial M$”. Sometimes we also find it convenient to use other intervals in our notation, e.g. we might write “let $[-3, 0] \times \partial M$ be a collar neighborhood”. It is then understood that $\{0\} \times \partial M = \partial M$.

For later we record the following corollary to the Topological Collar Neighborhood Theorem 44.5 which is the complete analogue of Corollary 8.14.

**Corollary 44.7.** Let $M$ be an $n$-dimensional topological manifold. Let $[0, 1] \times \partial M$ be a collar neighborhood.

1. The subset $W := M \setminus ([0, 1] \times \partial M)$ is an $n$-dimensional topological manifold with boundary given by $\{1\} \times \partial M$.
2. The subset $W = M \setminus ([0, 1] \times \partial M)$ is a deformation retract of $M$ and it is a deformation retract of $M \setminus \partial M$.
3. If $M$ is non-empty, then $M$ is homotopy equivalent to a non-compact $n$-dimensional topological manifold without boundary.

**Proof.** The proof of Corollary 44.7 is basically the same as the proof of Corollary 8.14. We just need to replace the Collar Neighborhood Theorem 8.12 by the Topological Collar Neighborhood Theorem 44.5 and we need to replace Proposition 6.27 by Proposition 44.2.

---

718 The proof in [Arm70] makes me slightly nervous, there is no hypothesis that $\partial M$ is compact, and there is no statement that the image of $[0, 1] \times \partial M$ needs to be closed. But that would imply that the “usual” collar neighborhood for $M = \{(x, y) \mid y \geq 0\}$ is equivalent to the one shown in Figure 194 which is certainly not the case.
We conclude this discussion of the Topological Collar Neighborhood Theorem with the following proposition that looks uncannily similar to Proposition 8.15.

**Proposition 44.8.** Let $M$ be an $n$-dimensional topological manifold (we do not assume that $M$ is connected). Let $A$ and $B$ be disjoint unions of boundary components of $M$. Furthermore let $f : A \to B$ be a homeomorphism. Then the following two statements hold:

1. The topological space
   
   $$M/a \sim f(a)$$

   for $a \in A$

   is an $n$-dimensional topological manifold.

2. If $M$ consists of two components $X$ and $Y$ and if $A \subset X$ and $B \subset Y$, then the images of $X$ and $Y$ in $M/a \sim f(a)$ are codimension-zero submanifolds.

3. If $M$ is compact, then $M/a \sim f(a)$ is also compact.

4. The boundary of $M/a \sim f(a)$ is given by $\partial M \setminus (A \cup B)$.

5. If each component of $M$ contains at least one component of $A$ or $B$, then $M/a \sim f(a)$ is connected.

In Chapter 86 we will introduce the notion of an orientation of a topological manifold. To preserve the symmetry with Proposition 8.15, we add the following statement, even though with the present knowledge it does not have any meaning yet.

6. Assume that $M$ is oriented. We equip $A$ and $B$ with the boundary orientations, as defined in Proposition 86.19.

   a. If $f$ is orientation-reversing, then $M/a \sim f(a)$ admits an orientation such that the inclusion $M \setminus (A \cup B) \to M/a \sim f(a)$ is orientation-preserving.

   b. If $M$ is connected and if $f$ is not orientation-reversing, then $M/a \sim f(a)$ is non-orientable.

**Diagram**

**Figure 737.** Illustration of Proposition 44.8.

**Proof.** For the most part the proof of Proposition 44.8 is almost the same as the proof of Proposition 8.15. For statements (1) to (5) we just need to make the following replacements:

1. We need to replace Proposition 6.27 (3a) by Lemma 6.7.

2. We need to replace the Collar Neighborhood Theorem 8.12 by the Topological Collar Neighborhood Theorem 44.5.

3. We need to replace Proposition 6.27 (1) by Proposition 44.2 (1).

The alert reader will notice that in the proof of Proposition 44.8, it is not really necessary to use the Topological Collar Neighborhood Theorem 44.5. For example, as we will see in Exercise 44.6, one can define an atlas for $M/a \sim f(a)$ “by hand.” Nonetheless we leave the proof as it is, since the Topological Collar Neighborhood Theorem 44.5 greatly simplifies the discussion.

Finally we will prove Statement (6) in Exercise 86.4. ■
44.4. Variations on the Excision Theorem 43.19. In this section we will state and prove two variations on the Excision Theorem 43.19. First we have the following rather technical sounding theorem.

**Theorem 44.9.** Let $X$ be a topological space and let $Z \subset A \subset X$ be two subsets. We suppose that there exists a subset $U \subset Z$ such that the closure of $U$ is contained in the interior of $A$ and such that following statements hold:

1. $X \setminus Z$ is a deformation retract of $X \setminus U$.
2. $A \setminus Z$ is a deformation retract of $A \setminus U$.

Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} H_n(X, A).$$

The hypotheses of Theorem 44.9 might sound complicated, but as we will see, in practice these conditions are often satisfied.

**Example.** Let $n \in \mathbb{N}$. As usual we denote by $S^n_{\geq 0}$ and $S^n_{\leq 0}$ the upper and lower hemisphere of $S^n$ and make the obvious identification $S^{n-1} = S^n_{\geq 0} \cap S^n_{\leq 0}$. It follows from Theorem 44.9 and the choices of $X, A, Z$ and $U$ illustrated in Figure 738 that the inclusion induced map

$$H_n(S^n_{\geq 0}, S^{n-1}) \to H_n(S^n_{\leq 0}, S^{n-1})$$

is an isomorphism.

![Figure 738](image)

We can easily generalize the above example. More precisely, Theorem 44.9 also allows us to prove the following variation on the Excision Theorem 43.19. It says, under mild technical hypotheses, that in the relative homology of an $m$-dimensional topological manifold we can excise the interior of a codimension-zero submanifold.

**Theorem 44.10. (Excision Theorem for Topological Manifolds)** Let $X$ be an $m$-dimensional topological manifold and let $A$ be a subset of $X$. Furthermore let $B$ be an $m$-dimensional submanifold of $X$ that is a closed subset of $X$. We write $\hat{B} := B \setminus \partial_0 B$.

If $\hat{B} \subset A$, then for every $n \in \mathbb{N}_0$ the inclusion induced map

$$H_n(X \setminus \hat{B}, A \setminus \hat{B}) \xrightarrow{\cong} H_n(X, A)$$

is an isomorphism.

**Example.** If we take $X = S^n$, $A = S^n_{\geq 0}$ and $B = S^n_{\leq 0}$, then all the hypothesis of the Excision Theorem 44.10 for Topological Manifolds are satisfied and we obtain, as above,
that the inclusion induced map

\[ H_n(S^n, S^{n-1}) \to H_n(S^n, S^{n-1}_0) \]

is an isomorphism.

**Remark.** In Theorem 44.9 we will generalize the statement of the Excision Theorem for Topological Manifolds to the setting that \( B \) is a submanifold “with corner”.

**Proof of Theorem 44.10 Assuming Theorem 44.9.** Note that by Proposition 44.3 we know that \( \partial_0B \) is a union of boundary components of \( B \) and that \( \hat{B} \) is indeed the interior of \( B \) viewed as a subset of \( X \). In particular we can apply the Topological Collar Neighborhood Theorem 44.5 to \( \partial_0B \). We obtain an embedding \( \varphi: [-1,0] \times \partial_0B \to B \) that is the identity map on \( \{0\} \times \partial_0B = \partial_0B \). To simplify the notation we identify \([-1,0] \times \partial_0B \) with its image in \( B \). We set \( Z = \hat{B} = B \setminus (\{0\} \times \partial_0B) \) and we set \( U = B \setminus ((-1,0] \times \partial_0B) \).

**Claim.** There exists a deformation retract from \( X \setminus U \) to \( X \setminus Z \).

First note that we can write \( X \setminus U = (X \setminus Z) \cup ([-1,0] \times \partial_0B) \). Furthermore note that \( (X \setminus Z) \cap ([-1,0] \times \partial_0B) = \{0\} \times \partial_0B \). The idea is to use Lemma 20.11 to conclude that the obvious deformation retraction from \([-1,0] \times \partial_0B \) to \( \{0\} \times \partial_0B \) gives rise to the desired deformation retraction.

We still have to perform the task of verifying the hypotheses of Lemma 20.11 i.e. we need to argue that \( X \setminus Z \) and \([[-1,0] \times \partial_0B \) are closed subsets of \( X \setminus U \). First note that by Proposition 44.3 we know that \( Z = \hat{B} \) is an open subset of \( X \). It follows that \( X \setminus Z \) is a closed subset of \( X \setminus U \). Furthermore by Statement (4) of the Topological Collar Neighborhood Theorem 44.5 we know that \([-1,0] \times \partial_0B \) is a closed subset of \( X \), in particular it is a closed subset of \( X \setminus U \).

**Claim.** There exists a deformation retract from \( A \setminus U \) to \( A \setminus Z \).

Since \( \hat{B} \subset A \) we have \( A \setminus U = (A \setminus Z) \cup ([-1,0] \times \partial_0B) \). Furthermore note that \( (A \setminus Z) \cap ([-1,0] \times \partial_0B) = \{0\} \times \partial_0B \). Thus basically the same argument as in the proof of the previous claim shows that such a deformation retraction exists.

The statement of Excision Theorem 44.10 for Topological Manifolds now follows immediately from Theorem 44.9.

We conclude this section with the proof of Theorem 44.9.
Figure 740. Illustration of the proof of the Excision Theorem 44.10

Proof of Theorem 44.9. We consider the following commutative diagram of inclusion induced maps

\[
\begin{array}{ccc}
\Rightarrow & H_n(X \setminus Z, A \setminus Z) & \Rightarrow H_n(X, A) \\
\downarrow & \downarrow & \Rightarrow \\
H_n(X \setminus U, A \setminus U).
\end{array}
\]

The diagonal map is an isomorphism by the Excision Theorem 43.19. Thus it suffices to show that the vertical map is an isomorphism.

We consider the following diagram:

\[
\begin{array}{cccccc}
H_n(A \setminus Z) & \rightarrow & H_n(X \setminus Z) & \rightarrow & H_n(X \setminus Z, A \setminus Z) & \rightarrow H_{n-1}(A \setminus Z) & \rightarrow H_{n-1}(X \setminus Z) \\
\downarrow & \Downarrow & \downarrow & \Downarrow & \downarrow & \Downarrow & \downarrow \\
H_n(A \setminus Z) & \rightarrow & H_n(X \setminus U) & \rightarrow & H_n(X \setminus U, A \setminus Z) & \rightarrow H_{n-1}(A \setminus Z) & \rightarrow H_{n-1}(X \setminus U) \\
\downarrow & \Downarrow & \downarrow & \Downarrow & \downarrow & \Downarrow & \downarrow \\
H_n(A \setminus U) & \rightarrow & H_n(X \setminus U) & \rightarrow & H_n(X \setminus U, A \setminus U) & \rightarrow H_{n-1}(A \setminus U) & \rightarrow H_{n-1}(X \setminus U).
\end{array}
\]

Here the horizontal maps are pieces of the long exact sequences of the various pairs of topological spaces provided by Corollary 43.16 (1). Note that by Corollary 43.16 (2) we know that the diagram commutes.

Furthermore the vertical maps are induced by the various inclusion maps. On the upper level the first and the fourth vertical maps are the identity. Furthermore it follows from the hypothesis that \(X \setminus Z\) is a deformation retract of \(X \setminus U\) and from Corollary 43.18 that the second and the fifth vertical map are also isomorphisms. It follows from the Five Lemma 43.12 that the upper middle vertical map is also an isomorphism.

Using the hypothesis that \(A \setminus Z\) is a deformation retract of \(A \setminus U\) one can show exactly the same way that the lower middle vertical map is also an isomorphism. Combining the two middle vertical maps we obtain the desired isomorphism.

44.5. The double of topological and smooth manifolds. In this short section we introduce the double of a topological manifold. This construction associates to a compact manifold with non-empty boundary a closed manifold. This procedure comes in handy on several occasions. In particular sometimes this procedure allows us to reduce the proof of a certain statement for compact manifolds to the closed case. As the reader will notice, this section has only a moderately convincing justification for fitting into this particular
chapter, but the material has to go somewhere, and some of the more technical statements in this section make use of the earlier results of this section.

After this apology, let us give the key definition of this section.

**Definition.** Let \( M \) be a topological manifold and let \( W \) be the union of some components of \( \partial M \). We refer to

\[
D_W M := (M \times \{1\}) \cup_{W \times \{1\}=W \times \{2\}} (M \times \{2\})
\]

as the *double of \( M \) along \( W \).* We refer to \( D \) \( := D_{\partial M} M \) as the *double of \( M \).*

**Example.** The double of \( M \) is given by taking two copies of \( M \) and identifying the boundary points “left and right” in the obvious way.

1. On page 116 we gave an explicit homeomorphism \( B^n \cong S^n_{\geq 0} \). Using this homeomorphism it is straightforward to see that the double of the \( n \)-ball \( B^n \) is homeomorphic to the \( n \)-dimensional sphere \( S^n \). We refer to Figure 741 for an illustration.

<table>
<thead>
<tr>
<th>Disk ( B^2 )</th>
<th>Homeomorphic to</th>
<th>Lower hemisphere ( S^2_{\geq 0} )</th>
<th>Doubling gives</th>
<th>Double is homeomorphic to ( S^2 )</th>
</tr>
</thead>
</table>

**Figure 741**

2. Figure 742 makes a convincing case that the double of the torus minus two open disks is homeomorphic to the surface of genus 3. We refer to Figure 742 for an illustration.

3. In Exercise 44.4 we will see that the double of the Möbius band and the Klein bottle minus an open disk are homeomorphic to well-known topological spaces.

The following definition allows us to relate a topological manifold to its double.

**Definition.** Let \( M \) be a topological manifold and let \( W \) be the union of some components of \( \partial M \). We refer to the map

\[
i: M \xrightarrow{P \to (P,1)} M \times \{1\} \to (M \times \{1\}) \cup (M \times \{2\}) \to D_W M
\]
as the *natural inclusion*. Furthermore we refer to the map

$$r: D_W M = ((M \times \{1\}) \cup (M \times \{2\}))/ \sim \rightarrow M \\
(P, i) \mapsto (P, 3 - i)$$

as the *folding map*. Finally we refer to the map

$$\rho: D_W M \rightarrow D_W M \\
(P, i) \mapsto (P, 3 - i)$$

as the *natural involution* on $D_W M$.

**Lemma 44.11.** Let $M$ be a topological manifold and let $W$ be the union of some components of $\partial M$.

1. The natural inclusion $i: M \rightarrow D_W M$ is an embedding.
2. The folding map $D_W M \rightarrow M$ is continuous and it satisfies $r \circ i = \text{id}_M$.
3. The natural involution $D_W M \rightarrow D_W M$ is continuous and it is an involution, i.e. $\rho \circ \rho = \text{id}$.

**Proof.** It follows from Lemmas \[3.3\] and \[3.21\] (3) that the natural inclusion $i$ is continuous and that the involution $\rho$ are continuous. It is clear that $\rho \circ \rho = \text{id}$. Furthermore it follows from Lemmas \[3.3\] and \[3.22\] that the folding map $r$ is continuous. Clearly we have $r \circ i = \text{id}_M$, which shows in particular that $i: M \rightarrow i(M)$ is a homeomorphism, i.e. $i$ is an embedding.

Finally it follows from Lemma \[3.3\], \[3.21\] (3) and \[3.22\] that the involution $\rho$ is continuous. It is clear that $\rho \circ \rho = \text{id}$. \[\Box\]

**Convention.** Sometimes we will use the fact, established in Lemma \[44.11\], that the natural inclusion $M \rightarrow D_W M$ is an embedding as an excuse to view $M$ as a subspace of $D_W M$ and to view $r: D_W M \rightarrow M$ as a retraction.

The following lemma summarizes a few key properties of the doubling operation.

**Lemma 44.12.** Let $M$ be an $n$-dimensional topological (smooth) manifold and let $W$ be the union of some components of $\partial M$. The following statements hold:

1. The double $D_W M$ is also an $n$-dimensional topological (smooth) manifold such that $M \subset D_W M$ is a (smooth) submanifold and such that $M$ is a closed subset of $D_W M$.
2. The boundary of the double $D_W M$ is given by two copies of $\partial M \setminus W$. In particular the boundary of the double $D_M$ is empty.
3. $M$ is compact if and only if the double $D_W M$ is compact.
4. If $M$ is connected and if $W \neq \emptyset$, then the double $D_W M$ is also connected.
If $M$ is an oriented smooth manifold, then $D_WM$ admits an orientation such that $M \to D_WM$ is an orientation-preserving embedding. Conversely, if $D_WM$ is oriented, then $M$ admits an orientation such that the inclusion $M \to D_WM$ is orientation-preserving.\footnote{In Lemma \ref{lem:oriented}, we will prove an analogous statement for topological manifolds.}

For every $k \in \mathbb{N}_0$ the inclusion induced map $H_k(M, W) \to H_k(D_WM, M)$ is an isomorphism.

Proof (⋆). Let $M$ be an $n$-dimensional topological (smooth) manifold. Statements (1), (2) and (4) follow immediately from applying Proposition \ref{prop:prop} and Proposition \ref{prop:prop} iteratively to $(W \times \{1\}) \sqcup (W \times \{2\}) \subseteq (M \times \{1\}) \sqcup (M \times \{2\})$.

We turn to the proof of Statement (3). Note that it follows easily from Lemmas \ref{lem:lemma} and \ref{lem:lemma} that $M$ is compact if and only if the double $D_WM$ is compact.

Next we provide the proof of Statement (5). Thus we suppose that $M$ is an oriented smooth manifold. We equip $M \times \{1\}$ with the obvious orientation. Furthermore we equip $M \times \{2\}$ with the opposite orientation. With these orientations it is straightforward to see that the map $\partial(M \times \{1\}) \supseteq (P_1) \to (P_2) \supseteq \partial(M \times \{2\})$ is orientation-reversing. Thus it follows from Proposition \ref{prop:prop} that the double $D_WM$ admits an orientation such that $M \to D_WM$ is an orientation-preserving embedding. Conversely, if $D_WM$ is oriented, then it follows from Lemma \ref{lem:lemma} that $M$ inherits an orientation such that the inclusion $M \to D_WM$ is orientation-preserving.

Finally note that Statement (6) is an immediate consequence of the Excision Theorem \ref{thm:excision} for Topological Manifolds, and the fact, established in (1), that $M$ is a closed subset of $D_WM$.\[\Box\]

The following lemma relates some of the algebraic invariants of a manifold $M$ to the invariants of its double $D_WM$.

**Lemma 44.13.** Let $M$ be a topological manifold and let $W$ be the union of some components of $\partial M$.

(1) For every $j \in \mathbb{N}_0$ the inclusion induced map $H_j(M) \to H_j(D_WM)$ is a monomorphism.

(2) If $\partial M$ is non-empty and if $x_0$ is a point in $\partial M$, then for every $j \in \mathbb{N}_0$ the inclusion induced map $\pi_j(M, x_0) \to \pi_j(D_WM, x_0)$ is a monomorphism.

**Remark.** In Proposition \ref{prop:prop} we will calculate the homology groups of $D_WM$ in terms of the homotopy groups of $M$.\[\Box\]

Proof. Let $i: M \to D_WM$ be the natural inclusion map and let $r: D_WM \to M$ be the folding map. In Lemma \ref{lem:lemma} we saw that both maps are continuous and that $r \circ i = \text{id}_M$. The two statements now follow as usual from the functoriality of homology groups and homotopy groups. More precisely, in both cases we have $r_* \circ i_* = \text{id}_*$, i.e. $i_*$ needs to be a monomorphism.\[\Box\]
In favorable circumstances we can fully control the fundamental group of the double.

**Proposition 44.14.** Let \( M \) be a compact connected \( n \)-dimensional topological manifold, let \( W \) be a component of \( \partial M \) and let \( P \in W \). If the inclusion induced map \( \pi_1(W, P) \to \pi_1(M, P) \) is an epimorphism, then the inclusion induced map \( \pi_1(M, P) \to \pi_1(D_W M, P) \) is an isomorphism.

The proof of Proposition 44.14 results on the following group-theoretic lemma, which is precisely the content of Exercise 21.11.

**Lemma 44.15.** Let \( A \) and \( G \) be groups and let \( \varphi: A \to G \) be an epimorphism. Furthermore let \( G' \) be a copy of \( G \). We consider the amalgamated product \( G *_A G' \) given by using twice the epimorphism \( \varphi: A \to G \) and \( \varphi: A \to G' \). In this setting the natural homomorphism \( G \to G *_A G' \) is an isomorphism.

**Proof of Lemma 44.15.** By Proposition 21.21 there exists a unique homomorphism \( \Theta: G *_A G' \to G' \) that makes the following diagram commutes:

\[
\begin{array}{ccc}
A & \to & G \\
\downarrow & & \downarrow \\
G' & \to & G *_A G'
\end{array}
\]

In particular we see that the right vertical map is a monomorphism. The left vertical map is by hypothesis an epimorphism. It follows from Lemma 21.22 (3) that the right vertical map is also an epimorphism. Thus we shown that the right vertical map is indeed an isomorphism. \( \blacksquare \)

**Proof of Proposition 44.14.** Let \( P \in W \). Since \( W \) is non-empty and connected we obtain from the Seifert-van Kampen Theorem 22.2 that the inclusions of the two copies of \( M \) into the double \( D_W M \) induce an isomorphism \( \pi_1(D_M, P) \cong \pi_1(M, P) * \pi_1(W, P) * \pi_1(M, P) \). By our hypothesis the map \( \pi_1(W, P) \to \pi_1(M, P) \) is an epimorphism. It follows from the above, together with Lemma 44.15 that the map \( \pi_1(M, P) \to \pi_1(D_W M, P) \) is indeed an epimorphism. \( \blacksquare \)

We conclude this introduction to the double of a topological manifold with the following harmless but at times useful lemma. The lemma follows almost immediately from the definitions, hence we leave it to the conscientious reader to fill in the details.

**Lemma 44.16.** (*) Let \( M \) be a topological manifold and let \( W \) be the union of some components of \( \partial M \). Given \( i \in \{1, 2\} \), we denote by \( j_i: M \to M \times \{i\} \to D_W M \) the obvious map.

1. For every \( k \in \mathbb{N}_0 \) the map

\[
D: C_k(M, W) \to C_k(D_W M) \quad \sigma \mapsto j_1^*(\sigma) - j_2^*(\sigma)
\]
is well-defined.

(2) The maps from (1) define a natural chain map, in particular for every $k \in \mathbb{N}_0$ these maps induce a map

$$D: H_k(M, W) \to H_k(D_W M)$$

which is called the doubling homomorphism.

(3) We make the identification $M = j_1(M \times \{1\})$ and we write $M' = j_2(M \times \{2\})$. The doubling homomorphism has the property that the following diagram commutes

$$\begin{array}{ccc}
H_k(M, W) & \rightarrow & H_k(D_W M) \\
\downarrow & & \downarrow \\
H_k(D_W M, M') & \leftarrow & H_k(D_W M, M')
\end{array}$$

where the diagonal maps are the obvious maps. (As an aside we mention that it follows from the Excision Theorem 44.10 that the left diagonal map is an isomorphism.)

![Figure 744. Illustration of Lemma 44.16 (1).](image)

**Exercises for Chapter 44**

**Exercise 44.1.** Let $M$ be a topological manifold. Furthermore let $x_1, \ldots, x_k$ be distinct points in $M$. Let $n \in \mathbb{N}_0$. For $i \in \{1, \ldots, k\}$ we denote by

$$\nu_i: H_n(M, M \setminus \{x_1, \ldots, x_k\}) \to H_n(M, M \setminus \{x_i\})$$

the map that is induced by the inclusion $M \setminus \{x_1, \ldots, x_k\} \to M \setminus \{x_i\}$. Show that the map

$$\bigoplus_{i=1}^k \nu_i: H_n(M, M \setminus \{x_1, \ldots, x_k\}) \to \bigoplus_{i=1}^k H_n(M, M \setminus \{x_i\})$$

is an isomorphism.

*Hint.* Use Excision Theorem 43.20

**Exercise 44.2.** Let $X$ be a finite topological graph, in other words, let $X$ be a finite 1-dimensional CW-complex. Given any point $x \in X$ compute the local homology groups $H_*(X, X \setminus \{x\})$.

**Exercise 44.3.** Let $n_1, \ldots, n_k \in \mathbb{N}$. We form the wedge $X := S^{n_1} \vee \cdots \vee S^{n_k}$. We denote by $P$ the wedge point. Compute the local homology groups $H_*(X, X \setminus \{P\})$.

**Exercise 44.4.** Let $M$ be a connected topological manifold. Show that $M \setminus \partial M$ is still connected.
Exercise 44.5. Let $X$ be a topological space and let $n \in \mathbb{N}_0$. We consider the following two maps.

(1) Let $p : X \times S^1 \to X$ be the projection.
(2) Secondly we consider the homomorphism $\psi : H_n(X \times S^1) \to H_{n-1}(X)$ that is given by

$$
H_n(X \times S^1) \to H_n(X \times S^1, X \times S^1_{\leq 0}) \xleftarrow{\cong} H_n(X \times S^1_{\geq 0}, X \times \pm 1) \xrightarrow{\cong} H_n\left(\overset{\Rightarrow}{X} \times \{ \pm 1 \}\right) \cong H_{n-1}(X).
$$

isomorphism by the Excision Theorem

connecting homomorphism projection induced homomorphism

Show that the map

$$
p_* \oplus \psi : H_n(X \times S^1) \to H_n(X) \oplus H_{n-1}(X)
$$

is an isomorphism.

Hint. Consider the long exact sequence of the pair $(X \times S^1, X \times S^1_{\leq 0})$.

Remark. In Lemma 46.22 we will give a different approach to calculating $H_n(X \times S^1)$.

Exercise 44.6. Let $M$ be an $n$-dimensional topological manifold and let $A$ and $B$ be disjoint unions of boundary components of $M$. Furthermore let $f : A \to B$ be a homeomorphism. Show, without using the Topological Collar Neighborhood Theorem 44.5 that the topological space

$$
M/a \sim f(a) \quad \text{for } a \in A
$$

is an $n$-dimensional topological manifold.

Exercise 44.7. We recall the following definitions:

(1) The suspension of a topological space $X$ is defined to be the topological space

$$
\Sigma(X) := (X \times [-1, 1]) / \sim
$$

where we identify all points in $X \times \{-1\}$ and we identify all points in $X \times \{1\}$.

(2) A topological space $X$ that has the property that for each $x \in X$ we have

$$
H_k(X, X \setminus \{x\}; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = n, \\
0, & \text{otherwise}
\end{cases}
$$

is called an $n$-dimensional homology manifold.

(3) We say that an $n$-dimensional topological manifold $X$ is a topological homology $n$-sphere if for every $k \in \mathbb{N}_0$ we have $H_k(X; \mathbb{Z}) \cong H_k(S^n; \mathbb{Z})$.

Let $Y$ be a homology $n$-sphere.

(a) Show that $Y \times \mathbb{R}$ is an $(n+1)$-dimensional homology manifold.
(b) Show that the suspension $\Sigma(Y)$ of $Y$ is an $(n+1)$-dimensional homology manifold.
(c) Show that if $\pi_1(Y)$ is non-trivial, then the suspension $\Sigma(Y)$ is not a topological manifold.
Remark. In Proposition 66.11 we will see that there exists a closed orientable 3-dimensional smooth manifold $Y$ that is a homology 3-sphere, but such that $\pi_1(Y)$ is a non-trivial group. Together with the above this shows that there exist homology manifolds that are not topological manifolds.

Exercise 44.8. What is a familiar topological space that is homeomorphic to the double of the Möbius band? Furthermore, which one is homeomorphic to the double of the Klein bottle minus an open disk?

Exercise 44.9. Let $M$ be a compact connected $n$-dimensional topological manifold such that $\partial M$ has $k \in \mathbb{N}$ components.

(a) Show that $\text{rank}(H_1(DM)) \geq k - 1$.
(b) Show that $\pi_1(M)$ admits an epimorphism onto a free group of rank $k - 1$. 

By Proposition 43.4 we know that for any \( n \in \mathbb{N}_0 \) we have
\[
\widetilde{H}_k(S^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{if } k \neq n. \end{cases}
\]
Thus we have determined the homology groups of all finite-dimensional spheres. In this chapter, given \( n \in \mathbb{N}_0 \), we will determine an explicit singular \( n \)-chain which is a generator of \( \widetilde{H}_n(S^n) \). Furthermore, given a map \( f: S^n \to S^n \) we will get to know several techniques for determining the induced map \( f_*: \widetilde{H}_n(S^n) \to \widetilde{H}_n(S^n) \). These results will allow us to prove various interesting results, e.g. the mysterious sounding Hair Ball Theorem. The results of this chapter will also be essential later on in Chapter 48 when we will introduce cellular homology.

45.1. Explicit generators of relative homology groups. We start out with the following elementary lemma that we will use explicitly and implicitly on many occasions.

**Lemma 45.1.** Let \( n \in \mathbb{N}_0 \). We have
\[
\widetilde{H}_k(B^n, S^{n-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise}. \end{cases}
\]

**Proof.** We consider the long exact sequence in reduced homology of the pair \((B^n, S^{n-1})\):
\[
\ldots \to \widetilde{H}_k(B^n) \to H_k(B^n, S^{n-1}) \xrightarrow{\partial} \widetilde{H}_{k-1}(S^{n-1}) \to \widetilde{H}_{k-1}(B^n) \to \ldots
\]
where the statement of the lemma is now an immediate consequence of Proposition 43.4.

We continue with the following lemma.

**Lemma 45.2.** For any \( n \in \mathbb{N}_0 \) the following two statements hold:

1. \( H_n(\Delta^n, \partial \Delta^n) \cong \mathbb{Z} \).
2. The identity map \( \text{id}: \Delta^n \to \Delta^n \) represents a generator of \( H_n(\Delta^n, \partial \Delta^n) \cong \mathbb{Z} \).

**Proof.** The first statement is an immediate consequence of Lemmas 45.1 and 41.1. Now we turn to the proof of the second statement. We prove the second statement by induction on \( n \). It follows easily from Proposition 41.5 that the statement holds for \( n = 0 \). Now we suppose that the desired statement holds for \( n - 1 \) with \( n \in \mathbb{N} \).

Our next goal is to find a connection between the two homology groups \( H_n(\Delta^n, \partial \Delta^n) \) and \( H_{n-1}(\Delta^{n-1}, \partial \Delta^{n-1}) \). We introduce the following notation:

1. We consider
\[
\Lambda := \bigcup_{i=0}^{n-1} \{ (t_0, \ldots, t_n) \in \Delta^n \mid t_i = 0 \},
\]
i.e. \( \Lambda \) is the union of all \((n - 1)\)-dimensional faces of \( \Delta^n \) except for the face given by \( t_n = 0 \). A generalization of the argument of Exercise 18.24(c) shows that \( \Lambda \) is a deformation retract of \( \Delta^n \). We refer to Figure 745 for an illustration.
(2) We write
\[ \hat{\Lambda} := \bigcup_{i=0}^{n-1} \{ (t_0, \ldots, t_n) \in \Lambda | t_i = 0 \text{ and } t_n > 0 \} , \]

the set \( \hat{\Lambda} \) is thus the “interior\(^{721}\) of \( \Lambda \).

![Deformation retraction from \( \Delta^2 \) to \( \Lambda \)](image)

\textbf{Figure 745}

In the following we view \( \mathbb{R}^n \) as the subset of \( \mathbb{R}^{n+1} \) given by setting the last coordinate equal to zero. This point of view allows us to view \( \Delta^{n-1} \) as a subset of \( \Delta^n \). Note that with this convention we have \( \partial \Delta^{n-1} \subset \Lambda \).

\textbf{Claim.} We consider the maps
\[
H_n(\Delta^n, \partial \Delta^n) \xrightarrow{\partial} H_{n-1}(\partial \Delta^n, \Lambda) \leftrightsquigarrow H_{n-1}(\Delta^{n-1}, \partial \Delta^{n-1}) .
\]

Here the map on the left is the connecting homomorphism in the long exact sequence of the triple \( (\Delta^n, \partial \Delta^n, \Lambda) \) and the right-hand map is induced by the inclusion. Then the following holds:

(1) Both maps are isomorphisms.

(2) \( \partial([\text{id}_{\Delta^n}]) = (-1)^n \cdot i_*( [\text{id}_{\Delta^{n-1}}] ) \).

![Illustration of the pairs \( (\Delta^n, \partial \Delta^n) \), \( (\partial \Delta^n, \Lambda) \) and \( (\Delta^{n-1}, \partial \Delta^{n-1}) \).](image)

\textbf{Figure 746.}

It is clear that a proof of the claim together with the induction hypothesis implies that \( [\text{id}_{\Delta^n}] \) is a generator of \( H_n(\Delta^n, \partial \Delta^n) \). In particular a proof of the claim implies Lemma 45.2

Now we turn to the proof of the claim. Of the two maps in the claim we first consider the map \( \partial \) on the left. It follows from the exact sequence of the triple \( (\Delta^n, \partial \Delta^n, \Lambda) \) that

\(^{721}\)Why is “interior” put in quotes?
the following sequence is exact:

\[ H_n(\Delta^n, \Lambda) \xrightarrow{\partial} H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} H_{n-1}(\partial\Delta^n, \Lambda) \xrightarrow{i_*} H_{n-1}(\Delta^n, \Lambda). \]

= 0 by Corollary 43.18 since \( \Lambda \) is a def. retract of \( \Delta^n \)

This shows that \( H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} H_{n-1}(\partial\Delta^n, \Lambda) \) is an isomorphism. Furthermore we have

\[ \partial([\text{id}_{\Delta^n}]) = [\partial\text{id}_{\Delta^n}] = \left[ \sum_{j=0}^{n-1} (-1)^j \text{id} \circ i_j^n + (-1)^n \cdot \text{id} \right] \bigg|_{\partial\Delta^{n-1}} \]

lies in \( C_{n-1}(\Delta^n) \)

Proposition 43.15 \[ \rightarrow \]

lies in \( C_{n-1}(\Lambda) \) \[ \rightarrow \]

since we work in \( H_{n-1}(\partial\Delta^n, \Lambda) \)

Now we turn our attention to the right-hand map in the statement of the claim. It follows from Theorem 44.9 applied to \( X = \partial\Delta^n, A = \Lambda, Z = \hat{\Lambda} \) and \( U = (0, \ldots, 0, 1) \)\(^{722}\) that the inclusion induced map

\[ H_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}) = H_{n-1}(\partial\Delta^{n-1} \setminus \hat{\Lambda}, \Lambda \setminus \hat{\Lambda}) \xrightarrow{i_*} H_{n-1}(\partial\Delta^n, \Lambda) \]

is an isomorphism. Furthermore we evidently have \( i_*(\text{[id}_{\Delta^{n-1}}]) = \text{[id}_{\Delta^{n-1}}]. \)

Thus we have proved that both maps in the claim are isomorphisms and that

\[ \partial([\text{id}_{\Delta^n}]) = (-1)^n \cdot \text{[id}_{\Delta^{n-1}}] = (-1)^n \cdot i_*(\text{[id}_{\Delta^{n-1}}]). \]

This concludes the proof of the claim and thus also of the lemma. \( \blacksquare \)

In the remainder of this section we explain how to find explicit generators of the local homology groups of a topological manifold. We recall the following lemma from the previous section.

**Lemma 44.1.** Let \( M \) be a \( k \)-dimensional topological manifold. Then for any \( P \in M \), any \( l \in \mathbb{N}_0 \) and any open neighborhood \( U \) of \( P \) we have

\[ H_l(M, M \setminus \{ P \}) \cong \begin{cases} \mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and } l = k, \\ \mathbb{Z} & \text{otherwise.} \end{cases} \]

**Examples.** Our goal now is to give explicit generators for the relative homology groups \( H_k(M, M \setminus \{ x \}) \cong \mathbb{Z} \). We first do so for open subsets of \( \mathbb{R}^k \) and then we “transport” those generators to topological manifolds using charts.

1. Let \( U \subset \mathbb{R}^k \) be an open subset that contains 0. Let \( \sigma: \Delta^k \to U \) be an injective affine linear map. We suppose that 0 lies in the image of the “interior” \( \hat{\Delta}^k := \Delta^k \setminus \partial\Delta^k \) of \( \Delta^k \). We claim that \( \sigma \) represents a generator of \( H_k(U, U \setminus \{ 0 \}) \). To prove this claim we consider the commutative diagram

\[
\begin{array}{ccc}
H_k(\hat{\Delta}^k, \sigma(\partial\Delta^k)) & \xrightarrow{\sigma_*} & H_k(U, U \setminus \{ 0 \}) \\
\downarrow{\sigma_*} & & \downarrow{\cong} \\
H_k(\sigma(\Delta^k), \sigma(\partial\Delta^k)) & \longrightarrow & H_k(\mathbb{R}^k, \sigma(\partial\Delta^k))
\end{array}
\]

\[ \text{One can easily show that } U \text{ has the property required in Theorem 44.9} \]
where the maps that are not induced by $\sigma$ are induced by the obvious inclusions. The left vertical map is an isomorphism since we know by Proposition 2.43 (3) that $\sigma: \Delta^k \to \sigma(\Delta^k)$ is a homeomorphism. The bottom horizontal maps are isomorphisms by Corollary 43.18 since one can easily show that $\sigma(\Delta^k)$ is a deformation retract of $\mathbb{R}^k$ and similarly one can show that $\sigma(\partial \Delta^k)$ is deformation retract of $\mathbb{R}^k \setminus \{0\}$. By Lemma 45.2 we know that $\text{id}_{\Delta^n}$ represents a generator of $H_n(\Delta^n, \partial \Delta^n)$. It follows from the above that $\sigma \circ \text{id}_{\Delta^n} = \sigma$ represents a generator of $H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{0\})$. But the right vertical map is an isomorphism by the Excision Theorem 43.20 hence $\sigma$ also represents a generator of $H_k(U, U \setminus \{0\})$.

(2) Let $M$ be a $k$-dimensional topological manifold and let $P \in M \setminus \partial M$. In the following we want to give an example of an explicit singular $k$-simplex that represents a generator for $H_k(M, M \setminus \{P\}) \cong \mathbb{Z}$. We pick a chart $\Phi: U \to B^k$ around $P$ with $\Phi(P) = 0$ and we pick an affine linear map $\sigma: \Delta^k \to B^k$ as in (1). It follows from (1) together with the proof of Lemma 44.1 that $\Phi^{-1} \circ \sigma: \Delta^k \to M$ represents a generator of $H_k(M, M \setminus \{P\})$. We refer to Figure 747 for an illustration.

**Figure 747**

45.2. The standard generator of $H_n(S^n)$. In this section we want to find explicit generators of $H_n(S^n) \cong \mathbb{Z}$ for $n \geq 1$. We consider the map $\alpha: \Delta^n \to S^n$ that is given by the concatenation of the following two maps

$$\Delta^n \xrightarrow{\text{homeomorphism given by Lemma 11.1}} \overline{B^n} \to S^n \subset \mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R} \quad x \mapsto (x, \sqrt{1 - \|x\|^2}).$$

We refer to Figure 748 for an illustration of the definition of the map $\alpha$. It follows easily from the definitions and Proposition 2.43 (3) that this map $\alpha$ defines a homeomorphism $\Delta^n \to S^n_{\geq 0} = \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0\}$ and that it restricts to a homeomorphism $\partial \Delta^n \to S^{n-1} = \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} = 0\}$. Furthermore we denote by $\beta: \Delta^n \to S^n$

**Figure 748**

the map which is the composition of $\alpha$ with reflection in the hyperplane defined by $x_{n+1} = 0$. The maps $\alpha: \Delta^n \to S^n$ and $\beta: \Delta^n \to S^n$ both define singular $n$-chains in $S^n$. Note that $\alpha$ and $\beta$ agree on $\partial \Delta^n$. Both maps are sketched in Figure 749.
Lemma 45.3. Let \( n \geq 1 \). The above singular \( n \)-chain \( \alpha - \beta \in C_n(S^n) \) is a cycle and it represents a generator of \( \tilde{H}_n(S^n) = H_n(S^n) \).

**Definition.**

1. Let \( n \geq 1 \). We refer to the generator from Lemma 45.3 as the standard generator of \( H_n(S^n) \). With great foresight we denote it by \([S^n]^\Delta\).
2. We define \([c_1 - c_{-1}] \in \tilde{H}_0(S^0)\) to be the standard generator of \( \tilde{H}_0(S^0) \).

**Proof.** We start out with the following claim.

**Claim.** The singular \( n \)-chain \( \alpha - \beta \) is a cycle.

We denote by \( \rho \) the reflection in the hyperplane defined by \( x_{n+1} = 0 \). We have

\[
\partial(\alpha - \beta) = \partial(\alpha - \rho_\ast(\alpha)) = (\text{id} - \rho_\ast)(\partial \alpha) = 0.
\]

since \( \rho \) is a chain map since \( \rho = \text{id} \) on \( \mathbb{R}^n \times 0 \subset \mathbb{R}^{n+1} \).

As usual we denote by

\[
S_{\geq 0}^n := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0\}
\]

and

\[
S_{\leq 0}^n := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \leq 0\}
\]

the two “hemispheres”. By the discussion on page 1106 both hemispheres are homeomorphic to the closed ball \( \overline{B}^n \), in particular they are contractible which implies by the discussion on page 1106 that their reduced homology groups vanish. We also consider the “equator”

\[
S_{= 0}^n := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} = 0\}.
\]

\[\footnote{It follows easily from Lemma 41.3 and the definitions that the two definitions of standard generator of \( H_1(S^1) \) agree.}\]
Next we consider the following sequence of maps:

\[
\begin{array}{ccc}
\tilde{H}_n(S^n) & \to & H_n(S^n, S^n_{\leq 0}) \\
\downarrow & & \downarrow \\
[\alpha - \beta] & \mapsto & [\alpha] - [\beta] = [\alpha]
\end{array}
\]

isomorphism by the long exact isomorphism sequence in reduced homology since \(\alpha\) is a homeomorphism.

So we have shown that all maps are isomorphisms. Furthermore, by Lemma 45.2 we know that \([\text{id}_{\Delta^n}]\) is a generator of \(H_n(\Delta^n, \partial \Delta^n)\). But \([\text{id}_{\Delta^n}]\) and \([\alpha - \beta]\) get sent to the same element in \(H_n(S^n, S^n_{\leq 0})\), therefore \([\alpha - \beta]\) must also be generator of \(\tilde{H}_n(S^n)\).

In the following lemma we give an alternative description of the standard generator of \(H_1(S^1)\).

**Lemma 45.4.** The singular 1-simplex

\[\sigma: \Delta^1 \to S^1 \quad \quad (1 - t, t) \mapsto e^{2\pi it}\]

is a cycle that represents the standard generator \([S^1]\) of \(H_1(S^1) \cong \mathbb{Z}\).

**Proof.** We denote by \(\alpha, \beta: \Delta^1 \to S^1\) the singular 1-simplices in the definition of the standard generator of \(H_1(S^1)\). We have

\[
[\alpha - \beta] = [\alpha + \beta] = [\sigma] \in H_1(S^1).
\]

by Lemma 41.3 (2) and (3)

We refer to Figure 750 for an illustration.

**Remark.** By Lemma 45.4 we know that there exists a singular 1-simplex \(\sigma\) that represents a generator of \(H_1(S^1)\). In Exercise 45.3 we will discuss the question, for which \(n \in \mathbb{N}\) does there exist a singular \(n\)-simplex \(\sigma: \Delta^n \to S^n\) that represents a generator of \(H_n(S^n)\).

We conclude this section with a short discussion of several related homology groups and their “standard generators”.

---

**Figure 750.** Two representatives of the standard generator of \(H_1(S^1)\).
**Definition.** Let $n \in \mathbb{N}$. The *standard generator of* $H_n(\overline{B}^n, S^{n-1})$ is defined to be the unique element that gets sent to the standard generator of $\tilde{H}_{n-1}(S^{n-1})$ under the connecting homomorphism $H_n(\overline{B}^n, S^{n-1}) \to \tilde{H}_{n-1}(S^{n-1})$ of the long exact sequence in reduced homology of the pair $(\overline{B}^n, S^{n-1})$. We denote the standard generator by $[\overline{B}^n]$.

**Example.** Recall that the standard generator of $\tilde{H}_0(S^0)$ is defined as $[c_1 - c_{-1}] \in \tilde{H}_0(S^0)$. It follows easily from the explicit description of the connecting homomorphism, see Proposition 43.15, and the explicit description of the boundary of a singular 1-simplex, see page 1079, that the standard generator of $H_1(\overline{B}^1, S^0)$ is represented by the cycle

$$\Delta^1 \to \overline{B}^1 \quad (1 - t, t) \mapsto 2t - 1.$$  

We refer to Figure 751 for an illustration.

*Figure 751*

We have now introduced several standard generators of homology groups. The following proposition shows the relationship between these standard generators under various maps. The proposition, let alone the proof, are not much fun to read, but it is an absolutely essential proposition since it settles several rather subtle signs.

**Proposition 45.5.** Let $n \in \mathbb{N}$. We denote by $f: (\Delta^n, \partial \Delta^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from Lemma 41.1 and we denote by $g: \overline{B}^n/S^{n-1} \to S^n$ the homeomorphism from page 182. We set $* := g([S^{n-1}])$. We consider the following diagram:

$$\begin{array}{cccc}
H_n(\Delta^n, \partial \Delta^n) & \xrightarrow{f_*} & H_n(\overline{B}^n, S^{n-1}) & \xrightarrow{g_*} & \tilde{H}_n(S^n) \\
\partial & \downarrow & \overline{H}_n(\overline{B}^n/S^{n-1}) & \xrightarrow{\approx} & \tilde{H}_n(S^n) \\
\tilde{H}_{n-1}(\partial \Delta^n) & \xrightarrow{f_*} & \tilde{H}_{n-1}(S^{n-1}) & & \\
\end{array}$$

The following statements hold:

1. The diagram commutes and the top vertical maps are isomorphisms.
2. We have $f_*(\{id_{\Delta^n}\}) = (-1)^n \cdot \text{standard generator} \ [\overline{B}^n] \ 	ext{of} \ H_n(\overline{B}^n, S^{n-1})$.
3. The standard generator $[\overline{B}^n]$ of $H_n(\overline{B}^n, S^{n-1})$ has the same image in $H_n(S^n, *)$ as the standard generator $[S^n]$ of $H_n(S^n)$. 

45. HOMOLOGY AND SELF-MAPS OF SPHERES

(4) The image of the standard generator \([\overline{B}^n]\) \(\in H_n(\overline{B}^n, S^{n-1})\) in \(H_{n-1}(S^{n-1})\) equals the standard generator \([S^{n-1}]\) of \(H_{n-1}(S^{n-1})\).

(5) We have

\[ f_*(\partial[\text{id}_{\Delta^n}]) = (-1)^n \cdot \text{standard generator } [S^{n-1}] \text{ of } H_{n-1}(S^{n-1}). \]

Proof of Proposition 45.5 (\(*\)).

(1) The triangle commutes by definition of \(\text{id}\), see page 1129. Furthermore it follows from Lemma 43.14 and Corollary 43.16 that the two squares commute.

(3),(4) The calculation of these two signs is delicate and tricky. It becomes somewhat easier after we have developed a few more tools. Thus we postpone the proof of these two statements to Section 45.7.

(4) This statement is just a repetition of the definition of the standard generator \([\overline{B}^n]\).

(5) This statement is an immediate consequence of (1), (2) and (4).

We conclude this section with the following lemma which gives us another slightly subtle sign calculation.

Lemma 45.6. (\(*\)) Let \(n \in \mathbb{N}\). We consider the following sequence of maps

\[ H_n(S^n) \xrightarrow{\pi} H_n(S^n, S^n_{\geq 0}) \xleftarrow{\cong} H_n(S^n_{\geq 0}, S^{n-1}) \xrightarrow{\partial} \tilde{H}_{n-1}(S^{n-1}). \]

The image of the standard generator \([S^n]\) \(\in H_n(S^n)\) under this map is \((-1)^n \cdot [S^{n-1}]\).

Proof (\(*\)). We recall and introduce the following notation:

(1) Let \(f : (\Delta^n, \partial \Delta^n) \to (\overline{B}^n, S^{n-1})\) be the homeomorphism from Lemma 41.1.

(2) Let \(p_+: S^n_{\geq 0} \to \overline{B}^n\) be the obvious projection and let \(q_+: \overline{B}^n \to S^n_{\geq 0}\) be the map given by \(x \mapsto (x, \sqrt{1 - \|x\|^2})\). Evidently \(p\) and \(q\) are inverses of one another. We define \(p_- : S^n_{\leq 0} \to \overline{B}^n\) and \(q_- : \overline{B}^n \to S^n_{\leq 0}\) in an analogous fashion.

(3) Note that \(\alpha := q_+ \circ f : \Delta^n \to S^n\) and \(\beta := q_- \circ f : \Delta^n\) are the singular \(n\)-simplices that we introduced on page 1173.

Next we consider the following diagram

\[ \begin{array}{ccc}
H_n(S^n) & \xrightarrow{\pi} & H_n(S^n, S^n_{\geq 0}) \\
\downarrow q_+ & & \downarrow p_+ \\
H_n(\overline{B}^n, S^{n-1}) & \xrightarrow{\partial} & H_{n-1}(S^{n-1}).
\end{array} \]
Note that the triangle to the right commutes by the naturality of the connecting homomorphism, see Corollary \[43.16\] Now we see that

\[
\begin{align*}
\partial(i_+^{-1}(\mathfrak{n}([S^n]))) &\overset{\phi}{=} \partial(i_+^{-1}(\mathfrak{n}([\alpha - \beta]))) \\
&= \partial(q_+([p_+ \circ \alpha])) \\
&= \partial([f]) \\
&= (-1)^n \cdot [S^{n-1}].
\end{align*}
\]

since \( p_+ = q_+^{-1} \)

definition of \([S^n]\)  
definition of \(\mathfrak{n}\)  
since \( \beta = 0 \in \mathcal{C}_n(S^n, S^n) \)

\[
\begin{array}{c}
\begin{array}{c}
S^n \rightarrow \ \\
\alpha \rightarrow \\
\rightarrow -\beta \\
\rightarrow S^n_0 \\
\end{array} \\
\begin{array}{c}
\begin{array}{c}
\Sigma(X) \\
\rightarrow \\
\rightarrow \ \\
\rightarrow C_-X \\
\rightarrow C_+X \\
\end{array}
\end{array}
\end{array}
\]

**Figure 752.** Illustration for the proof of Lemma \[45.6\]

45.3. **Suspensions and homology groups.** In the next section we will study self-maps of spheres. In that section it will be useful to consider the effect of taking suspensions on homology. Since this is going to be interesting for larger classes of topological spaces we dedicate this short section to the study of homology groups of suspensions of topological spaces.

The following definition follows the definition on page \[694\] and the convention given by Lemma \[24.2\] (3).

**Definition.** Let \( X \) be a non-empty topological space.

1. We define the suspension of \( X \) to be the topological space

\[
\Sigma(X) := (X \times [-1, 1]) / \sim
\]

where we identify all points in \( X \times \{ -1 \} \) to a single point and we identify all points in \( X \times \{ 1 \} \) to a single point.

2. We denote by \( p : X \times [-1, 1] \rightarrow \Sigma(X) \) the obvious projection. We write

\[
C_-X := p(X \times [-1, 1]) \quad \text{and} \quad C_+X := p(X \times (-1, 1]).
\]

By Lemma \[24.2\] (3) we know that the map \( X \xrightarrow{x \rightarrow p(x,0)} \Sigma(X) \) is a closed embedding. We use this embedding to view \( X \) as a subspace of \( C_-X \) and of \( \Sigma(X) \).

**Figure 753**

In Lemma \[24.3\] and Exercise \[26.5\] we calculated the fundamental group of the suspension of a non-empty topological space with finitely many path components. The following
proposition, which is the main result of this section, determines the homology groups of a suspension.

**Proposition 45.7.** Let $X$ be a non-empty topological space and let $n \in \mathbb{Z}$.\(^{725}\)

1. The following maps are isomorphisms:

\[
\begin{array}{c}
\tilde{H}_n(X) \xleftarrow{\beta} H_{n+1}(C_+X, X) \rightarrow H_{n+1}(\Sigma(X), C_-X) \xrightarrow{\kappa} \tilde{H}_{n+1}(\Sigma(X)).
\end{array}
\]

\[\text{connecting homomorphism of the pair (C}_+X, X) \text{ from Corollary 43.16}\]

\[\text{inclusion induced} \quad \xrightarrow{\kappa} \quad \text{the natural map given by Lemma 43.1 (3)}\]

2. The resulting isomorphism

\[\Sigma_X : \tilde{H}_n(X) \xrightarrow{\cong} \tilde{H}_{n+1}(\Sigma(X))\]

is natural. In other words, given any map $f : X \rightarrow Y$ between topological spaces the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{H}_n(X) & \xrightarrow{\Sigma_X} & \tilde{H}_{n+1}(\Sigma(X)) \\
\downarrow f_* & & \downarrow \Sigma(f)_* \\
\tilde{H}_n(Y) & \xrightarrow{\Sigma_Y} & \tilde{H}_{n+1}(\Sigma(Y)).
\end{array}
\]

**Example.** Let $n \in \mathbb{N}$ and let $X$ be the disjoint union of $n$ intervals. It follows from Proposition 45.7 together with Lemma 43.1 that $H_1(\Sigma(X)) \cong \mathbb{Z}^{n-1}$. In Figure 754 we show a generating set for $H_1(\Sigma(X))$ for $n = 3$. We leave it to the reader to deduce from the proof of Proposition 45.7 that the given cycles do indeed form a generating set for $H_1(\Sigma(X))$.

![Figure 754](image)

**Proof (\star).** Let $n \in \mathbb{Z}$.

1. (a) By the same argument as in the proof of Lemma 24.1 we see that both $C_-X$ and $C_+X$ admit a deformation retraction to a point. It follows from Lemma 18.14 that both are contractible, therefore by Lemma 43.1 (7) the reduced homologies of $C_-X$ and $C_+X$ vanish. Note that it follows in particular that the connecting homomorphism $\partial : H_{n+1}(C_+X, X) \rightarrow \tilde{H}_n(X)$ is an isomorphism.

(b) We denote by $S := [X \times \{-1\}] \in \Sigma(X)$ the South Pole of the suspension. Note that $\Sigma(X) \setminus S = C_+X$ and $C_-X \setminus S = C_-X \cap C_+X$. Using this observation we obtain from the Excision Theorem 43.19\(^{726}\) that the second horizontal map is an isomorphism.

\(^{725}\)Note that the proposition has non-trivial content for $n = -1$.

\(^{726}\)One can easily verify that the hypotheses for the Excision Theorem 43.19 are satisfied.
(c) Similar to (a) we obtain from Corollary 43.16 that the third horizontal map is an isomorphism.

(2) First note that the connecting homomorphism is natural by Proposition 43.15 (2) and the fact that $\Sigma(f)|_{X} = f$. It is clear that the second horizontal map is natural. Finally it follows from Lemma 43.1 (3) that the map $\gamma$ is natural. The combination of these observations shows that $\Sigma_{X}$ itself is natural.

Example. Let $n \in \mathbb{N}$. Let $\Sigma(S^{n}) \to S^{n+1}$ be the homeomorphism from page 695. It follows quite easily from the definition of the suspension isomorphism $\Sigma_{S^{n}} : H_{n}(S^{n}) \to H_{n+1}(S^{n+1})$ and Lemma 45.6 that

$$\Sigma_{S^{n}}([S^{n}]) = (-1)^{n+1} \cdot [S^{n+1}] \in H_{n+1}(S^{n+1}).$$

We conclude this section with the following corollary.

**Corollary 45.8.** (⋆) Let $X$ be a topological space that is compact and Hausdorff. Furthermore let $k \in \mathbb{N}_{\geq -1}$. For every $n \in \mathbb{Z}$ there exists a natural isomorphism

$$\widetilde{H}_{n}(X) \xrightarrow{\cong} \widetilde{H}_{n+k+1}(S^{k} \ast X).$$

Here, recall that if $X$ is the empty topological space, then by Lemma 43.1 (0) we have $\widetilde{H}_{-1}(\varnothing) = \mathbb{Z}$.

**Proof (⋆).** First note that the case $X = \varnothing$ follows from the fact that, by definition, $S^{k} \ast \varnothing = S^{k}$, and the calculation of the reduced homology groups of $S^{k}$ that we gave in Proposition 43.4.

Now assume that $X \neq \varnothing$. If $k = -1$, then we have, again by definition, the equality $S^{-1} \ast X = \varnothing \ast X = X$ which implies the desired statement. Thus it remains to deal with case that $k \geq 0$. To simplify the notation we only consider the case $k = 1$. In this case we have

$$\widetilde{H}_{n+2}(S^{1} \ast X) \cong \widetilde{H}_{n+2}((S^{0} \ast S^{0}) \ast X) \cong \widetilde{H}_{n+2}(S^{0} \ast (S^{0} \ast X)) \cong \widetilde{H}_{n+2}(\Sigma(\Sigma(X))) \cong \widetilde{H}_{n}(X).$$

Lemma 3.50 by Proposition 3.52 Exercise 24.3 Proposition 45.7

It follows easily from the definitions of the maps that the isomorphism is in fact natural.

45.4. **The degree of a self-map of a sphere.** Now that we know the homology groups of spheres, we want to study the maps on homology induced by maps $f : S^{n} \to S^{n}$. This is interesting in its own right, but it will also play a major role later on in Chapter 48 when we will try to determine the homology groups of CW-complexes.

Throughout the remaining sections of this chapter we will work a lot with the following simple-minded definition.
Definition. Let \((G, +)\) be a group that is isomorphic to \(\mathbb{Z}\). Furthermore let \(\Phi: G \to G\) be a homomorphism. Note that \(\Phi\) is given by multiplication by a unique integer which we refer to as the degree \(\deg(\Phi)\).

For completeness’ sake we record two basically obvious statements regarding the degree.

**Lemma 45.9.** Let \((G, +)\) be a group that is isomorphic to \(\mathbb{Z}\).

1. Let \(g \in G\) be any non-trivial element. Furthermore let \(\Phi: G \to G\) be a homomorphism. The degree \(\deg(\Phi)\) is uniquely determined by the equality \(\Phi(g) = \deg(\Phi) \cdot g\).
2. Let \(\varphi: G \to H\) be an isomorphism and let \(f: H \to H\) be a homomorphism. Then \(\deg(\varphi^{-1} \circ f \circ \varphi: G \to G) = \deg(f: H \to H)\).

Next we relate the above definition to topology.

**Definition.** Let \(n \in \mathbb{N}_0\) and let \(f: S^n \to S^n\) be map. Since \(\tilde{H}_n(S^n)\) is isomorphic to \(\mathbb{Z}\) we can define the degree of \(f\) as

\[
\deg(f) := \deg(f_*: \tilde{H}_n(S^n) \to \tilde{H}_n(S^n)).
\]

**Example.** We consider the map \(f: S^1 \to S^1\) that is illustrated in Figure 755 on the left. We denote by \(\tau: \Delta^1 \to S^1\) the singular 1-simplex that is given by \(\tau(1-t, t) = e^{2\pi i t}\). By Lemma 45.4 we know that \([\tau] \in H_1(S^1)\) is a generator.

We pick singular 1-simplices \(\sigma_1, \ldots, \sigma_5\) as in the middle of Figure 755 and we denote by \(\gamma: \Delta^1 \to S^1\) the constant singular 1-simplex that sends all points to 1. Then

\[
\begin{align*}
\downarrow & \quad \uparrow \\
\gamma & = \tau \\
\sigma_1 \circ f + \sigma_2 \circ f + \sigma_3 \circ f + \sigma_4 \circ f + \sigma_5 \circ f & = 2 \cdot \tau + \tau + 2 \cdot \gamma & = (\tau + 2 \cdot \gamma) & = (\tau + 2 \cdot \gamma) = [\tau]\end{align*}
\]

Lemma 41.3 (2) \(\Rightarrow\) \(\deg(f)\)

Summarizing we have shown that \(\deg(f) = 1\). With almost the same approach we can calculate the degrees of the maps that are illustrated in Figure 756.

\[
\begin{align*}
\operatorname{deg}(a) & = 0 \\
\operatorname{deg}(b) & = 5 \\
\operatorname{deg}(c) & = -3
\end{align*}
\]

Figure 756

---

727 More precisely, given an “interval” on \(S^1\) going from \(e^{i\alpha}\) to \(e^{i\beta}\) we mean the singular 1-simplex that is given by \((1-t, t) \mapsto e^{i(\alpha -(1-t)+\beta \cdot t)}\)
Almost the same arguments that we used in the discussion of the above example gives us the following lemma.

**Lemma 45.10.** For any \( k \in \mathbb{Z} \) the degree of the map \( S^1 \rightarrow S^1 \)
\[
z \mapsto z^k
\]
equals \( k \).

**Proof.** We denote by \( \tau : \Delta^1 \rightarrow S^1 \) the singular 1-simplex that is given by \( \tau(1-t,t) = e^{2\pi i t} \).

By Lemma 45.4 we know that \([\tau] \in H_1(S^1)\) is a generator.

Now we first consider the case \( k \geq 1 \). For \( j = 0, \ldots, k - 1 \) we denote by \( \sigma_j : \Delta^1 \rightarrow S^1 \) the singular 1-simplex that is given by \( (1-t,t) \mapsto e^{2\pi i (t+j)} \).

Then
\[
\tau \cdot (\sigma_0 + \cdots + \sigma_{k-1}) = \tau \cdot \sigma_0 + \cdots + \tau \cdot \sigma_{k-1}
\]
and by Lemma 45.4 (3) we have
\[
\text{deg}(\tau) = \text{deg}(\sigma_0 + \cdots + \sigma_{k-1}) = k \cdot [\tau].
\]

The case \( k < 0 \) is proved in a similar fashion using Lemma 45.4 (2). Finally the case \( k = 0 \) follows from the fact that the map \( S^1 \rightarrow S^1, z \mapsto 1 \) is constant, hence, as discussed on page 1089 the induced map on first homology is the zero map. \( \blacksquare \)

Before we move on to the next lemma it is convenient to introduce the following notation.

**Notation.** As on page 1089 given a matrix \( A \in O(n+1) \) we denote by \( \rho(A) : S^n \rightarrow S^n \) the map given by \( x \mapsto A \cdot x \).

The following lemma summarizes several important properties of the degree of the self-map of a sphere.

**Lemma 45.11.** Let \( f, g : S^n \rightarrow S^n \) be two maps. Then the following hold:

1. \( \text{deg}(\text{id}_{S^n}) = 1. \)
2. If \( f \) is not surjective, then \( \text{deg}(f) = 0. \)
3. If \( f \) is homotopic to \( g \), then \( \text{deg}(f) = \text{deg}(g). \) (In Proposition 54.8 we will see that the converse to this statement holds.)
4. \( \text{deg}(f \circ g) = \text{deg}(f) \cdot \text{deg}(g). \)
5. If \( f \) is a self-homeomorphism of \( S^n \), then \( \text{deg}(f^{-1}) = \text{deg}(f). \)
6. Given any \( A \in O(n) \) we have \( \text{deg}(\rho(A)) = \det(A) \in \{-1, 1\}. \)

**Examples.**

1. If \( f : S^n \rightarrow S^n \) is the reflection in a hyperplane, then it follows from Lemma 45.11 (6) that \( \text{deg}(f) = -1. \)
2. If \( f : S^n \rightarrow S^n \) is the reflection in the origin i.e. if \( f(x) = -x \) for all \( x \in S^n \), then it follows from Lemma 45.11 (6) we have \( \text{deg}(f) = (-1)^{n+1}. \)
3. Let \( A \in O(n+1) \). Let \( f : S^n \rightarrow S^n \) be the map that is given by \( f(P) = A \cdot P. \) If \( \det(A) = 1 \), then we saw on page 538 that \( f \) is actually homotopic to the identity. On the other hand, if \( \det(A) = -1 \), then it now follows from Lemma 45.11 (1), (3) together with Lemma 45.11 (6) that \( f \) is not homotopic to the identity.
Proof.

(1) Since \((\text{id}_{S^n})_* = \text{id}_{H_*(S^n)}\) we know that \(\deg(\text{id}_{S^n}) = 1\).

(2) Suppose that the map \(f: S^n \to S^n\) misses the point \(P \in S^n\). We consider the commutative diagram

\[
\begin{array}{c}
S^n \xrightarrow{f} S^n \setminus \{P\} \\
\downarrow{f} \quad \downarrow{i} \\
S^n \end{array}
\]

which gives rise to the commutative diagram

\[
\begin{array}{c}
H_n(S^n) \xrightarrow{f_*} H_n(S^n) \setminus \{P\} \\
\downarrow{f_*} \quad \downarrow{i_*} \\
H_n(S^n) \end{array}
\]

By Lemma 3.32 (6) we know \(S^n \setminus \{P\}\) is homeomorphic to \(\mathbb{R}^n\). Thus we see that \(S^n \setminus \{P\}\) is contractible which implies by Corollary 42.8 that \(H_n(S^n \setminus \{P\}) = 0\). But this means that \(f_*: H_n(S^n) \to H_n(S^n)\) factors through the zero group, i.e. \(f_*\) is the zero map.

(3) If \(f\) is homotopic to \(g\), then it follows from Proposition 42.5 that \(\deg(f) = \deg(g)\).

(4) We consider the following diagram

\[
\begin{array}{c}
H_n(S^n) \xrightarrow{f_* - \deg(f)} H_n(S^n) \setminus \{P\} \\
\downarrow{f_*} \\
H_n(S^n) \end{array}
\]

This diagram commutes since \((f \circ g)_* = f_* \circ g_*\). It follows that the curved map is given by multiplication by \(\deg(f) \cdot \deg(g)\), i.e. \(\deg(f \circ g) = \deg(f) \cdot \deg(g)\).

(5) This statement follows immediately from (1) and (4).

(6) We start out with the following claim.

Claim. Let \(\mu: S^n \to S^n\) be the reflection in the \((x_{n+1} = 0)\)-hyperplane. Then we have \(\deg(\mu) = -1\).

To prove the claim we consider again the singular chain

\[
\alpha: \Delta^n \xrightarrow{\sim} \{ (x_1, \ldots, x_n) \in [0,1]^n \mid \sum_{i=1}^n x_i \in [0,1] \} \xrightarrow{\sim} \mathbb{B}^n \to S^n.
\]

\((t_0, \ldots, t_n) \mapsto (t_0, \ldots, t_{n-1})\)

\(x \mapsto (x, \sqrt{1 - ||x||^2})\).

that we had already considered on page 1173. We write \(\beta = \mu \circ \alpha\). In Lemma 45.3 we saw that the singular \(n\)-chain \(\alpha - \beta\) is a generator of \(H_n(S^n)\). Next we calculate

\[
\mu_*([\alpha - \beta]) = [\mu \circ \alpha] - [\mu \circ \beta] = [\beta] - [\mu \circ \mu \circ \alpha] = [\beta] - [\mu] = -[\mu - \beta].
\]

The map \(\mu_*\) is therefore given by multiplication with \(-1\). \(\square\)

Now let \(A \in O(n+1)\). First we consider the case \(\det(A) = 1\), i.e. we assume that \(A \in SO(n+1)\). By Lemma 2.65 we know that \(SO(n+1)\) is path-connected, so there exists a map \(h: [0,1] \to SO(n+1)\) with \(h(0) = \text{id}\) and \(h(1) = A\). But then \(F(x,t) = h(t) \cdot x\) defines a homotopy from \(\text{id}\) to \(\rho(A)\). It follows from Lemma 45.11 (1) and (3) that \(\deg(\rho(A)) = \deg(\text{id}) = 1\).
Finally, we consider the case that \( \det(A) \neq 1 \). Let \( R \in O(n+1) \) be the matrix such that \( \rho(R) = \mu \). Now we see that
\[
\deg(\rho(A)) = \deg(\rho(A \cdot R \cdot R^{-1})) = \deg(\rho(A \cdot R)) \cdot \deg(\rho(R)) = 1 \cdot (-1) = -1.
\]
\( \uparrow \) by (4) since \( \det(A \cdot R) = 1 \) and by the claim.

We have now seen that the circle admits self-maps of arbitrary degrees and that every sphere admits self-maps of degree \(-1, 0, 1\). It is natural to ask whether there are also maps on higher-dimensional spheres that have other degrees. The combination of Lemma 45.10 and the following lemma shows that in fact every \( k \in \mathbb{Z} \) is realized as the degree of every high-dimensional sphere.

**Lemma 45.12.** Let \( n \in \mathbb{N} \) and let \( f: S^n \to S^n \) be a map. Let \( \Sigma(f): \Sigma(S^n) \to \Sigma(S^n) \) be the suspension of \( f \) that we defined on page 696. Furthermore, let \( \Theta: \Sigma(S^n) \to S^{n+1} \) be the homeomorphism from page 695. Then
\[
\deg(\Theta \circ \Sigma(f) \circ \Theta^{-1}: S^{n+1} \to S^{n+1}) = \deg(f: S^n \to S^n).
\]

**Examples.**

1. Let \( k \in \mathbb{Z} \). We view \( S^2 \) as a subset of \( \mathbb{R}^3 = \mathbb{C} \times \mathbb{R} \). We consider the map
\[
g: S^2 \to S^2,
(re^{i\varphi}, w) \mapsto (re^{i\varphi k}, w).
\]
One can easily verify that the map \( g \) equals \( \Theta \circ \Sigma(z \mapsto z^k) \circ \Theta^{-1} \). Thus it follows from Lemmas 45.10 and 45.12 that \( \deg(g) = \deg(\Sigma(z \mapsto z^k)) = k \).

2. Let \( n \in \mathbb{N} \) and let \( k \in \mathbb{Z} \). It follows from Lemmas 45.10 and 45.12 that there exists a self-map \( f: S^n \to S^n \) of degree \( k \).

**Proof.** We consider the following diagram
\[
\begin{array}{cccccc}
\tilde{H}_n(S^n) & \xrightarrow{\Sigma(S^n)} & \tilde{H}_n(\Sigma(S^n)) & \xrightarrow{\Theta_*} & \tilde{H}_{n+1}(S^{n+1}) \\
 \cdot \deg(f) \downarrow f_* & & \downarrow \Sigma(f)_* & & \downarrow (\Theta \circ \Sigma(f) \circ \Theta^{-1})_* \\
\tilde{H}_n(S^n) & \xrightarrow{\Sigma(S^{n+1})} & \tilde{H}_{n+1}(\Sigma(S^n)) & \xrightarrow{\Theta_*} & \tilde{H}_{n+1}(S^{n+1}).
\end{array}
\]
First note that it follows from Proposition 45.7 that the square to the left commutes and that the horizontal maps to the left are isomorphisms. It is clear that the square to the right commutes. Furthermore, since \( \Theta \) is a homeomorphism we see that the horizontal maps to right are isomorphism. Note that it follows immediately from the above discussion together with Lemma 45.9 (2) that \( \deg(\Theta \circ \Sigma(f) \circ \Theta^{-1}) = \deg(f) \).

The following theorem is an interesting application of our discussion of degrees of self-maps of spheres.

**Theorem 45.13.** Let \( f: S^n \to S^n \) be a map. If \( \deg(f) \neq (-1)^{n+1} \), then \( f \) has a fixed point.
Example. Theorem 45.13 says in particular that every map \( f: S^2 \to S^2 \) of degree one has a fixed point. Together with Lemma 45.11 this implies that every map \( f: S^2 \to S^2 \) that is homotopic to the identity has a fixed point. This means that we cannot "deform" the identity to a map that is fixed point free. This is in contrast to the case \( n = 1 \) where we can "deform" the identity into the map that is given by rotation by a small angle, which is of course a fixed point free map.

Proof. Let \( f: S^n \to S^n \) be a map which admits no fixed point. This means that for all \( x \in S^n \) we have \( f(x) \neq x \). We need to show that \( \deg(f) = (-1)^{n+1} \). We will do this by showing that \( f \) is homotopic to \(-\text{id}\).

Our hypothesis implies that \((1-t)f(x) \neq tx \) for all \( t \in [0,1] \) and all \( x \in S^n \).\(^{728}\) Therefore we can consider the map

\[
F: S^n \times [0,1] \to S^n \\
(x,t) \mapsto \frac{(1-t)f(x) - tx}{\|(1-t)f(x) - tx\|}.
\]

This map is a homotopy between the maps \( x \mapsto f(x) \) and \( x \mapsto -x \). Thus it follows that

\[
\deg(f) \uparrow \deg(-\text{id}) = (-1)^{n+1}.
\]

Lemma 45.11 (3) Lemma 45.11 (6)\(^{\blacksquare}\)

In the following we recall the definition of the "naive" tangent space of a submanifold of \( \mathbb{R}^n \).

Definition. Let \( M \subset \mathbb{R}^n \) be a submanifold. Given \( P \in M \setminus \partial M \) we denote by \( V_P M \subset \mathbb{R}^n \) the visual tangent vector space as defined on page 292. A vector field on \( M \) is a continuous map \( v: M \to \mathbb{R}^n \) such that for any \( P \in M \) we have \( v(P) \in V_P M \).

Examples.

1. Let \( P \) be a point on \( S^n \). As discussed on page 293 we have

\[
V_P S^n = \{ v \in \mathbb{R}^{n+1} \mid \langle P, v \rangle = 0 \}.
\]

2. For an odd-dimensional sphere \( S^{2k-1} \) a vector field is given by\(^{729}\)

\[
v: S^{2k-1} \to \mathbb{R}^{2k} \\
(x_1, x_2, \ldots, x_{2k-1}, x_{2k}) \mapsto (-x_2, x_1, \ldots, -x_{2k}, x_{2k-1}).
\]

This vector field has the property that it is nowhere vanishing. In the case of the 1-sphere \( S^1 \) this is just the vector field of constant length 1 that points in the "counterclockwise direction".

3. For an even-dimensional sphere \( S^{2k} \) a vector field is similarly given by

\[
v: S^{2k} \to \mathbb{R}^{2k+1} \\
(x_1, x_2, \ldots, x_{2k-1}, x_{2k}, x_{2k+1}) \mapsto (-x_2, x_1, \ldots, -x_{2k}, 0).
\]

\(^{728}\)This case be seen as follows: if \( t \neq \frac{1}{2} \) we have \( \|(1-t)f(x)\| = 1 - t \neq t = \|tx\| \). On the other hand, for \( t = \frac{1}{2} \) we have \( (1-t)f(x) = \frac{1}{2} f(x) \neq \frac{1}{2} x = tx \).

\(^{729}\)Indeed, for any \( P \in S^{2k-1} \) we have \( \langle P, v(P) \rangle = 0 \), i.e. \( v(P) \) does indeed lie in the tangent space \( T_P S^{2k-1} \).
This vector field vanishes at the “North Pole” \((0, \ldots, 0, 1)\) and it also vanishes at the “South Pole” \((0, \ldots, 0, -1)\). Both types of vector fields are sketched in Figure \ref{fig:vectorfields-north-south-poles}.

The vector field \(v(x, y) = (-y, x)\) on \(S^1\) is nowhere-vanishing. The vector field \(v(x, y, z) = (-y, x, 0)\) on \(S^2\) vanishes at \((0, 0, \pm 1)\).

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{vectorfields-north-south-poles}
\caption{Vector fields at the North and South Poles.}
\end{figure}

One can now ask whether it is possible to find a nowhere-vanishing vector field on even-dimensional spheres. The following proposition says that this is not possible.

**Theorem 45.14. (Hairy Ball Theorem)** Every vector field on an even-dimensional sphere \(S^{2k}\) vanishes on at least one point.\footnote{On \(S^{2k}\) we had so far found vector fields which vanish at \textit{two} points. Can we find a vector field on \(S^{2k}\) which vanishes on only \textit{one} point? We will discuss this question in Exercise 45.6.}

**Remark.**

1. For \(n = 2\) we get the following “real life application”: on the surface of earth there always exists at least one point where the wind does not blow at all. This fact is illustrated at the following website:

   \[\text{https://earth.nullschool.net/}\]

2. The “Hairy Ball Theorem” gets its observation that for \(n = 2\) the theorem says that “you can’t comb a hairy ball flat without creating a cowlick”.

3. Contrary to most other languages in German the Hairy Ball Theorem 45.14 is called the “Satz vom (gekämmten) Igel”, i.e. it is referred to as the “Combed Hedgehog Theorem”.

4. Evidently the fun never stops. Now that we know that odd-dimensional spheres admit one nowhere vanishing vector field the question arises, how many linearly independent vector fields can we find on a given odd-dimensional sphere. It turns out that there is complete and highly non-trivial answer, see \[\text{Adam62, MillH89}\] and \[\text{Vogl}\] for details.

**Proof.** Let \(v\) be a vector field on the sphere \(S^n\) which is nowhere-vanishing. We have to show that \(n\) is odd. We consider the vector field \(w\) on \(S^n\) that is given by rescaling \(v\) to length one, i.e. that is given by

\[
S^n \to \mathbb{R}^{n+1} \\
x \mapsto w(x) := \frac{1}{\|v(x)\|} v(x).
\]

Furthermore we consider the map

\[
F : S^n \times [0, 1] \to S^n \\
(x, t) \mapsto \cos(\pi t) \cdot x + \sin(\pi t) \cdot w(x).
\]
We refer to Figure 758 for an illustration. The map does indeed take values in $S^n$, since
\[ \langle \cos(\pi t)x + \sin(\pi t)w(x), \cos(\pi t)x + \sin(\pi t)w(x) \rangle = \cos(\pi t)^2\|x\|^2 + \sin(\pi t)^2\|w(x)\|^2 = 1. \]
\[ \uparrow \quad \uparrow \quad \text{since } \langle x, w(x) \rangle = 0 \quad \text{since } \|x\| = \|w(x)\| = 1 \]

The map $F_0 = F(-,0)$ is the identity and the map $F_1 = F(-,1)$ equals $F$ is $-\text{id}$. Put differently, the map $F$ is a homotopy between the two maps $\text{id}$ and $-\text{id}$. It follows that
\[ 1 = \deg(\text{id}) = \deg(-\text{id}) = (-1)^{n+1}. \]

But this means that $n$ is odd. ■

45.5. The local degree I. As the reader will have noticed, it is not entirely trivial to compute the isomorphism types of the homology groups of a given topological space. In the following two sections we will get to know a few tricks to address this problem.

We start out with the following harmless lemma which is a variation on Lemma 44.1.

**Lemma 45.15.** Let $U$ be a subset of $\mathbb{R}^n$. For every point $P$ in the interior of $U$ we have
\[ H_k(U,U \setminus \{P\}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases} \]

**Proof.** Since $P$ lies in the interior of $U$ there exists an $r > 0$ such that $B_r^c(P) \subset U$. Now we see that
\[ H_k(U,U \setminus \{P\}) \leftarrow H_k(B_r(P),B_r^c(P) \setminus \{P\}) \xrightarrow{\partial} \widetilde{H}_{k-1}(B_r^c(P) \setminus \{P\}) \leftarrow \widetilde{H}_{k-1}(S^{n-1}). \]

Excision Theorem 43.20 isomorphism by the long exact sequence in reduced homology isomorphism since $S^{n-1}$ is homotopy equivalent to $B_r^c(P) \setminus \{P\}$

The lemma now follows from the calculation of $\widetilde{H}_*(S^{n-1})$ in Proposition 43.4. ■

We move on to the following much more interesting proposition.

**Proposition 45.16.** Let $W$ be a subset of $\mathbb{R}^n$ and let $A$ be a subset of $W$ such the origin $0$ is contained in the interior of $U$. Let $f: A \to W$ be an injective map with $f(0) = 0$. We suppose that $f$ is a local diffeomorphism at $0$. Then the degree of the map $f_*$
\[ H_n(W,W \setminus \{0\}) \xrightarrow{\sim} H_n(A,A \setminus \{0\}) \xrightarrow{f_*} H_n(W,W \setminus \{0\}) \]
equals $+1$ if $f$ is orientation-preserving at $0$ and $-1$ if $f$ is orientation-reversing at $0$. 

In the proof of Proposition 45.16 we will make use of the following two lemmas which we will also use on several other occasions later on.

**Lemma 45.17.** Let \( f: U \rightarrow V \) be a diffeomorphism between two open subsets of \( \mathbb{R}^n \). Let \( P \in U \). We denote by
\[
\lambda: \mathbb{R}^n \rightarrow \mathbb{R}^n
\]
\[
x \mapsto (D f_P)(x) + f(P)
\]
the linearization of \( f \) at \( P \). There exists an open neighborhood \( U' = B^n_\epsilon(P) \) of \( P \) such that the restrictions of \( f \) and \( \lambda \) to maps \((U', U' \setminus \{P\}) \rightarrow (\mathbb{R}^n, \mathbb{R}^n \setminus \{f(P)\})\) are homotopic.

**Remark.** Lemma 45.17 is the key to translating information from smooth methods into topology and later on homology groups.

**Proof.** Let \( f: U \rightarrow V \) be a diffeomorphism between two open subsets of \( \mathbb{R}^n \). To simplify the notation we assume that \( P = 0 \) and that \( f(P) = 0 \). Furthermore, by restriction to an open ball we might as well assume that \( U \) is convex. We write \( D := D f_0 \). Thus the linearization of \( f \) at \( P = 0 \) is given by the map \( \lambda(x) = D x \). Since \( f \) is in particular a local diffeomorphism a \( P = 0 \) we know by the chain rule, see Proposition 6.15 and 6.17 that \( D \) is an invertible matrix.

Since \( U \subset \mathbb{R}^n \) is convex we obtain from Proposition 6.16 that there exists a smooth map \( A: U \rightarrow M(n \times n, \mathbb{R}) \) such that \( A(0) = D f_0 \) and such that \( f(x) = A(x) \cdot x \) for all \( x \in U \). Since \( \det(A(0)) \neq 0 \) we see that there exists an \( r > 0 \) such that \( \det(A(x)) \neq 0 \) for all \( x \in B^n_\epsilon(0) \). This implies that the map
\[
B^n_\epsilon(0) \times [0, 1] \rightarrow \mathbb{R}^n
\]
\[
(x, t) \mapsto A(x \cdot (1 - t)) \cdot x
\]
is a homotopy of the maps \( f \) and \( \lambda \) as maps \((B^n_\epsilon(0), B^n_\epsilon \setminus \{0\}) \rightarrow (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})\) of pairs of topological spaces.

We adopt the following notation:

**Notation.**

(1) Given a matrix \( P \in \text{GL}(n, \mathbb{R}) \) we denote by \( \rho(P): \mathbb{R}^n \rightarrow \mathbb{R}^n \) the map given by \( x \mapsto P \cdot x \).

(2) Given a non-zero real number \( r \) we denote its sign by \( \text{sign}(r) \in \{-1, +1\} \).

\footnote{By Lemma 45.15 we know that \( H_n(W, W \setminus \{0\}) \cong \mathbb{Z} \), thus it makes sense to talk of the degree of an automorphism of \( H_n(W, W \setminus \{0\}) \).}
Lemma 45.18. Let \( n \in \mathbb{N} \). Given \( A \in \text{GL}(n, \mathbb{R}) \) we have
\[
\deg \left( \rho(A)_* : H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \to H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \right) = \text{sign}(\det(A))
\]
and given \( A \in \text{O}(n) \) we have
\[
\deg \left( \rho(A)_* : H_n(B^n, B^n \setminus \{0\}) \to H_n(B^n, B^n \setminus \{0\}) \right) = \text{sign}(\det(A)).
\]

Proof of Lemma 45.18. For simplicity we only prove the first statement of the lemma. Thus let \( A \in \text{GL}(n, \mathbb{R}) \). We start out by picking an orthogonal matrix \( B \in \text{O}(n) \) such that \( \text{sign}(\det(B)) = \text{sign}(\det(A)) \). Next we consider the following diagram

\[
\begin{array}{cccccc}
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & \xrightarrow{\text{id}} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & \xrightarrow{\partial} & H_{n-1}(\mathbb{R}^n \setminus \{0\}) & \xleftarrow{H_{n-1}(S^{n-1})} \\
\downarrow{\rho(A)} & & \downarrow{\rho(B)} & & \downarrow{\rho(B)} & \\
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & \xrightarrow{\text{id}} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & \xrightarrow{\partial} & H_{n-1}(\mathbb{R}^n \setminus \{0\}) & \xleftarrow{H_{n-1}(S^{n-1})} \\
\end{array}
\]

We make the following observations:

1. Since \( \text{sign}(\det(B)) = \text{sign}(\det(A)) \) we obtain from Lemma 2.65 (1) that there exists a path \([0, 1] \to \text{GL}(n, \mathbb{R}) \) from \( A \) to \( B \). Similar to the discussion on page 538 this path gives rise to a homotopy between \( \rho(A) \) and \( \rho(B) \). We obtain from Proposition 43.17 that \( \rho(A)_* = \rho(B)_* \), in other words, the square to the left commutes.

2. The square in the middle commutes by the naturality of the connecting homomorphism, see Corollary 43.16.

3. The horizontal maps to the right are induced by the inclusion \( S^{n-1} \to \mathbb{R}^n \setminus \{0\} \). It is clear that the square to the right commutes.

Now we see that

\[
\deg \left( H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \xrightarrow{\rho(A)} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \right) = \deg(\rho(B) : S^{n-1} \to S^{n-1}) = \text{det}(B) = \text{sign}(\det(B)) = \text{sign}(\det(A)).
\]

by the above commutative diagram together with Lemma 45.9 (2)

\[
\text{by Lemma 45.11 (6) since } B \in \text{O}(n) \text{ we have } \text{det}(B) \in \{ \pm 1 \}
\]

Proof of Proposition 45.16 (*). Let \( W \) be a subset of \( \mathbb{R}^n \) and let \( A \) be a subset of \( W \) such that the origin 0 is contained in the interior. Let \( f : A \to W \) be an injective map with \( f(0) = 0 \). We suppose that \( f \) is a local diffeomorphism at 0. Recall that this means that there exists an open neighborhood \( U \) of 0 that is contained in \( A \) and an open neighborhood \( V \) of 0 that is contained in \( B \) such that the map \( f : U \to V \) is a diffeomorphism.

We start out with the following preparations.

1. We set
\[
\epsilon := \begin{cases} 
+1, & \text{if } f \text{ is orientation-preserving at } 0, \\
-1, & \text{if } f \text{ is orientation-reversing at } 0. 
\end{cases}
\]

Note that by Lemma 6.44 we have \( \epsilon = \text{sign}(\det(Df_0)) \).
(2) By Lemma 45.17 there exists an open neighborhood $U'$ of 0 that is contained in $U$ such that the restrictions of $f$ and $\rho(Df_0)$ to maps $(U', U' \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$ are homotopic.

Now we consider the following diagram

$$
\begin{array}{ccc}
H_n(W, W \setminus \{0\}) & \cong & H_n(A, A \setminus \{0\}) \\
\downarrow & & \downarrow \cong \\
H_n(U', U' \setminus \{0\}) & \cong & H_n(U, U \setminus \{0\}) \\
\downarrow \cong & & \downarrow \cong \\
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & \cong & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\
\end{array}
$$

We continue with the following clarifications and observations:

(3) The undecorated maps are induced by inclusions. All of them are isomorphisms by the Excision Theorem 43.20.

(4) It follows from (2) and Proposition 43.17 that the central square commutes. All other regions of the diagram commute by the functoriality of homology groups.

(5) By Lemma 45.18 the bottom horizontal map equals multiplication by $\text{sign} \det(Df_0)$.

(6) It follows from all of the above that the top map is given by multiplication by $\epsilon$. But that is precisely what we wanted to show.

45.6. The local degree II. As mentioned in the previous section, we want to develop some tools for addressing the following problem: given a map $f: X \to Y$ between topological spaces, how can we determine the induced map on homology? For example, let us consider the following question.

**Question 45.19.** Let $f$ be a complex polynomial of degree $\geq 1$. By Exercise 2.33 we know that the map

$$
\Theta(f): S^2 = \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\} = S^2
$$

$$
z \mapsto \begin{cases} 
  f(z), & \text{if } z \in \mathbb{C}, \\
  \infty, & \text{if } z = \infty
\end{cases}
$$

is continuous. What is the induced map on homology, i.e. what is the degree of $\Theta(f)$?

In this section we will develop a method for determining the degree of a self-map of a sphere which can be applied in many “reasonable” cases. In particular we will be able to answer Question 45.19. The answer will give us an alternative proof of the Fundamental Theorem of Algebra.

We start out with the following observation.
Observation. Let \( n \geq 1 \). Now let \( x \in S^n \) be a point and let \( U \) be a neighborhood of \( x \) in \( S^n \). We have isomorphisms

\[
H_n(S^n) \xrightarrow{\sim} H_n(S^n, S^n \setminus \{x\}) \xleftarrow{\sim} H_n(U, U \setminus \{x\}).
\]

Throughout this section will use frequently that these maps are isomorphisms.

Definition. We say a map \( f: X \to Y \) between two topological spaces is **nice at a point** \( x \in X \) if there exists a neighborhood \( U \) of \( x \) such that for all \( x' \neq x \) in \( U \) we have \( f(x') \neq f(x) \). We refer to such a neighborhood as a **nice neighborhood of** \( x \).

Examples.

1. Let \( f: X \to Y \) be a map between two topological spaces and let \( x \in X \). If \( U \) is a neighborhood such that \( f|_U \) is injective, then \( U \) is evidently a nice neighborhood of \( x \).

2. We consider the functions

\[
f: \mathbb{R} \to \mathbb{R} \quad \text{and} \quad g: \mathbb{R} \to \mathbb{R}
\]

\[
f(t) = t^2 \quad \text{and} \quad g(t) = \begin{cases} 0, & \text{if } t = 0, \\ t \sin(\frac{1}{t}), & \text{if } t \neq 0. \end{cases}
\]

For the function \( f \) every point on \( \mathbb{R} \) is nice, in fact for \( x < 0 \) we can take \( U = (-\infty, 0) \), for \( x > 0 \) we can take \( U = (0, \infty) \) and for \( x = 0 \) we can take \( U = \mathbb{R} \). On the other hand it is straightforward to see that for the function \( g \) the point \( x = 0 \) is not nice.

The following is the key definition of this section.

Definition. Let \( n \geq 1 \), let \( f: S^n \to S^n \) be a map and let \( x \in S^n \) be a nice point. Let \( U \) be a nice neighborhood of \( x \). The **local degree of** \( f \) **at the point** \( x \) is defined as the degree of the homomorphism

\[
H_n(S^n) \xrightarrow{\sim} H_n(S^n, S^n \setminus \{x\}) \xleftarrow{\sim} H_n(U, U \setminus \{x\}) \xrightarrow{f_*} H_n(S^n, S^n \setminus \{f(x)\}) \xleftarrow{\sim} H_n(S^n).
\]

We denote this local degree by \( \deg(f, x) \).

Lemma 45.20. The local degree \( \deg(f, x) \) of a map \( f: S^n \to S^n \) at a nice point \( x \in S^n \) is well-defined.

Proof. Let \( n \geq 1 \), let \( f: S^n \to S^n \) be a map and let \( x \in S^n \) be a nice point. Let \( U, U' \) be nice neighborhoods of \( x \). After replacing \( U' \) by \( U \cap U' \) we can without loss of generality

\[\text{Note that } f \text{ induces a map of pairs } (U, U \setminus \{x\}) \to (S^n, S^n \setminus \{f(x)\}) \text{ since } U \text{ is nice.}\]
assume that $U' \subset U$. We consider the following commutative diagram

$$
\begin{array}{ccc}
H_n(S^n) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{x\}) \\
\cong & & \cong \\
H_n(U', U' \setminus \{x\}) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{f(x)\}) \\
\cong & & \cong \\
H_n(U, U \setminus \{x\}) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{f(x)\}).
\end{array}
$$

All the non-decorated maps are induced by inclusions. It is clear that the diagram commutes. Also note that the left vertical map is an isomorphism by the Excision Theorem [43.20]. It follows immediately from these observations that the local degree defined using $U'$ agrees with the local degree defined using $U$. □

**Lemma 45.21.** Let $n \geq 1$, let $f : S^n \rightarrow S^n$ be a map and let $x \in S^n$. If $f$ is a homeomorphism, then for every nice point $x \in S^n$ we have

$$
\deg(f, x) = \deg(f).
$$

**Proof.** From the hypothesis that $f$ is a homeomorphism we obtain that $U = S^n$ is a nice neighborhood for $x$. We take $V = S^n$ and we consider the following diagram

$$
\begin{array}{ccc}
H_n(S^n) & \xrightarrow{f_*} & H_n(S^n) \\
\cong & & \cong \\
H_n(S^n, S^n \setminus \{x\}) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{f(x)\}).
\end{array}
$$

The statement now follows immediately from the definitions. □

The following proposition can often be used to determine the local degree of a map.

**Proposition 45.22.** Let $f : S^n \rightarrow S^n$ be a map with $n \geq 1$ and let $x \in S^n$.

1. If $f$ is a local homeomorphism around $x$, then $x$ is nice and
   $$
   \deg(f, x) = \pm 1.
   $$

2. If $f$ is a local diffeomorphism around $x$, then $x$ is nice and
   $$
   \deg(f, x) = \begin{cases} 
   1, & \text{if } f \text{ is orientation-preserving at } x, \\
   -1, & \text{if } f \text{ is orientation-reversing at } x.
   \end{cases}
   $$

**Example.** We consider the map $f : S^1 \rightarrow S^1$ given by $(x, y) \mapsto (x, |y|)$. It follows from Proposition 45.22 (2) that for every point on the open upper semicircle the local degree is $+1$ and that for every point on the open lower semicircle the local degree is $-1$. In Exercise 45.10 we will prove that the local degree at the points $\pm 1$ is in both cases zero.

Now we can provide the proof of Proposition 45.22.

**Proof of Proposition 45.22.** Let $f : S^n \rightarrow S^n$ be a map with $n \geq 1$ and let $x \in S^n$.

1. Suppose that $f$ is a local homeomorphism around the point $x$. Recall that this means that there exists an open neighborhood $U$ of $x$ and an open neighborhood $V$ of $f(x)$...
such that \( f: U \to V \) is a homeomorphism. This implies in particular that \( U \) is nice. Now we consider the following rather simple diagram:

\[
\begin{array}{cccc}
H_n(S^n) & \cong & H_n(S^n, S^n \setminus \{x\}) & \cong H_n(U, U \setminus \{x\}) \twoheadrightarrow H_n(S^n, S^n \setminus \{f(x)\}) \cong H_n(S^n).
\end{array}
\]

\[
\begin{array}{c}
\downarrow_{f^*}
\end{array}
\]

\[
\begin{array}{c}
H_n(V, V \setminus \{f(x)\})
\end{array}
\]

It is clear that the diagram commutes. Since the map \( f \) restricts to a homeomorphism \((U, U \setminus \{x\}) \to (V, V \setminus \{f(x)\})\) of pairs we see that the vertical map is an isomorphism. Furthermore the diagonal map is an isomorphism by the Excision Theorem [43.20]. Thus we see that all horizontal maps are isomorphism. This implies immediately that \( \text{deg}(f, x) = \pm 1 \).

(2) Let \( f: S^n \to S^n \) be a map with \( n \geq 1 \) and let \( x \in S^n \). We assume that \( f \) is a local diffeomorphism around \( x \). By Lemma 3.32 we know that there exists an \( A \in \text{SO}(n-1) \) with \( A \cdot f(x) = x \). By Exercise 6.28 we know that the map \( z \mapsto A \cdot z \) is orientation-preserving and by Lemma 45.11 (6) we know that \( \text{deg}(z \mapsto A \cdot z) = 1 \). Thus, after replacing \( f \) by the \( z \mapsto A \cdot f(z) \), we might as well assume that \( f(x) = x \).

We make a few further preparations.

(a) We pick a chart \( \Phi: V \to W \) around \( x \).

(b) Since \( f \) is a local diffeomorphism around \( x \) there exists an open neighborhood \( U \) of \( x \) such that \( f: U \to f(U) \) is a diffeomorphism. Note that after possibly replacing \( U \) by \( U \cap V \cap f^{-1}(V) \) we can assume that \( U \subset V \) and \( f(U) \subset V \).

(c) We set \( y := \Phi(x) \).

(d) We set \( \epsilon := \begin{cases} 
1, & \text{if } f \text{ is orientation-preserving at } x, \\
-1, & \text{if } f \text{ is orientation-reversing at } x.
\end{cases} \)
Next we consider the following diagram

\[
\begin{array}{c}
\xymatrix{
H_n(S^n) \ar[r]^{\cdot \deg(f,x)} & H_n(S^n) \\
H_n(S^n, S^n \setminus \{x\}) \ar[r]^{\cong} \ar[d]_{\cong} & H_n(U, U \setminus \{x\}) \ar[r]^{f_*} \ar[d]_{\Phi_*} & H_n(S^n, S^n \setminus \{x\}) \ar[d]_{\Phi_*} \\
H_n(W, W \setminus \{y\}) \ar[r]^{\cong} \ar[d]_{\Phi_*} & H_n(\Phi(U), \Phi(U) \setminus \{y\}) \ar[r]^{(\Phi \circ f \circ \Phi^{-1})_*} & H_n(W, W \setminus \{y\}).
\end{array}
\]

We make the following observations and clarifications.
(a) As usual the undecorated maps are induced by inclusions.
(b) The top rectangle commutes by the definition of \(\deg(f, x)\). The middle regions of the diagram commute by the functoriality of relative homology. Finally, note that \(\Phi \circ f \circ \Phi^{-1}\) is orientation-preserving at \(y\) if and only if \(f\) is orientation-preserving at \(x\). Thus we see that the bottom part of the diagram commutes by Proposition 45.16.
(c) It follows from the above together with Lemma 45.9 (2) that \(\deg(f, x) = \epsilon\).

Using the following proposition we can now determine the degree of a map from local degrees.

**Proposition 45.23.** Let \(f: S^n \to S^n\) be a map where \(n > 0\) and let \(y \in S^n\) such that \(f^{-1}(\{y\})\) consists of finitely many points \(x_1, \ldots, x_m\). Then

\[
\deg(f) = \sum_{i=1}^{m} \deg(f, x_i).
\]

**Remark.** In Proposition 87.32 we will generalize Proposition 45.23 to a more general setting.

**Proof (\(*\).** Since \(S^n\) is Hausdorff we can choose disjoint open neighborhoods \(U_1, \ldots, U_m\) for \(x_1, \ldots, x_m\) and we choose an open neighborhood \(V\) of \(y\) such that \(f(U_i) \subset V\) for \(i = 1, \ldots, m\). We consider the following diagram:

---

733 Does there always exist such a \(y\)?
734 The hypothesis implies immediately that all the points \(x_1, \ldots, x_m\) are nice, hence the local degrees are defined.
We make the following clarifications and observations:

1. The maps \( r_i, s_i, p_i \) and \( \iota \) are the maps induced by the obvious inclusions of pairs of topological spaces. Furthermore the maps \( f_i: (U_i, U_i \setminus \{x_i\}) \to (S^n, S^n \setminus \{y\}) \) are given by the restriction of \( f \) to \( U_i \).

2. It follows easily from the functoriality of relative homology groups that the diagram commutes.

3. The argument on page 1092 shows that the diagonal map \( \bigoplus_{i=1}^m s_i \) to the bottom left is an isomorphism.

4. It follows from the Excision Theorem 43.19 that the vertical map \( \iota \) and that the maps \( r_i \) are isomorphisms.

5. It follows from the fact that the diagram commutes together with (3) and (4) that the horizontal map \( \bigoplus_{i=1}^m p_i \) is also an isomorphism.

Since \( \iota: H_n(S^n) \to H_n(S^n, S^n \setminus \{y\}) \) is an isomorphism it suffices to prove the following claim.

**Claim.** We have

\[
\iota(f_*([S^n])) = \sum_{i=1}^m \deg(f, x_i) \cdot \iota([S^n]) \in H_n(S^n, S^n \setminus \{y\}).
\]
We verify the claim by performing the following calculation:

\[
\text{by Lemma } \ref{11.12} (1) \text{ and } (2) \text{ and since each } r_i \text{ is an isomorphism.}
\]

\[
\mathfrak{R}(f_\ast([S^n])) = \left( \bigoplus_{i=1}^m f_{i\ast} \circ \left( \bigoplus_{i=1}^m r_{i\ast} \right) \mathfrak{R} \right) ([S^n]) = \left( \bigoplus_{i=1}^m f_{i\ast} \right) \circ \left( \bigoplus_{i=1}^m r_{i\ast}^{-1} \circ r_i \right) ([S^n])
\]

\[
\begin{aligned}
&\left( \bigoplus_{i=1}^m f_{i\ast} \right) \left( \sum_{i=1}^m (r_i^{-1} \circ \mathfrak{R}) \right) ([S^n]) = \sum_{i=1}^m (f_i \circ r_i^{-1} \circ \mathfrak{R}) ([S^n]) = \sum_{i=1}^m \deg(f, x_i) \cdot \mathfrak{R} ([S^n]).
\end{aligned}
\]

\[
\text{definition of direct sum of type (II) definition of direct sum of type (I) definition of local}
\]

\[
\text{of homomorphisms, see page } \ref{1090} \text{ of homomorphisms, see page } \ref{1090} \text{ degree, see page } \ref{1191} \]

\[
\square
\]

**Examples.**

1. The map \( f : S^1 \to S^1 \) given by \( f(x, y) = (x, |y|) \) that is illustrated in Figure 760 has degree zero by Lemma 45.11. Taking preimages of points in \( S^1 \) one sees that in each case the sum of the local degrees of the preimages is zero.

2. In Figure 762 we sketch a map \( f : S^1 \to S^1 \) and we choose several points \( y \in S^1 \). We use Proposition 45.22 to determine the various degrees at the given points.\(^{735}\) We see that the number of preimages and the degrees at the points in the preimages vary, but in all three cases the sum of the degrees at the points in the preimage is the same.

3. We consider the map

\[
f : S^1 \to S^1 \\
z \mapsto z^m
\]

\(^{735}\)Why is in the third example the degree \( \deg(f, x_1) \) equal to zero?
\[ j \in \{1, \ldots, m\} \text{ we have} \]
\[ \deg(f, x_j) = \begin{cases} 1, & \text{if } m > 0, \\ -1, & \text{if } m < 0. \end{cases} \]

Thus it follows from Proposition 45.23 that \( \deg(f) = |m| \cdot \text{sign}(m) = m \). If \( m = 0 \), then \( \deg(f) = 0 \). The easiest way to see this is to take \( y = -1 \), since in this case the preimage is the empty set.

As promised, we can now provide an answer to Question 45.19:

**Proposition 45.24.** Let \( f \) be a complex polynomial of degree \( \geq 1 \). The degree of the map
\[ \Theta(f): S^2 = \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\} = S^2 \]
\[ z \mapsto \begin{cases} f(z), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \]
equals the degree of the polynomial \( f \).

**Sketch of proof.** Let \( f \) be a complex polynomial of degree \( n \geq 1 \). We also consider the polynomial \( g(z) = z^n \). We calculate that

by Lemma 45.11 (3), since by Exercise 18.5 we know that \( \Theta(f) \) and \( \Theta(g) \) are homotopic
\[ \deg(\Theta(f)) = \deg(\Theta(g(z) = z^n)) = n. \]

follows from Proposition 45.23 and Proposition 45.22 see Exercise 45.7

More excitingly, we can provide a new proof for the Fundamental Theorem of Algebra.

**Theorem 16.21.** (Fundamental Theorem of Algebra) \( \diamond \) Every nonconstant polynomial in \( \mathbb{C} \) has a zero in \( \mathbb{C} \).

**Proof.** Let \( f \) be a nonconstant polynomial with complex coefficients. In other words, \( f \) is a complex polynomial of degree \( n \geq 1 \). By Proposition 45.24 we know that the degree of the self-map \( \Theta(f) \) of \( S^2 = \mathbb{C} \cup \{\infty\} \) equals \( n \geq 1 \). By Lemma 45.11 (2) this implies that \( \Theta(f): \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\} \) is surjective, in particular 0 lies in the image of \( \Theta(f) \). Since \( \Theta(f)(\infty) = \infty \) we see that 0 lies in the image of \( f: \mathbb{C} \to \mathbb{C} \cup \{\infty\} \). In other words, there exists a \( z \in \mathbb{C} \) with \( \Theta(f)(z) = 0 \).

45.7. **Proof of Proposition 45.5 (\( \ast \)).** For the tenacious reader we now provide the long-delayed proof of Statements (2) and (3) of Proposition 45.5. For the convenience of the reader we recall the relevant two statements.

**Proposition 45.5.** Let \( n \in \mathbb{N} \). We denote by \( f: (\Delta^n, \partial \Delta^n) \to (\bar{B}^n, S^{n-1}) \) the homeomorphism from Lemma 41.1 and we denote by \( g: \bar{B}^n / S^{n-1} \to S^n \) the homeomorphism from page 182 We set \( * := g([S^{n-1}]) \). We consider the following sequence of maps:

\[ H_n(\Delta^n, \partial \Delta^n) \xrightarrow{f_*} H_n(\bar{B}^n, S^{n-1}) \xrightarrow{g_*} H_n(\bar{B}^n / S^{n-1}, [S^{n-1}]) \xrightarrow{\rho_*} H_n(S^n, *) \cong H_n(S^n). \]
The following statements hold:

(2) We have
\[ f_*(\mathrm{id}_{\Delta^n}) = (-1)^n \cdot \text{standard generator } [B^n] \text{ of } H_n(B^n, S^{n-1}). \]
defined by the condition \( \partial([B^n]) = [S^{n-1}] \), see page 1176

(3) The standard generator \([B^n]\) of \(H_n(B^n, S^{n-1})\) has the same image in \(H_n(S^n, \ast)\) as the standard generator \([S^n]\) of \(H_n(S^n)\).

Notation. Let \(n \in \mathbb{N}_0\).

(1) Given \(P \in S^n\) we denote by \([S^n])_P\) the image of the standard generators \([S^n]\) under the map \(H_n(S^n) \to H_n(S^n, S^n \setminus \{P\})\).

(2) Let \(\Psi : \Delta^n \to \Delta_n\) be \(\Delta^n \to \Delta\) and \(\Delta^n \to \Delta\) the obvious projection. In Lemma 41.1 \(1\) we saw that \(\Psi\) is a homeomorphism. We write \(\Phi := \Psi^{-1} : \Delta_n \to \Delta^n\).

(3) Let \(\alpha : \Delta^n \to S_{\geq 0} \subset S^n\) and \(\beta : \Delta^n \to S_{\leq 0} \subset S^n\) be the two maps defined on page 1173.

(4) We denote by \(N = (0, \ldots, 0, 1)\) the North Pole of \(S^n\).

The proof of Proposition 45.3 requires the following lemma.

Lemma 45.25. (*) Let \(k \in \mathbb{N}_0\) and let \(f : \Delta^k \to S^k\) be an injective map such that the map \(f \circ \Phi : \Delta_k \to S^k\) is a smooth embedding.\(^{736}\) Then for every \(Q \in f(\Delta^k)\) we have the following equality in \(H_k(S^k, S^k \setminus \{Q\})\):

\[ [f_*(\mathrm{id}_{\Delta^n})] = \epsilon \cdot [S^k]_Q \text{ where } \epsilon = \begin{cases} +1, & \text{if } f \circ \Phi : \Delta_k \to S^k \text{ is orientation-preserving,} \\ -1, & \text{if } f \circ \Phi : \Delta_k \to S^k \text{ is orientation-reversing.} \end{cases} \]

Proof of Lemma 45.25 (*). First we deal with the special case that \(Q = N\) and that \(f(\Delta^k) \subset S^k_{\geq 0}\). We consider the following diagram:

\[ \begin{array}{cccccc}
H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{0\}) & \xrightarrow{\epsilon} & H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{0\}) \\
i_* & \approx & j_* \\
H_k(t_P(\Delta_k), t_P(\Delta_k) \setminus \{0\}) & \xrightarrow{\Psi_0^{-1} \circ f \circ \Psi^{-1}} & H_k(t_X(\Delta_k), t_X(\Delta_k) \setminus \{0\}) \\
i_* \circ t_P \approx & \approx & j_* \circ t_X \\
H_k(\Delta_k, \partial \Delta_k) & \xrightarrow{\Psi_*} & H_k(S^k, S^k \setminus \{N\}) \\
\approx & \approx & \approx \\
H_k(\Delta_k, \partial \Delta_k) & \xrightarrow{\Psi_*} & H_k(\Delta_k, \partial \Delta_k) \\
\end{array} \]

\(^{736}\)Note that \(\Delta_k\) is an open subset of \(\mathbb{R}^k\), in particular, following the convention established on page 296 we will view it as an oriented \(k\)-dimensional smooth manifold.
We make the following clarifications and observations:

1. We set $P := \Psi(f^{-1}(N)) \in \overset{\circ}{\Delta}_k$ and $X := \Psi(\alpha^{-1}(N)) \in \overset{\circ}{\Delta}_k$. Evidently we have the equality $(f \circ \Psi^{-1})(P) = N = (\alpha \circ \Psi^{-1})(X)$.
2. Given $v \in \mathbb{R}^k$ we denote by $t_v : \mathbb{R}^k \to \mathbb{R}^k$ the map that is given by $x \mapsto x - v$.
3. The maps $i : t_P(\Delta_k) \to \mathbb{R}^k$ and $j : t_X(\Delta_k) \to \mathbb{R}^k$ are the inclusion maps.
4. The maps $\mu : (\Delta_k, \partial \Delta_k) \to (\Delta_k, \Delta_k \setminus \{P\})$ and $\mu : (\Delta_k, \partial \Delta_k) \to (\Delta_k, \Delta_k \setminus \{X\})$

are the inclusion maps of pairs of topological spaces.
5. Since $f(\Delta^k) \subset S^k_{\geq 0}$ we have in particular that $f(\Delta^k) \subset \alpha(\Delta^k)$ which means that the map $\alpha^{-1} \circ f$ is actually defined.
6. One can easily verify that $\alpha \circ \Psi^{-1}$ is orientation-preserving. As mentioned on page 299 the translation maps $t_v$ are also orientation-preserving. Therefore we see that the map $t_{X}^{-1} \circ \Psi \circ \alpha^{-1} \circ \Psi^{-1} \circ t_P$ is orientation-preserving if and only if the map $f \circ \Psi^{-1} = f \circ \Phi$ is orientation-preserving. Thus we obtain from Proposition 45.16 that the top square commutes.
7. The second square from the top, the top triangle and the two triangles to the left and right commute basically by definition.
8. It is straightforward to see that the maps $i \circ t_P \circ \Psi$ and $j \circ t_X \circ \Psi$ are homotopic as maps of pairs $(\Delta^k, \partial \Delta^k) \to (\mathbb{R}^k, \mathbb{R}^k \setminus \{0\})$. In particular we obtain from this observation together with Proposition 43.17 that the two sequences of vertical maps on the left and on the right are actually the same map.
9. Using Corollary 43.18 (2a) and using the Excision Theorem 43.20 one can show fairly easily that all the vertical maps are isomorphisms and we see that the upper diagonal maps are isomorphisms. Since the triangles to the left and right commute we see that all diagonal maps are isomorphisms.
10. It follows from (6), (7), (8) and (9) that the bottom triangle also commutes.

Now we are basically done with the proof for our special case. Indeed we see that

$$[f_\epsilon(\text{id}_{\Delta^k})] = \epsilon \cdot [\alpha_\epsilon(\text{id}_{\Delta^k})] = \epsilon \cdot [\alpha] = \epsilon \cdot [\alpha - \beta]_Q = \epsilon \cdot [S^k]_Q.$$

by (10) since $\beta = 0 \in C_k(S^n, S^n \setminus \{N\})$ definition of $[S^k]$

Now we still need to deal with the general case. In all likelihood few readers will have made it so far. So let us just sketch the ingredients for reducing the general case to the above special case:

1. By Lemma 3.32 (4) there exists an $A \in SO(n+1)$ with $A \cdot Q = N$. By the discussion on page 338 the map $\varphi : S^n \to S^n$ that is given by $\varphi(x) = A \cdot x$ is homotopic to the identity.
2. Every map $\varphi : \Delta^k \to S^k$ which contains $N$ in its image is homotopic to some map $\psi : \Delta^k \to S^\leq_{\geq 0}$ into the upper hemispheres which has otherwise “the same properties”.

We leave it to the reader to fill in the details.

Now we can provide the proof of Proposition 45.5 (2) and (3).

Proof of Proposition 45.5 (2) and (3).
(2) We need to show that \( f_\ast([id_{\Delta^n}]) = (-1)^n \cdot [B^n] \). To do so we recall the following maps:

(a) As on page 1077 we denote by \( i = i_{n1} : \Delta^n \to \Delta^n \) the \( n \)-th face map that is given by \( i(t_0, \ldots, t_{n-1}) = (t_0, \ldots, t_{n-1}, 0) \).

(b) Below we will denote by \( \jmath \) the natural map from reduced homology to relative homology that we introduced in Lemma 43.14.

We consider the following diagram

\[
\begin{array}{cccccc}
H_n(\Delta^n, \partial \Delta^n) & \xrightarrow{\partial} & \tilde{H}_{n-1}(\partial \Delta^n) & \xrightarrow{\jmath} & H_{n-1}(\partial \Delta^n, \Lambda) & \xleftarrow{\cong} & H_{n-1}(\Delta^{n-1}, \partial \Delta^{n-1}) \\
\downarrow{f} & & \downarrow{f} & & \downarrow{f} & & \downarrow{(f \circ i)\ast} \\
H_n(B^n, S^{n-1}) & \xrightarrow{\partial} & \tilde{H}_{n-1}(S^{n-1}) & \xrightarrow{\jmath} & H_{n-1}(S^{n-1}, S^{n-1}\setminus\{N\}) & \xleftarrow{\cong} & H_1(\Delta^{n-1}, \partial \Delta^{n-1}).
\end{array}
\]

(Here we put on top and above of the various groups the elements which will play a role in the subsequent argument.) Note that the diagram commutes by Corollary 43.16 (2) and Lemma 43.14 (1). Now we see that we have the following equalities in \( H_{n-1}(S^{n-1}, S^{n-1}\setminus\{N\}) \):

since the diagram \( \jmath(\partial(id_{\Delta^n})) = (-1)^n \cdot i_\ast(id_{\Delta^{n-1}}) \in C_{n-1}(\partial \Delta^n, \Lambda) \) since \( \partial(id_{\Delta^n}) \) are all other summands of \( \partial(id_{\Delta^n}) \) are zero in \( C_{n-1}(\partial \Delta^n, \Lambda) \)

\[
\jmath(\partial(f_\ast([id_{\Delta^n}]))) = f_\ast(\jmath(\partial(id_{\Delta^n}))) = f_\ast((-1)^n \cdot i_\ast ([id_{\Delta^{n-1}}])) = (-1)^n \cdot [\alpha] = (-1)^n \cdot (f \circ i)_\ast([id_{\Delta^{n-1}}]) = (-1)^n \cdot \alpha_\ast([id_{\Delta^{n-1}}])
\]

we leave it to the reader to verify that \( f \circ i : \Delta^n \to S^{n-1} \) and \( \alpha : \Delta^{n-1} \to S^{n-1} \) are both orientation-preserving, thus the equality follows from Lemma 45.25

\[
((-1)^n \cdot ([\alpha - \beta]) = (-1)^n \cdot \jmath([S^{n-1}]) = (-1)^n \cdot \jmath(\partial(B^n)).
\]

As discussed earlier, by the various long exact sequences we know that the maps \( \partial \) and \( \jmath \) are both isomorphisms. Thus we obtain from the above the desired equality \( f_\ast([id_{\Delta^n}]) = (-1)^n \cdot [B^n] \).

(3) We consider the following commutative diagram:

\[
H_n(\Delta^n, \partial \Delta^n) \xrightarrow{f} H_n(B^n, S^{n-1}) \xrightarrow{\cong} H_n(B^n/S^{n-1}, [S^{n-1}]) \xrightarrow{g_\ast} H_n(S^n, *) \xlongleftarrow{\cong} H_n(S^n, S^n \setminus \{-*\}).
\]

Let \( \Phi : \Delta_n \to \Delta^n \) be the map that we introduced above. One can easily verify that the map \( g \circ f \circ \Phi : \Delta_n \to S^n \) is orientation-preserving if and only if \( n \) is even. This observation, together with Lemma 45.25 implies that the image of \([id_{\Delta^n}]\) in \( H_n(S^n, S^n \setminus \{-*\}) \) under the diagonal map agrees with \([S^n]_{-*} \). Since the vertical map is an isomorphism we obtain the desired equality. \( \blacksquare \)
Exercises for Chapter 45

Exercise 45.1. Let \( n \in \mathbb{N}_0 \) and let \( P \in \Delta^n \). Show that \( H_n(\Delta^n, \Delta^n \setminus \{P\}) = \mathbb{Z} \cdot [\text{id}_{\Delta^n}] \).

Hint. Make use of Lemma 45.2.

Exercise 45.2. Let \( n \in \mathbb{N} \). Let \( \rho: \Delta^n \to \Delta^n \) be the map that swaps the first two coordinates of \( \Delta^n \). Show that the induced map \( \rho_*: H_n(\Delta^n, \partial \Delta^n) \to H_n(\Delta^n, \partial \Delta^n) \) is given by multiplication by \(-1\).

Hint. First prove the statement for \( n = 1 \). Then use an induction argument similar to the proof of Lemma 45.2 (2). Hereby you need to use the naturality of the connecting homomorphism of the long exact sequence in homology of a pair of topological spaces.

Exercise 45.3. For which \( n \in \mathbb{N} \) does there exist a singular simplex \( \sigma: \Delta^n \to S^n \) that represents a generator of \( H_n(S^n) \)?

Exercise 45.4. Let \( f: \mathbb{R}^n \to \mathbb{R}^n \) be a map with \( f(0) = 0 \), with \( f(\mathbb{R}^n \setminus \{0\}) \subset \mathbb{R}^n \setminus \{0\} \) and with \( f(S^{n-1}) \subset S^{n-1} \). Show that

\[
\deg(f_*: H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \to H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})) = \deg(f_*: H_{n-1}(S^{n-1}) \to H_n(S^{n-1})).
\]

Remark. The analogous statement also holds if we replace \( \mathbb{R}^n \) by \( B^n \).

Exercise 45.5.

(a) Let \( n \in \mathbb{N}_{\geq 2} \). Show that given any \( k \in \mathbb{N} \) there exists a map \( f: B^n \to B^n \) with \( f(S^{n-1}) \subset S^{n-1} \) such that

\[
\deg(f_*: H_n(B^n, S^n) \to H_n(B^n, S^n)) = k.
\]

(b) Show that the conclusion of (a) does not hold for \( n = 1 \).

Exercise 45.6. On \( S^{2k} \) we had found a vector field which vanishes at precisely two points. Does there exist a vector field on \( S^2 \) which vanishes on only one point?

Exercise 45.7. Let \( n \geq 1 \). We consider the complex polynomial \( g(z) = z^n \). Show that the degree of the map \( \Theta(g): S^2 \to S^2 \) equals \( n \).

Hint. Use Proposition 45.23 and Proposition 45.22.

Exercise 45.8. Let \( X \) be a topological space. Suppose that the suspension \( \Sigma(X) \) is a closed \( n \)-dimensional topological manifold. Show that \( X \) is a topological homology \( (n-1) \)-sphere, i.e. show that \( H_i(X) \cong H_i(S^{n-1}) \) for all \( i \in \mathbb{N}_0 \).

Remark. Also have a look at Exercise 45.9.

Exercise 45.9. Let \( n \in \mathbb{N}_{\geq 3} \) and let \( M \) be a 0-connected topological space with non-trivial fundamental group.
(a) Show that the suspension $\Sigma(M)$ is not an $n$-dimensional topological manifold.

Hint. There are many different approaches one can take. One possibility is to study the fundamental group of $\Sigma(M)$ and to study the fundamental group of $\Sigma(M)$ with some points removed, and to use Exercise 20.3.

(b) Show that the suspension $\Sigma(M)$ is not a topological manifold of any dimension.

Remark. In Exercise 45.8 we just showed that if $\Sigma(M)$ is a closed $n$-dimensional topological manifold, then $M$ is a topological homology $(n-1)$-sphere, i.e. $H_i(M) \cong H_i(S^{n-1})$ for all $i \in \mathbb{N}_0$. Together with (a) and the proof of the Poincaré Conjecture in all dimensions, see Chapter ?, this shows that if $n \in \mathbb{N}_{\geq 2}$ and if $M$ is a $0$-connected $n$-dimensional topological manifold such that $\Sigma(M)$ is a topological manifold, then $M$ is necessarily homeomorphic to $S^n$.

Exercise 45.10.

(a) We consider the map $f : S^1 \to S^1$ given by $(x, y) \mapsto (x, |y|)$. Show that the local degree at the point $-1$ is zero.

(b) Let $f : S^1 \to S^1$ be a map and let $z \in S^1$ be a nice point. Suppose that $\deg(f, z) = 1$. Does it follow that $f$ is a local homeomorphism at $z$? It suffices to give a short justification for your answer.

Exercise 45.11. Let $f = f(z)$ be a polynomial with complex coefficients of degree $\geq 1$. Let $\Theta(f)$ be the corresponding self-map of $S^2 = \mathbb{C} \cup \{\infty\}$ that we introduced on page 1190. Show that the local degree of $\Theta(f)$ at a root of $f(z)$ equals the multiplicity of the root.

Exercise 45.12. Let $n \in \mathbb{N}$ be even. Show that every map $f : \mathbb{R}P^n \to \mathbb{R}P^n$ has a fixed point.

Hint. Apply Lemma 29.11 to get a suitable map $\tilde{f} : S^n \to S^n$. If $\deg(\tilde{f}) \neq -1$, then we are basically done by Theorem 45.13. What can we do if $\deg(\tilde{f}) = -1$?

Exercise 45.13. Let $n \in \mathbb{N}_{\geq 2}$. In this exercise we identify $S^{n-1}$ with the equatorial sphere $\{(x, 0) \in S^n \mid x \in S^{n-1}\}$.

(a) Let $f : S^n \to S^n$ be a map with $f(S^n_{\geq 0}) \subseteq S^n_{\geq 0}$ and with $f(S^n_{\leq 0}) \subseteq S^n_{\leq 0}$. Show that $\deg(f : S^n \to S^n) = \deg(f : S^{n-1} \to S^{n-1})$.

(b) Let $f : S^n \to S^n$ be a map with $f(S^n_{\geq 0}) \subseteq S^n_{\geq 0}$ and with $f(S^n_{\leq 0}) \subseteq S^n_{\geq 0}$. Show that $\deg(f : S^n \to S^n) = -\deg(f : S^{n-1} \to S^{n-1})$.

Exercise 45.14. Let $X$ be a topological space. Given a homology class $\varphi \in H_k(X)$ we define

$$
\|\varphi\|_Z := \inf \left\{ \sum_{i=1}^n |a_i| \mid \sigma = \sum_{i=1}^n a_i \cdot \sigma_i \text{ is a cycle with } [\sigma] = \varphi \in H_k(X) \right\}.
$$

with $\sigma_i \neq \sigma_j$ for $i \neq j$

(a) Let $X$ be a path-connected topological space. Show that for any $\varphi \in H_1(X)$ we have $\|\varphi\|_Z = 1$.

(b) Let $n \in \mathbb{N}$. Determine $\|[S^n]\|_Z$.

Remark. The notation with the subscript ”$Z$” is used to distinguish this definition from the concept that we will introduce in Exercise 68.16.
Exercise 45.15. Let $f: S^n \to S^n$ be an orientation-preserving diffeomorphism. Show that $f$ is homotopic to the identity.

*Hint.* You can easily arrange that $f$ fixes say the North Pole $N = (0, \ldots, 0, 1)$. Now use Lemma 45.17 and push everything that is “awkward” into the South Pole.

Exercise 45.16. Given $z \in S^1$ we denote by $\Phi_z: S^2 \to S^2$ the map that is given by rotating $S^2$ along the $z$-axis by the angle $z$. The map

$$G: S^1 \times S^2 \mapsto S^1 \times S^2$$

$$(z, v) \mapsto (z, \Phi_z(v))$$

is called the *Gluck twist*. Show that the Gluck twist is homotopic to the identity.

*Hint.* The exercise builds on Exercise 45.15.

*Remark.* The Gluck twist is in so far remarkable as it is not diffeotopic to the identity. This non-trivial fact is proved in [Glu62, Chapter 5] and [Wall70, p. 232].

Exercise 45.17. Let $n \in \mathbb{N}$. Show that every vector field on $\overline{B}^n$ that points outwards on $S^{n-1}$ admits at least one zero in $\overline{B}^n$.

![Figure 763. Illustration for Exercise 45.17](image)

Exercise 45.18. Let $k, l \in \mathbb{Z}$. We consider the sphere $S^3 = \{(z, w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1\}$ and the self-map

$$f: S^3 \to S^3$$

$$(z, w) \mapsto (z^k, w^l).$$

Determine the degree of $f$.

Exercise 45.19. Let $X$ be a topological space with subsets $A, B, U, V$ and suppose that we have the following diagram of inclusion maps

$$\begin{array}{ccc}
A & \xrightarrow{i} & U \\
\downarrow{j} & & \uparrow{k} \\
V & \leftarrow{l} & B.
\end{array}$$

Suppose that the inclusion induced maps $i_{*}, j_{*}, k_{*}, l_{*}$ on the first homology groups are isomorphisms. Does it follow that $i_{*} \circ j_{*}^{-1} = k_{*} \circ l_{*}^{-1}: H_1(V) \to H_1(U)$?

Exercise 45.20. Let $n \in \mathbb{N}$ and let $f: S^n \times S^n \to S^n$ be a map. We pick $x_0, y_0 \in S^n$. We define the *bidegree* of $f$ as

$$\text{bideg}(f) := (p, q) \text{ where } p := \deg \left( S^n \xrightarrow{i} S^n \xrightarrow{f} f(x, y_0) \right) \text{ and } q := \deg \left( S^n \xrightarrow{y} S^n \xrightarrow{f} f(x_0, y) \right).$$
(a) Show that the definition not depend on the choice of \(x_0\) and \(y_0\).

(b) Let \(f: S^1 \times S^1 \to S^1\) be the map that is given by complex multiplication. Show that the bidegree of \(f\) equals \((1, 1)\).

Remark. If you already know quaternions, perform the same exercise for the map \(f: S^3 \times S^3 \to S^3\) that is given by quaternionic multiplication.

(c) Show that the map
\[
H_n(S^n) \oplus H_n(S^n) \xrightarrow{i \oplus j} H_n(S^n \times S^n) \xrightarrow{f} H_n(S^n)
\]
is of the form \(\varphi \oplus \psi \mapsto p \cdot \varphi + q \cdot \psi\).

**Exercise 45.21.** Let \(n \in \mathbb{N}\) and let \(G\) be a group that acts continuously on \(S^n\). We suppose that the action of \(G\) is free. Recall that according to the definition on page 185 this means that for every \(g \neq e\) and every \(x \in S^n\) we have \(g \cdot x \neq x\).

(a) Show that if \(n\) is even, then the map
\[
G \to \{\pm 1\} \\
g \mapsto \deg\left( \begin{array}{c} S^n \to S^n \\ x \mapsto g \cdot x \end{array} \right)
\]
is a monomorphism.

Remark. This exercise shows in particular that if a group admits a continuous free action on an even-dimensional sphere, then \(G\) has order at most 2. This gives in particular a complete answer to Question 16.8. We will give a different proof of this statement in Proposition 55.10.

(b) Show that the conclusion of (a) does not necessarily hold if \(n\) is odd.
46. The Mayer–Vietoris sequence and its applications

In this chapter we will state and prove the Mayer–Vietoris sequence for homology groups. It makes often allows us to compute the homology groups of a topological space from the homology groups of appropriate subspaces together with the knowledge of the nature of inclusion induced maps on homology.

The role of the Mayer–Vietoris sequence in homology theory is similar to the role of the Seifert–van Kampen Theorem [22.1] for fundamental groups. The Mayer–Vietoris sequence will give us the tool to compute the homology groups of many topological spaces that we are interested in. In particular we will determine the homology groups of $\mathbb{R}P^2$, the torus and the Klein bottle.

46.1. Split exact sequences. We already saw in Theorem [43.3] that homology groups of different topological spaces are sometimes related by a long exact sequence of homology groups. The Mayer–Vietoris sequence that we will introduce later on in this chapter is another instance of such a long exact sequence. Very often one ends up in the situation that one knows the homology groups of two out of three topological spaces and hopefully one knows something about maps between these homology groups, and given this data one would like to determine the homology groups of the third topological space from the long exact sequence. Algebraically the question is as follows: suppose we are given an exact sequence

$$
\ldots \to A_n \to B_n \to C_n \to A_{n-1} \to \ldots
$$

of abelian groups where we know the groups $A_n$ and $C_n$, can we determine the groups $B_n$ from this long exact sequence? The same question of course also arises when the roles of $A$, $B$ and $C$ are switched.

In this section we will study the simplest case, namely the case of a short exact sequence

$$
0 \to A \to B \to C \to 0.
$$

If we know $A$ and $C$, can we read “read off” $B$ from this short exact sequence? In general the answer is no. For example the short exact sequence

$$
0 \to \mathbb{Z}_2 \to B \to \mathbb{Z}_2 \to 0
$$

could be of the form

$$
0 \to \mathbb{Z}_2 \xrightarrow{x \mapsto (x,0)} \mathbb{Z}_2 \oplus \mathbb{Z}_2 \xrightarrow{(x,y) \mapsto y} \mathbb{Z}_2 \to 0
$$

but it could also be of the form

$$
0 \to \mathbb{Z}_2 \xrightarrow{x \mapsto 2x} \mathbb{Z}_4 \xrightarrow{x \mapsto x} \mathbb{Z}_2 \to 0.
$$

In this short section we will give a criterion for when the naive guess $B \cong A \oplus C$ is actually the correct answer.

**Definition.** We say that a short exact sequence

$$
0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0
$$

of (not necessarily abelian) groups splits, if there exists a splitting $s \colon C \to B$, i.e. a homomorphism $s \colon C \to B$ such that $p \circ s = \text{id}_C$.

---

\[73.7\] Are there any other possibilities for the isomorphism type of $B$?
For example the short exact sequence
\[ 0 \to \mathbb{Z} \xrightarrow{k \mapsto (k,0)} \mathbb{Z} \oplus \mathbb{Z}_n \xrightarrow{(k,l) \mapsto l} \mathbb{Z}_n \to 0 \]
splits, in fact a splitting is given by the map \( b \mapsto (0, b) \). On the other hand the short exact sequence
\[ 0 \to \mathbb{Z} \xrightarrow{k \mapsto nk} \mathbb{Z} \to \mathbb{Z}_n \to 0 \]
does not split.\[738\]

**Lemma 46.1.** Let
\[ 0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0 \]
be a short exact sequence of abelian groups. If \( C \) is a free abelian group, then the short exact sequence splits.

**Proof.** Let \( \{c_i\}_{i \in I} \) be a basis of the free abelian group \( C \). For each \( i \in I \) we choose a \( b_i \in B \) with \( p(b_i) = c_i \). By Lemma [19.1](#) there exists a unique homomorphism \( s: C \to B \) with \( s(c_i) = b_i \) for all \( i \). We have \((p \circ s)(c_i) = c_i\) for each \( c_i \). But then it follows from the uniqueness part of Lemma [19.1](#) that \( p \circ s = \text{id}_C \). The homomorphism \( s \) is thus indeed a splitting. \(\blacksquare\)

The following lemma gives two useful criteria for a short exact sequence to split.

**Lemma 46.2. (Splitting Lemma)** Let
\[ \{e\} \to A \xrightarrow{i} B \xrightarrow{p} C \to \{e\} \]
be a short exact sequence of groups. The following two statements are equivalent:

1. There exists a homomorphism \( t: B \to A \) such that \( t \circ i = \text{id}_A \).
2. There exists an isomorphism \( \Phi: B \to A \times C \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\{e\} & \xrightarrow{i} & A \\
& \searrow & \downarrow \cong \\
& & \Phi \\
& \nearrow & \uparrow \\
& & C \\
& \swarrow & \downarrow \\
& & A \times C \\
\end{array}
\]

where the lower left diagonal map is the obvious inclusion and the lower right diagonal map is the obvious projection map.

Furthermore, if \( B \) is abelian, then the above statements are also equivalent to the following statement:

3. The short exact sequence splits.

**Remark.** If \( B \) is not abelian, then the implication (3) \(\Rightarrow\) (1) of Splitting Lemma [46.2](#) does in general not hold. For example consider the sequence
\[ 0 \to \mathbb{Z}_3 \xrightarrow{\phi} S_3 \xrightarrow{\sigma} \mathbb{Z}_2 \to 0 \]
where \( S_3 \) is as always the permutation group on the three elements, where \( \phi: \mathbb{Z}_3 \to S_3 \) is the homomorphism given by \( \phi(1) = (1 2 3) \) and where \( \sigma: S_3 \to \mathbb{Z}_2 \) is the unique epimorphism.
from the permutation group $S_3$ onto $Z_2$. A splitting of $\sigma$ is given by $\varphi(1) = (1\ 2)$. Since $\sigma$ is also the only epimorphism from $S_3$ onto a non-trivial group we see that the sequence does not split, hence (1) is not satisfied.

Proof.

$(1) \Rightarrow (2)$ Let $t: B \to A$ be a homomorphism such that $t \circ i = \text{id}_A$. We define

$$
\Phi: B \to A \times C \\
b \mapsto (t(b), p(b)).
$$

It follows easily from the exactness of the initial sequence that this map is in fact an isomorphism. It is straightforward to verify that $\Phi$ has all the other desired properties.

$(2) \Rightarrow (1),(3)$ Now suppose we are given an isomorphism $\Phi: B \to A \times C$ such that the given diagram commutes. It follows immediately from the definitions and given properties that the maps

$$
B \xrightarrow{\Phi} A \times C \xrightarrow{(a,c) \mapsto a} A \quad \text{and} \quad C \xrightarrow{c \mapsto (0,c)} A \times C \xrightarrow{\Phi^{-1}} B
$$

have the required properties.

Finally we assume that $B$ is abelian.

$(3) \Rightarrow (1)$ Let $s: C \to B$ be a splitting, i.e. let $s$ be a homomorphism such that $p \circ s = \text{id}_C$. We need to find an appropriate homomorphism $t: B \to A$. Since the sequence is exact, our task is basically the same as finding an appropriate homomorphism $B \to \ker(p)$. Let $b \in B$. We have

$$
p(b - s(p(b))) = p(b) - (p \circ s)(p(b)) = p(b) - p(b) = 0.
$$

By the exactness of the short exact sequence there exists a unique $a \in A$ with $i(a) = b - s(p(b))$. We define $t(b) := a$. It follows easily from the fact that $p$ and $s$ are homomorphisms that the map $t: B \to A$ is a homomorphism. It remains to show that $t \circ i = \text{id}_A$. Let $a \in A$. We have to show that $t(i(a)) - a = 0$. Since $i$ is injective it suffices to show that $i(t(i(a))) - i(a) = 0$. We have

$$
i(t(i(a))) - i(a) = (i(a) - s(p(i(a)))) - i(a) = i(a) - i(a) = 0.
$$

Since $t(y)$ is the unique element with $i(t(y)) = y - s(p(y))$ (since $p \circ i = 0$).

In many applications we only need the following corollary that is an immediate consequence of Lemmas 46.1 and 46.2.

Corollary 46.3. Let

$$
0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0
$$

In fact the argument is basically the same as in the proof of Lemma 43.1 (4a).
be a short exact sequence of abelian groups. Then the following hold:

1. If $C$ is a free abelian group, then $B \cong A \oplus C$.
2. Suppose $A$ and $C$ are free abelian groups. If $X$ is a basis for $A$ and if $Y \subset B$ is a subset such that $p(Y)$ is a basis for $C$, then $X \cup Y$ is a basis for the free abelian group $B$.

**Proof.** The first statement is an immediate consequence of Lemmas [46.1](#) and [46.2](#) The second statement follows easily from Splitting Lemma [46.2](#) (1) $\Rightarrow$ (3). We leave the details to the reader. ■

**Example.** Let $B$ be an abelian group, let $b \in B$ and let $p: B \to \mathbb{Z}$ be a homomorphism with $p(b) = 1$. It follows immediately from Corollary [46.3](#) applied to the short exact sequence $0 \to \ker(p) \to B \to \mathbb{Z} \to 0$, that we can write $B = K \oplus \mathbb{Z} \cdot b$ for some subgroup $K$ that is isomorphic to $\ker(p)$.

The above discussion gives us tools for dealing with short exact sequence. The following lemma allows us to break a long exact sequence into shorter exact sequences.

**Lemma 46.4.** Let

$$
\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \to \ldots
$$

be an exact sequence of abelian groups. Then for any $n$ the sequences

$$
0 \to \text{coker} \left( A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \right) \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} \ker \left( A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \right) \to 0
$$

and

$$
\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} \ker \left( A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \right) \to 0
$$

are also exact. In particular

$$
0 \to \text{coker} \left( A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \right) \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} \ker \left( A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \right) \to 0
$$

is a short exact sequence.

**Proof.** The statements follow immediately from the definitions. We leave it to the reader to fill in the details. ■

**Example.** A typical application is that if we are given an exact sequence

$$
\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3} \ldots
$$

of abelian groups such that the map $f_n$ is the zero map, then the exact sequence can be split “into the two halves” along that zero map, i.e.

$$
0 \to A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3} \ldots
$$

and

$$
\ldots \to A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \to 0
$$

are also exact sequences. In the remainder of this course we will frequently use this fact without explicitly citing Lemma [46.4](#).

46.2. **The Mayer–Vietoris sequence.** In the following theorem and throughout the subsequent discussion we will use the following notation: given a topological space $D$ and a
subset $C \subset D$, we denote the corresponding inclusion map $C \to D$ by $i_C$. To avoid pandemonium with subscripts we often drop denote the inclusion induced maps on homology by $i_C$ instead of the more accurate $(i_C)_*$.

**Theorem 46.5. (Mayer–Vietoris)**  
Let $X$ be a topological space and let $A, B \subset X$ be subsets such that $X = \hat{A} \cup \hat{B}$. Then the following two statements hold:

1. For each $n \in \mathbb{N}$ there exists a unique homomorphism
   $$\partial_n : H_n(X) \to H_{n-1}(A \cap B)$$
   which has the following property: for every $a \in C_n(A)$ and $b \in C_n(B)$ such that $a + b \in C_n(X)$ is a cycle we have
   $$\partial_n([a + b]) = [\partial a] - [\partial b] \in H_{n-1}(A \cap B).$$
   We refer to the maps $\partial_n : H_n(X) \to H_{n-1}(A \cap B)$ as the connecting homomorphisms corresponding to $(X, A, B)$.

2. $\ast$ The connecting homomorphism of (1) is natural in the following sense. Let $X$ and $Y$ be two topological spaces and let $A, B \subset X$ and $C, D \subset Y$ be subsets with $X = \hat{A} \cup \hat{B}$ and $Y = \hat{C} \cup \hat{D}$. If $f : X \to Y$ is a map with $f(A) \subset C$ and $f(B) \subset D$, then for every $n \in \mathbb{N}$ the following diagram commutes
   $$\begin{array}{ccc}
   H_n(X) & \xrightarrow{\partial_n} & H_{n-1}(A \cap B) \\
   f_* \downarrow & & f_* \downarrow \\
   H_n(Y) & \xrightarrow{\partial_n} & H_{n-1}(C \cap D)
   \end{array}$$
   where the horizontal maps are the connecting homomorphisms from (1).

3. The following sequence is exact:
   $$\ldots \to H_n(A \cap B) \xrightarrow{i_{A \cap B} + i_{A \cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \to \ldots$$
   $$s \mapsto (i_{A \cap B}(s), -i_{A \cap B}(s))$$
   $$s \mapsto i_A(s) + i_B(s)$$

Totally analogous statements also hold if we replace the homology groups of $A \cap B, A, B$ and $X$ by the corresponding reduced homology groups.\footnote{Walther Mayer (1887-1948) and Leopold Vietoris (1891-2002) were two Austrian mathematicians. Vietoris was the longest living Austrian mathematician ever.}

The long exact sequence in Theorem 46.5 is usually called the Mayer–Vietoris sequence of the decomposition $X = A \cup B$.

**Example.** In Figure 765 we consider the annulus $X$ together with two closed subsets $A$ and $B$ with $X = \hat{A} \cup \hat{B}$. Furthermore we show chains $a \in C_1(A)$ and $b \in C_1(B)$ such

\footnote{Here in the expression “$\partial a$” we mean by $\partial$ the boundary map $\partial : C_n(A) \to C_{n-1}(A)$. In our case we will see that $\partial a \in C_{n-1}(A \cap B) \subset C_{n-1}(A)$. A similar statement holds for $\partial b$.}

\footnote{Note though that for reduced homology groups we might need to use the fact, obtained in Lemma 43.1 (0), that $\hat{H}_{-1}(\emptyset) = \mathbb{Z}$.}
Walther Mayer (1887-1948) with some other person

Leopold Vietoris (1891-2002) at 110

Figure 764

that $a + b$ form a cycle in $C_1(X)$. The connecting homomorphism of the Mayer–Vietoris sequence sends $[a + b] \in H_1(X)$ to $[\partial a] = -[\partial b] \in H_0(A \cap B)$.

Figure 765

Remark.

1. In many applications some of the inclusions appearing in Mayer–Vietoris Theorem 46.5 are homotopy equivalences, in particular, by Corollary 42.8 many of the inclusion induced maps on homology will be isomorphisms. If that is the case, then it is worth looking up Exercise 41.12 which might greatly simplify the calculations.

2. Suppose that we are given a topological space $X$ together with an open cover $\{U_i\}_{i \in I}$. If the cover consists of precisely two sets $U_1$ and $U_2$, then the Mayer–Vietoris Theorem 46.5 relates the homology groups of $X$, $U_1$, $U_2$ and the intersection $U_1 \cap U_2$. If the open cover consists of more than two sets, then the situation is much more tricky.

Proof. Let $X$ be a topological space and let $A, B \subset X$ be subsets such that $X = \overset{\circ}{A} \cup \overset{\circ}{B}$. There are two approaches to proving the Mayer–Vietoris Theorem 46.5.

The more elegant approach is as follows: In Exercise 46.1 we prove a purely algebraic statement, namely we construct the algebraic Mayer–Vietoris sequence. In Exercise 46.2 we use this exact sequence together with the Excision Theorem 43.19 and the long exact sequences of pairs of topological spaces to prove the desired statements. This approach allows us to prove Statements (2) and (3) of the Mayer–Vietoris Theorem 46.5 without working again on the “chain level”.

In the following we will carry out the second approach. It works on the “chain level” and is thus arguably less conceptual. On the other hand it has the advantage that it is
We make the following clarifications and observations. After this long preamble, let us remind the reader of the following the notation from page 1133:

$$C_n^{(A,B)}(X) := \{a + b \mid a \in C_n(A) \text{ and } b \in C_n(B)\}.$$ 

The inclusion maps induce the following sequence of chain maps:

$$0 \rightarrow C_*(A \cap B) \xrightarrow{i_{A \cap B} \oplus -i_{A \cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{(A,B)}(X) \rightarrow 0.$$ 

**Claim.** The above sequence of chain maps is exact.

We prove the claim in the following four steps:

(a) It is clear that each of the maps $C_*(A \cap B) \rightarrow C_*(A)$ and $C_*(A \cap B) \rightarrow C_*(B)$ is already injective, in particular the map $i_{A \cap B} \oplus -i_{A \cap B}$ is injective.

(b) It is an immediate consequence of the definition of $C_*^{(A,B)}(X)$ that the map $i_A + i_B$ is surjective.

(c) It follows immediately from the definitions that the composition of both maps is the zero map, i.e., $\text{im}(i_{A \cap B} \oplus -i_{A \cap B}) \subseteq \ker(i_A + i_B)$.

(d) It remains to show that $\ker(i_A + i_B) \subseteq \text{im}(i_{A \cap B} \oplus -i_{A \cap B})$. Thus let $x \in C_n(A)$ and $y \in C_n(B)$ such that $(i_A + i_B)(x + y) = 0$. By definition this means that $x$ and $y$, viewed as elements in $C_n(X)$, satisfy $x = -y$. This means that $x$ lies in $C_n(A)$ and also in $C_n(B)$. But then we have $(i_{A \cap B} \oplus -i_{A \cap B})(x) = x + y$. 

Next we consider the following maps:

$$\cdots \rightarrow H_n(A \cap B) \xrightarrow{i_{A \cap B} \oplus -i_{A \cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_*^{(A,B)}(X) \xrightarrow{p_n} H_{n-1}(A \cap B) \rightarrow \cdots$$

$$\xrightarrow{\Phi_n} H_n(X) \xrightarrow{\partial_n} H_{n-1}(X).$$

We make the following clarifications and observations:

(a) Given $n \in \mathbb{N}$ we denote by $p_n : H_*^{(A,B)}(X) \rightarrow H_{n-1}(A \cap B)$ the connecting homomorphism of the above short exact sequence of chain complexes, as defined on page 1115.

(b) By Proposition 43.11 the top horizontal sequence is exact.

(c) It follows from Proposition 43.24 together with our hypothesis that $X = \hat{A} \cup \hat{B}$, that for every $n \in \mathbb{N}_0$ the inclusion map

$$C_*^{(A,B)}(X) \rightarrow C_*(X)$$

induces an isomorphism

$$\Phi_n : H_*^{(A,B)}(X) \xrightarrow{\cong} H_n(X).$$

For each $n \in \mathbb{N}_0$ we now write $\partial_n := p_n \circ \Phi_n^{-1}$. It remains to show that these maps have the two desired properties stated in the theorem:

(3) It is clear from the above discussion that the sequence given in (3) is indeed exact.

---

Note that here we use the minus-sign that appears in the first map.
We leave it to the reader to verify that it follows from the definition of the connecting homomorphism $p_n$ that for every $a \in C_n(A)$ and $b \in C_n(B)$ such that $a + b \in C_n(X)$ is a cycle we have

$$\partial_n([a + b]) = p_n([a + b]) = [\partial a] = -[\partial b] \in H_{n-1}(A \cap B).$$

Furthermore, the isomorphism $\Phi_n : H_n^{A,B}(X) \xrightarrow{\cong} H_n(X)$ shows that every element in $H_n(X)$ is of the form $[a + b]$ for some $a \in C_n(A)$ and $b \in C_n(B)$, which implies that $\partial_n$ is uniquely determined by the above rule.

(2) It follows basically immediately from the existence and uniqueness of the connecting homomorphisms $\partial_n$ that these maps are also natural.

We leave it to the reader to verify, using Lemma 43.1, that the analogous statements also hold if we replace the homology groups of $A \cap B, A, B$ and $X$ by the corresponding reduced homology groups.

The following lemma gives an alternative description of the connecting homomorphism of the Mayer–Vietoris sequence.

**Lemma 46.6.** Let $X$ be a topological space and let $A, B$ be two open subsets of $X$ with $X = A \cup B$. The connecting homomorphism $\partial_n : H_n(X) \to H_{n-1}(A \cap B)$ equals the map

$$H_n(X) \xrightarrow{\partial_n} H_n(X) \oplus H_n(X) \xrightarrow{i_0^*} H_n(A, A \cap B) \xrightarrow{\partial_n} H_{n-1}(A \cap B).$$

The inclusion induced map is an isomorphism by the Excision Theorem 43.19 connecting homomorphism of the pair $(B, A \cap B)$.

**Proof.** This equality follows easily from the precise description of the connecting homomorphisms given in the Mayer–Vietoris Theorem 46.5 and in Proposition 43.15.

We conclude this section with the following variation on the Mayer–Vietoris Theorem 46.5. This theorem might sound rather unnatural, but it will play an important role in the proof of Theorem 88.19.

**Theorem 46.7. (Inverted Mayer–Vietoris Theorem) (*)& **\ Let $X$ be a topological space and let $U$ and $V$ be open subsets. Then for all $n \in \mathbb{N}$ there exists a natural homomorphism $\partial_n : H_n(X, U \cup V) \to H_{n-1}(X, U \cap V)$ such that

$$\cdots \to H_n(X, U \cap V) \xrightarrow{i_{-1}} H_n(X, U) \oplus H_n(X, V) \xrightarrow{i+1} H_n(X, U \cup V) \xrightarrow{\partial} H_{n-1}(X, U \cap V) \to \cdots$$

is an exact sequence.

**Proof.** (*)& *\ Note that as in the proof of Theorem 46.5 we have a short exact sequence

$$0 \to C_n(X, U \cap V) \to C_n(X, U) \oplus C_n(X, V) \to C_n(X) / C_n^{U,V}(U \cup V) \to 0.$$

Thus we get a corresponding long exact sequence of homology groups. It suffices to show that the homology groups of the chain complex on the right are precisely the homology groups of the pair $(X, U \cup V)$. To do so we consider the following commutative pair of
short exact sequences
\[
\begin{array}{ccccccc}
0 & \to & C_*^{(U,V)}(U \cup V) & \to & C_*(X) & \to & C_*^{(U,V)}(U \cup V) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & C_*(U \cup V) & \to & C_*(X) & \to & C_*(X, U \cup V) & \to & 0.
\end{array}
\]
We obtain the corresponding long exact sequence of homology groups:
\[
\begin{array}{ccccccc}
\ldots & \to & H_*^{(U,V)}(U \cup V) & \to & H_*(X) & \to & H_*( C_*(X)/C_*^{(U,V)}(U \cup V)) & \to & H_*^{(U,V)}(U \cup V) & \to & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \to & H_*(U \cup V) & \to & H_*(X) & \to & H_*(X, U \cup V) & \to & H_{*-1}(U \cup V) & \to & \ldots
\end{array}
\]
It follows from Proposition 43.24 that the first and fourth vertical map are isomorphisms. The second map and the fifth map (which for space reasons is not shown) are the identity. Hence it follows from the Five Lemma 43.12 that the third vertical map is also an isomorphism.

46.3. Applications of the Mayer–Vietoris sequence. As a warm-up we first consider the homology groups of the suspension $\Sigma(X)$ of a topological space $X$. More precisely, we have the following lemma which basically gives a new proof for Proposition 45.7.

**Lemma 46.8.** Let $k \in \mathbb{Z}$. Given any topological space $X$ we have a natural isomorphism
\[
\Sigma_X : \tilde{H}_k(X) \cong \tilde{H}_{k+1}(\Sigma(X)).
\]

**Example.** Let $n \in \mathbb{N}_0$. We perform the following calculation:
\[
\tilde{H}_k(S^n) \cong \tilde{H}_k(\ldots(\Sigma(S^0))) \cong \tilde{H}_{k-n}(S^0) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{else.} \end{cases}
\]

This recovers the calculation we made in Proposition 43.4.

**Remark.** Let $X$ be a topological space. In Exercise 46.11 we will see that the two natural isomorphisms $\tilde{H}_k(\Sigma(X)) \cong \tilde{H}_{k-1}(X)$ that we constructed in Proposition 45.7 and that we construct in the proof of Lemma 46.8 are actually the same on the nose.

**Proof.** Let $k \in \mathbb{Z}$.

1. Let $X$ be a topological space. We denote by $p : X \times [-1, 1] \to \Sigma(X)$ the obvious projection. As on page 1178 we consider the subspaces $C_+ := C_+X = p(X \times (-1, 1])$ and $C_- := C_-X = p(X \times [-1, 1))$. Note that $C_+X$ and $C_-X$ are both open subsets of $\Sigma(X)$ and that $\Sigma(X) = C_+X \cup C_-X$. We consider the corresponding long exact sequence in reduced homology from the Mayer–Vietoris Theorem 46.5:
\[
\begin{array}{ccc}
\tilde{H}_{k+1}(C_+) \oplus \tilde{H}_{k+1}(C_-) & \to & \tilde{H}_{k+1}(\Sigma(X)) \\
\Sigma_X \downarrow & & \downarrow \partial_k \\
\tilde{H}_k(C_+ \cap C_-) & \to & \tilde{H}_{k+1}(C_+ \cap C_-) \\
\uparrow i_* & & \uparrow i_* \\
\tilde{H}_k(X). & & \\
\end{array}
\]
We make the following clarifications and observations:
(a) Note that by the same argument as in the proof of Lemma 24.1 we see that both $C_+ = C_+ X$ and $C_- = C_- X$ admit a deformation retraction to a point. It follows from Lemma 18.14 that both $C_+$ and $C_-$ are contractible, therefore we know by Lemma 43.1 (7) the reduced homology groups of $C_+ X$ and $C_- X$ vanish.
(b) It follows immediately from (1) that the connecting homomorphism
$$\partial: \tilde{H}_{k+1}(\Sigma(X)) \to \tilde{H}_k(C_+ X \cap C_- X)$$
is in fact an isomorphism.
(c) We consider the following little diagram:

\begin{align*}
X \xrightarrow{\sim} X \times \{0\} \xrightarrow{p} C_+ X \cap C_- X
\end{align*}

The vertical map is evidently a homotopy equivalence. Furthermore one can easily show, either by hand, or using Lemma 3.29 that the diagonal map is a homeomorphism. We obtain that the map $i: X \to C_+ X \cap C_- X$ is a homotopy equivalence. Thus we obtain from Lemma 43.1 (6) that the induced map $i_*: \tilde{H}_k(X \times \{0\}) \to \tilde{H}_k(C_+ X \cap C_- X)$ is an isomorphism.

We define $\Sigma_X$ to be the map
$$\tilde{H}_k(X) = \tilde{H}_k(X \times \{0\}) \xrightarrow{i_*} \tilde{H}_k(C_+ X \cap C_- X) \xrightarrow{\partial_k^{-1}} \tilde{H}_{k+1}(\Sigma(X)).$$

(2) It follows easily from the definition of $\Sigma_X$ and the naturality of the connecting homomorphisms of the Mayer–Vietoris sequence, see Theorem 46.5 (2), that the isomorphism $\Sigma_X$ is natural.

As our next example we want to determine the homology groups of the 2-dimensional projective space $\mathbb{R}P^2$.

**Lemma 46.9.** We have

$$\tilde{H}_n(\mathbb{R}P^2) \cong \begin{cases} 
0, & \text{if } n \geq 2, \\
\mathbb{Z}_2, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}$$

**Remark.** In Exercise 46.10 we will determine an explicit cycle that represents the unique non-trivial element of $\tilde{H}_1(\mathbb{R}P^2)$. 
Proof. In the proof of Lemma 46.9 we use the description from page 196 of $\mathbb{RP}^2$ as

$$\mathbb{RP}^2 = \mathcal{B}^2 / \sim \quad \text{where } x \sim y \text{ if } x, y \in \partial \mathcal{B}^2 \text{ and } x = -y.$$ 

In the following we denote by $p$ the projection map $\mathcal{B}^2 \to \mathcal{B}^2 / \sim$. We consider the open subsets

$$A := p(\{z \in \mathcal{B}^2 \mid |z| > \frac{1}{4}\}) \quad \text{and} \quad B := p(\{z \in \mathcal{B}^2 \mid |z| < \frac{3}{4}\}).$$

Evidently we have $\hat{A} \cup \hat{B} = A \cup B = \mathbb{RP}^2$. From the Mayer–Vietoris Theorem 46.5 we obtain the following long exact sequence of reduced homology groups:

$$\cdots \to \tilde{H}_2(A) \oplus \tilde{H}_2(B) \to \tilde{H}_2(\mathbb{RP}^2) \to \tilde{H}_1(A \cap B) \to \tilde{H}_1(A) \oplus \tilde{H}_1(B) \to \tilde{H}_1(\mathbb{RP}^2) \to \cdots$$

Now we have to collect all the available information on the reduced homology groups of

$$\mathbb{RP}^2 = \mathcal{B}^2 / \sim.$$

Figure 767. Illustration for the proof of Lemma 46.9.

A, B and $A \cap B$. We make the following observations:

1. We remarked on page 1106 that the reduced homology of a disk vanishes, i.e. we have $\tilde{H}_n(B) = 0$ for all $n \in \mathbb{N}_0$.

2. Note that $p(\frac{1}{2}S^1)$ is a deformation retract of $A \cap B = p(\{z \in \mathcal{B}^2 \mid |z| \in (\frac{1}{4}, \frac{3}{4})\})$. This implies that the map $j: S^1 \to A \cap B = p(\{z \in \mathcal{B}^2 \mid |z| \in (\frac{1}{4}, \frac{3}{4})\})$ given by $z \mapsto \frac{1}{2}z$ is a homotopy equivalence. It follows from Corollary 42.8 (2) and Proposition 43.4 that $\tilde{H}_n(A \cap B) = 0$ for $n \neq 1$ and that $j_*: \tilde{H}_1(S^1) \to \tilde{H}_1(A \cap B)$ is an isomorphism.

3. We consider the retraction

$$r: A \to \{z \in \partial \mathcal{B}^2 \}/z \sim -z$$

$$p(se^{i\varphi}) \mapsto e^{i\varphi}$$

which is easily seen to be a homotopy equivalence and we also consider the homeomorphism

$$f: \{z \in \partial \mathcal{B}^2 \}/z \sim -z \to S^1$$

$$z \mapsto z^2.$$ 

As in (2) it follows that $\tilde{H}_n(A) = 0$ for $n \neq 1$ and that $(f \circ r)_*: \tilde{H}_1(A) \to \tilde{H}_1(S^1)$ is an isomorphism.

The above Mayer–Vietoris sequence is thus in our case of the following form:

$$\cdots \to 0 \to \tilde{H}_3(\mathbb{RP}^2) \to 0 \to 0 \to \tilde{H}_2(\mathbb{RP}^2) \xrightarrow{j_*} \tilde{H}_1(A \cap B) \xrightarrow{i_*} \tilde{H}_1(A) \oplus \tilde{H}_1(B) \xrightarrow{\approx} \tilde{H}_1(\mathbb{RP}^2) \to 0$$

$$\tilde{H}_1(S^1) \xrightarrow{(\text{forioj})_*} \tilde{H}_1(\mathbb{RP}^2) \xrightarrow{\deg(\text{forioj})_*} \tilde{H}_1(S^1).$$
We obtain immediately that $\tilde{H}_n(\mathbb{R}P^2) = 0$ for $n \geq 3$. Furthermore it follows immediately from the definitions that the map $f \circ r \circ i \circ j : S^1 \to S^1$ is given by $z \mapsto z^2$. By Lemma 45.10 this implies that $\deg(f \circ r \circ i \circ j) = 2$. Thus we obtain the following exact sequence

$$0 \to \tilde{H}_2(\mathbb{R}P^2) \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \tilde{H}_1(\mathbb{R}P^2) \to 0.$$ 

It follows from the discussion on page 1108 that $\tilde{H}_2(\mathbb{R}P^2) \cong \ker (\mathbb{Z} \xrightarrow{2} \mathbb{Z}) = 0$ and $\tilde{H}_1(\mathbb{R}P^2) \cong \operatorname{coker} (\mathbb{Z} \xrightarrow{2} \mathbb{Z}) = \mathbb{Z}_2$. ■

**Remark.** It is a non-trivial, but certainly very amusing exercise to generalize the calculation of Lemma 46.9 to compute the homology groups of any real projective space $\mathbb{R}P^n$. We cordially invite the reader to try to make an educated guess of what the homology groups of $\mathbb{R}P^n$ might be. We will compute the homology groups later on in Proposition 48.10 using a somewhat different approach.

46.4. **The Mayer–Vietoris Theorem for manifolds and CW-complexes.** Recall that when we studied fundamental groups we first proved the Seifert–van Kampen Theorem 22.1 for the decomposition of a topological space $X$ into two open subsets. Afterwards we showed in Theorem 22.2 and Theorem 37.1 that an analogous statement holds if we decompose a smooth manifold into suitable submanifolds and if we decompose a CW-complex into subcomplexes.

In a similar fashion we now state and prove the “manifold version” and the “CW-complex version” of the Mayer–Vietoris Theorem 46.5.

**Theorem 46.10. (Mayer–Vietoris Theorem for Topological Manifolds)** Let $X$ be an $m$-dimensional topological manifold and let $A, B \subset X$ be two $m$-dimensional submanifolds such that the following statements hold:

(a) $X = A \cup B$,
(b) $A \cap B$ is a union of components of $\partial A$ and it is a union of components of $\partial B$,
(c) $A$ and $B$ are closed subsets of $X$. (Note that by Lemma 2.17 (2) this condition is satisfied if $A$ and $B$ are compact.)

The following two statements hold:

(1) For each $n \in \mathbb{N}_0$ there exists a unique homomorphism $\partial_n: H_n(X) \to H_{n-1}(A \cap B)$ which has the following property: If we are given $a \in C_n(A)$ and $b \in C_n(B)$ are such that $a + b \in C_n(X)$ is a cycle, then

$$\partial_n([a + b]) = [\partial a] = -[\partial b] \in H_{n-1}(A \cap B).$$

(2) The following sequence is exact:

$$\ldots \to H_n(A \cap B) \xrightarrow{i_A \cap B + i_B \cap A} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \to \ldots$$

A totally analogous statement also holds if we replace the homology groups of $A \cap B, A, B$ and $X$ by the corresponding reduced homology groups.

**Proof (⋆).** Let $X$ be an $m$-dimensional topological manifold and let $A, B \subset X$ be two $m$-dimensional submanifolds such that $A$ and $B$ are closed subset of $M$, such that $X = A \cup B$. 

and such that $A \cap B$ is a union of components of $\partial A$ and also a union of components of $\partial B$.

We pick maps $f: [0,1) \times \partial A \to A$ and $g: [0,1) \times \partial B \to B$ that are provided by the Topological Collar Neighborhood Theorem \[44.5\] and \[46.5\]. We set

$$U := A \cup (g([0,1) \times (A \cap B)) \quad \text{and} \quad V := B \cup (f([0,1) \times (A \cap B)).$$

As in the proof of Theorems \[20.10\] and \[22.2\] we note that the following statements hold:

1. $U$ and $V$ are open subsets of $X$.
2. $A$ is a deformation retract of $U$,
3. $B$ is a deformation retract of $V$, and
4. $A \cap B$ is a deformation retract of $U \cap V$.

Now we consider the following diagram

$$
\begin{array}{ccccccccc}
\ldots & \longrightarrow & H_n(A \cap B) & \xrightarrow{i_{n-1}} & H_n(A) \oplus H_n(B) & \xrightarrow{i_{n+1}} & H_n(X) & \xrightarrow{\partial_n} & H_{n-1}(A \cap B) & \longrightarrow & \ldots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
\ldots & \longrightarrow & H_n(U \cap V) & \xrightarrow{i_{n-1}} & H_n(U) \oplus H_n(V) & \xrightarrow{i_{n+1}} & H_n(X) & \xrightarrow{\partial_n} & H_{n-1}(U \cap V) & \longrightarrow & \ldots
\end{array}
$$

where the bottom sequence is given by the Mayer–Vietoris Theorem \[46.5\]. We make the following observations:

(a) The two squares to the left commute since all the relevant maps are given by inclusions.

(b) The vertical maps are isomorphisms by Corollary \[42.8\].

(c) By (2) we can now define the dotted map $H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B)$ such that the third square also commutes.

It now follows from the Mayer–Vietoris Theorem \[46.5\] that the sequence in (2) is exact. We leave the somewhat technical task of verifying Statement (1) to the reader.

\[\square\]

\[\text{Figure 768. Illustration of the proof of Theorem } 46.10\]

Now we turn to CW-complexes.

---

\[744\] Of course, if $X$ is a smooth manifold, then we could also use the Collar Neighborhood Theorem \[8.12\].

\[745\] At this point we secretly use our hypothesis that $A$ and $B$ are closed subsets of $X$. 

---
Theorem 46.11. (Mayer–Vietoris Theorem for CW-complexes) Let $X$ be a CW-complex. If $A$ and $B$ are two subcomplexes of $X$ such that $X = A \cup B$, then exactly the same conclusion as in the Mayer–Vietoris Theorem 46.10 for Manifolds holds.

Proof (*). Let $X$ be a CW-complex and let $A$ and $B$ be two subcomplexes of $X$ with $X = A \cup B$. By Proposition 36.10 (8) there exist open neighborhoods $U$ of $A$ and $V$ of $B$ such that the following statements hold:

1. $A$ is a deformation retract of $U$,
2. $B$ is a deformation retract of $V$, and
3. $A \cap B$ is a deformation retract of $U \cap V$.

The proof is now verbatim the same as the proof of the Mayer–Vietoris Theorem 46.10 for Manifolds.

Later on in Theorem 74.14 we will generalize the above Mayer–Vietoris theorems to an even more general setting, namely to “excisive triads”. But for the time being we will be able to handle most situations with the Mayer–Vietoris theorems that we stated above.

46.5. The homology groups of the torus and the Klein bottle. In this section we will determine the homology groups of the torus and the Klein bottle. We do so partly since the results are interesting, but partly also to get to some practice for applying the various Mayer–Vietoris Theorems.

Lemma 46.12. Let $T = S^1 \times S^1$ be the torus. The following two statements hold.

1. We have the following isomorphisms

$$H_n(T) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 2, \\ \mathbb{Z}^2, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

2. The homology groups are generated by the following cycles:

(a) The singular 1-simplices $c$ and $d$ shown in Figure 769 on the left are generators for $H_1(T) \cong \mathbb{Z}^2$.

(b) The singular 2-chain $\alpha - \beta$ that is given by the singular 2-simplices $\alpha$ and $\beta$ shown in Figure 769 on the right is a generator for $H_2(T) \cong \mathbb{Z}$. Note that this singular 2-chain is precisely the one that we had already considered in Figure 704. In particular this answers our question from page 1083, the cycle $\alpha - \beta$ does indeed represent a non-trivial element in $H_2(T)$.

Note that Lemma 46.12 (2) shows in particular that the cycles considered in Figure 700 represent non-trivial homology classes.

To increase readability we break the proof of Lemma 46.12 into two parts.

Proof of Lemma 46.12 (1). First we point out that throughout the proof we identify the torus $T$ with $S^1 \times \mathbb{R}/4\mathbb{Z}$ in the obvious way. Next we introduce some notation. We denote by $p : S^1 \times \mathbb{R} \rightarrow T = S^1 \times \mathbb{R}/4\mathbb{Z}$ the projection map. In the following we write

\[\Delta^n \rightarrow ([0, 1] \times [0, 1]) / \sim.\]
torus $T = S^1 \times S^1 = S^1 \times \mathbb{R}/\mathbb{Z}$

\[ A := p(S^1 \times ([0, 1] \cup [3, 4])) \text{ and } B := p(S^1 \times [1, 3]). \]
Evidently we have $T = A \cup B$. Furthermore we write $C_1 := p(S^1 \times \{1\})$ and $C_2 := p(S^1 \times \{3\})$. Evidently we have $A \cap B = C_1 \cup C_2$.

\[ \begin{array}{c}
 0 \rightarrow \\
 C_1 \cap \beta \rightarrow \rightarrow 4 \rightarrow \\
 C_2 \cap A \rightarrow \\
 B \rightarrow \\
 \end{array} \]

Figure 769.

\[ \begin{array}{c}
 B \cap y \\
 A \cap x \\
 \end{array} \]

Figure 770. Illustration for the proof of Lemma 46.12 (1).

It is fairly easy\(^{747}\) to verify that the hypotheses for the Mayer–Vietoris Theorem\(^{46.10}\) for Manifolds are satisfied for $T = A \cup B$. Thus we obtain the following long exact sequence in homology\(^{748}\)

\[ \begin{array}{c}
 \rightarrow \\
 H_1(C_1) \rightarrow H_1(C_2) \rightarrow \cdots \rightarrow H_2(T) \rightarrow \rightarrow \\
 H_1(A) \rightarrow H_1(B) \rightarrow \rightarrow \\
 H_0(A) \rightarrow H_0(B) \rightarrow \rightarrow \\
 H_0(T) \rightarrow 0.
\end{array} \]

Given $x \in [0, 4]$ we consider the 0-cycle $Q_x := (1, x)$ and we consider the 1-cycle

\[ \sigma_x : \Delta^1 \rightarrow S^1 \times \mathbb{R}/4\mathbb{Z} \]

\[ (1-t, t) \mapsto e^{2\pi it}. \]

Let $I \subset \mathbb{R}$ be a compact interval of length less than four. We make the following four observations:

\(^{747}\)To be completely fair, it might take a few lines to write down a complete argument why $A$ and $B$ are submanifolds of $T$.

\(^{748}\)Here we write $H_i(C_1)$ instead of $H_i(C_1) \oplus H_i(C_2)$ and $H_i(A)$ instead of $H_i(A) \oplus H_i(B)$.

The reason is that we think of direct sums as columns vectors so that we can use the usual matrix notation for describing the maps between the direct sums.
(a) Since the length of $I$ is less than four one obtains almost immediately from Proposition 2.43 (3) that $p: S^1 \times I \to p(S^1 \times I)$ is a homeomorphism.

(b) It is a straightforward consequence of Proposition 42.5 that for any two points $x, x'$ in $I$ we have $[Q_x] = [Q_{x'}] \in H_1(p(S^1 \times I))$ and $[\sigma_x] = [\sigma_{x'}] \in H_1(p(S^1 \times I))$.

(c) It follows from (1) together with Proposition 41.5 that for each $x \in I$ we have $H_0(p(S^1 \times I)) = \mathbb{Z} \cdot [\sigma_x]$.

(d) It follows from (1) together with Lemma 45.4 and Proposition 42.5 that for each $x \in I$ we have $H_1(p(S^1 \times I)) = \mathbb{Z} \cdot [Q_x]$.

It follows from (c) and (d) that we can rewrite the above Mayer–Vietoris sequence as follows:

$$
\begin{array}{cccccccc}
0 & \rightarrow & H_2(T) & \stackrel{\partial}{\rightarrow} & \mathbb{Z} \cdot [\sigma_1] & \rightarrow & \mathbb{Z} \cdot [\sigma_3] & \rightarrow & \mathbb{Z} \cdot Q_{x_1} \\
& & & & \uparrow{\text{id}} & & \downarrow{i_{C_1}} & & \uparrow{i_{C_1}} \\
0 & \rightarrow & H_1(T) & \stackrel{\partial}{\rightarrow} & \mathbb{Z} \cdot [\sigma_0] & \rightarrow & \mathbb{Z} \cdot [\sigma_2] & \rightarrow & \mathbb{Z} \cdot Q_{x_0} \\
& & & & \uparrow{\text{id}} & & \downarrow{i_{C_2}} & & \uparrow{i_{C_2}} \\
0 & \rightarrow & \mathbb{Z} \cdot [Q_1] & \rightarrow & \mathbb{Z} \cdot [Q_2] & \rightarrow & \mathbb{Z} \cdot [Q_2] & \rightarrow & 0.
\end{array}
$$

To determine the homology groups $H_2(T)$ and $H_1(T)$ we now need to understand the maps in the above long exact sequence. For example, it follows immediately from (b) that we have $i_{C_1}([\sigma_1]) = [\sigma_1] = [\sigma_0]$. Basically identical considerations using (b) tell us that we obtain the following long exact sequence:

$$
\begin{array}{cccccccc}
0 & \rightarrow & H_2(T) & \stackrel{\partial}{\rightarrow} & \mathbb{Z} \cdot [\sigma_1] & \rightarrow & \mathbb{Z} \cdot [\sigma_3] & \rightarrow & \mathbb{Z} \cdot Q_{x_1} \\
& & & & \uparrow{\text{id}} & & \downarrow{1} & & \uparrow{-1} \\
0 & \rightarrow & H_1(T) & \stackrel{\partial}{\rightarrow} & \mathbb{Z} \cdot [\sigma_0] & \rightarrow & \mathbb{Z} \cdot [\sigma_2] & \rightarrow & \mathbb{Z} \cdot Q_{x_0} \\
& & & & \uparrow{\text{id}} & & \downarrow{1} & & \uparrow{-1} \\
0 & \rightarrow & \mathbb{Z} \cdot [Q_1] & \rightarrow & \mathbb{Z} \cdot [Q_2] & \rightarrow & \mathbb{Z} \cdot [Q_2] & \rightarrow & 0.
\end{array}
$$

We will now calculate the homology groups by hand. Alternatively one could now also use Exercise 41.12 to quickly calculate the homology groups. Note that it follows from the discussion on page 1108 that

$$
H_2(T) \cong \ker \left( \frac{\mathbb{Z}}{\mathbb{Z}} \left( \begin{array}{c} 1 \\ -1 \\ -1 \end{array} \right) \right) = \mathbb{Z} \cdot \left( \begin{array}{c} 1 \\ -1 \end{array} \right) \cong \mathbb{Z}.
$$

To determine $H_1(T)$ we consider the following diagram:

$$
\begin{array}{cccccccc}
0 & \rightarrow & \text{coker} \left( \begin{array}{cc} \mathbb{Z} \cdot [\sigma_1] & \mathbb{Z} \cdot [\sigma_0] \\
\mathbb{Z} \cdot [\sigma_3] & \mathbb{Z} \cdot [\sigma_2] \end{array} \right) & \rightarrow & H_1(T) & \stackrel{\partial}{\rightarrow} & \ker \left( \begin{array}{cc} \mathbb{Z} \cdot [\sigma_0] & \mathbb{Z} \cdot [\sigma_1] \end{array} \right) & \rightarrow & 0. \\
\uparrow{\cong} & & & \uparrow{\text{id}} & & \uparrow{\text{id}} & & \uparrow{\cong} \\
0 & \rightarrow & \mathbb{Z} \cdot [\sigma_1] & \rightarrow & \mathbb{H}_1(T) & \rightarrow & \mathbb{Z} \cdot [Q_1] & \rightarrow & 0.
\end{array}
$$

It follows from the above discussion and Lemma 46.4 that the top horizontal sequence is exact. Elementary linear algebra shows that the vertical maps are isomorphisms. Finally
it is basically clear that the diagram commutes. Since in the bottom the groups to the left and right are both isomorphic to $\mathbb{Z}$ we obtain from Corollary 46.3 that $H_1(T) \cong \mathbb{Z}^2$. Finally it follows from the above long exact sequence and the discussion on page 1108 that

$$H_0(T) \cong \text{coker} \left( \frac{\mathbb{Z} \cdot [Q_1]}{\mathbb{Z} \cdot [Q_3]} \rightarrow \frac{\mathbb{Z} \cdot [Q_0]}{\mathbb{Z} \cdot [Q_2]} \right) \cong \mathbb{Z}.$$ 

This concludes the proof of statement (1) of the lemma.

Now we turn to proof of the second statement of Lemma 46.12.

**Proof of Lemma 46.12 (2).** We continue with the notation that we introduced in the proof of statement (1) of Lemma 46.12. Next we provide the proof of (2a). Note that $[c] = [\sigma_1] \in H_1(C)$. Let $a$ and $b$ be the singular simplices in $A$ and $B$ that are indicated in Figure 771. Recall that we have the following short exact sequence:

$$0 \rightarrow \mathbb{Z} \cdot [\sigma_1] \rightarrow H_1(T) \xrightarrow{\partial} \mathbb{Z} \cdot \left( \frac{[Q_1]}{[Q_2]} \right) \rightarrow 0.$$ 

Evidently $[c] = [\sigma_1]$ represents a generator of the group on the left-hand side. Furthermore note that $a + b$ is a cycle in $T$ with $a \in C_1(A)$ and $b \in C_1(B)$, thus we have

$$\partial_1([a + b]) = [\partial a] = [P - Q] = \left( \begin{array}{c} 1 \\ -1 \end{array} \right) \in \frac{H_1(C_1)}{H_1(C_2)} = \mathbb{Z}.$$ 

see the definition of $\partial_1$ in Theorem 46.10 (1)

Thus we see that $\partial_1([a + b])$ is a generator of the group on the right-hand side of the above short exact sequence. It follows from Corollary 46.3 (2) that $[c]$ and $[a + b]$ generate the free abelian group $H_1(T) \cong \mathbb{Z}^2$. The desired statement now follows from the observation that Lemma 41.3 (3) implies that $[a + b] = [d]$. This concludes the proof of (2a).

Now we turn to the proof of (2b). Let $\alpha$ and $\beta$ be the two singular 2-simplices that are shown in Figure 769 on the right. It is straightforward to verify that the singular 2-chain $\alpha - \beta$ is indeed a cycle. Note that the proof that $\alpha - \beta$ represents a generator of $H_2(T)$ is less immediate than the previous argument since the singular simplices $\alpha$ and $\beta$ do not “fit” into any of the groups of our long exact sequence. In fact, as we will see, the proof that $\alpha - \beta$ represents a generator of $H_2(T)$ is quite similar to the proof of Lemma 45.3

\footnote{Of course we already knew by Proposition 41.5 that $H_0(T) \cong \mathbb{Z}$.}
We denote by \( A \) and \( B \) the images of \( \alpha: \Delta^2 \to T \) and \( \beta: \Delta^2 \to T \). (We refer to Figure 772 for an illustration.) We consider the following maps

\[
\begin{align*}
H_2(T) & \xrightarrow{\alpha - \beta \to [\alpha - \beta]} H_2(T/B, B/B) \cong \mathbb{Z} \cong H_2(\Delta^2, \partial \Delta^2) \xrightarrow{\id_{\Delta^2} \to [\alpha]} H_2(\Delta^2, \partial \Delta^2),
\end{align*}
\]

We make the following observations:

(i) By Lemma 45.2 we know that \([\id_{\Delta^2}] \in H_2(\Delta^2, \partial \Delta^2) \cong \mathbb{Z}\) is a generator.

(ii) The two horizontal maps on the right are induced by homeomorphisms of pairs of topological spaces, hence they are isomorphisms.

(iii) The vertical homomorphism on the right is an isomorphism by Proposition 43.22 and Lemma 13.1.

(iv) Note that statements (i), (ii) and (iii) imply that \([\alpha]\) represents a generator of the group \(H_2(T/B, B/B) \cong \mathbb{Z}\).

(v) The singular 2-simplex \(\beta: \Delta^2 \to B\) is zero in \(C_2(T/B, B/B)\). Therefore we have \([\alpha - \beta] = [\alpha] \in H_2(T/B, B/B)\).

(vi) Next note that statements (iv) and (v) imply that the image of \([\alpha - \beta] \in H_2(T) \cong \mathbb{Z}\) under the map \(H_2(T) \to H_2(T/B, B/B)\) is a generator of \(H_2(T/B, B/B) \cong \mathbb{Z}\). But this implies that \([\alpha - \beta]\) is a generator of \(H_2(T) \cong \mathbb{Z}\).

\[\text{Figure 772. Illustration for the proof of Lemma 46.12 (2b).}\]

In Exercise 46.3 we will determine the homology groups of the Klein bottle. More precisely, using the Mayer–Vietoris Theorem 46.10 for Manifolds we will prove the following lemma.

**Lemma 46.13.** We denote by \( K \) the Klein bottle. Then

\[
H_n(K) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z} \oplus \mathbb{Z}_2, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}
\]

Furthermore we can determine explicitly two generators of \(H_1(K)\). More precisely, we consider Figure 773. There the singular 1-simplex \( d \) generates the \( \mathbb{Z}_2 \)-summand and the singular 1-simplex \( c \) generates a \( \mathbb{Z} \)-summand of \( H_1(K) \).\(^{750}\) We leave the verification of this statement to the reader.

\(^{750}\)It is straightforward to see that \( c \) generates an element of infinite order since the “vertical projection” \( K \to [0,1]/\sim \) sends \( c \) to a generator of \( H_1([0,1]/\sim) = H_1(S^1) \).
Remark. With some effort one could now use the Mayer–Vietoris Theorem \[46.10\] for Manifolds to compute the homology groups of the surfaces of genus \(\geq 2\). We will not carry out the argument in this chapter since in Proposition \[48.9\] we will perform the calculation using an alternative argument, namely using “cellular homology” which greatly simplifies the calculation. For the impatient reader we state the calculation of the homology groups of surfaces of genus \(\geq 2\) as Exercise \[46.13\].

46.6. The first homology group of a knot complement. Finally we want to determine the first homology group of the complement of a knot. We recall the relevant definitions from pages \[385\] and \[390\]:

(1) A knot is a 1-dimensional submanifold of \(S^3\) that is diffeomorphic to \(S^1\).

(2) Let \(K\) be an oriented knot in \(S^3\). By the Tubular Neighborhood Theorem \[8.24\] there exists an orientation-preserving smooth embedding \(F: \mathcal{B}^2 \times K \to S^3\) such that \(\Phi(0, P) = P\) for all \(P \in K\). For any \(* \in S^1\) we refer to the oriented submanifold \(F(S^1 \times \{*\})\) as a meridian of the knot \(K\).

We refer to Figure \[774\] for an illustration of an oriented knot and a meridian. We also introduce one new definition:

(3) Let \(M\) be a smooth manifold and let \(C\) be a closed oriented curve in \(M\), see page \[544\] for the definition. Sometimes, by a slight abuse of notation, we denote by \(C\) also the element in \(H_1(M)\) that is given by the image of the standard generator \([S^1]\) of \(H_1(S^1)\) under the map \(H_1(S^1) \xrightarrow{\Phi} H_1(C) \to H_1(M)\)\(^{751}\).

\[\hfill \]

\[d\] generates the \(\mathbb{Z}_2\)-summand

\[\hfill \]

\[c\] generates a \(\mathbb{Z}\)-summand

\[\hfill \]

\[\text{Klein bottle } K\]

\[\hfill \]

\[\text{Figure 773}\]

\[\hfill \]

\[\text{Lemma 46.14. Let } K \subset S^3 \text{ be a knot. Then }^{732}\]

\[\hfill \]

\[H_0(S^3 \setminus K) \cong \mathbb{Z} \quad \text{and} \quad H_1(S^3 \setminus K) = \mathbb{Z} \cdot [\mu].\]

\[\hfill \]

\[\uparrow \]

\[\text{here } \mu \text{ is any meridian of } K\]

\[\hfill \]

\[^{751}\text{It follows from Proposition } 30.1 \text{ and Proposition } 42.5 \text{ that, up to a sign, the homology class does not depend on the choice of the orientation-preserving diffeomorphism } \Phi.\]

\[\hfill \]

\[\text{Figure 774}\]
Later, in Lemma 68.16 we will compute the remaining homology groups of $S^3 \setminus K$.

**Remark.** The result of Lemma 46.14 is easy to state but also slightly disappointing since it shows that the first homology groups cannot be used to distinguish different knots. In contrast to this fact we saw in Proposition 27.5 and Proposition 27.6 that the fundamental group can be used to distinguish the trivial knot from the trefoil.

**Proof.** Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem 8.24 there exists a smooth embedding $\Phi: \mathcal{B}^2 \times K \to S^3$ with $\Phi(0, P) = P$ for all $P \in K$. To simplify the notation we drop $\Phi$ from the notation, in particular we write $\mathcal{B}^2 \times K$ instead of $\Phi(\mathcal{B}^2 \times K)$. It is basically clear that the interiors of $S^3 \setminus K$ and $\mathcal{B}^2 \times K$ cover $S^3$. Therefore we can apply the Mayer–Vietoris Theorem 46.5 to the decomposition $S^3 = (S^3 \setminus K) \cup (\mathcal{B}^2 \times K)$ and we obtain the following exact sequence

\[
\begin{align*}
\tilde{H}_2(S^3) & \to H_1((\mathcal{B}^2 \setminus \{0\}) \times K) \to H_1(S^3 \setminus K) + H_1(\mathcal{B}^2 \times K) \to \tilde{H}_1(S^3) \\
& \to \tilde{H}_0((\mathcal{B}^2 \setminus \{0\}) \times K) \to \tilde{H}_0(S^3 \setminus K) + \tilde{H}_0(\mathcal{B}^2 \times K) \to \tilde{H}_0(S^3) \to 0.
\end{align*}
\]

Now we have to study the homology groups of the various spaces in more detail.

1. We denote by $[\mu] = S^1 \times \{\ast\}$ the meridian and we define $[\lambda] = \{\ast\} \times K$. It follows from Lemma 46.12 (2) that $[\mu]$ and $[\lambda]$ is a basis for $H_1(S^1 \times K)$. The inclusion $S^1 \times K \to (\mathcal{B}^2 \setminus \{0\}) \times K$ is a homotopy equivalence. It follows from the above, Proposition 41.5 and Corollary 42.8 that $H_1((\mathcal{B}^2 \setminus \{0\}) \times K) \cong \mathbb{Z} \cdot [\mu] \oplus \mathbb{Z} \cdot [\lambda]$ and that $\tilde{H}_0((\mathcal{B}^2 \setminus \{0\}) \times K) = 0$.

2. We write $[\gamma] = \{0\} \times K$. The inclusion $\{0\} \times K \to \mathcal{B}^2 \times K$ is a homotopy equivalence. Similar to (1) we see that $H_1(\mathcal{B}^2 \times K) \cong \mathbb{Z} \cdot [\gamma]$ and that $\tilde{H}_0(\mathcal{B}^2 \times K) = 0$.

3. Under the inclusion induced map

\[
\tilde{H}_1((\mathcal{B}^2 \setminus \{0\}) \times K) = \mathbb{Z} \cdot [\mu] \oplus \mathbb{Z} \cdot [\lambda] \to \tilde{H}_1(\mathcal{B}^2 \times K) = \mathbb{Z} \cdot [\gamma]
\]

we have $[\mu] \mapsto 0$ and we have $[\lambda] \mapsto [\gamma]$.

Thus we obtain an exact sequence of the following form

\[
0 \to \mathbb{Z} \cdot [\mu] \oplus \mathbb{Z} \cdot [\lambda] \xrightarrow{[\mu] \mapsto ([\mu], 0) \atop [\lambda] \mapsto ([\lambda], [\gamma])} H_1(S^3 \setminus K) + \mathbb{Z} \cdot [\gamma] \to 0 \to \tilde{H}_0(S^3 \setminus K) \oplus 0 \to 0 \to 0.
\]

\[\text{By Proposition 41.5 the first statement just says that } S^3 \setminus K \text{ is path-connected. This seems obvious from the pictures, but it is nonetheless somewhat non-trivial to prove. For example, as discussed in Corollary 9.14, this statement can be viewed as a consequence of the Transversality Theorem 9.10.}\]

\[\text{We will do the calculation by hand. Alternatively this calculation is also a good moment to use Exercise 41.12.}\]

\[\text{This can be seen as follows: the map } H_1(S^3 \setminus \{\ast\}) \to H_1(\mathcal{B}^2 \times K) \text{ factors through } H_1(\mathcal{B}^2 \times \{\ast\}) = 0.\]

\[\text{Why is that?}\]
Now it follows immediately from Corollary 46.3 and Lemma 19.8 (1) that $H_1(S^3 \setminus K) \cong \mathbb{Z}$ and that $H_2(S^3 \setminus K) \cong 0$. Furthermore it follows easily that $[\mu] \in H_1(S^3 \setminus K) = H_1(S^3 \setminus K)$ is a generator.

Remark.

(1) In the proof of Lemma 46.14 we used the Mayer–Vietoris Theorem 46.5 in a different way than in the previous examples. More precisely, instead of decomposing $S^3 \setminus K$ into smaller pieces, we used that for a decomposition $X = U \cup V$ the Mayer–Vietoris sequence not only relates the homology groups of $U, V$ and $U \cap V$ to the homology groups of $X$, but also that it relates the homology groups of $U$ to the homology groups of $V, U \cap V$ and $X$.

(2) The reader might wonder what the approach of Lemma 46.14 can say about the groups $H_2(S^3 \setminus K)$ and $H_3(S^3 \setminus K)$. In fact the approach shows that the exists an exact sequence

$$H_3(S^3 \setminus K) \to H_3(S^3) \xrightarrow{\partial} H_2((B^2 \setminus \{0\}) \times K) \to H_2(S^3 \setminus K) \to 0.$$ 

Since do not know whether the connecting homomorphism is the zero map, injective or perhaps even an isomorphism we cannot determine $H_2(S^3 \setminus K)$ and $H_3(S^3 \setminus K)$. Later, in Chapter 68 will acquire the tools necessary to study this map. This will allow us in Lemma 68.16 to completely determine the isomorphism classes of the homology groups of $S^3 \setminus K$.

The following lemma will be proved in Exercise 46.12

**Lemma 46.15.** Let $X \subset \mathbb{R}^n$ be a non-empty compact subset. We denote by $S^n = \mathbb{R}^n \cup \{\infty\}$ the topological space $\mathbb{R}^n$ with a “point at infinity”. Then for any $k \in \mathbb{N}_0$ we have

$$H_k(\mathbb{R}^n \setminus X) \cong \begin{cases} H_k(\mathbb{R}^n \cup \{\infty\} \setminus X) \oplus \mathbb{Z}, & \text{if } k = n - 1, \\ H_k(\mathbb{R}^n \cup \{\infty\} \setminus X), & \text{otherwise.} \end{cases}$$

46.7. The homology groups of a mapping cone (*). In this section we will discuss the homology groups of a mapping cone. Before we start the discussion we recall the relevant definitions.

(1) On page 692, given a non-empty topological space $A$ we defined the cone on $A$ as

$$\text{Cone}(A) := (A \times [0, 1]) / \sim \quad \text{where } (a, 0) \sim (a', 0) \text{ for all } a, a' \in A.$$ 

If $A = \emptyset$, then we defined $\text{Cone}(\emptyset) = \{\ast\}$ to be the topological space consisting of a single point $\ast$.

(2) Given a map $f: A \to X$ between topological spaces we defined on page 701 the corresponding mapping cone as

$$\text{Cone}(f: A \to X) := (\text{Cone}(A) \sqcup X) / \sim \quad \text{where } (a, 1) \sim f(a) \text{ for all } a \in A.$$ 

\footnote{Why does this follow?}
We refer to $[A \times 0]$ respectively $*$ as the cone point of $\text{Cone}(A)$ and of $\text{Cone}(i: A \to X)$.

The following lemma gives an elegant calculation of the homology groups of a mapping cone of an inclusion.

**Lemma 46.16.**

(1) Let $X$ be a topological space and let $A \subset X$ be a subset. We denote by $i: A \to X$ the inclusion map. For any $n \in \mathbb{N}_0$ the two maps

$$H_n(X, A) \to H_n(\text{Cone}(i: A \to X), \text{Cone}(A)) \xleftarrow{\cong} \tilde{H}_n(\text{Cone}(i: A \to X))$$

are isomorphisms.

(2) We denote by $\text{PairTop}$ the category of pairs of topological spaces and we denote by $\text{AbGr}$ the category of abelian groups. The composition of the two isomorphisms in (1) define a natural isomorphism from the functor $\text{PairTop} \to \text{AbGr}$ $(X, A) \mapsto \tilde{H}_n(\text{Cone}(i: A \to X))$ to the functor $\text{PairTop} \to \text{AbGr}$ $(X, A) \mapsto H_n(X, A)$.

**Proof.**

(1) Just for kicks we throw in one more map:

$$H_n \left( \text{Cone}(A \xrightarrow{i} X) \setminus \{P\}, \text{Cone}(A) \setminus \{P\} \right)$$

$\xrightarrow{(a)}$

$$H_k(X, A) \to H_k(\text{Cone}(i: A \to X), \text{Cone}(A)) \xleftarrow{\cong} \tilde{H}_k(\text{Cone}(i: A \to X)).$$

Since the diagram commutes it suffices to show that the maps (a), (b) and (c) are isomorphisms.

(a) From a slight variation on Lemma 24.8 (1) we obtain a deformation retraction from $\text{Cone}(i: A \to X) \setminus \{P\}$ to $X$ which restricts to a deformation retraction from $\text{Cone}(A)$ to $A$. Thus it follows from Exercise 43.15 that the map (a) is an isomorphism.

(b) It follows from the Excision Theorem 43.19 that the vertical map (b) is an isomorphism.

(c) By Lemma 24.1 we know that the cone $\text{Cone}(A)$ is contractible. It follows from Corollary 43.16 that the map (c) is an isomorphism.

(2) It is clear that the two maps in (1) are natural. Thus it follows that the two maps together define a natural isomorphism. $\blacksquare$

**Remark.**

(1) It is worth comparing Lemma 46.16 to Lemma 43.14 which says that given a pointed topological space $(X, x_0)$ the reduced homology groups $\tilde{H}_i(X)$ are naturally isomorphic to the relative homology groups $H_i(X, \{x_0\})$.  

---

As in Lemma 24.10 (3) we see that the left-hand side does indeed define a functor.
(2) In Proposition 43.22 we showed that, under favorable circumstances, we can replace the relative homology group $H_n(X, A)$ by the homology group $\tilde{H}_n(X/A)$. Lemma 46.16 says that we can replace any relative homology group by the homology group of the mapping cone of the inclusion.

(3) Loosely speaking, Lemma 46.16 says that for all intents and purposes we can usually replace the relative homology groups of a pair $(X, A)$ of topological spaces by the reduced homology of the mapping cone of the inclusion $A \to X$.

**Proof.** We had just seen that the map is an isomorphism. It is straightforward to verify that the maps define a natural transformation. \hfill \blacksquare

We obtain the following convenient corollary which is a very close relative of Proposition 43.22.

**Corollary 46.17.** Let $X$ be a topological space and let $A \subset X$ be a subset. We denote by $i: A \to X$ the inclusion map. If $i$ is a closed cofibration, then for any $n \in \mathbb{N}_0$ the natural map $\iota: H_n(X, A) \to \tilde{H}_n(X/A)$ from page 1129 is an isomorphism.

**Proof.** The case that $A = \emptyset$ is basically trivial and is left to the reader. In the following we assume that $A \subset X$ is a non-empty subset. Let $n \in \mathbb{N}_0$. We consider the following diagram

$$
\begin{array}{ccc}
H_n(X, A) & \xrightarrow{\iota} & \tilde{H}_n(X/A) \\
\cong & & \Downarrow \varphi \\
\tilde{H}_n(\text{Cone}(i: A \to X)).
\end{array}
$$

We make the following clarifications and observations:

1. The top horizontal map is the natural homomorphism that we introduced on page 1129.
2. The left diagonal map is the natural isomorphism of Lemma 46.16.
3. The right diagonal map is the map

$$
\varphi: \text{Cone}(i: A \to X) \to X/A \\
P \mapsto \begin{cases} 
[P], & \text{if } P \in X, \\
[A], & \text{if } P = [(a, t)] \text{ with } a \in A \text{ and } t \in [0, 1]
\end{cases}
$$

that we introduced in Lemma 39.9 (1).
4. It follows easily from the definitions that the diagram commutes.
(5) Since \( i : A \to X \) is by hypothesis a closed cofibration we obtain from Lemma 39.9(1) that \( \varphi \) is a homotopy equivalence. Therefore we obtain from Corollary 42.8 that the right diagonal map is also an isomorphism.

(6) Putting everything together we see that the top map is indeed an isomorphism. □

Let \( A \) be a subset of a topological space \( X \). We denote by \( i : A \to X \) the corresponding inclusion map. It follows from Corollary 43.16 together with Lemma 46.16 that the inclusion induced maps \( i_* : \text{H}_k(A) \to \text{H}_k(X) \) fit into the following natural long exact sequence

\[
\ldots \to \text{H}_k(A) \overset{i_*}{\to} \text{H}_k(X) \to \text{H}_k(X,A) \overset{\partial}{\to} \text{H}_{k-1}(A) \overset{i_*}{\to} \text{H}_{k-1}(X) \to \ldots
\]

The following lemma generalizes this neat fact to the setting of any map \( f : A \to X \) between topological spaces.

**Lemma 46.18.**

(1) Let \( f : A \to X \) be a map between topological spaces.

(a) We denote by \( j(f) : X \to \text{Cone}(f) = (\text{Cone}(A) \sqcup X)/\sim \) the obvious inclusion map.

(b) We denote by \( U \) the image of \( A \times [0, \frac{3}{4}] \) in \( \text{Cone}(f) \) and we denote by \( V \) the complement of the image of \( A \times [0, \frac{1}{4}] \). (See also Figure 776) We consider the following diagram

\[
\begin{array}{ccccccccc}
\ldots & \to & \text{H}_k(U) & \oplus & \text{H}_k(V) & \to & \text{H}_k(\text{Cone}(f)) & \overset{\partial_k}{\to} & \text{H}_{k-1}(U \cap V) & \to & \ldots \\
& & & & & & & & & & \\
& & & & & & \uparrow \Phi & & \uparrow \cong & & \\
& & & & & & \text{H}_k(\text{Cone}(f)) & \overset{\partial_k}{=} \overset{f_\ast}{\to} & \text{H}_{k-1}(A) \\
\end{array}
\]

Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 46.4 and the vertical map is induced by the inclusion \( a \mapsto (a, \frac{1}{2}) \) which is a homotopy equivalence. From the above diagram we obtain a map

\[ \partial_k(f) : \widetilde{\text{H}}_k(\text{Cone}(f)) \to \text{H}_{k-1}(A). \]

With these definitions the following sequence is exact

\[
\ldots \to \text{H}_k(A) \overset{f_*}{\to} \text{H}_k(X) \overset{j(f)_*}{\to} \widetilde{\text{H}}_k(\text{Cone}(f)) \overset{\partial_k(f)}{\to} \text{H}_{k-1}(A) \to \ldots
\]

(2) The connecting homomorphism in (1) is natural. In particular given any commutative diagram

\[
\begin{array}{ccc}
A & \overset{f}{\longrightarrow} & X \\
\downarrow \varphi & & \downarrow \psi \\
\tilde{A} & \overset{\tilde{f}}{\longrightarrow} & \tilde{X}
\end{array}
\]
of maps between topological spaces the following diagram commutes:

\[\ldots \longrightarrow H_k(A) \overset{i_*}{\longrightarrow} H_k(X) \longrightarrow H_k(X, A) \longrightarrow \tilde{H}_k(A) \longrightarrow \tilde{H}_{k-1}(A) \longrightarrow \ldots \]

Here the vertical maps between the homology groups of the mapping cones are induced by the maps from Lemma 24.10 (3).

(3) Let \( X \) be a topological space and let \( A \subset X \) be a subset. We denote by \( i: A \to X \) the inclusion map. The following diagram

\[\ldots \longrightarrow H_k(A) \overset{i_*}{\longrightarrow} H_k(X) \longrightarrow H_k(X, A) \longrightarrow \tilde{H}_k(A) \longrightarrow \tilde{H}_{k-1}(A) \longrightarrow \ldots \]

commutes. Here the middle vertical map is the natural isomorphism from Lemma 46.16, the top sequence is the long exact sequence arising from Corollary 43.16 and the bottom sequence is the exact sequence from (1).

The obvious analogues of the above statements for reduced homology of \( A \) and \( X \) also hold.

\[\begin{array}{c}
\includegraphics[width=0.5\textwidth]{figure776.png}
\end{array}\]

**Figure 776.** Illustration of Lemma 46.18

---

**Proof.**

---

\(^{758}\) In the statement and the proof of the lemma we implicitly use Lemmas 24.2 and 24.9 (2) several times to show that various maps are open and closed embeddings. For example it follows from Lemma 24.2 that the map \( j(f) \) given in (1a) is actually a closed embedding.

\(^{759}\) We leave it to the reader to give a reasonable interpretation of what we say here in the special case that \( A = \emptyset \).

\(^{760}\) Note that \( U \) and \( V \) are open subsets of \( \text{Cone}(f) \).
We consider the following diagram:

\[
\begin{array}{cccccccc}
\vdots & \longrightarrow & H_k(U \cap V) & \longrightarrow & H_k(U) \oplus H_k(V) & \longrightarrow & H_k(\text{Cone}(f)) & \partial_k & H_{k-1}(U \cap V) & \longrightarrow & \vdots \\
\cong & \uparrow & & & & & & & & & \cong \\
\vdots & \longrightarrow & H_k(A) & \longrightarrow & H_k(\{\ast\}) \oplus H_k(X) & \longrightarrow & H_k(\text{Cone}(f)) & \longrightarrow & H_{k-1}(A) & \longrightarrow & \vdots \\
\cong & \uparrow & & & & & & & & \cong & \uparrow \\
\vdots & \longrightarrow & H_k(A) & \longrightarrow & \widetilde{H}_k(\{\ast\}) \oplus H_k(X) & \longrightarrow & \widetilde{H}_k(\text{Cone}(f)) & \partial_k(f) & H_{k-1}(A) & \longrightarrow & \vdots \\
& & & & & & & & & & =0 \\
\end{array}
\]

We make the following clarifications and observations:

(a) The top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 46.5 applied to the open cover \(\text{Cone}(f) = U \cup V\).

(b) We denote by \(\ast\) the cone point of \(\text{Cone}(f)\).

(c) The vertical maps are the almost obvious inclusion maps. The map \(c : A \to \{\ast\}\) is the constant map. It follows almost immediately from the definitions together with Proposition 42.5 that the upper part of the diagram commutes.

(d) As in Lemma 24.1 we see that the inclusion \(\{\ast\} \to U\) is a homotopy equivalence. Furthermore, by Lemma 43.1 (7) we know that \(\widetilde{H}_k(\{\ast\}) = 0\).

(e) It follows now fairly easily from Lemma 43.2 that the lower part of the diagram also commutes and that the lower sequence is exact. But that is what we wanted to show.

(2) This statement follows from the naturality of the connecting homomorphisms of the Mayer–Vietoris sequence, see Theorem 46.5 (2).

(3) We will prove this statement in Exercise 46.18.

In Proposition 37.11 we saw how attaching an \(n\)-cell to a topological space affects its fundamental group. Basically for free we now get a corresponding statement for homology groups.

**Lemma 46.19.** Let \(X\) be a topological space, let \(n \geq 2\) and let \(\varphi : S^{n-1} \to X\) be a map. We denote by \(i : X \to X \cup_{\varphi} B^n\) the obvious map. (Note that by Lemma 34.3 we know that \(i\) is a closed embedding.) There exists a natural exact sequence of the form

\[
0 \to H_n(X) \overset{i_*}{\longrightarrow} H_n(X \cup_{\varphi} B^n) \to H_{n-1}(S^{n-1}) \overset{\varphi_*}{\longrightarrow} H_{n-1}(X) \overset{i_*}{\longrightarrow} H_{n-1}(X \cup_{\varphi} B^n) \to 0.
\]

Furthermore, for any \(k \neq n - 1, n\) the inclusion induced map

\[
i_* : H_k(X) \cong H_k(X \cup_{\varphi} B^n)
\]

is an isomorphism.

**Example.** Let \(X\) be a topological space with finitely generated homology groups. Let \(n \geq 2\) and let \(\varphi : S^{n-1} \to X\) be a map. Loosely speaking Lemma 46.19 says that gluing on
a copy of $B^n$ along $\varphi$ has the following effect on homology:

<table>
<thead>
<tr>
<th>$H_{n-1}(S^{n-1}) \xrightarrow{\varphi^*} H_{n-1}(X)$ has infinite image</th>
<th>$H_n$</th>
<th>$H_{n-1}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$H_{n-1}(S^{n-1}) \xrightarrow{\varphi} H_{n-1}(X)$ has finite image</td>
<td>unchanged</td>
<td>rank goes down by 1</td>
</tr>
<tr>
<td></td>
<td>rank goes up by 1</td>
<td>unchanged.</td>
</tr>
</tbody>
</table>

We illustrate these two different behaviors in Figure 777.

![Figure 777](image)

\(\varphi_*: H_1(S^1) \to H_1(X)\) has infinite image \(\varphi_*: H_1(S^1) \to H_1(X)\) has trivial image

**Proof.** On page 991 we made the, almost trivial, observation that there exists a homeomorphism $\text{Cone}(\varphi: S^{n-1} \to X) \cong X \cup_{\varphi} B^n$ which is the identity on $X$. The conclusion of Lemma 46.19 follows immediately from this observation together with Lemma 46.18, the calculation of the homology groups of $S^{n-1}$, see Proposition 43.4 and the observation that our hypothesis that $n \geq 2$ implies that we do not need to worry about reduced homology groups.

The last lemma of this section gives a neat reinterpretation of the connecting homomorphism in the long exact sequence of Lemma 46.18.

**Lemma 46.20.** (*) Let $f: A \to X$ be a map between topological spaces. For every $k \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
\tilde{H}_k(\text{Cone}(f: A \to X)) & \xrightarrow{\partial} & \tilde{H}_{k-1}(A) \\
\downarrow & & \downarrow_{\cong \Sigma_A} \\
\tilde{H}_k(\text{Cone}(f: A \to X)/X) & \xrightarrow{\varphi_*} & \tilde{H}_k(\Sigma(A)).
\end{array}
$$

Here we used the following notation:

1. The top horizontal map is the connecting homomorphism of the long exact sequence given in Lemma 46.18.
2. The left vertical map is induced by the obvious projection.
3. The map $\varphi: \text{Cone}(f: A \to X)/X \to \Sigma(A)$ is the natural homeomorphism from Lemma 24.9 (4).
4. The map $\Sigma_A: \tilde{H}_{k-1}(A) \to \tilde{H}_k(\Sigma(A))$ is the natural isomorphism from Lemma 46.8.

**Proof (\(*\)).** The statement follows immediately from the explicit definition of the maps $\partial$ and $\Sigma_A$ via Mayer–Vietoris sequences, from the explicit definition of the map $\varphi$, and from the naturality of the connecting homomorphism of the Mayer–Vietoris sequence, see
Theorem 46.5 (2), that the isomorphism $\Sigma_X$ is natural. We leave it to the reader to fill in the details.

46.8. The homology groups of a mapping torus (*). On page 711 we defined the mapping torus of a self-homeomorphism and in Proposition 24.28 we had determined the fundamental group of the mapping torus. In this section we will determine the isomorphism types of the homology groups of a mapping torus.

For convenience we recall from page 711 the definition of the mapping torus. Let $X$ be a topological space and let $f : X \to X$ be a map. We refer to

$$\text{Tor}(X, f) := (X \times [0, 1])/(x, 0) \sim (f(x), 1)$$

as the mapping torus of $(X, f)$. In the following we will use on several occasions Lemma 24.19 which says that for any closed respectively open interval $I \subset \mathbb{R}$ of length less than one, the map

$$\varphi : X \times I \xrightarrow{(x,t)\mapsto ([x,t])} (X \times \mathbb{R})/\sim \xrightarrow{([x,t])\mapsto ([x,t])} \text{Tor}(X, f)$$

is a closed respectively open embedding. Now we can state the main result of this section.

Proposition 46.21. Let $X$ be a topological space and let $f : X \to X$ be a map. For every $n \in \mathbb{N}_0$ we have a natural short exact sequence,

$$0 \to \ker(H_n(X) \xrightarrow{f_*-\text{id}} H_n(X)) \xrightarrow{i} \text{Tor}(X, f) \to \ker(H_{n-1}(X) \xrightarrow{f_*-\text{id}} H_{n-1}(X)) \to 0,$$

where the map $i$ is induced by the embedding $X \xrightarrow{x \mapsto ([x,0])} \text{Tor}(X, f)$.

Example. First let $X = S^1$ and let $f : S^1 \to S^1$ be the self-homeomorphism that is given by $f(z) = \overline{z} = z^{-1}$. On page 713 we saw that the mapping torus $\text{Tor}(S^1, f)$ is homeomorphic to the Klein bottle. It follows from the discussion on page 1088 the induced map $f_* : H_0(S^1) \to H_0(S^1)$ is the identity map. Furthermore we showed in Lemma 45.10 that the induced homomorphism $f_* : H_1(S^1) \to H_1(S^1)$ is given by multiplication by -1. Since $H_0(S^1) \cong \mathbb{Z}$ and $H_1(S^1) \cong \mathbb{Z}$ we now see that the short exact sequences of Proposition 46.21 are of the form

$$n = 2: \quad 0 \to H_2(\text{Tor}(S^1, f)) \to \ker(\mathbb{Z} \xrightarrow{2} \mathbb{Z}) \to 0$$

$$n = 1: \quad 0 \to \ker(\mathbb{Z} \xrightarrow{-1} \mathbb{Z}) \to H_1(\text{Tor}(S^1, f)) \to \ker(\mathbb{Z} \xrightarrow{-1} \mathbb{Z}) \to 0$$

and

$$n = 0: \quad 0 \to \ker(\mathbb{Z} \xrightarrow{-1} \mathbb{Z}) \to H_0(\text{Tor}(S^1, f)) \to 0.$$
Using Corollary 46.3 we now deduce that
\[ H_2(\text{Tor}(S^1, f)) = 0, \quad H_1(\text{Tor}(S^1, f)) \cong \mathbb{Z}_2 \oplus \mathbb{Z} \quad \text{and} \quad H_0(\text{Tor}(S^1, f)) = \mathbb{Z}. \]

This confirms, as it should, the calculation that we had made in Lemma 46.13.

**Proof.** The proof of the proposition is quite similar to the calculation of the homology groups of the torus.\(^{762}\) Let \( X \) be a topological space and let \( f: X \to X \) be a homeomorphism. We compute the homology of the following space that is clearly naturally homeomorphic to the mapping torus:
\[ M := (X \times [0, 10])/ (x, 0) \sim (f(x), 10). \]

We denote by \( p: X \times [0, 10] \to M \) the obvious projection map. Furthermore we write \( A := p(X \times ([0, 4] \cup (6, 10])) \subset M \) and \( B := p(X \times (2, 8)) \subset M \).\(^{763}\) Finally, given \( t \in [0, 10] \) we denote by
\[ i_t: X \to p(X \times \{t\}) \]
\[ x \mapsto p(x, t) \]
the obvious inclusion map. We write \( i_{3,A} \) for the composition of \( i_3 \) with the inclusion map \( p(X \times \{3\}) \to A \). We denote analogous compositions by the obvious variations in the notation. The proof below crucially relies on the following claim.

**Claim.** For any \( n \in \mathbb{N}_0 \) the following two diagrams commute
\[
\begin{array}{ccc}
H_n(X) & \xrightarrow{id} & H_n(X) \\
i_{3,B} & & \downarrow i_{7,B} \\
H_n(B) & & H_n(B)
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
H_n(X) & \xrightarrow{f_{r}^{-1}} & H_n(X) \\
i_{3,A} & & \downarrow i_{r,A} \\
H_n(B) & & H_n(B)
\end{array}
\]

It follows almost immediately from Proposition 42.5 that the two triangles commute. We leave the details to the reader. \( \square \)

\[ \text{Figure 779. Illustration for the proof of Proposition 46.21} \]

---

\(^{762}\) In fact if one reads the subsequent proof with \( X = S^1 \) and \( f = \text{id} \) in mind, then one obtains almost the same argument as for the torus.

\(^{763}\) Throughout this proof we will freely use Lemma 24.19 which says that \( p: X \times [0, 1] \to M \), restricted to reasonable open subsets, is in fact an open embedding.
Next we consider the following diagram:

\[
\begin{array}{cccccccc}
H_n(C_1) & \xrightarrow{i_{C_1}} & H_n(A) & \xrightarrow{i_A} & H_n(B) & \xrightarrow{\partial} & H_n(M) & \xrightarrow{\partial} & H_n(C_2) \\
& \downarrow{i_{i_1}} & & \downarrow{i_{i_2}} & & \downarrow{id} & & \downarrow{id} \\
H_n(X) & \xrightarrow{id-f_*} & H_n(X) & \xrightarrow{i} & H_n(M) & \xrightarrow{\partial} & H_n-1(X) & \xrightarrow{id-f_*} & H_n-1(X)
\end{array}
\]

The above diagram arose as follows:

1. Note that the interiors of \(A = p(X \times ([0, 4] \cup (6, 10])) \subset M\) and \(B = p(X \times (2, 8)) \subset M\) cover all of \(M\). Furthermore note that we have \(A \cap B = C_1 \cup C_2\). On the top of the diagram we wrote down the corresponding exact Mayer-Vietoris sequence from Theorem 46.5.

2. Note that the maps \(i_3: X \to A\), \(i_3: X \to C_1\), \(i_7: X \to C_2\) and \(i_7: X \to B\) are homotopy equivalences. It follows from Corollary 42.8 that the induced maps on homology are isomorphisms. In particular the vertical maps between the first and the second horizontal sequence are isomorphisms.

3. Next we want to show that the top part of the diagram commutes. The squares involving \(id: H_n(M) \to H_n(M)\) commute by the functoriality of homology groups and by definition of the connecting homomorphism \(\partial\) in the middle row. It remains to consider the squares which in our excerpt above are to the left and right. The discussion is perhaps less confusing if we explain how the maps on the middle row were found. The task was to find maps \(a, b, c, d: H_n(X) \to H_n(X)\) such that the following equality holds:

\[
\begin{pmatrix}
  i_{C_1,A} & i_{C_2,A} \\
-i_{C_1,B} & -i_{C_2,B}
\end{pmatrix}
\begin{pmatrix}
  i_{i_3,C_1} & 0 \\
0 & i_{i_7,C_2}
\end{pmatrix}
= \begin{pmatrix}
  i_{i_3,A} & 0 \\
0 & i_{i_7,B}
\end{pmatrix}
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}.
\]

It follows from the above claim that a solution is given by \(a = id, b = f_*, c = -id\) and \(d = -id\).

4. It is straightforward to see that the bottom squares in the above diagram commute. We leave it to the reader to verify that the bottom sequence is also exact.

As we had just pointed out, the bottom horizontal sequence is exact. The proposition is thus an immediate consequence of Lemma 46.4.
Now we can also easily prove the following lemma.

**Lemma 46.22.** Let $X$ be a topological space. We denote by $p: X \times S^1 \to X$ the natural projection. For every $n \in \mathbb{N}_0$ there exists a natural map $\psi: H_n(X \times S^1) \to H_{n-1}(X)$ such that the map

$$
\Xi_X := p_* \circ \psi: H_n(X \times S^1) \xrightarrow{\approx} H_n(X) \oplus H_{n-1}(X)
$$

is a natural isomorphism. Here natural means that for any map $f: X \to Y$ between topological spaces the following diagram commutes:

$$
\begin{array}{ccc}
H_n(X \times S^1) & \xrightarrow{\Xi_X} & H_n(X) \oplus H_{n-1}(X) \\
\downarrow_{(f \times \text{id})_*} & & \downarrow_{f_*} \\
H_n(Y \times S^1) & \xrightarrow{\Xi_Y} & H_n(X) \oplus H_{n-1}(X).
\end{array}
$$

**Example.** Using an elementary and amusing induction argument one can show quite easily, using Lemma [46.22](#) that for $k = 0, \ldots, n$ we have

$$
H_k(\text{n-dimensional torus } (S^1)^n) = \text{free abelian group of rank } \binom{n}{k}
$$

and that all other homology groups vanish.

**Remark.** We gave a different proof of Lemma [46.22](#) in Exercise [44.5](#).

**Proof.** Let $n \in \mathbb{N}_0$. Note that by Lemma [24.21](#) the map $\Theta: \text{Tor}(X, f := \text{id}) \to X \times S^1$ given by $[(x, t)] \mapsto (x, e^{2\pi it})$ is a natural homeomorphism. We denote by $i: X \to \text{Tor}(f)$ the natural embedding given by $x \mapsto [(x, 0)]$ and we denote by $j: X \to X \times S^1$ the natural embedding given by $x \mapsto (x, 1)$. Next we consider the following diagram:

$$
\begin{array}{ccccccc}
0 & \to & \ker(H_n(X)) & \xrightarrow{j_*-\text{id}} & H_n(X) & \xrightarrow{i_*} & \ker(H_{n-1}(X)) & \xrightarrow{\partial} & \ker(H_{n-1}(X)) & \to & 0 \\
\downarrow{\text{id}} & & \downarrow{\text{id}} & & \downarrow{\text{id}} & & \downarrow{\text{id}} & & \downarrow{\text{id}} & & \\
0 & \to & H_n(X) & \xrightarrow{i} & \ker(H_{n-1}(X)) & \xrightarrow{\partial} & H_{n-1}(X) & \to & 0 \\
\downarrow{\text{id}} & & \downarrow{\Theta_*} & & \downarrow{\text{id}} & & \downarrow{\text{id}} & & \\
0 & \to & H_n(X) & \xrightarrow{j_*-\text{id}} & H_n(X \times S^1) & \xrightarrow{i} & H_{n-1}(X) & \to & 0.
\end{array}
$$

We make the following clarifications and observations:

1. The top sequence is the short exact sequence obtained from Proposition [46.21](#).
2. Since $f_* - \text{id}_* = 0$ we obtain the two vertical identities on top.
3. Since $\Theta$ is an isomorphism and since $\Theta \circ i = j$ we see that the bottom sequence also commutes.
4. The map $p: X \times S^1 \to X$ is the natural map that is given by projection onto the first factor. Note that $p_* \circ i_* = (p \circ i)_* = \text{id}$.

As in the proof of Splitting Lemma [46.2](#) we now see that the map

$$
\Xi_X: H_n(X \times S^1) \to H_n(X) \oplus H_{n-1}(X) \\
\sigma \mapsto p_*(\sigma) \oplus \partial(\sigma - (j_* \circ p_*)(\sigma))
$$

...
is an isomorphism. Since all maps involved are natural we see that this isomorphism is in fact natural.

We conclude this long chapter with the following lemma which can be viewed as the analogue of Proposition 24.28.

**Lemma 46.23.** Let $X$ be a path-connected topological space and let $f: X \to X$ be a map. We denote by $i: X \xrightarrow{x \mapsto [x,0]} \text{Tor}(X,f)$ the natural embedding and we denote by $q: \text{Tor}(X,f) \to S^1$ the natural projection that we introduced on page 711. With this notation the following sequence is natural and exact:

$$0 \to \text{coker}(H_1(X) \xrightarrow{f_*-\text{id}} H_1(X)) \xrightarrow{i} H_1(\text{Tor}(X,f)) \to H_1(S^1) \to 0.$$  

In particular we have an isomorphism

$$H_1(\text{Tor}(X,f)) \cong \mathbb{Z} \oplus \text{coker}(H_1(X) \xrightarrow{f_*-\text{id}} H_1(X)).$$

**Remark.** Later in the Hurewicz Theorem 53.5 we will show that the abelianization of the fundamental group $\pi_1(X,x_0)$ of a pointed path-connected topological space $(X,x_0)$ is naturally isomorphic to the first homology group $H_1(X)$. Thus we see that Lemma 46.23 is a modest generalization of Exercise 24.18.

**Proof.** Since $X$ is path-connected we obtain immediately from the discussion on page 1088 that the map $f_* - \text{id}: H_0(X) \to H_0(X)$ is the zero map. We consider the following maps:

$$0 \to \text{coker}(H_1(X) \xrightarrow{f_*-\text{id}} H_1(X)) \xrightarrow{i} H_1(\text{Tor}(X,f)) \xrightarrow{p_*} \mathbb{Z} \xrightarrow{\Psi} 0.$$  

We make the following observations:

1. The horizontal map is the short exact sequence from Proposition 46.21.
2. Since $p \circ i$ is a constant map we see that $p_* \circ i_*$ is the trivial map.
3. It follows from (1) and (2) that there exists a map $\Psi: \mathbb{Z} \to H_1(S^1)$ that makes the diagram commute.
4. Furthermore, since $X$ is path-connected one can easily construct a left-inverse to $p: \text{Tor}(X,f) \to S^1$. This implies that $p_*: H_1(\text{Tor}(X,f)) \to H_1(S^1)$ is an epimorphism.
5. Since $H_1(S^1) \cong \mathbb{Z}$ and since any epimorphism from $\mathbb{Z} \to \mathbb{Z}$ is an isomorphism we obtain from the above that $\Psi$ is an isomorphism.

This concludes the proof that the sequence in the statement of the lemma is indeed exact.

Finally note that since $\mathbb{Z}$ is free abelian it follows from Corollary 46.3 that we have an isomorphism

$$H_1(\text{Tor}(X,f)) \cong \mathbb{Z} \oplus \text{coker}(H_1(X) \xrightarrow{f_*-\text{id}} H_1(X)).$$
Exercises for Chapter 46

Exercise 46.1. We consider the following commutative diagram of homomorphisms between abelian groups:

\[
\begin{array}{cccccccccc}
\vdots & \longrightarrow & C_{n+1}'' & \partial_{n+1} & \longrightarrow & C_n' & \overset{i_n}{\longrightarrow} & C_n & \overset{p_n}{\longrightarrow} & C_n'' & \partial_n & \longrightarrow & C_{n-1}' & \longrightarrow & \vdots \\
\downarrow f''_{n+1} & & \downarrow f''_n & & \downarrow f_n & & \downarrow f'_n & & \downarrow f'_n & & \downarrow f_{n-1} & & \downarrow f_{n-1} & & \\
\vdots & \longrightarrow & D_{n+1}'' & \partial_{n+1} & \longrightarrow & D_n' & \overset{j_n}{\longrightarrow} & D_n & \overset{q_n}{\longrightarrow} & D_n'' & \partial_n & \longrightarrow & D_{n-1}' & \longrightarrow & \vdots 
\end{array}
\]

We suppose that the horizontal sequences are exact and we suppose that each \( f''_n \) is an isomorphism. For each \( n \in \mathbb{N}_0 \) we set \( \Delta_n := \partial_n \circ (f''_n)^{-1} \circ q_n : D_n \to C_{n-1}' \). Show that the following sequence is exact

\[
\ldots \longrightarrow C_n' \overset{i_n + f'_n}{\longrightarrow} C_n + D_n' \overset{f_n + j_n}{\longrightarrow} D_n \overset{\Delta_n}{\longrightarrow} C_{n-1}' \longrightarrow \ldots
\]

Remark. The resulting exact sequence is sometimes called the algebraic Mayer–Vietoris sequence. The name will become clear in Exercise 46.2.

Exercise 46.2. Let \( X \) be a topological space and let \( A, B \subset X \) be subsets such that \( X = \hat{A} \cup \hat{B} \). Use the algebraic Mayer–Vietoris sequence from Exercise 46.1 together with the Excision Theorem 43.19 and the long exact sequence of the pair of topological spaces to give a new proof of of the Mayer–Vietoris Theorem 46.5 (92) and (3). More precisely you need to show that there exists a long exact sequence of the form

\[
\ldots \to H_n(A \cap B) \overset{i_{A \cap B} + i_{A \cap B}}{\longrightarrow} H_n(A) \oplus H_n(B) \overset{i_A + i_B}{\longrightarrow} H_n(X) \overset{\partial_n}{\longrightarrow} H_{n-1}(A \cap B) \to \ldots
\]

where \( \partial_n \) is natural.

Hint. Consider the commutative diagram

\[
\begin{array}{ccc}
A \cap B & \overset{i_{A \cap B}}{\longrightarrow} & A \\
\downarrow i_{A \cap B} & & \downarrow i_A \\
B & \overset{i_B}{\longrightarrow} & X
\end{array}
\]

Exercise 46.3.

(a) We denote by

\[
K = ([0, 1] \times [0, 1]) / \sim \quad \text{with} \quad (x, 0) \sim (x, 1) \quad \text{and} \quad (0, y) \sim (1, 1 - y)
\]

the Klein bottle. Show that

\[
H_n(K) \cong \begin{cases} 
\mathbb{Z}, & \text{if } n = 0, \\
\mathbb{Z} \oplus \mathbb{Z}_2, & \text{if } n = 1, \\
0, & \text{otherwise.}
\end{cases}
\]

(b) Give an example of an explicit map \( f : S^1 \to K \) such that the inclusion induced map \( f_* : H_1(S^1) \to H_1(K) \) is a monomorphism. Prove that the map \( f \) that you provide does indeed have this property.
**Exercise 46.4.** Let $X$ be a topological space and let $U$ and $V$ be two open subset of $X$ such that $X$ and $U \cap V$ are path-connected and such that $U \cap V$ is non-empty. Show that $U$ and $V$ are path-connected.

*Remark.* This is of course just a special case of Exercise 2.55 (a). But it is great fun to prove this statement using the Mayer–Vietoris Theorem 46.3

**Exercise 46.5.** Compute the isomorphism types of the homology groups of the real line with two zeros.

**Exercise 46.6.** Determine the isomorphism types of the homology groups of the topologist’s sine curve that we introduced on page 131.

*Figure 780. Illustration for Exercises 46.5 and 46.6*

**Exercise 46.7.** Let $K = (V, E, i, t)$ be a connected abstract graph. Determine the isomorphism types of the homology groups of the topological realization $|K|$.

*Hint.* Figure 781 shows an example of a convenient covering by open sets.

*Figure 781. Illustration for Exercise 46.7*

**Exercise 46.8.** In Lemma 46.12 we computed the homology groups of the torus $T = S^1 \times S^1$ the Mayer–Vietoris Theorem 46.10 for Manifolds. Compute the reduced homology of the torus using the Mayer–Vietoris sequence with reduced homology groups.

*Remark.* Depending on how you go about this calculation you can easily end up with a contradictory calculation.

**Exercise 46.9.** Let $T = S^1 \times S^1$ be the torus. We denote by $p, q : S^1 \times S^1 \to S^1$ the two obvious projections. Show that the map

$$p_* \oplus q_* : H_1(S^1 \times S^1) \to H_1(S^1) \oplus H_1(S^1)$$

$$\varphi \mapsto p_*(\varphi) + q_*(\varphi)$$

is an isomorphism.

*Hint.* You could make use of Lemma 46.12 (2).

**Exercise 46.10.** We consider the real projective plane

$$\mathbb{R}P^2 = B^2 / \sim \text{ where } x \sim y \text{ if } x, y \in \partial B^2 \text{ and } x = -y.$$ Determine an explicit cycle in $C_1(\mathbb{R}P^2)$ that represents the unique non-trivial element of $H_1(\mathbb{R}P^2)$. 
Exercise 46.11. Let $X$ be a topological space and let $k \in \mathbb{Z}$. Show that the two natural isomorphisms $\tilde{H}_k(X) \cong \tilde{H}_{k-1}(\Sigma(X))$ that we constructed in Proposition 45.7 and in the proof of Lemma 46.8 are actually the same.

Exercise 46.12. Let $X \subset \mathbb{R}^n$ be a non-empty compact subset. As in Lemma 2.44 we make the identification $S^n = \mathbb{R}^n \cup \{\infty\}$ of the sphere with the space $\mathbb{R}^n$ together with a “point at infinity”.

(a) Show that for every $k \neq n - 1$ the inclusion induced map

$$H_k(\mathbb{R}^n \setminus X) \to H_k((\mathbb{R}^n \cup \{\infty\}) \setminus S^n)$$

is an isomorphism.

(b) Show that there exists a short exact sequence

$$0 \to \mathbb{Z} \to H_{n-1}(\mathbb{R}^n \setminus X) \to H_{n-1}((\mathbb{R}^n \cup \{\infty\}) \setminus X) \to 0.$$

(c) Show that the short exact sequence in (b) splits.

Exercise 46.13. Let $g \in \mathbb{N}_{\geq 2}$. Use the Mayer–Vietoris Theorem 46.10 for Manifolds, or some other flavor of the Mayer–Vietoris sequence, to determine the isomorphism types of the surface of genus $g$.

Hint. In Figure 782 we show two possible approaches to decomposing the surface of genus two.

Remark. We will give the calculation in Proposition 48.9 using “cellular homology”.

Exercise 46.14. Let $X$ be a topological space, let $k \in \mathbb{N}$ and let $n \in \mathbb{N}_0$. What is the isomorphism type of $H_n(X \times S^k)$ in terms of the homology groups of $X$?

Exercise 46.15. Let $k \in \mathbb{N}$. We consider the topological space

$$X_k := ([-k, k] \cup S^2 \times \{-k, \ldots, k\})/\sim$$

where given $i \in \{-k, \ldots, k\}$ we identify $i \in [-k, k]$ with $((0, 0, -1), i) \in S^2 \times \{-k, \ldots, k\}$.

For $i = -k, \ldots, k$ we denote by

$$f_i : S^2 \to X_k \quad P \mapsto (P, i)$$

the various “obvious” inclusion maps. (We refer to Figure 783 for an illustration.)

(a) Show that $H_0(X_k) \cong \mathbb{Z}$.

(b) Show that $H_i(X_k) = 0$ for $i \neq 0, 2$. 

\[ \text{Figure 782. Illustration of Exercise 46.13} \]
(c) Let $[S^2] \in H_2(S^2)$ be the standard generator. Show that the map
\[
\mathbb{Z}^{2k+1} \to 2(X_k) \\
(a_{-k}, \ldots, a_k) \to \sum_{i=-k}^{k} a_i \cdot f_{i*}([S^2])
\]
is an isomorphism.

\[\text{Figure 783. Illustration of Exercise 46.15}\]

**Exercise 46.16.** Let $X$ be a topological space. We consider the corresponding suspension $\Sigma(X) = (X \times [-1,1])/\sim$ which is given by identifying all points in $X \times \{-1\}$ and by identifying all points in $X \times \{1\}$.

(a) Given a singular $k$-simplex $\sigma: \Delta^k \to X$ we define the two maps
\[
c_{\pm}(\sigma): \Delta^{k+1} \to \Sigma(X) \\
(t_0, t_1, \ldots, t_{k+1}) \mapsto \begin{cases} \left(\sigma\left(\frac{1}{1-t_0}(t_1, \ldots, t_{k+1})\right), \pm t_0\right), & \text{if } t_0 < 1, \\
[X \times \{\pm 1\}], & \text{if } t_0 = 1.
\end{cases}
\]
Show that the maps $c_-(\sigma)$ and $c_+(\sigma)$ are continuous. (We refer to Figure 784 for an illustration of the definition of $c_{\pm}(\sigma)$.)

**Hint.** Consider $\Delta^k \times [0,1]$ and $(\Delta^k \times [0,1])/(\Delta^k \times \{1\})$.

(b) Note that the maps $\sigma \mapsto c_{\pm}(\sigma)$ define a homomorphisms $c_{\pm}: C_k(X) \to C_{k+1}(\Sigma(X))$. We set $s = (-1)^{k+1} \cdot (c_+ - c_-)$. Show that for any $\sigma: \Delta^k \to X$ we have
\[
\partial s(\sigma) = \begin{cases} s(\partial \sigma), & \text{if } k > 0, \\
[X \times \{1\}] - [X \times \{-1\}], & \text{if } k = 0.
\end{cases}
\]

(c) Let $k \in \mathbb{N}_0$. Show that the map
\[
\tilde{H}_k(X) \to H_{k+1}(\Sigma(X)) \\
\sigma \mapsto s(\sigma)
\]
is well-defined and that it is an isomorphism.

**Remark.** We refer to $c_+, c_-$ as cone operators and we refer to $s$ as the suspension operator.

\[\text{Figure 784}\]
Exercise 46.17. Let $k \in \mathbb{N}_{\geq 3}$ and let $m \in \mathbb{N}$. We consider the topological space
\[ X_k := S^1 \cup \{re^{2\pi ij/k} \mid r \in [0, 1] \text{ and } j \in \{0, \ldots, k-1\} \} \]
and we consider the homeomorphism
\[ f_m: X_k \rightarrow X_k \quad z \mapsto e^{2\pi im/k} \cdot z. \]
Determine the homology groups of the mapping torus $\text{Tor}(X_k, f_m)$.

Exercise 46.18. Let $X$ be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i: A \rightarrow X$ the inclusion map. We consider the following diagram
\[
\begin{array}{cccccccc}
\ldots & \rightarrow & \tilde{H}_n(A) & \overset{i}{\rightarrow} & \tilde{H}_n(X) & \rightarrow & H_n(X, A) & \overset{\partial}{\rightarrow} & \tilde{H}_{n-1}(A) & \rightarrow & \tilde{H}_{n-1}(X) & \rightarrow & \ldots \\
\downarrow & \simeq & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
\ldots & \rightarrow & \tilde{H}_n(A) & \overset{i}{\rightarrow} & \tilde{H}_n(X) & \rightarrow & H_n(Cone(i)) & \overset{\partial}{\rightarrow} & \tilde{H}_{n-1}(A) & \rightarrow & \tilde{H}_{n-1}(X) & \rightarrow & \ldots
\end{array}
\]
where the middle vertical map is the natural isomorphism from Lemma 46.16 where the top sequence is the long exact sequence arising from Corollary 43.16 and where the bottom sequence is the exact sequence from Lemma 46.18 Show that the diagram commutes.

Exercise 46.19. Let $X$ be a topological space and let $U_1$, $U_2$ and $U_3$ be open subsets of $X$ with $X = U_1 \cup U_2 \cup U_3$.

(a) We suppose that $U_1 \cap U_2 \cap U_3 = \emptyset$. Show that there exists a long exact sequence of the form
\[
\begin{array}{cccccccc}
\ldots & \rightarrow & H_n(U_1 \cap U_2) & \rightarrow & H_n(U_1 \cap U_3) & \rightarrow & H_n(U_2 \cap U_3) & \rightarrow & H_n(U_1) & \rightarrow & H_n(U_2) & \rightarrow & H_n(U_3) & \rightarrow & \ldots \\
\downarrow & & & & & & & & & & & & & \downarrow \\
\ldots & \rightarrow & H_n(U_1 \cap U_2) & \rightarrow & H_n(U_1 \cap U_3) & \rightarrow & H_n(U_2 \cap U_3) & \rightarrow & H_n(U_1) & \rightarrow & H_n(U_2) & \rightarrow & H_n(U_3) & \rightarrow & \ldots
\end{array}
\]
where the middle vertical map is the natural isomorphism from Lemma 46.16 where the top sequence is the long exact sequence arising from Corollary 43.16 and where the bottom sequence is the exact sequence from Lemma 46.18 Show that the diagram commutes.

(b) Show that in general the conclusion of (a) does not hold if $U_1 \cap U_2 \cap U_3 \neq \emptyset$.

Remark. This exercise is related to the discussion on page 1210.

Exercise 46.20. Let $X$ and $Y$ be topological spaces. We consider the join $X \ast Y$ as defined on page 207. Show that for each $k \in \mathbb{N}_0$ there exists a short exact sequence of the following form:
\[
0 \rightarrow \tilde{H}_k(X \ast Y) \rightarrow \tilde{H}_{k-1}(X) \oplus \tilde{H}_{k-1}(Y) \rightarrow \tilde{H}_{k-1}(X \times Y) \rightarrow 0.
\]

Hint. In Exercise 24.11 we gave an explicit homeomorphism
\[ X \ast Y \cong (\text{Cone}(X) \times Y) \cup_{(X \times \{1\}) \times Y} (Y \times (X \times \{1\})) (X \times \text{Cone}(Y)). \]
Note though that you need to argue why you can use this decomposition.

Remark. In the Künneth Theorem \[58.8\] we will learn how to calculate the homology groups of the product \(X \times Y\).

**Exercise 46.21.** Let \(X = \mathbb{Z}_n\) be the topological space whose underlying set is \(\mathbb{Z}_n\) and whose topology is given by the discrete topology. Let \(f : X = \mathbb{Z}_n \to X = \mathbb{Z}_n\) be the homeomorphism given by \(f(x) = x + 1 \in \mathbb{Z}_n\). Compute the homology groups of the mapping torus \(\text{Tor}(X,f)\).

**Exercise 46.22.** Let \(p, q \in \mathbb{N}\) be coprime. We consider the torus knot \(T_{p,q}\) as defined on page \[777\]. Compute the homology groups of \(S^3 \setminus T_{p,q}\).

**Hint.** Use the decomposition of \(S^3 \setminus T_{p,q}\) given in the proof of Proposition \[27.5\].

**Exercise 46.23.** Let \(K\) be the Klein bottle minus one open disk. Show that \(\partial K\) is not a retract of \(K\).

**Exercise 46.24.** Let \(n \in \mathbb{N}\) and let \(M\) be \(S^2\) minus \(n\) open disks. Show that the inclusion induced map \(H_1(\partial M) \to H_1(M)\) is an epimorphism.

**Exercise 46.25.** We consider the two topological manifolds \(X\) and \(Y\) that are shown in Figure \[786\]. Use (relative?) homology groups to show that \(X\) and \(Y\) are not homeomorphic.

**Remark.** In Exercise \[20.6\] we attacked the same problem using fundamental groups. It should be much easier to deal with the problem at hand using (relative) homology groups.

**Figure 786.** Illustration of Exercise \[46.25\].
47. Homology groups and direct limits

In this chapter we will discuss the relationship between homology groups and direct limits. This will allow us to determine the homology groups of suitable nested sequences of topological spaces. In a similar vein we will determine the homology groups of the wedge of arbitrarily many topological spaces. We conclude this chapter with the introduction of the Moore spaces. We will in particular see that all abelian group can appear as homology groups of topological spaces.

For the reader who is in a hurry only few of the results of this chapter are really important. In particular, very soon we will make use of Proposition 47.9. For this proposition we give two proofs, one building on the theme of this chapter. The other proof can be read independently of the rest of the chapter.

47.1. Direct limits and induced maps. Given a directed set \((I, \leq)\) and a direct system \(\left(\{K_i\}_{i \in I}, \{\chi_{ij}\}_{i \leq j}\right)\) of abelian groups we write, as on page 733

\[ \lim_{\longrightarrow} K_i := \left( \bigsqcup_{i \in I} K_i \right) / \sim \] where \(k_i \sim \chi_{ij}(k_j)\) for all \(i \leq j, k_i \in K_i\)

We adopt the following notation, given \(k_i \in K_i\) we denote by \([k_i] \in \lim_{\longrightarrow} K_i\) the element represented by \(k_i\). We make the following observation that follows immediately from the above definition of the direct limit.

Observation 47.1. Any element in \(\lim_{\longrightarrow} K_i\) is of the form \([k_i]\) for some \(k_i \in K_i\).

Definition. Let \((I, \leq)\) be a directed set and let \(\left(\{K_i\}_{i \in I}, \{\chi_{ij}\}_{i \leq j}\right)\) and \(\left(\{L_i\}_{i \in I}, \{\lambda_{ij}\}_{i \leq j}\right)\) be direct systems of abelian groups.

(1) We define a homomorphism between the above two direct systems to be a family \(\{f_i : K_i \to L_i\}_{i \in I}\) of homomorphisms that has the property that for any \(i \leq j\) the following diagram commutes:

\[
\begin{array}{c}
K_i \xrightarrow{f_i} L_i \\
\downarrow \chi_{ij} \quad \downarrow \lambda_{ij} \\
K_j \xrightarrow{f_j} L_j
\end{array}
\]

(2) Given such a homomorphism we refer to

\[
\lim_{\longrightarrow} K_i \to \lim_{\longrightarrow} L_i
\]

\([k_i] \mapsto [f_i(k_i)]\)

as the induced map. Sometimes we denote it by \(\lim_{\longrightarrow} f_i\). It is straightforward to verify that the induced maps are functorial.

\[\text{Footnote:} \quad \text{It follows immediately from the definitions that this map is well-defined, i.e. the map does not depend on the choice \([k_i]\) of a representative for an element in the direct limit.}\]\n
\[\text{Footnote:} \quad \text{More formally one could say that the maps } K_i \to L_i \to \lim_{\longrightarrow} L_i \text{ induce, by the universal property of a direct limit, a map } \lim_{\longrightarrow} K_i \to \lim_{\longrightarrow} L_i. \text{ It is straightforward to see that this map is exactly the one we wrote down.}\]
Proposition 47.2. Let \((I, \leq)\) be a directed set. Also let \((\{K_i\}_{i \in I}, \{k_{ij}\}_{i \leq j})\), \((\{L_i\}_{i \in I}, \{l_{ij}\}_{i \leq j})\) and \((\{M_i\}_{i \in I}, \{m_{ij}\}_{i \leq j})\) be direct systems of abelian groups. Furthermore suppose that we are given homomorphisms \(f_i: K_i \to L_i\) and \(g_i: L_i \to M_i\) of the direct systems. If for all \(i \in I\) the sequence

\[
K_i \xrightarrow{f_i} L_i \xrightarrow{g_i} M_i
\]

is exact, then the induced sequence

\[
\lim K_i \xrightarrow{\lim f_i} \lim L_i \xrightarrow{\lim g_i} \lim M_i
\]

is also exact.

Proof. We write \(f = \lim f_i\) and \(g = \lim g_i\). We have to prove that \(g \circ f = 0\) and we need to show that \(\ker(g) \subseteq \text{im}(f)\). Both statements follow our hypothesis together with Observation 47.1 and the fact that in the definition of the induced map between direct limits we can take any representative. We leave the few remaining details to the reader. ■

The following corollary says that direct limits commute with kernels and cokernels.

Corollary 47.3. Let \((I, \leq)\) be a directed set and let \((\{K_i\}_{i \in I}, \{k_{ij}\}_{i \leq j})\) and \((\{L_i\}_{i \in I}, \{l_{ij}\}_{i \leq j})\) be direct systems of abelian groups. Furthermore suppose that we are given a homomorphism \(f_i: K_i \to L_i\) of the direct systems. There exist canonical isomorphisms

\[
\lim \ker(f_i: K_i \to L_i) \xrightarrow{\cong} \ker \left( \lim K_i \to \lim L_i \right)
\]

and

\[
\lim \coker(f_i: K_i \to L_i) \xrightarrow{\cong} \coker \left( \lim K_i \to \lim L_i \right).
\]

Proof. For each \(i \in I\) the sequence

\[
0 \to \ker(f_i) \to K_i \xrightarrow{f_i} L_i \to \coker(f_i) \to 0.
\]

is exact. Evidently these homomorphisms form a homomorphism between the various direct systems. It follows from Proposition 47.2 (applied four times!) that the sequence

\[
0 \to \lim \ker(f_i) \to \lim K_i \to \lim L_i \to \lim \coker(f_i) \to 0
\]

is also exact. But this observation already implies the desired statements. ■

47.2. The homology groups of a nested sequence of topological spaces. In Propositions 25.7 and 40.11 we saw that in favorable situations the homotopy groups of a union of a nested sequence of topological spaces is the direct limit of the corresponding fundamental groups. Now we will see that a similar statement holds for homology groups.

Proposition 47.4. Let \(X\) be a topological space and let \(X_1 \subset X_2 \subset X_3 \subset \ldots\) be a sequence of subsets such that \(X = \bigcup_{i \in \mathbb{N}} X_i\) and such that one the following three conditions holds:

1. every compact subset of \(X\) is already contained in one of the \(X_i\), or
2. each \(X_i\) is open in \(X\), or
(3) $X$ is a CW-complex and each $X_i$ is a subcomplex.

Then for any $n \in \mathbb{N}_0$ the inclusion induced maps $H_n(X_i) \to H_n(X)$ induce an isomorphism

$$\lim_{\rightarrow} H_n(X_i) \xrightarrow{\cong} H_n(X).$$

We remark that it follows easily from the Finiteness Theorem 36.14 that hypothesis (3) implies hypothesis (1). Furthermore we point out that it follows from Lemma 25.8 that hypothesis (2) implies hypothesis (1). Thus it suffices to prove Proposition 47.4 under the hypothesis (1). But in that case the proposition is an immediate consequence of the next two lemmas.

**Lemma 47.5.** Let $X$ be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \ldots$ be a sequence of subsets such that every compact subset of $X$ is already contained in one of the $X_i$. Then the chain complexes $C_*(X_i), i \in \mathbb{N}$ together with the inclusion induced chain maps $C_*(X_i) \to C_*(X_j)$ for $i \leq j$ form a direct system of chain complexes. Furthermore the inclusion induced maps $C_*(X_i) \to C_*(X)$ induce an isomorphism

$$\lim_{\rightarrow} C_*(X_i) \xrightarrow{\cong} C_*(X)$$

of chain complexes.

**Proof.** Given a topological space $Y$ and $n \in \mathbb{N}_0$ we denote by $S_n(Y)$ the set of singular $n$-simplices in $Y$. It follows immediately from our hypothesis on the $X_i$, the fact that $\Delta^n$ is compact and Lemma 2.40 that

$$S_n(X) = \bigcup_{i \in \mathbb{N}} S_n(X_i).$$

As in the example on page 730 we now see that

$$\lim_{\rightarrow} C_n(X_i) = \lim_{\rightarrow} \mathbb{Z}^{(S_n(X_i))} = \mathbb{Z}^{(S_n(X))} = C_n(X).$$

We leave it to the reader to verify that the inclusion maps also induce an isomorphism of chain complexes. $lacksquare$

The second lemma required for the proof of Proposition 47.4 is purely algebraic.

**Lemma 47.6.** Let $(I, \leq)$ be a directed set and furthermore let $(\{C_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})$ be a direct system of chain complexes. Then for each $n \in \mathbb{N}_0$ we obtain an induced direct system $(\{H_n(C_i)\}_{i \in I}, \{f_{ij}\}_{i \leq j})$ of abelian groups. Furthermore, given any $n \in \mathbb{N}_0$ the maps $H_n(C_i) \to H_n \left( \lim_{\rightarrow} C_i \right)$ induce an isomorphism

$$\lim_{\rightarrow} H_n(C_i) \xrightarrow{\cong} H_n \left( \lim_{\rightarrow} C_i \right).$$

---

767 We refer to page 728 for the definition of a direct system.

768 The argument of Proposition 25.1 or respectively of page 733 shows that the direct limit of a direct system of chain complexes always exists.
Proof. We have
\[
\lim_{\to} H_n(C_i) = \lim_{\to} \ker(C_{i+1} \to C_i) = \ker(\lim_{\to} C_{i+1} \to \lim_{\to} C_i) = H_n(\lim_{\to} C_i).
\]
Corollary 47.3 applied twice

The fact that this isomorphism is induced by the maps \(H_n(C_i) \to H_n(\lim_{\to} C_i)\) follows easily from the various definitions.

We conclude this short section with a few examples:

Example. For any \(n \in \mathbb{N}_0\) we have
\[
H_n(S^\infty) = \lim_{k \in \mathbb{N}} H_n(S^k) = \lim_{k \in \mathbb{N}} \begin{cases} \mathbb{Z}, & \text{if } n = k, 0, \\ 0, & \text{else} \end{cases} = \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{else}. \end{cases}
\]
by Proposition 47.4, Proposition 43.4, Lemma 25.2
where we view \(S^\infty\) as a CW-complex as on page 942

The next lemma is basically also just an example. But since we will need it later on we formulate it as a lemma.

Lemma 47.7. We consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider
\[
X := (\mathbb{R} \cup (S^2 \times \mathbb{Z}))/\sim \quad \text{where } n \sim ((0,0,-1), n) \text{ for } n \in \mathbb{Z}.
\]

Then
\[
H_n(X) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^\infty, & \text{if } n = 2, \\ 0, & \text{else}. \end{cases}
\]
In fact we can specify an isomorphism on \(H_2(X)\). Given \(i \in \mathbb{Z}\) we denote by \(f_i : S^2 \to X\) the “obvious” \(i\)-th inclusion map. Then an isomorphism is given by
\[
\mathbb{Z}^\infty \cong \bigoplus_{i \in \mathbb{Z}} \mathbb{Z} \to H_2(X),
\]
\[
\bigoplus_{i \in \mathbb{Z}} a_i \mapsto \sum_{i \in \mathbb{Z}} a_i \cdot f_i([S^2]).
\]

Recall that
\[
\mathbb{Z}^\infty := \mathbb{Z}^{(\infty)} = \{(x_1, x_2, \ldots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\}.
\]

Proof. We view \(X\) as a CW-complex in the obvious way. Furthermore, given \(k \in \mathbb{N}\) we consider the subcomplex
\[
X_k := ([-k,k] \cup S^2 \times \{-k, \ldots, k\})/\sim.
\]
Note that $X_k$ is the interval $[-k, k]$ with $2k + 1$ spheres attached. (We refer to Figure 787 for an illustration.) We have

$$H_n(X) = \lim_{\uparrow} H_n(X_k) = \lim_{\uparrow} \left\{ \begin{array}{lcl} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{2k+1}, & \text{if } n = 2, \\ 0, & \text{else} \end{array} \right. \quad \left\{ \begin{array}{lcl} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^\infty, & \text{if } n = 2, \\ 0, & \text{else} \end{array} \right.$$ 

Proposition 47.3 see Exercise 46.13 see page 730 and Lemma 25.2

The statement about the precise isomorphism of $H_2(X)$ also follows from the explicit description of the isomorphism Exercise 46.15 and the discussion on page 730.

47.3. The homology groups of the wedge of topological spaces. The following proposition says that under a mild hypothesis “homology groups are additive” under the operation of taking the wedge of two topological spaces. The proposition is very similar in vein to Proposition 20.3

**Proposition 47.8.** Let $A$ and $B$ be two topological spaces and let $a \in A$ and $b \in B$ be good points. We denote by $A \vee B$ the wedge defined using $a$ and $b$. Then the natural inclusion maps $i: A \to A \vee B$ and $j: B \to A \vee B$ that we introduced on page 561 induce for every $n \in \mathbb{N}_0$ an isomorphism

$$i_* \oplus j_*: \tilde{H}_n(A) \oplus \tilde{H}_n(B) \to \tilde{H}_n(A \vee B).$$

Furthermore, if we denote by $p: A \vee B \to A$ and $q: A \vee B \to A$ the natural projection maps, then an inverse to the above isomorphism is given by

$$p_* + q_*: \tilde{H}_n(A \vee B) \to \tilde{H}_n(A) \oplus \tilde{H}_n(B).$$

**Proof.** We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. We pick an open neighborhood $C$ in $A$ of $a$ such that $\{a\}$ is a deformation retract of $C$. Furthermore we pick an open neighborhood $D$ of $b$ in $B$ such that $b$ is a deformation retract of $D$. We consider $U := A \vee D$...
and $V := B \lor C$. We consider the following diagram of maps

\[
\begin{align*}
\tilde{H}_n(A) \oplus \tilde{H}_n(B) & \cong \tilde{H}_n(U \cap V) \cong \tilde{H}_n(U) \oplus \tilde{H}_n(V) \rightarrow \tilde{H}_n(X) \rightarrow \tilde{H}_{n-1}(U \cap V) \rightarrow \ldots \\
\rightarrow & \tilde{H}_n(U \cap V) \rightarrow \tilde{H}_n(U) \oplus \tilde{H}_n(V) \rightarrow \tilde{H}_n(X) \rightarrow \tilde{H}_{n-1}(U \cap V) \rightarrow \ldots
\end{align*}
\]

We make the following observations:

1. The bottom sequence is exact by the Mayer–Vietoris Theorem 46.5.
2. As in the proof of Proposition 20.3, we see that the intersection $U \cap V$ deformation retracts to $x_0$, in particular we obtain from Corollary 42.8 that we have the equality $\tilde{H}_n(U \cap V) = \tilde{H}_{n-1}(U \cap V) = 0$.
3. By the proof of Proposition 20.3, we know that $A$ is a deformation retract of $U$ and that $B$ is a deformation retract of $V$. Therefore the vertical maps are isomorphisms by Corollary 42.8.

The combination of these three observations shows that $i_* + j_* : \tilde{H}_n(A) \oplus \tilde{H}_n(B) \rightarrow \tilde{H}_n(A \lor B)$ is an isomorphism. It is clear that $(p_* + q_*) \circ (i_* + j_*)$ is the identity on $\tilde{H}_n(A) \oplus \tilde{H}_n(B)$, so we also get the second isomorphism.

Proposition 47.8 has nothing to do with the content of the present chapter, we could easily have proved it in Chapter 46. But odd as it may sound, soon we will be quite interested in the homology groups of the wedge $\lor X_i$ of an arbitrary family of topological spaces. If $I$ is a finite set, i.e., if we take the wedge of finitely many topological spaces, then we can use Proposition 47.8 and an elementary induction argument to determine the homology groups.

It is a priori less clear how one can deal with the case that $I$ is an infinite set. Fortunately the next proposition allows us to handle the general situation. Proposition 47.8 to the wedge of an arbitrary family of topological spaces.

**Proposition 47.9.** Let $\{A_k\}_{k \in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. We use these points to form the wedge $\lor_{k \in K} A_k$. Given $j \in K$ we denote by $i_j : A_j \rightarrow \lor_{k \in K} A_k$ respectively $p_j : \lor_{k \in K} A_k \rightarrow A_j$ the natural inclusion map respectively the natural projection map that we introduced on page 561. Then for every $n \in \mathbb{N}_0$ the map

$$
\bigoplus_{k \in K} p_{k*} : \tilde{H}_n\left(\lor_{k \in K} A_k\right) \rightarrow \bigoplus_{k \in K} \tilde{H}_n(A_k)
$$

is an isomorphism where the inverse is given by

$$
\bigoplus_{k \in K} i_{k*} : \bigoplus_{k \in K} \tilde{H}_n(A_k) \rightarrow \tilde{H}_n\left(\lor_{k \in K} A_k\right).
$$
We like Proposition 47.9 so much that we provide two different proofs. The first proof is quick and slick, but depending on your taste the first proof might have feel slightly unsatisfactory. The second proof is somewhat longer, but it fits in better with the discussion of this chapter. In fact, as an encore we will suggest one more proof of Proposition 47.9 in Exercise 47.2.

First proof of Proposition 47.9. We have the following isomorphisms:

\[ \tilde{H}_n \left( \bigvee_{k \in K} A_k \right) = \tilde{H}_n \left( \bigcup_{k \in K} A_k / \bigcup_{k \in K} \{ a_k \} \right) \xrightarrow{\sim} H_n \left( \bigcup_{k \in K} A_k, \bigcup_{k \in K} \{ a_k \} \right) \xrightarrow{\sim} \bigcup_{k \in K} H_k(A_k, \{ a_k \}) \]

definition of the wedge operation

since each \( a_k \in A_k \) is good we see that \( \bigcup_{k \in K} \{ a_k \} \) is a good subset of \( \bigcup_{k \in K} A_k \),

by the obvious generalization of Lemma 41.14

thus we can apply Proposition 43.22

\[ \xleftarrow{\sim} \bigcup_{k \in K} H_k(A_k). \]

Lemma 43.14

We leave it to the reader to verify that the isomorphism is indeed given by \( \bigoplus_{k \in K} p_{k*} \) and that the inverse is the map \( \bigoplus_{k \in K} i_{k*} \). \( \blacksquare \)

The second proof of Proposition 47.9 is almost embarrassingly similar to the proof of Proposition 20.7.

Second proof of Proposition 47.9. Let \( \{ A_k \}_{k \in K} \) be a family of topological spaces. For each \( k \in K \) suppose that we are given a good point \( a_k \in A_k \). We use these points to form the wedge \( \bigvee_{k \in K} A_k \). Recall that the fact that \( a_k \) is good means that

(1) \( \{ a_k \} \) is a closed subset of \( A_k \)

(2) that there exists an open neighborhood \( U_k \) of \( a_k \) in \( A_k \) such that \( a_k \) is a deformation retract of \( U_k \).

We will show that the map

\[ \bigoplus_{k \in K} i_k : \bigoplus_{k \in K} \tilde{H}_n(A_k) \to \tilde{H}_n \left( \bigvee_{k \in K} A_k \right) \]

is an isomorphism. Once we will have established this fact it is straightforward to show that the inverse is given by \( \bigoplus_{k \in K} p_{k*} \).

The idea of the proof is to show that the map is a monomorphism and an epimorphism, in a way which is reminiscent to the approach taken in the proofs of Proposition 47.4.

Claim. The map

\[ \bigoplus_{k \in K} i_k : \bigoplus_{k \in K} \tilde{H}_n(A_k) \to \tilde{H}_n \left( \bigvee_{k \in K} A_k \right) \]

is an epimorphism.

\[ \text{Recall that by the discussion on page 604 any point on a topological manifold is good and that by Proposition 36.10(5) any point on a CW-complex is good.} \]
We introduce the following notation:

1. We write $B := \bigvee_{k \in K} A_k$ and we set $U := \bigcup_{k \in K} U_k \subset B$.
2. Given a subset $J \subset K$ we write $B_J := \bigvee_{j \in J} A_j$ and we write $\hat{B}_J := U \cup B_J$.

Given a finite subset $J \subset K$ we have the following commutative diagram

$$
\begin{array}{ccc}
\bigoplus_{j \in J} \tilde{H}_n(A_j) & \xrightarrow{\cong} & \tilde{H}_n(B_J) \\
\downarrow & & \downarrow \\
\bigoplus_{k \in K} \tilde{H}_n(A_k) & \xrightarrow{\cong} & \tilde{H}_n(B)
\end{array}
$$

We make the following observations and comments:

1. The maps are either the obvious algebraic inclusion maps or they are the obvious maps induced by inclusions of topological spaces. It follows almost immediately from the definitions that the diagram commutes.
2. Since $J$ is finite we obtain, as pointed out above, from Proposition 47.8 that the top horizontal map is an isomorphism.
3. By Exercise 18.32 we know that $B_J$ is a deformation retract of $\hat{B}_J$. It follows from Corollary 42.8 that the top diagonal map is an isomorphism.
4. By Exercise 18.33 we know that given any compact subset $L \subset B$ there exists a finite subset $J \subset K$ such that $L \subset \hat{B}_J$.

Now we show that the above map $\bigoplus_{k \in K} i_k \ast$ is an epimorphism. So suppose we are given a homology class $[\sigma] \in \tilde{H}_n(B)$. As in the proof of Lemma 47.5 we see that it follows from (4) there exists a finite subset $J \subset K$ such that $\sigma \in C_n(B_J)$. But considering the above diagram, and using the fact that the top horizontal map is an isomorphism we see that $[\sigma]$ actually lies in the image of $\bigoplus_{k \in K} i_k$.

\begin{center}
Claim. The map
\end{center}

$$
\bigoplus_{k \in K} i_k : \bigoplus_{k \in K} \tilde{H}_n(A_k) \to \tilde{H}_n \left( \bigvee_{k \in K} A_k \right)
$$

is a monomorphism.

We continue with the notation that we introduced in the proof of the previous claim. Given any two finite subsets $J \subset \hat{J} \subset K$ we have the following commutative diagram
The diagram together with the argument of Exercise 20.7 shows that the map $\bigoplus_{k \in K} i_k \ast$ is also a monomorphism. ■

47.4. Moore spaces (*). Now that we have played with homology groups the following question arises: which sequences of abelian groups can appear as the sequence of homology groups $H_\ast(X)$ of a non-empty topological space? It turns out that anything goes, there are basically no restrictions, except that we know by Corollary 41.15 that $H_0(X)$ is necessarily a non-trivial free abelian group.

In other words, we have the following proposition.

**Proposition 47.10.** If $\{A_n\}_{n \in \mathbb{N}_0}$ is a sequence of abelian groups. If $A_0$ is a non-trivial free abelian group, then there exists a CW-complex $Z$ such that for any $n \in \mathbb{N}_0$ we have $H_n(Z) \cong A_n$.

This proposition is hardly the most exciting result of these notes. But the following definition, which we will need in the proof of Proposition 47.10 will in fact turn out to be convenient.

**Definition.** Let $n \in \mathbb{N}$ and let $\pi$ be an abelian group. We say that a non-empty topological space $X$ is a Moore space of type $M(\pi, n)$ if the following conditions are satisfied:

1. $X$ admits a CW-structure,
2. for any $i \neq n$ we have $\tilde{H}_i(X) = 0$,
3. $H_n(X) \cong \pi$,
4. If $n \geq 2$, then we also demand that $X$ is simply connected.

**Example.** Let $n \in \mathbb{N}$. It follows from Proposition 14.14 and Proposition 43.4 that $S^n$ is a Moore space of type $(\mathbb{Z}, n)$.

**Proposition 47.11.** Given any $n \in \mathbb{N}$ and given any abelian group $\pi$ there exists an $(n+1)$-dimensional CW-complex that has no cells in dimensions $1, \ldots, n-1$ and that is a Moore space of type $M(\pi, n)$.

**Proof of Proposition 47.10 assuming Proposition 47.11.** Let $\{A_n\}_{n \in \mathbb{N}_0}$ be a sequence of abelian groups such that $A_0$ is a non-trivial free abelian group. In other words, we have $A_0 \cong \mathbb{Z}^{(S)}$ for some non-empty set $S$.

By Proposition 47.11 we can find for each $n \in \mathbb{N}$ a CW-complex $X_n$ that is a Moore space of type $M(\pi, n)$. We consider the wedge $Y := \bigvee_{n \in \mathbb{N}} X_n$. By Lemma 36.32 (4) we can equip $Y$ with a CW-structure. It follows from Proposition 47.9 that for every $n \in \mathbb{N}$ we have $H_n(Y) \cong H_n(X_n) \cong A_n$ and that $H_0(Y) \cong \mathbb{Z}$. Since $S$ is non-empty we can pick a point $\ast \in S$. We define $Z := Y \sqcup (S \setminus \{\ast\})$ where we equip $S \setminus \{\ast\}$ with the discrete topology. It follows from Lemma 36.32 that $Z$ is a CW-complex. Finally it follows from Proposition 41.5 and Lemma 41.13 that $Z$ has the promised homology groups. ■

In the proof of Proposition 47.11 we will also need the following little calculation which will be of independent use.
Lemma 47.12. Let \((X, x_0)\) be a pointed topological space, let \(n \in \mathbb{N}\), let \(\omega \in H_n(I^n, \partial I^n)\) and let \(f, g: (I^n, \partial I^n) \to (X, x_0)\) be two maps. Then
\[
[f_*(\omega)] + [g_*(\omega)] = [(f \ast g)_*(\omega)] \in H_n(X, x_0) = H_n(X).
\]

Proof (*). We write \(J = I^n, J_1 = [0, \frac{1}{2}] \times I^{n-1}\) and \(J_2 = [\frac{1}{2}, 1] \times I^{n-1}\). Furthermore we write \(K = \partial J \cup (\{\frac{1}{2}\} \times I^{n-1})\). We refer to Figure 789 for an illustration. For \(k = 1, 2\) we denote by \(i_k: (J_k, \partial J_k) \to (J, \partial J)\) the inclusion map. Finally we denote by \(\varphi_k: (J_k, \partial J_k) \to (J, \partial J)\) the obvious homeomorphism given by stretching the last coordinate.

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure.png}
\caption{Illustration for the proof of Lemma 47.12.}
\end{figure}

The map \(f \ast g: (J, \partial J) \to (X, x_0)\) factors through a map \((J, K) \to (X, x_0)\) that we also denote by \(f \ast g\). Thus we have the following commutative diagram

\[
\begin{array}{c}
(J, \partial J) \xrightarrow{i} (J, K) \xrightarrow{\varphi_1} (J_1, \partial J_1) \\
\downarrow \quad \downarrow \quad \downarrow \varphi_1^{-1} \\
(J, \partial J) \xrightarrow{i} (J, K) \xrightarrow{\varphi_2} (J_2, \partial J_2).
\end{array}
\]

\[
(j_1)(i(\omega)) = (k_1 \circ \varphi_1)(\omega) = j_1(i_1(\omega_1)) = j_1(i_1(\omega_1)) + j_1(i_2(\omega_2))
\]

since \(j_1 \circ i_2 = 0\)

and similarly we show that \((j_2)(i(\omega)) = j_2(i_1(\omega_1)) + j_2(i_2(\omega_2))\).

To simplify the notation we denote the induced map by the same symbol as the map between pairs of topological spaces, i.e. we drop the subscript \(*\) from the notation.
It remains to show that \( \ker(j_1) \cap \ker(j_2) = 0 \). We consider the following diagram

\[
\begin{array}{c}
\longrightarrow & H_n(J, \partial J_1 \cup J_2) \\
\downarrow^{j_1} & \\
H_n(J, K) & \downarrow^{j_2} \\
\uparrow_{i_2} & \\
\longrightarrow & H_n(J, \partial J_1 \cup J_2) \\
\end{array}
\]

We make the following clarifications and observations:

1. The diagonal map to the bottom left of the diagram is induced by the inclusion \((J, \partial J_1 \cup J_2) \to (J, K)\).
2. It follows easily from Corollary 43.18 (2a) and (2c) that the bottom two horizontal maps are isomorphisms.
3. The diagonal sequence is exact by Proposition 43.15.
4. It now follows from some mild diagram chasing that \( \ker(j_1) \cap \ker(j_2) = 0 \).

Lemma 47.13.

1. Let \( f: S^n \to S^n_1 \vee S^n_2 \) be the pinching map that we introduced on page 1060. Let \( i \in \{1, 2\} \). If we denote by \( S^n_1 \vee S^n_2 \to S^n_i = S^n \) the obvious projection, then the induced map \( (p_i \circ f)_*: H_n(S^n) \to H_n(S^n_i) \) is the identity.
2. Given any \( k \in \mathbb{Z} \) there exists a map \( g_k: S^n \to S^n \) with \( g_k(*) = * \) such that \( g_k*: H_n(S^n) \to H_n(S^n) \) is given by multiplication by \( k \).

Proof.

1. The first statement follows easily from Lemma 47.12.
2. The second statement follows almost immediately from Lemma 45.10 together with Proposition 43.7.

Now we turn to the proof of Proposition 47.11.

Proof of Proposition 47.11. Let \( n \in \mathbb{N} \) and let \( \pi \) be an abelian group. Since \( \pi \) is abelian it follows immediately from Lemma 57.16 (1) that there exist sets \( A \) and \( B \), a homomorphism \( \varphi: \mathbb{Z}^A \to \mathbb{Z}^B \) and a homomorphism \( \rho: \mathbb{Z}^B \to \pi \) such that the following sequence is exact:

\[
0 \to \mathbb{Z}^A \xrightarrow{\varphi} \mathbb{Z}^B \xrightarrow{\rho} \pi \to 0.
\]

We let \( X := \bigvee_{a \in A} S^n_a \) and we let \( Y := \bigvee_{b \in B} S^n_b \). By Lemma 36.32 (4) we can equip \( X \) with the obvious CW-structure which has precisely one 0-cell and which has precisely one \( n \)-cell for each \( a \in A \). Similarly we equip \( Y \) with the obvious CW-structure. Using Proposition 47.9 and using the standard generator of \( H_n(S^n) \) we can make the obvious identifications \( H_n(X) = \mathbb{Z}^A \) and \( H_n(Y) = \mathbb{Z}^B \).

\[^{771}\text{In this case the fact that we refer to a later lemma need not worry us. As the reader can see, the proof of Lemma 57.16 (1) relies only on information that we already know.}\]
Claim. There exists a map \( h : X \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
H_n(X) & \xrightarrow{h_*} & H_n(Y) \\
\downarrow & & \downarrow \\
\mathbb{Z}^{(A)} & \xrightarrow{\varphi} & \mathbb{Z}^{(B)}.
\end{array}
\]

This map \( \varphi \) can be constructed explicitly using the following ingredients:

1. the pinching map \( f : S^n \to S^n_1 \vee S^n_2 \),
2. the maps \( g_k : S^n \to S^n \) from Lemma 47.13,
3. the natural inclusions and projections from page 561,
4. and the wedge of maps as introduced on page 559.

The notation becomes somewhat cumbersome, thus in a short moment of lassitude we decide to leave it to the reader to fill in the details. A baby example is the content of Exercise 47.3.

Now let \( Z := \text{Cone}(h : X \to Y) \) be the mapping cone of the map \( h : X \to Y \). It follows from the above claim and Lemma 46.18 that we have the following commutative diagram of long exact sequences

\[
\begin{array}{cccccccccccc}
\cdots & \to & H_{n+1}(Y) & \xrightarrow{=} & H_{n+1}(Z) & \xrightarrow{h_*} & H_n(X) & \xrightarrow{h_*} & H_n(Y) & \xrightarrow{=} & H_n(Z) & \xrightarrow{=} & H_{n-1}(X) & \to & \cdots \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\cdots & \to & 0 & \xrightarrow{=} & H_{n+1}(Z) & \xrightarrow{=} & \mathbb{Z}^{(A)} & \xrightarrow{=} & \mathbb{Z}^{(B)} & \xrightarrow{=} & \mathbb{Z}(A) & \xrightarrow{=} & \mathbb{Z}(B) & \to & 0 & \to & \cdots 
\end{array}
\]

It follows that \( H_n(Z) \cong \text{coker}(\varphi) \cong \pi \). Furthermore, since \( \varphi \) is injective we see that \( H_{n+1}(Z) = 0 \). Furthermore we see that all other reduced homology groups of \( Z \) are also zero.

Next we equip \( Z \) with the natural CW-structure coming from Corollary 36.35. There is one small fly in the ointment. The CW-structure has two 0-cells (namely one corresponding to the tip of the cone and the 0-cell of \( Y \)), one 1-cell and otherwise indeed only cells in dimensions \( n \) and \( n+1 \). Let \( A \) be the subcomplex that consists of the 1-cell that connects the two 0-cells. By Lemma 36.32 we can view \( Z/A \) as a CW-complex which now has only one 0-cell and otherwise only cells in dimension \( n \) and \( n+1 \). By the discussion on page 1108 we know that \( A \) is a good subset of \( Z \). It follows from Theorem 43.3 that the reduced homology groups of \( Z/A \) coincide with the reduced homology groups of \( Z \). Thus we see that \( Z/A \) is the CW-complex of our dreams.

Given an abelian group \( \pi \) and \( n \in \mathbb{N} \) there are in general infinitely many pairwise non-homeomorphic Moore spaces of type \( M(\pi, n) \). For example the topological spaces \( \overline{B}^k \), \( k \in \mathbb{N}_0 \) are Moore spaces of type \( M(\{e\}, 1) \). It is slightly less absurd to wonder whether Moore spaces are well-defined up to say homotopy equivalence. We formulate this as a question, we will come back to it at a later point.

**Question 47.14.** Let \( \pi \) be an abelian group and let \( n \in \mathbb{N} \). Are any two Moore spaces of type \((\pi, n)\) homotopy equivalent?
Exercises for Chapter 47

Exercise 47.1. Let $X$ and $Y$ be topological spaces and let $x_0 \in X$ and $y_0 \in Y$ be good points. We write $\tilde{x}_0 = [(x_0, 0)] \in \Sigma(X)$ and $\tilde{y}_0 = [(y_0, 0)] \in \Sigma(Y)$.

(a) Show that $\tilde{x}_0 \in \Sigma(X)$ and $\tilde{y}_0 \in \Sigma(Y)$ are good points. We use these points to define the wedge $\Sigma(X) \vee \Sigma(Y)$.

(b) Let $i : X \to X \vee Y$ and $j : Y \to X \vee Y$ be the obvious maps. Show that the map

$$\left(\Sigma(i) \vee \Sigma(j)\right)_* : H_k(\Sigma(X) \vee \Sigma(Y)) \to H_k(\Sigma(X \vee Y))$$

is an isomorphism for each $k$.

Remark. You could make use of the natural isomorphism of Lemma 46.8.

Figure 790. Illustration of Exercise 47.1

Exercise 47.2. Let $\{A_k\}_{k \in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. By definition, see page 604, this means that given any $k \in K$ the following statements hold:

1. $\{a_k\}$ is a closed subset of $A_k$ and
2. there exists an open neighborhood $U_k$ of $a_k$ in $A_k$ such that $a_k$ is a deformation retract of $U_k$.

Provide a third proof of Proposition 47.9 using the following approach. First we write $W := \bigcup_{k \in K} (A_k \setminus \{a_k\})$. Now apply the (natural) reduced Mayer-Vietoris sequences from Theorem 46.5 to the decompositions

$$\bigvee_{k \in K} A_k = V \cup W \quad \text{and} \quad \bigcup_{k \in K} A_k = \left( \bigcup_{k \in K} (U_k \setminus \{a_k\}) \right) \cup \left( \bigcup_{k \in K} (A_k \setminus \{a_k\}) \right).$$

Remark. Do not forget to make use of the analogue of Exercise 20.7.

Figure 791. Illustration for Exercise 47.2
Exercise 47.3. Let $n \in \mathbb{N}$ and let $X = S^n \vee S^n$ and let $Y = S^n \vee S^n \vee S^n$. As in the proof of Proposition 47.11 we can make the identification $H_n(X) = \mathbb{Z}^2$ and $H_n(Y) = \mathbb{Z}^3$. Show that there exists a map $\varphi : X \to Y$ such that the map $\varphi_* : H_n(X) \to H_n(Y)$ is represented by the matrix

$$
\begin{pmatrix}
2 & 1 \\
-5 & 1 \\
0 & 7
\end{pmatrix}.
$$
48. Cellular homology

We saw in Theorem \[37.9\] and Proposition \[37.11\] that it is quite easy to compute the fundamental group of a finite CW-complex. In this section we will develop a relatively straightforward method for computing the homology groups of a finite CW-complex. We will use this method for finally determining the homology groups of the surfaces of genus $\geq 2$ and all the projective spaces $\mathbb{R}P^n$ and $\mathbb{C}P^n$.

48.1. The definition of cellular homology. Now we turn, as promised, to the study of homology groups of CW-complexes. We need to recall two definitions:

1. First recall that in Lemma \[41.1\] we gave a homeomorphism $f: (\Delta^n, \partial \Delta^n) \to (B^n, \partial B^n)$. This homeomorphism together with Lemma \[45.2\] gives us the following isomorphism:

\[
\begin{align*}
\mathbb{Z} \xrightarrow{\cong} H_n(\Delta^n, \partial \Delta^n) & \xrightarrow{f_*} H_n(B^n, \partial B^n) \\
1 & \mapsto [\text{id}_{\Delta^n}]
\end{align*}
\]

In the following we will usually identify $H_n(B^n, \partial B^n)$ with $\mathbb{Z}$ using the above isomorphism.

2. Let $X$ be a topological space and let $A \subset X$ be a non-empty subset. As on page 1129 we consider the map

\[
H_n(X, A) \xrightarrow{\cong} H_n(X/A, A/A) \xleftarrow{\cong} \tilde{H}_n(X/A).
\]

By Lemma \[43.21\] we know that the map is a natural homomorphism.

Now we can formulate one of the key lemmas regarding homology groups of CW-complexes.

**Lemma 48.1.** For every CW-complex $X$ the following statements hold:

1. Given $n \in \mathbb{N}_0$ we denote by $I_n$ the set of $n$-cells and given $i \in I_n$ we denote by $\Phi_i: B^n_i \to X^n$ the corresponding characteristic map. Then for every $k \in \mathbb{N}_0$ we have the following commutative diagram where all maps are isomorphisms:

\[
\begin{array}{ccc}
\bigoplus_{i \in I_n} H_k(X^n, X^n \setminus \Phi_i(B_i)) & \xrightarrow{\bigoplus \Phi_i} & \bigoplus_{i \in I_n} H_k(B^n_i, \partial B^n_i) \\
\bigoplus_{i \in I_n} \tilde{H}_k(B^n_i/\partial B^n_i) & \xrightarrow{\bigoplus \Phi_i} & \tilde{H}_k(X^n/X^{n-1}) \\
\bigoplus_{i \in I_n} \tilde{H}_k(B^n_i/\partial B^n_i) & \xrightarrow{\bigoplus \Phi_i} & \tilde{H}_k(X^n/X^{n-1}).
\end{array}
\]

In particular the following holds:

(a) For $k \neq n$ we have $H_k(X^n, X^{n-1}) = 0$. 

(b) The group $H_n(X^n, X^{n-1})$ is a free abelian group where the rank equals the cardinality of the set of $n$-cells in the CW-structure.

(2) For $k > n$ we have $H_k(X^n) = 0$.

(3) For $k < n$ the inclusion $i : X^n \to X$ induces an isomorphism $i_* : H_k(X^n) \cong H_k(X)$.

(4) The inclusion $i : X^n \to X$ induces an epimorphism $i_* : H_n(X^n) \twoheadrightarrow H_n(X)$.

Remark. The statements (3) and (4) of Lemma 48.1 can be viewed as “homology analogues” of Proposition 40.9.

Proof (*). Let $X$ be a CW-complex.

(1) We consider the following diagram

$$
\begin{array}{cccccc}
\bigoplus_{i \in I_n} H_k(B^n_i, \partial B^n_i) & \xrightarrow{\bigoplus \Phi_1} & \bigoplus_{i \in I_n} H_k(X^n, X^n \setminus \Phi_i(B_i)) & \xleftarrow{\bigoplus \Phi_1} & \bigoplus_{i \in I_n} H_k(X^n, X^{n-1}) \\
\bigoplus_{i \in I_n} \widetilde{H}_k(B^n_i / \partial B^n_i) & \xrightarrow{\bigoplus \Phi_1} & \bigoplus_{i \in I_n} \widetilde{H}_k(X^n / (X^n \setminus \Phi_i(B_i))) & \xleftarrow{\bigoplus \Phi_1} & \bigoplus_{i \in I_n} \widetilde{H}_k(X^n / X^{n-1}) \\
\end{array}
$$

We make the following observations:

(i) It follows from the definitions that the two triangles at the top and bottom commute.

(ii) It follows almost immediately from the naturality of the maps to that the square in the middle commutes and that the quadrilateral to the left commutes.

It remains to show that the maps numbered with (a) to (h) are isomorphisms.

(a) This map is an isomorphism by Proposition 43.22.

(b) This map is an isomorphism by Proposition 47.9.

(c) This map is an isomorphism by Lemma 36.33 (1).

(d) It follows from Proposition 43.22 together with Proposition 36.10 (8) that this map is an isomorphism.

(e) It follows from the commutativity of the diagram and the fact that (a) to (d) are isomorphisms that this map is an isomorphism.

(f) This map is an isomorphism by Lemma 36.33 (3).

(g) It follows immediately from Proposition 43.22 together with Proposition 36.10 (8) and Lemma 36.33 (3) that this map is an isomorphism.

(h) It follows from the fact that the quadrilateral commutes and the fact that (a), (f) and (g) are isomorphisms that this map is an isomorphism.
(i) It follows from the fact that the top triangle commutes and the fact that (e) and (h) are isomorphisms that this map is an isomorphism.

The remaining statements of (1) are now an immediate consequence of Lemma 45.1.

(2) We fix $k \in \mathbb{N}$. We want to show that $H_k(X^n) = 0$ for $n = 0, \ldots, k - 1$. First of all we have $H_k(X^0) = 0$ by Proposition 41.5 and Lemma 41.14. Now assume that we already know that $H_k(X^n) = 0$ for some $n < k - 1$. We want to show that $H_k(X^{n+1}) = 0$. We consider the long exact sequence of the pair $(X^{n+1}, X^n)$:

\[
\cdots \to H_{k+1}(X^{n+1}, X^n) \to H_k(X^n) \to H_k(X^{n+1}) \to \overbrace{H_k(X^{n+1}, X^n)}^{= 0} \to 0 \text{ by (1) since } n < k - 1
\]

Thus we obtain that indeed $H_k(X^{n+1}) = 0$.

(3) We fix $k \in \mathbb{N}_0$. Let $m > k$. This time we consider the following excerpt from the long exact sequence of the pair $(X^{m+1}, X^m)$:

\[
\cdots \to H_{k+1}(X^{m+1}, X^m) \to H_k(X^m) \to H_k(X^{m+1}) \to \overbrace{H_k(X^{m+1}, X^m)}^{= 0} \to 0 \text{ by (1) since } k < m
\]

This implies in particular that for each $k < n \leq l$ we have inclusion induced isomorphisms $H_k(X^n) \cong H_k(X^{n+1}) \cong \cdots \cong H_k(X^l)$. In particular, if $X$ is finite-dimensional, then claim (3) follows immediately from this observation. The infinite-dimensional case follows from the finite-dimensional case together with Proposition 47.4.

(4) In (3) we showed that $H_n(X^{n+1}) \to H_n(X)$ is an isomorphism. Hence it suffices to show that $H_n(X^n) \to H_n(X^{n+1})$ is an epimorphism. To show this we consider the following excerpt from long exact sequence of the pair $(X^{n+1}, X^n)$:

\[
\cdots \to H_{n+1}(X^{n+1}, X^n) \to H_n(X^n) \to H_n(X^{n+1}) \to \overbrace{H_n(X^{n+1}, X^n)}^{= 0 \text{ by (1)}} \to 0
\]

We see that the inclusion induced map $H_n(X^n) \to H_n(X^{n+1})$ is indeed an epimorphism.

\[\square\]

**Definition.** Given a CW-complex $X$, we denote by $d = d_n$ the map

\[
H_n(X^n, X^{n-1}) \xrightarrow{\partial_n} H_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} H_{n-1}(X^{n-1}, X^{n-2}) =: d = d_n
\]

where $\partial_n$ is the connecting map in the long exact sequence of the pair $(X^n, X^{n-1})$ and where $j_{n-1}$ is the map induced by the projection $C_{n-1}(X^{n-1}) \to C_{n-1}(X^{n-1}, X^{n-2})$. We refer to $d_n$ as the **cellular boundary map**.\(^{773}\)

\(^{772}\)Here we use that $X^0$ has the discrete topology.

\(^{773}\)It follows easily from the definitions that $d_n$ is precisely the connecting homomorphism of the long exact sequence of the triple $(X^n, X^{n-1}, X^{n-2})$.\(^{773}\)
The name “cellular boundary map” already suggests that the maps $d_n$ have the following important property:

**Lemma 48.2.** For all $n \in \mathbb{N}_0$ we have $d_n \circ d_{n+1} = 0$.

**Proof.** We consider the following commutative diagram of maps

\[
\begin{array}{ccccccc}
H_{n+1}(X^{n+1}, X^n) & \xrightarrow{d_{n+1}} & H_n(X^n, X^{n-1}) & \xrightarrow{d_n} & H_{n-1}(X^{n-1}, X^{n-2}) \\
\partial_n & \searrow & \downarrow & & \downarrow & \swarrow & j_n \\
& & H_{n-1}(X^{n-1}) & \xrightarrow{d_n} & H_{n-1}(X^{n-1}) & \xrightarrow{\partial_n} & j_n^{-1} \\
\end{array}
\]

The map $\partial_n \circ j_n : H_n(X^n) \rightarrow H_{n-1}(X^{n-1})$ is the composition of two successive maps in the long exact sequence of the pair $(X^n, X^{n-1})$, i.e. the map $\partial_n \circ j_n$ is the zero map. Since the diagram commutes we obtain that $d_n \circ d_{n+1} = 0$. ■

**Definition.** Let $X$ be a CW-complex.

1. We write $C^n_{\text{CW}}(X) := H_n(X^n, X^{n-1})$ and we refer to $(C^n_{\text{CW}}(X), d_n)$ as the **cellular chain complex** of the CW-complex $X$.\[73\]
2. We denote the homology groups of the cellular chain complex by $H^n_{\text{CW}}(X)$ and we refer to these groups as the **cellular homology groups** of the CW-complex $X$.

**Remark.** Let us summarize the content of Lemma 48.1 (1) in light of the above definition. Given a CW-complex $X$ and given $n \in \mathbb{N}_0$ the $n$-th cellular chain group $C^n_{\text{CW}}(X)$ is a free abelian group and the characteristic maps of the $n$-cells give canonically rise to a basis of this free abelian group.

**Example.** We consider the $n$-sphere $S^n$ for $n \geq 2$. On page \[935\] we showed that we can view $S^n$ as a CW-complex with one 0-cell and one $n$-cell. The cellular chain complex $C^n_{\text{CW}}(X)$ is thus of the form

\[
0 \rightarrow \mathbb{Z}^{\cong C^n_{\text{CW}}(X)} \rightarrow 0 \rightarrow \ldots \rightarrow 0 \rightarrow \mathbb{Z}^{\cong C^n_{\text{CW}}(X)} \rightarrow 0.
\]

Since $n \geq 2$ both the $\mathbb{Z}$'s are separated by at least one zero group. The cellular boundary maps are therefore necessarily the zero maps and we obtain that

$$H^n_{\text{CW}}(X) \cong \begin{cases} 
\mathbb{Z}, & \text{if } i = 0, n, \\
0, & \text{otherwise}.
\end{cases}$$

These are of course isomorphic to the “usual” homology groups of $S^n$. In the next section we will see that this is not a coincidence.

The “usual” homology groups define functors from the category of topological spaces to the category of abelian groups. We will now see that in a more restricted setting cellular homology groups also define a functor.

\[77\]It follows from Lemma 48.2 that $(H_n(X^n, X^{n-1}), d_n)$ is indeed a chain complex.
Definition.

(1) A map \( f: X \to Y \) between CW-complexes is called cellular if for each \( n \in \mathbb{N}_0 \) we have \( f(X^n) \subseteq Y^n \).
(2) As before we denote by \( CW \) the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps.

We conclude this section with the following lemma.

Lemma 48.3.

(1) Every cellular map \( f: X \to Y \) induces a chain map

\[ f_*: C^\text{CW}_*(X) \to C^\text{CW}_*(Y) \]

and hence also maps

\[ f_*: H^\text{CW}_*(X) \to H^\text{CW}_*(Y) \]

on cellular homology.
(2) For each \( n \in \mathbb{N}_0 \) the maps

\[ X \mapsto H^\text{CW}_n(X) \]

\[ (f: X \to Y) \mapsto (f_*: H^\text{CW}_n(X) \to H^\text{CW}_n(Y)) \]

define a covariant functor from the category \( CW \) of CW-complexes to the category \( \mathbb{AbGr} \) of abelian groups.

Proof.

(1) Let \( f: X \to Y \) be a cellular map. Since the map \( f \) is cellular we get for every \( n \in \mathbb{N}_0 \) an induced map \( H_n(X^n, X^{n-1}) \to H_n(Y^n, Y^{n-1}) \), i.e. we get an induced map \( f_*: C^\text{CW}_n(X) \to C^\text{CW}_n(Y) \). It follows almost immediately from the naturality of the connecting homomorphism, see Proposition 43.15 (2), that the above maps \( f_*: C^\text{CW}_n(X) \to C^\text{CW}_n(Y), n \in \mathbb{N}_0 \) actually form a chain map.

(2) This statement follows easily from the fact that the usual chain complexes and homology groups are covariantly functorial.

48.2. The relationship between cellular and singular homology. Now we can formulate and prove the following proposition.

Proposition 48.4. Let \( n \in \mathbb{N}_0 \).

(1) For each CW-complex \( X \) there exists a uniquely determined isomorphism

\[ \Phi_X: H_n(X) \xrightarrow{\cong} H^\text{CW}_n(X) \]

with the property that the following diagram commutes:

\[ \begin{array}{ccc}
  H_n(X^n) & \xrightarrow{j_n} & \ker(d_n) \\
  \downarrow \Phi_X & & \downarrow \Phi_X \\
  H^\text{CW}_n(X) & \xrightarrow{\cong} & H_n(X) \\
\end{array} \]
Recall that we denote by \( \text{CW} \) the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps. The homomorphisms from (1) define a natural isomorphism between the functors \( X \mapsto H_n(X) \) and the functor \( X \mapsto H_n^{\text{CW}}(X) \). In other words, for every cellular map \( f: X \to Y \) and any \( n \in \mathbb{N}_0 \) the following diagram commutes

\[
\begin{array}{ccc}
H_n(X) & \xrightarrow{f_*} & H_n(Y) \\
\phi_X \cong & \cong & \phi_Y \\
H_n^{\text{CW}}(X) & \xrightarrow{f_*} & H_n^{\text{CW}}(Y)
\end{array}
\]

Remark. Later on, in Proposition 49.10, we will give an alternative proof that singular and cellular homology groups are naturally isomorphic. The latter proof has the advantage that it shows a stronger statement, namely it shows in fact that the singular and cellular chain complexes are chain homotopy equivalent.

Example. Even though the cellular boundary maps in the cellular chain complex are still somewhat mysterious we can already use the proposition to do some calculations. As an example, we return to the \( n \)-dimensional complex projective space \( \mathbb{CP}^n \) which he defined on page 194 as

\[
\mathbb{CP}^n := (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).
\]

In Lemma 36.1 we showed that we can view \( \mathbb{CP}^n \) as a CW-complex which admits exactly one cell in dimensions \( 0, 2, \ldots, 2n \) and which admits no other cells. In particular the cellular chain complex is of the form

\[
0 \to C_{2n}^{\text{CW}}(\mathbb{CP}^n) \cong \mathbb{Z} \to C_{2n-1}^{\text{CW}}(\mathbb{CP}^n) \to \cdots \to C_{2}^{\text{CW}}(\mathbb{CP}^n) \cong \mathbb{Z} \to C_{1}^{\text{CW}}(\mathbb{CP}^n) \cong \mathbb{Z} \to C_{0}^{\text{CW}}(\mathbb{CP}^n) \to 0.
\]

Since every other group is trivial it follows that all boundary maps are also zero. In particular the homology groups equal the cellular chain groups. Thus we have shown that

\[
H_k(\mathbb{CP}^n) \cong H_k^{\text{CW}}(\mathbb{CP}^n) \cong C_k^{\text{CW}}(\mathbb{CP}^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\
0, & \text{otherwise}.
\end{cases}
\]

Remark. By the naturality of the isomorphism of Proposition 48.4 the same conclusion also holds for the inclusion induced map

\[
H_i^{\text{CW}}(\mathbb{CP}^k; \mathbb{Z}) \cong H_i(\mathbb{CP}^k; \mathbb{Z}) \xrightarrow{\cong} H_i(\mathbb{CP}^l; \mathbb{Z})
\]

on singular homology. It follows from Lemma 36.6 (2) that we can view the infinite-dimensional complex projective space \( \mathbb{CP}^\infty \) as a CW-complex that has precisely one cell

\[
775 \text{Here we again denote by } j_n: H_n(X^n) \to H_n(X^n, X^{n-1}) \text{ the obvious map. In the long exact sequence of the pair } (X^n, X^{n-1}) \text{ we see that the image of } H_n(X^n) \text{ in } H_n(X^n, X^{n-1}) \text{ lies in the kernel of the connecting homomorphism } \partial_n. \text{ This implies that the map } j_n: H_n(X^n) \to H_n(X^n, X^{n-1}) \text{ takes values in ker}(d_n).
\]
in each even dimension and no cells in odd dimensions. From the arguments above it now follows that
\[ H_k(\mathbb{C}P^\infty) \cong H_k^{CW}(\mathbb{C}P^\infty) \cong C_k^{CW}(\mathbb{C}P^\infty) \cong \begin{cases} \mathbb{Z}, & \text{if } k \text{ is even,} \\ 0, & \text{if } k \text{ is odd.} \end{cases} \]

Furthermore, as above we see that the inclusion induced map
\[ H_i(\mathbb{C}P^k; \mathbb{Z}) \cong H_i(\mathbb{C}P^\infty; \mathbb{Z}) \]
is an isomorphism for \( i \leq k + 1 \).

**Proof of Proposition 48.4.** We add a couple of maps to the commutative diagram that we had already encountered in the proof of Lemma 48.2:

\[
\begin{array}{c}
0 \\
\downarrow \partial_{n+1} \\
H_n(X^{n+1}) \\
\downarrow j_n \\
H_n(X^n) \\
\downarrow d_{n+1} \\
H_n(X^{n+1}, X^n) \\
\downarrow d_n \\
H_n(X^n, X^{n-1}) \\
\downarrow \partial_n \\
H_{n-1}(X^{n-1}) \\
\downarrow j_{n-1} \\
H_{n-1}(X^{n-1}) \\
\downarrow d_{n-1} \\
H_{n-2}(X^{n-2}) \\
\downarrow \partial_{n-1} \\
0
\end{array}
\]

**Claim.** All the diagonal sequences in the above commutative diagram are exact.

From Lemma 48.1 (1) and (2) we know that
\[ H_n(X^{n+1}, X^n) = 0, \quad H_n(X^{n-1}) = 0 \quad \text{and} \quad H_{n-1}(X^{n-2}) = 0. \]

It thus follows that the diagonal sequences in the above commutative diagram are just the long exact sequences of the corresponding pairs of topological spaces. In particular all the diagonal sequences are exact.

Next we prove the following claim.

**Claim.** The map \( j_n : H_n(X^n) \to H_n(X^n, X^{n-1}) \) induces an isomorphism
\[ \Phi : H_n(X^n)/\text{im}(\partial_{n+1}) \to \ker(d_n)/\text{im}(d_{n+1}) = H_n^{CW}(X). \]

We will prove this claim once again by a “diagram chase”[776]

1. Since \( \partial_n \circ j_n = 0 \) it follows that \( j_n(H_n(X^n)) \subset \ker(d_n) \).
2. The map \( j_{n-1} \) is injective, i.e. \( \ker(d_n) = \ker(\partial_n) = \text{im}(j_n) \), i.e. the map \( j_n \) induces an epimorphism
\[ H_n(X^n) \to \ker(d_n). \]

Since the left triangle commutes it also induces an epimorphism
\[ H_n(X^n)/\text{im}(\partial_{n+1}) \to \ker(d_n)/\text{im}(d_{n+1}). \]

[776]It is arguably best not to read the remainder of the proof but to go on the chase on one’s own.
(3) If an element \( j_n(c) \in H_n(X^n, X^{n-1}) \) lies in the image of \( d_{n+1} = j_n \circ \partial_{n+1} \), then \( j_n(c) = j_n(\partial_{n+1}(d)) \) for some \( d \in H_{n+1}(X^{n+1}, X^n) \). Since \( j_n \) is injective it follows that \( c = \partial_{n+1}(d) \). Thus we have now shown that the map

\[ H_n(X^n)/\text{im}(\partial_{n+1}) \to \text{ker}(d_n)/\text{im}(d_{n+1}) \]

is injective.

Next we consider the diagram which gives us the definition of the isomorphism \( \Phi \):

\[
\begin{array}{cccc}
H_n(X^n)/\text{im}(\partial_{n+1}) & \xrightarrow{\cong} & H_n(X^{n+1}) & \xrightarrow{\cong} H_n(X).
\end{array}
\]

By the claim we know that \( j_n \) induces an isomorphism

\[
\begin{array}{ccc}
\text{ker}(d_n)/\text{im}(d_{n+1}) & \xrightarrow{id} & H_n^{\text{CW}}(X)
\end{array}
\]

By construction the isomorphism \( \Phi \) has the property that the following diagram commutes:

\[
\begin{array}{ccc}
H_n(X^n) & \xrightarrow{j_n} & \text{ker}(d_n)
\end{array}
\]

\[
\begin{array}{ccc}
& & \text{ker}(d_n)
\end{array}
\]

\[
\begin{array}{ccc}
& & H_n^{\text{CW}}(X)
\end{array}
\]

\[
\begin{array}{ccc}
& & H_n(X)
\end{array}
\]

\[
\begin{array}{ccc}
& & \Phi
\end{array}
\]

Note that the top-left diagonal map is an epimorphism by Lemma [48.1] (4). This implies immediately that \( \Phi \) is uniquely determined.

Finally we leave it as a straightforward exercise to the reader that the maps \( \Phi \) define a natural isomorphism.

On page 1262 we already saw that Proposition [48.4] can be useful, even if we cannot determine the boundary maps \( d_n \). Another, more theoretical application is, that the cellular chain complex is “much smaller” than the singular chain complex. For example, if \( X \) is a CW-complex with finitely many cells, then the chain group \( C_n^{\text{CW}}(X) \) in the cellular chain complex are finitely generated free abelian groups. This is in contrast to the singular chain groups \( C_n(X) \) which are in almost all cases free abelian groups of uncountable rank.\[777\]

Using this observation we can now easily prove the following proposition. It can be viewed as an analogue to Proposition [37.13]

**Proposition 48.5.** Let \( X \) be a CW-complex. The following statements hold:

(1) If \( X \) contains precisely \( d \in \mathbb{N}_0 \) cells of dimension \( n \), then \( H_n(X) \) is generated by at most \( d \) elements. In particular, if \( X \) has no cells of dimension \( n \), then \( H_n(X) = 0 \). Similarly, if \( X \) contains only countable many cells of dimension \( n \), then \( H_n(X) \) is countable.

\[777\] For which topological spaces and which \( n \) is the singular chain complex \( C_n(X) \) finitely generated? Can you give a complete answer?
(2) If $X$ consists only of finitely many cells, then all homology groups of $X$ are finitely generated groups.

(3) If $X$ is finite-dimensional, then

$$H_k(X) = 0 \text{ for all } k > \dim(X).$$

(4) If $X$ is an $n$-dimensional CW-complex, then $H_n(X)$ is a free abelian group.

**Example.** It follows from Proposition 48.5 that for any topological graph $G$ we have $H_i(G) = 0$ for every $i \geq 2$ and that $H_1(G)$ is a free abelian group.

**Remark.**

(1) Later on, in Proposition 49.10 we will give an alternative proof that singular and cellular homology groups are naturally isomorphic. The latter proof has the advantage that it shows a stronger statement, namely it shows in fact that the singular and cellular chain complexes are chain homotopy equivalent.

(2) In Chapter 106 in particular in Proposition 106.8 we will formulate and prove a pretty elementary algebraic statement that allows us in Proposition 106.10 (2) to prove that the “size” of homology groups give a lower bound on the number of cells in a CW-structure. This result can be viewed as a refinement of Proposition 48.5 (1).

**Proof.** Let $X$ be a CW-complex $X$.

(1) If $X$ contains precisely $d \in \mathbb{N}_0$ cells of dimension $n$, then it follows from Lemma 48.1 that $C_n^{CW}(X) \cong \mathbb{Z}^d$. By Lemma 19.8 any subgroup $U$ of $\mathbb{Z}^d$ is a free abelian group such that $\mathrm{rank}(U) \leq d$. Thus it follows that

$$H_n(X) \cong \ker (d_n: C_n^{CW}(X) \to C_{n-1}^{CW}(X)) / \mathrm{im} (d_{n+1}: C_{n+1}^{CW}(X) \to C_n^{CW}(X))$$

is generated by at most $d$ elements. The argument in the case that $X$ has countably many cells of dimension $n$ is very similar, we just need to use Lemma 1.7 several times.

(2) This statement follows immediately from (1).

(3) This statement is in fact already a consequence of Lemma 48.1 (2).

(4) Now suppose that $X$ is an $n$-dimensional CW-complex $X$. We have

$$H_n(X) \cong H_n^{CW}(X) = \ker (d_n: C_n^{CW}(X) \to C_{n-1}^{CW}(X)), \quad \uparrow \quad \uparrow$$

Proposition 48.4 we have $C_{n+1}^{CW}(X) = 0$ since $X$ is $n$-dimensional

i.e. $H_n(X)$ is a subgroup of the free abelian group $C_n^{CW}(X)$. It follows from Lemma 19.2 that the group $H_n(X)$ itself is a free abelian group.

By Theorem 64.5 which we already mentioned in a sneak preview on page 936 we know that every compact $n$-dimensional smooth manifold admits a CW-structure with finitely many cells and such that the maximal dimension of a cell is $n$. If we combine this result with Proposition 48.5 we obtain immediately the following useful result.
Proposition 64.6. Let $M$ be a compact $n$-dimensional smooth manifold. Then the following holds:

1. All homology groups are finitely generated abelian groups.
2. For any $k > n$ we have $H_k(M) = 0$.

Remark. We have now shown that for a CW-complex $X$ the singular homology groups $H_n(X)$ are isomorphic to the cellular homology groups $H_n^{CW}(X)$. One might now ask, whether one can generalize this statement, namely whether the singular chain complex $(C_*(X), d_*)$ and the cellular chain complex $(C_*(X), d_*)$ are in fact chain homotopic. This is indeed the case. But the proof requires more homological algebra than we have at the moment at our disposal. Therefore we postpone the proof to a later chapter.

48.3. The cellular boundary maps. If we want to use Proposition 48.4 to calculate homology groups of CW-complexes we need to develop tools for computing the cellular boundary maps $d_n$ in the cellular chain complex. Let $X$ be a CW-complex and let $n \in \mathbb{N}_0$. Throughout this section we will use the following notation:

1. We denote by $I_n$ the set of $n$-cells of $X$.
2. Given an $n$-cell $\alpha$ we denote by $\varphi_\alpha: S^{n-1}_\alpha \to X^{n-1}$ the corresponding attaching map and we denote by $\Phi_\alpha: B^n_\alpha \to X^n$ the corresponding characteristic map.
3. We denote by $
abla_{\alpha \in I_n} B^n_\alpha / \partial B^n_\alpha \to X^n / X^{n-1}$ the map that is given by $x \mapsto \Phi_\alpha(x)$, if $x \in B^n_\alpha$.

It is straightforward to verify that $\Psi_n$ is a homeomorphism.

4. Given $\beta \in I_n$ we denote by $i_\beta: B^n_\beta / \partial B^n_\beta \to \nabla_{\alpha \in I_n} B^n_\alpha / \partial B^n_\alpha$ and $p_\beta: \nabla_{\alpha \in I_n} B^n_\alpha / \partial B^n_\alpha \to B^n_\beta / \partial B^n_\beta$ the obvious inclusion map respectively the obvious projection map. By Proposition 17.9 the maps

$$
\bigoplus_{\beta \in I_n} H_n \left( B^n_\beta / \partial B^n_\beta \right) \xleftarrow{\Theta_i} H_n \left( \bigvee_{\beta \in I_n} B^n_\beta / \partial B^n_\beta \right) \xrightarrow{\Theta_p} H_n \left( \bigvee_{\beta \in I_n} B^n_\beta / \partial B^n_\beta \right).
$$

are inverses of one another.

5. Given $\alpha \in I_n$ we denote, by a slight abuse of notation, the standard generator of $H_n(B^n_\alpha / \partial B^n_\alpha) \cong \mathbb{Z}$, as defined on page 1176 by $\alpha$. Put differently, we make the identification $H_n(B^n_\alpha / \partial B^n_\alpha) = \mathbb{Z} \cdot \alpha$. 

By Lemma 48.1 we have the following commutative diagram where all maps are isomorphisms:

\[
\begin{array}{ccc}
\bigoplus_{i \in I_n} H_n(B^n_i, \partial B^n_i) & \xrightarrow{\Omega_n := \oplus \Phi_i} & H_k(X^n, X^{n-1}) \\
\bigoplus_{i \in I_n} \tilde{H}_n(B^n_i / \partial B^n_i) & \xrightarrow{\Phi_i} & \tilde{H}_n(X^n / X^{n-1}).
\end{array}
\]

By another abuse of notation we often denote \(\Omega_n(\alpha)\) also by \(\alpha\). Put differently, we identify \(C_n^{CW}(X) = H_n(X^n, X^{n-1})\) with the free abelian group generated by the set \(I_n\) of all \(n\)-cells.

Our goal now is to determine the matrix of the cellular boundary map

\[
d_n : \frac{H_n(X^n, X^{n-1})}{\text{free abelian group generated by } I_n} \to \frac{H_{n-1}(X^{n-1}, X^{n-2})}{\text{free abelian group generated by } I_{n-1}}
\]

corresponding to the bases given by the cells. As a warm-up with start out with the case \(n = 1\).

**Lemma 48.6.** Let \(X\) be a CW-complex. We adopt all the notations introduced above.

1. For a 1-cell \(\alpha\) with attaching map \(\varphi_\alpha : B^1 \to X^0\) we have
   \[
d_1(\alpha) = \varphi_\alpha(1) - \varphi_\alpha(-1).
   \]
2. If \(X\) has precisely one 0-cell, then the cellular boundary map \(d_1\) is the zero map.

**Proof.** The second statement of the lemma is evidently a consequence of the first statement. Therefore it suffices to prove the first statement. So let \(\alpha\) be a 1-cell with characteristic map \(\Phi_\alpha : B^1 \to X^0\). We have to determine the map

\[
\begin{array}{ccc}
\mathbb{Z} \cdot \alpha & \xrightarrow{Z} & \bigoplus_{j \in I_1} H_1(B^1_j, \partial B^1_j) \\
& & \xrightarrow{\Omega_1} H_1(X^1, X^0) \\
& & \xrightarrow{d_1} \bigoplus_{i \in I_0} H_0(B^0_i, \partial B^0_i).
\end{array}
\]

Since \(X^{-1} = \emptyset\) we see that in the present case we have \(d_1 = \partial_1\), i.e. the cellular boundary map \(d_1\) is the connecting homomorphism \(H_1(X^1, X^0) \to H_0(X^0)\) of the long exact sequence of the pair \((X^1, X^0)\). It follows immediately from the definitions of the connecting homomorphism, as defined in Proposition 43.15 (1), that \(d_1(\alpha) = \varphi_\alpha(1) - \varphi_\alpha(-1)\). \(\blacksquare\)

**Example.** We consider the topological graph \(G\) that is given in Figure 792 with two vertices \(\beta_1, \beta_2\) and four edges \(\alpha_1, \ldots, \alpha_4\). We view it as a CW-complex in the obvious way. According to Lemma 48.6 the cellular chain complex of \(X\) is of the following form
Thus we obtain from Proposition 48.4 that
\[ H_1(G) \cong \ker \left( \mathbb{Z}^4 \to \mathbb{Z}^2 \right) \cong \mathbb{Z}^3 \quad \text{and} \quad H_0(G) \cong \operatorname{coker} \left( \mathbb{Z}^4 \to \mathbb{Z}^2 \right) \cong \mathbb{Z}. \]

After this example we return to the discussion of the cellular boundary maps. Now let \( n > 1 \). We want to determine the cellular boundary map
\[ d_n : H_n(X^n, X^{n-1}) \to H_{n-1}(X^{n-1}, X^{n-2}). \]

Given an \( n \)-cell \( \alpha \) and an \((n-1)\)-cell \( \beta \) we consider the map
\[ S^{n-1}_\alpha = \partial B^n_{\alpha} \xrightarrow{\varphi_\alpha} X^{n-1} \xrightarrow{q} X^{n-1}/X^{n-2} \xrightarrow{\Psi_{n-1}} \bigvee_{j \in I_{n-1}} B^{n-1}_j / \partial B^{n-1}_j \xrightarrow{p_\beta} B^{n-1}_\beta / \partial B^{n-1}_\beta \xrightarrow{\Theta} S^{n-1}_\beta \]

where \( q : X^{n-1} \to X^{n-1}/X^{n-2} \) is the quotient map and where \( \Theta : B^{n-1}_\beta / \partial B^{n-1}_\beta \to S^{n-1}_\beta \) denotes the homeomorphism from page 1181. Since \( S^{n-1}_\alpha \) and \( S^{n-1}_\beta \) are copies of \( S^{n-1} \) we can consider the degree of the map as defined on page 1181.

Now we will see that this degree is just the \( \beta \times \alpha \)-entry of the matrix that represents the cellular boundary map \( d_n \) with respect to the bases given by all \( n \)-cells and all \((n-1)\)-cells. More precisely we have the following proposition:

**Proposition 48.7.** Let \( X \) be a CW-complex. We use all the notation that we introduced above. Then for each \( n \)-cell \( \alpha \) we have
\[ d_n(\alpha) = \sum_{\beta \in I_{n-1}} d_{\alpha, \beta} \cdot \beta \]

where \( d_{\alpha, \beta} := \text{degree of the map } S^{n-1}_\alpha \xrightarrow{\Theta \circ p_\beta \circ \Psi_{n-1}^{-1} \circ q \circ \varphi_\alpha} S^{n-1}_\beta. \]

**Proof.** We write \( I := I_n \) and \( J := I_{n-1} \). We consider the following diagram:\n
778The strange shape of the diagram is due to space constraints.
We make the following claim.

**Claim.** The diagram commutes.

We consider the various parts of the diagram.

1. It follows from Lemma 48.1 (1) that the pentagon at the top and the large triangle at the bottom commute.
2. It follows from the naturality of the connecting homomorphism, see Corollary 43.16 (2), that the following diagram commutes:

   \[
   H_n(B^n_\alpha, \partial B^n_\alpha) \xrightarrow{\Phi_\alpha} H_n(X^n, X^{n-1})
   \]

   \[
   \partial_n \downarrow \quad \partial_n \downarrow
   \]

   \[
   H_{n-1}(S^{n-1}_\alpha) \xrightarrow{\varphi_\alpha} H_{n-1}(X^{n-1})
   \]

   From this observation it follows that the upper rectangle in the diagram commutes.
3. It follows immediately from the definitions that the pentagon to the left commutes.
4. It follows again immediately from the definitions that the triangle involving the map \( p_\beta \) commutes.
5. It follows from Lemma 43.21 (1) that the triangle to the bottom right commutes. □
Finally note that it follows from the definition of the standard generator of $H_n(B^n, \partial B^n)$ on page 1176 and from Proposition 45.5 that the two maps
\[ \partial_n : H_n(B^n, \partial B^n) \rightarrow \tilde{H}_{n-1}(\Sigma) \quad \text{and} \quad \Theta_\ast \circ \zeta : H_{n-1}(B^{n-1}_\beta, \partial B^{n-1}_\beta) \rightarrow \tilde{H}_{n-1}(\Sigma) \]
send the standard generator to the standard generator. The reader who is still awake will notice that the proposition follows immediately from the claim and this observation. \[ \blacksquare \]

**Example.** We consider the surface $\Sigma$ of genus 2. As usual we view $\Sigma$ as a CW-complex with one 0-cell $P$, four 1-cells $a, b, c, d$ and one 2-cell $F$. We denote by $\varphi : S^1 \rightarrow \Sigma$ the attaching map of the 2-cell $F$. (We refer to Figure 793 for an illustration.) It follows from the discussion on page 1181 that the degree of the map $p_a \circ \Psi^{-1} \circ q \circ \varphi : S^1_F \rightarrow S^1_4$ is zero. The same conclusion holds for all other 1-cells. It follows from Proposition 48.7 that the cellular boundary map $d_2$ in the cellular chain complex of $\Sigma$ is zero. Since $\Sigma$ has only one 0-cell we know from Lemma 48.6 that the cellular boundary map $d_1$ is also zero. Thus we see that

\[
H_n(\Sigma) \cong H_n^{\text{CW}}(\Sigma) = C_n^{\text{CW}}(\Sigma) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
\mathbb{Z}, & \text{if } n = 2, \\
\mathbb{Z}^4, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}
\]

In Figure 794 on the left-hand side we show closed curves $a, b, c, d$. It follows fairly easily from the above calculation and the explicit isomorphism of Proposition 48.4 that these curves represent a basis for $H_1(\Sigma) \cong \mathbb{Z}^4$. These curves in turn are isotopic to the curves $a', b', c', d'$ on the right-hand side, which therefore, by Proposition 42.3, also represent a basis for $H_1(\Sigma) \cong \mathbb{Z}^4$.

In the previous example we determined that $H_1(\Sigma) \cong \mathbb{Z}^4$ and we gave an explicit basis for $H_1(\Sigma)$. One might think that we now fully understand the homology groups of $\Sigma$. We will try to challenge this idea in Exercise 48.16.
48. CELLULAR HOMOLOGY

Example. As a reality check we also consider once again the Klein bottle $K$. We view $K$ as a CW-complex with one 0-cell $P$, two 1-cells $a, b$ and one 2-cell $F$. (We refer to Figure 795 for an illustration.) It follows from Proposition 48.7 the discussion on page 1181 and Lemma 48.6 that the cellular chain complex is of the form

$$0 \rightarrow \mathbb{Z} \xrightarrow{(-2, 0)} \mathbb{Z}^2 \xrightarrow{(0, 0)} \mathbb{Z} \rightarrow 0.$$ 

Therefore we see that $H_2(K) = 0$, $H_1(K) \cong \mathbb{Z}_2 \oplus \mathbb{Z}$ and $H_0(K) \cong \mathbb{Z}$. This is of course the same result that we had already obtained in Lemma 16.13.

48.4. The homology groups of 2-dimensional smooth manifolds. Recall that given any $g, m \in \mathbb{N}_0$ we write $\Sigma_{g,m}$ := the surface of genus $g$ minus $m$ open disks

and for $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$ we write $N_{k,m} :=$ the non-orientable surface of genus $g$ minus $m$ open disks.

In the Surface Classification Theorem 23.4 we saw that every connected, compact 2-dimensional topological manifold is homeomorphic to either $\Sigma_{g,m}$ for unique $g, m \in \mathbb{N}_0$ or to $N_{k,m}$ for unique $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$.

Our goal in this section will be to determine the homology groups of $\Sigma_{g,n}$ and $N_{k,n}$. Before we consider the general case we will consider the special case $\Sigma_{2,1}$ in great detail.

Example. We consider $\Sigma_{2,1}$ and we equip it with the CW-structure that is illustrated in Figure 796. This CW-structure has two 0-cells $P, Q$, six 1-cells $a, b, c, d, w, z$ and it has one

\footnote{779 Also recall the definition on page 668 what we mean by a “surface minus $m$ open disks”.

Figure 794. A basis for $H_1(\Sigma)$.}

Figure 795

\begin{center}
\includegraphics[width=\textwidth]{figure794.png}
\end{center}

\begin{center}
\includegraphics[width=\textwidth]{figure795.png}
\end{center}
2-cell $F$. Given $i = 1, 2$ we denote by $A_i$ the matrix that represents the cellular boundary map $d_i: C^\text{CW}_i(\Sigma_{2,1}) \rightarrow C^\text{CW}_{i-1}(\Sigma_{2,1})$ with respect to the given bases.

![Figure 796](image)

The argument on page 1270 shows that

$$A_2 = \begin{pmatrix} a & F \\ b & 0 \\ c & 0 \\ d & 0 \\ w & 0 \\ z & 1 \end{pmatrix}$$

It follows from Lemma 48.6 that we have

$$A_1 = \begin{pmatrix} a & b & c & d & w & z \\ P & 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}.$$

Some elementary linear algebra shows that

$$H_n(\Sigma_{2,1}) \cong H_n(\Sigma_{2,1}) = H_n\left(0 \rightarrow \mathbb{Z} \xrightarrow{A_2} \mathbb{Z}^6 \xrightarrow{A_1} \mathbb{Z}^2 \rightarrow 0\right) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^4, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

From this discussion we get in fact a more precise statement. Namely, by the choice of the CW-structure on $\Sigma_{2,1}$ we have that the map inclusion map $\partial \Sigma_{2,1} \rightarrow \Sigma_{2,1}$ is in fact a cellular map. Therefore it follows from Proposition 48.4(2) that the following diagram commutes

$$\begin{array}{ccc}
H_1(\partial \Sigma_{2,1}) & \xrightarrow{f_*} & H_1(\Sigma_{2,1}) \\
\cong & & \cong \\
\mathbb{Z} = H^\text{CW}_1(\partial \Sigma_{2,1}) & \xrightarrow{f_*} & H^\text{CW}_1(\Sigma_{2,1}) = \mathbb{Z}^4 \\
\end{array}$$

where the vertical maps denote the isomorphisms from Proposition 48.4. The 1-cell $z$ is null-homologous in $C^\text{CW}_1(\Sigma_{2,1})$ since we have just seen that it is the boundary of the 2-cell $F$. Thus we see that the bottom horizontal map is the zero map, but that implies that the top horizontal map is also the zero map.

After the calculations that we just did it we can now easily prove the following lemma.

**Lemma 48.8.**

(1) Let $g \in \mathbb{N}_0$. Then the inclusion induced map

$$H_1(\partial \Sigma_{g,1}) \rightarrow H_1(\Sigma_{g,1})$$
is the zero map.

(2) Let $M$ be a smooth manifold and let $C$ be an oriented curve in $M$. If there exists a $g \in \mathbb{N}_0$ and a map $\psi : \Sigma_{g,1} \to M$ such that $\psi(\partial \Sigma_{g,1}) = C$, then $C = 0 \in H_1(M)$.\textsuperscript{780}

**Remark.** In Exercise 48.14 we will prove a generalization of Lemma 48.8 (1).

**Example.** Loosely speaking Lemma 48.8 (2) says that if a curve $C$ is the boundary of a compact orientable surface in $M$, then $C$ is null-homologous. For example in Figure 797 we see a curve $C$ on a surface $M$. Since $C$ is the boundary of a compact orientable subsurface contained in $M$ we see that $C = 0 \in H_1(M)$.

![Figure 797](image)

**Figure 797**

**Proof.**

(1) For $g = 1$ we proved the statement in the previous example. The general case is proved entirely the same way.

(2) Now let $M$ be a smooth manifold and let $C$ be an oriented curve in $M$. Suppose there exists a $g \in \mathbb{N}_0$ and a map $\psi : \Sigma_{g,1} \to M$ such that $\psi(\partial \Sigma_{g,1}) = C$. We get the commutative diagram

\[
\begin{array}{ccc}
H_1(S^1) & \longrightarrow & H_1(C) \\
\downarrow & & \downarrow \psi_* \\
H_1(\partial \Sigma_{g,1}) & \longrightarrow & H_1(\Sigma_{g,1})
\end{array}
\]

By the first statement the bottom horizontal map is the zero map. But that shows that the homology class represented by $C$ is also zero.

In the following proposition we give the calculation for the homology groups of all connected, compact 2-dimensional topological manifolds.

---

\textsuperscript{780}Following the convention of page 223 the curve $C$ defines a homology class in $H_1(M)$ that we also denote by $C$. 

**Proposition 48.9.** For any \( g \in \mathbb{N}_0 \) we have

\[
H_n(\Sigma_g) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
\mathbb{Z}, & \text{if } n = 2, \\
\mathbb{Z}^{2g}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}
\]

Furthermore, for \( m \geq 1 \) we have

\[
H_n(\Sigma_{g,m}) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
0, & \text{if } n = 2, \\
\mathbb{Z}^{2g+m-1}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}
\]

For any \( k \in \mathbb{N} \) we have

\[
H_n(N_k) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
0, & \text{if } n = 2, \\
\mathbb{Z} \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}
\]

Furthermore, for \( m \geq 1 \) we have

\[
H_n(N_{k,m}) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
0, & \text{if } n = 2, \\
\mathbb{Z}^{k+m-1}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases}
\]

**Proof.** The calculation of the homology groups \( \Sigma_{g,m} \) is a slight generalization of the arguments that we provided above and on page 1270. We leave the details to the reader.

We will deal with the homology of \( N_{k,m} \) in Exercise 48.1. The calculation is evidently just a variation on the arguments we provided for \( \Sigma_2 \) and \( \Sigma_{2,2} \).

**Remark.** A careful reading of the Proof of Proposition 48.9 gives us some extra information. First of all we endow \( \Sigma_{g,m} \) with an orientation. The boundary components of \( \Sigma_{g,m} \) then inherit an orientation. By the discussion on page 1223 the boundary components, viewed as oriented curves, then define elements \( c_1, \ldots, c_m \in H_1(\Sigma_{g,m}) \). Then there exists an exact sequence

\[
0 \rightarrow \mathbb{Z} \xrightarrow{1-\sum c_i} \bigoplus_{i=1}^m \mathbb{Z} \cdot c_i \rightarrow H_1(\Sigma_{g,m}) \rightarrow H_1(\Sigma_g) \rightarrow 0.
\]

As we saw in Figure 794, a basis for \( H_1(\Sigma_g) \) is given by a pair of curves for each “hole”. The above exact sequence shows that a basis for the homology group \( H_1(\Sigma_{g,m}) \cong \mathbb{Z}^{2g+m-1} \) is obtained by a pair of curves for each “hole” together with boundary curves for all except one boundary component. This statement is illustrated in Figure 798.

![Figure 798](image)

We conclude this section with the surface \( \Sigma_\infty \) of infinite genus that we had already encountered on page 740. Using a variation on the proof of Lemma 25.11 one can show,
using the above calculations and Proposition 47.4 that
\[ H_n(\Sigma_\infty) \cong \begin{cases} 
0, & \text{if } n \geq 2, 
\mathbb{Z}^\infty, & \text{if } n = 1, 
\mathbb{Z}, & \text{if } n = 0.
\end{cases} \]

We leave it to the reader to fill in the details.

48.5. **The homology groups of real projective spaces.** In this section we will compute the homology groups of real projective spaces \( \mathbb{R}P^n \). This calculation is significantly trickier than the previous ones, since the calculation of the cellular boundary maps is not as straightforward as in our previous examples. This time we will need the theory of local degrees that we developed in Section 45.6.

**Proposition 48.10.** For any \( n \in \mathbb{N}_0 \) we have\(^{781}\)
\[ H_k(\mathbb{R}P^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = 0, 
\mathbb{Z}_2, & \text{if } k \text{ is odd and } k < n, 
0, & \text{if } k \text{ is even and } 0 < k \neq 0, 
0, & \text{if } k > n, 
\mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd}.
\end{cases} \]

**Proof (\(*\). As a reminder we defined
\[ \mathbb{R}P^n = S^n / \sim \quad \text{where } x \sim -x \text{ for all } x \in S^n. \]

In Lemma 36.1 we already saw that we can view \( \mathbb{R}P^n \) as a CW-complex with the following two properties:

1. the CW-structure has exactly one cell in the dimensions \( 0, 1, \ldots, n \) and no other cells,
2. for each \( k \leq n \) the \( k \)-skeleton of \( \mathbb{R}P^n \) is given by \( \mathbb{R}P^k \).

Now we recall the definition of this CW-structure. For each \( k \in \mathbb{N}_0 \) we define
\[ \varphi_k: S^{k-1} = \partial B^k \to \mathbb{R}P^{k-1} \]
\[ (x_1, \ldots, x_k) \mapsto [(x_1, \ldots, x_k)]. \]

Then we obtain a homeomorphism
\[ \mathbb{R}P^{k-1} \cup_{\varphi_k} B^k \cong \mathbb{R}P^k \]
\[ x \mapsto \begin{cases} 
(x, 0), & \text{if } x \in \mathbb{R}P^{k-1}, 
[(x, \sqrt{1-\|x\|^2})], & \text{if } x \in B^k.
\end{cases} \]

\(^{781}\)For \( n = 2 \) we thus obtain, as we should, the same result as in Section 46.3.
Thus we see inductively that we can view $\mathbb{RP}^n$ as a CW-complex with a single cell in the dimensions $0, \ldots, n$ where the attaching maps are given precisely by the maps $\varphi_1, \ldots, \varphi_n$. As usual we denote the characteristic map of the $k$-cell, which in this case is the obvious map $B^k \to \mathbb{RP}^k$, by $\Phi_k$.

**Claim.** For each $k = 1, \ldots, n$ the cellular boundary map

$$d_k : Z = C^k_{CW}(X) \to C^{k-1}_{CW}(X) = Z$$

is given by multiplication by $1 + (-1)^k$.

Let $k \in \{1, \ldots, n\}$. We denote by $\Theta : B^{k-1}/\partial B^{k-1} \to S^{k-1}$ the homeomorphism from page 182 and we denote by $q : \mathbb{RP}^{k-1} \to \mathbb{RP}^{k-1}/\mathbb{RP}^{k-2}$ the projection map. By Proposition 48.7 it suffices to show that the degree of the map

$$S^{k-1} \xrightarrow{\varphi_k} \mathbb{RP}^{k-1} \xrightarrow{q} \mathbb{RP}^{k-1}/\mathbb{RP}^{k-2} \xrightarrow{\Phi_{k-1}} B^{k-1}/\partial B^{k-1} \xrightarrow{\Theta} S^{k-1}$$

equals $1 + (-1)^k$. (We refer to Figure 800 for an illustration of the map.) We pick the point $y = (0, \ldots, 0, 1) \in S^{k-1}$. The preimages of $y$ under the map $\Omega$ are $x_1 = (0, \ldots, 0, 1)$ and $x_2 = (0, \ldots, 0, -1)$. We leave it to the reader to verify that $\deg \Omega|_{x_1} = 1$ and that $\deg \Omega|_{x_2} = (-1)^n$. The desired statement now follows from Proposition 45.23.

**Remark.** Using the approach of the proof of Proposition 48.10 applied to the infinite CW-complex $\mathbb{RP}^\infty$, or alternatively using $\mathbb{RP}^\infty = \bigcup_n \mathbb{RP}^n$ and Proposition 47.4 we see that

$$0 \to \mathbb{Z} \xrightarrow{1+(-1)^n} \mathbb{Z} \to \mathbb{Z} \to \mathbb{Z} \to 0.$$

It follows from the claim that the cellular chain complex of $X$ is of the form

$$0 \to \mathbb{Z} \to \mathbb{Z} \to \mathbb{Z} \to 0.$$

It is now straightforward to determine the cellular homology groups which, by Proposition 48.4, are isomorphic to the singular homology groups of $\mathbb{RP}^n$.

---

782 It is not entirely easy to struggle through all the orientation conventions and all the maps, but it can indeed be done.
Exercise 48.1.  

(a) Determine the homology groups of $\mathbb{R}P^2 \# \mathbb{R}P^2$.  
(b) Determine the homology groups of $\mathbb{R}P^2 \# \mathbb{R}P^2$ minus an open disk.

Note: In both parts you can make use of the CW-structure for $\mathbb{R}P^2 \# \mathbb{R}P^2$ illustrated in Figure 801.

Remark. The homology groups are stated as Proposition 48.9. But it is a very good exercise to try to determine the homology groups without looking at the proposition.

\[ H_k(\mathbb{R}P^\infty) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd}, \\ 0, & \text{if } k \text{ is even and } k > 0. \end{cases} \]

**Exercises for Chapter 48**

**Exercise 48.2.** Show that given any finitely generated abelian group $A$ there exists a topological space $X$ with $H_0(X) = \mathbb{Z}$ and $H_1(X) \cong A$ and with $H_i(X) = 0$ for $i \geq 2$.

**Exercise 48.3.** Let $A$ be a finitely generated abelian group. Does there exist a topological space $X$ with $H_0(X) = \mathbb{Z}$, $H_3(X) \cong A$ and $H_i(X) = 0$ for $i \neq 0, 3$?

**Exercise 48.4.**  

(a) Determine $\min \{ \# \text{cells of } X \mid X \text{ is a CW-complex with } H_2(X) \cong \mathbb{Z} \oplus \mathbb{Z}_2 \}$.  
(b) Determine $\min \{ \# \text{cells of } X \mid X \text{ is a CW-complex with } H_1(X) \cong \mathbb{Z} \oplus \mathbb{Z}_2 \}$.  
(c) Determine $\min \{ \# \text{cells of } X \mid X \text{ is a connected CW-complex with } \pi_1(X) \cong \mathbb{Z} \times \mathbb{Z}_2 \}$.  

---

**Figure 801**
Exercise 48.5.
(a) Let \( X \) be the quotient space of \( S^2 \) under the identification \( x \sim -x \) for all \( x \in S^1 \). Determine the homology groups of \( X = S^2/\sim \).
(b) Let \( m, n \in \mathbb{N} \) with \( m < n \). As usual we view \( \mathbb{R}P^m \) as a subset of \( \mathbb{R}P^n \). Compute the homology groups of the quotient space \( \mathbb{R}P^n/\mathbb{R}P^m \).

Exercise 48.6. Let \( C \) be a closed curve in a smooth manifold \( M \). Suppose that \( C \) is the boundary of an embedded compact orientable surface in \( M \). Show that the inclusion induced map \( H_1(C) \to H_1(M) \) is the zero map.
More concisely, if a closed curve bounds a compact orientable surface, then the closed curve represents the trivial element in homology.

Exercise 48.7.
(a) Let \( \Sigma \) be a compact orientable connected 2-dimensional smooth manifold and let \( F \subset \Sigma \) be a 2-dimensional submanifold. We denote by \( i : F \to \Sigma \) the inclusion map.
Show that \( i_*(H_1(F)) \subset H_1(\Sigma) \) is a summand.
Hint. Consider the long exact sequence of the pair \((\Sigma, F)\).
(b) Does the conclusion of (a) also hold if we do not assume that \( \Sigma \) is orientable?

Exercise 48.8. Let \( X \) be a topological space and let \( n \in \mathbb{N}_0 \). Suppose \( X \) is compact. Does it follow that \( H_n(X) \) is a finitely generated group?

Exercise 48.9. Let \( n \in \mathbb{N}_0 \). In Lemma 36.1 we showed that \( \mathbb{R}P^n \) admits a CW-structure which has exactly one cell in the dimensions \( 0, 1, \ldots, n \) and no other cells. Show that this is the “smallest” CW-structure on \( \mathbb{R}P^n \). More precisely, show that every CW-structure for \( \mathbb{R}P^n \) has at least one cell in the dimensions \( 0, 1, \ldots, n \).
Hint. Consider the (cellular) homology groups of \( \mathbb{R}P^n \).

Exercise 48.10. Let \( m \leq n \). We denote by \( i : \mathbb{R}P^m \to \mathbb{R}P^n \) the inclusion map. Determine for each \( k \in \mathbb{N}_0 \) the induced map \( i_* : H_k(\mathbb{R}P^m) \to H_k(\mathbb{R}P^n) \).

Exercise 48.11. Let \( n \) be odd. By Proposition 48.10 we know that \( H_n(\mathbb{R}P^n) \cong \mathbb{Z} \). Show that there exists a singular simplex \( \sigma : \Delta^n \to \mathbb{R}P^n \) such that \([\sigma]\) is a generator of \( H_n(\mathbb{R}P^n) \).
Hint. First you need to find an “interesting” cycle \( \sigma \). You could use the identification \( \mathbb{R}P^n = B^n/\sim \) from page 196. Or perhaps better, write \( \mathbb{R}P^n = \Delta^n/\sim \) for a suitable equivalence relation \( \sim \).
(b) To show that the “interesting” cycle \( \sigma \) is actually a generator you could use the map \( B^n/\sim \to B^n/S^n-1 \) (which is continuous by Lemma 3.28 (2)) and results from Section 45.1.

Exercise 48.12. Let \( n \in \mathbb{N} \) be odd. By Proposition 48.10 we know that \( H_n(\mathbb{R}P^n) \cong \mathbb{Z} \). Let \( p : S^n \to \mathbb{R}P^n = S^n/\{\pm \text{id}\} \) be the projection map. Determine the induced map \( p_* : H_n(S^n) \to H_n(\mathbb{R}P^n) \).
Hint. You could use the fact that the isomorphism between cellular and singular homology is natural.
**Exercise 48.13.** Let \( n \in \mathbb{N} \) be odd. By Proposition 48.10 we know that \( H_n(\mathbb{R}P^n) \cong \mathbb{Z} \). Let \( A \in \text{GL}(n+1, \mathbb{R}) \). We denote by \( f: \mathbb{R}P^n \to \mathbb{R}P^n \) the map given by \( f(x) := A \cdot x \). Determine the degree of the map \( f_\ast: H_n(\mathbb{R}P^n) \to H_n(\mathbb{R}P^n) \).

**Remark.** You could make use of the homotopies considered on page 558.

**Exercise 48.14.** Let \( g \in \mathbb{N}_0 \) and let \( k \in \mathbb{N}_0 \). As on page 669 we consider \( \Sigma_{g,n} \), i.e. we consider the surface of genus \( g \) minus \( k \) open disks.

(a) Show that \( H_2(\Sigma_{g,n}, \partial \Sigma_{g,n}) \cong \mathbb{Z} \).

(b) Let \( C_1, \ldots, C_n \) be the boundary components. We equip \( \Sigma_{g,n} \) with an orientation and we equip its boundary \( \partial \Sigma_{g,n} = C_1 \sqcup \cdots \sqcup C_n \) with the corresponding orientation given by Lemma 6.50. For \( i = 1, \ldots, n \) we pick an orientation-preserving diffeomorphism \( \gamma_i: S^1 \to C_i \). We write \( [C_i] := \gamma_i([S^1]) \) and by a serious abuse of notation we denote by \( [C_i] \) also the image of \( [C_i] \) under the inclusion induced map \( C_i \to \Sigma_{g,n} \). Show that there exists a generator \( \varphi \) of \( H_2(\Sigma_{g,n}, \partial \Sigma_{g,n}) \cong \mathbb{Z} \) such that

\[
\partial_2(\varphi) = [C_1] + \cdots + [C_n] \in H_1(\partial \Sigma_{g,n}).
\]

connecting homomorphism of the pair \( (\Sigma_{g,n}, \partial \Sigma_{g,n}) \)

(c) Show that \( H_1(\Sigma_{g,n}, \partial \Sigma_{g,n}) \cong \mathbb{Z}^{2g} \).

(d) We denote by \( i: \partial \Sigma_{g,n} \to \Sigma_{g,n} \) and \( j: \Sigma_{g,n} \to \Sigma_n \) the inclusion maps. Show that the following sequence is exact:

\[
0 \to H_2(\Sigma_{g,n}) \xrightarrow{\partial_2} H_1(\partial \Sigma_{g,n}) \xrightarrow{i_\ast} H_1(\Sigma_{g,n}) \xrightarrow{j_\ast} H_1(\Sigma_n) \to 0.
\]

**Remark.** In Corollary 68.11 we will generalize Statement (a) to compact orientable manifolds in a suitable way.

**Figure 802.** Illustration of Exercise 48.14.

**Exercise 48.15.** Let \( k \in \mathbb{N} \) and let \( m \in \mathbb{N}_0 \). As on page 669 we denote by \( N_{k,m} \) the non-orientable surface of genus \( g \) minus \( m \) open disks.

(a) Determine the relative homology groups \( H_*(N_{k,m}, \partial N_{k,m}) \).

(b) Use (a) together with Exercise 48.14 and Proposition 48.9 to show that the topological spaces \( \Sigma_{g,n} \) and \( N_{k,n} \) are pairwise non-homeomorphic.

**Remark.** This gives a new, perhaps more natural proof for Theorem 23.6.

**Exercise 48.16.** In Figure 803 we see to the left the surface \( \Sigma \) of genus two together with four oriented curves \( a, b, c, d \) and to the right we see an oriented curve \( \sigma \). On page 1270 we showed that \( H_1(\Sigma) \cong \mathbb{Z}^4 \) and we showed that the curves \( a, b, c \) and \( d \) represent a basis for \( H_1(\Sigma) \). In particular we can write \( [\sigma] \in H_1(\Sigma) \) uniquely as a linear combination of \([a],[b],[c],[d] \). Determine the coefficients of this linear combination.
Remark. In Exercise 94.14 we will get to know a charming approach to dealing with problems of this form.

Figure 803. Illustration for Exercise 48.16.
49. CHAIN COMPLEXES WITH ISOMORPHIC HOMOLOGY GROUPS

On several occasions we have now shown that certain homology groups are isomorphic, and it is reasonable to ask whether the underlying chain complexes are in fact chain homotopy equivalent. In this chapter we will see that, for purely algebraic reasons, the question can always be answered in the affirmative.

49.1. Isomorphisms of homology groups are homotopy equivalences. The goal of this chapter is to prove the following three propositions.

Proposition 49.1. Suppose \((C_\ast, \partial_\ast)\) and \((C'_\ast, \partial'_\ast)\) are two chain complexes of free abelian groups. If \(\gamma_n: H_n(C_\ast) \to H_n(C'_\ast), n \in \mathbb{N}_0,\) is a family of homomorphisms, then there exists a chain map \(f: C_\ast \to C'_\ast\) such that for every \(n \in \mathbb{N}_0\) we have

\[ f_* = \gamma_n: H_n(C_\ast) \to H_n(C'_\ast). \]

Remark. We consider the following commutative diagram

\[
\begin{array}{c}
0 \to Z \\
\downarrow m \to (0,n) \to \id \downarrow \\
0 \to Z \oplus Z \\
\to \to Z \to 0.
\end{array}
\]

We view the top and bottom sequences as chain complexes \(C_\ast\) respectively \(D_\ast\) and we view the vertical maps as a chain map \(f\). It is straightforward to see that \(f\) induces the zero map on homology but that it is not chain homotopic to the zero chain map. This shows that the chain map from Proposition 49.1 is in general not unique up to chain homotopy.

The second proposition can be viewed as a converse to Lemma 42.2.

Proposition 49.2. Let \(f: C_\ast \to C'_\ast\) be a chain map between chain complexes of free abelian groups. If \(f\) induces an isomorphism of all homology groups, then \(f\) is in fact a chain homotopy equivalence.

Finally we have the following proposition that is a convenient variation on Proposition 49.2.

Proposition 49.3. Let \(C_\ast\) and \(D_\ast\) be two chain complexes of free abelian groups and let \(\iota: C_\ast \to D_\ast\) be a chain map with the following two properties:

(a) The chain map \(\iota: C_\ast \to D_\ast\) induces an isomorphism of homology groups.

(b) For each \(k \in \mathbb{N}_0\) the map \(\iota: C_k \to D_k\) is a monomorphism and the image is a subsummand of \(E_k\).

Then there exists a chain map \(\pi: D_\ast \to C_\ast\) with the following two properties:

1. For each \(k \in \mathbb{N}_0\) we have \(\pi_k \circ \iota_k = \id_{C_k}\).

2. The maps \(\iota\) and \(\pi\) are chain homotopy homotopy equivalences.

Before we provide the proofs of the above three proposition let us discuss some consequences. For example we have the following interesting corollary to Proposition 49.2.
**Corollary 49.4.** Let

\[ 0 \longrightarrow A_* \longrightarrow B_* \longrightarrow C_* \longrightarrow 0 \]
\[ \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \]
\[ 0 \longrightarrow A'_* \longrightarrow B'_* \longrightarrow C'_* \longrightarrow 0 \]

be a commutative diagram of short exact sequences of chain complexes. If two of the vertical maps are chain homotopy equivalences, then the third is also a chain homotopy equivalence.

**Proof.** By Proposition 43.11 we get a commutative diagram of long exact sequences

\[ \ldots \longrightarrow H_{n+1}(C_*) \xrightarrow{\partial} H_n(A_*) \longrightarrow H_n(B_*) \longrightarrow H_n(C_*) \xrightarrow{\partial} H_{n-1}(A_*) \longrightarrow \ldots \]
\[ \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \]
\[ \ldots \longrightarrow H_{n+1}(C'_*) \xrightarrow{\partial} H_n(A'_*) \longrightarrow H_n(B'_*) \longrightarrow H_n(C'_*) \xrightarrow{\partial} H_{n-1}(A'_*) \longrightarrow \ldots \]

By our hypothesis, together with Corollary 42.3 we know that always two out of three vertical maps are isomorphisms. But then it follows from the Five Lemma 43.12 that the third vertical map is also an isomorphism. Now Proposition 49.2 implies that the corresponding map of chain complexes is also a chain homotopy equivalence. □

As we pointed out above, the first time we had mentioned Proposition 49.2 was in the remark after Proposition 43.24. In fact Proposition 49.2 implies immediately that we can strengthen Proposition 43.24 to obtain the following result.

**Proposition 49.5.** Let \( X \) be a topological space and let \( \mathcal{U} = \{ U_i \}_{i \in I} \) be a comfortable cover of \( X \). Then the inclusion map

\[ C_\mathcal{U}^d(X) \rightarrow C_*(X) \]

is a chain homotopy equivalence.

We conclude this discussion of the consequences of Proposition 49.1 and 49.2 with the following lemma which we will use on several occasions.

**Lemma 49.6.** Let \((C_*, c_*)\) be a free chain complex such that for each \( k \in \mathbb{N}_0 \) the homology group \( H_k(C) \) is finitely generated. Then there exists a chain complex \((D_*, \partial_*)\) with the following two properties:

1. The chain complexes \((C_*, \partial_*)\) and \((D_*, \partial_*)\) are chain homotopy equivalent.
2. Each chain group \( D_k \) is a free abelian group of finite rank.

**Proof.** Let \( k \in \mathbb{N}_0 \). Recall that we assume that \( H_k(C_*) \) is finitely generated. It follows immediately from the classification of finitely generated abelian groups, see Theorem 19.4 that there exists a chain complex \( D_*^k \) and an isomorphism \( \varphi_k : H_k(D_*^k) \rightarrow H_k(C_*) \) such

---

783 Recall that a comfortable cover of \( X \) is a family \( \mathcal{U} = \{ U_i \}_{i \in I} \) of subsets of \( X \) such that the union of the interiors of the \( U_i \) equals \( X \). On page 1133 we defined

\[ C_\mathcal{U}^d(X) = \left\{ \sum_{j=1}^{k} a_j \sigma_j \right\} \text{ for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \}

and we had observed that these groups form a subcomplex of \( C_*(X) \). Note that these chain groups are free abelian groups generated by the union of the sets of singular \( n \)-simplices that lie in some \( U_i \).
that only the chain groups \( D_k^k \) and \( D_k^{k+1} \) are non-zero and such that both chain groups are finitely generated free abelian groups.

We define \( D_* = \bigoplus_{k \in \mathbb{N}_0} D_k^k \). It follows immediately from Proposition 49.1 and 49.2 that the chain complex \( D_* \) is chain homotopy equivalent to \( (C_*, \partial_*) \).

49.2. Proof of Propositions 49.1 and 49.2. We start out with the proof of Proposition 49.1.

Proof of Proposition 49.1. Let \( (C_*, \partial_*) \) and \( (C'_*, \partial'_*) \) be two chain complexes of free abelian groups. Furthermore let \( \gamma_n: H_n(C_*) \to H_n(C'_*) \), \( n \in \mathbb{N}_0 \) be a family of homomorphisms. We have to show that there exists a chain map \( f: C_* \to C'_* \) such that for every \( n \in \mathbb{N}_0 \) we have

\[
f_* = \gamma_n: H_n(C_*) \to H_n(C'_*)\]

We start out by recalling some of the usual notation and basic observations regarding chain complexes. More precisely, for each \( n \in \mathbb{N}_0 \) we write

\[
Z_n := \ker(\partial_n: C_n \to C_{n-1}), \quad B_n := \text{im}(\partial_{n+1}: C_{n+1} \to C_n) \quad \text{and} \quad H_n = Z_n/B_n.
\]

Recall that these groups form the following two types of short exact sequences

\[
\begin{align*}
(a) \quad 0 &\to Z_n \to C_n \xrightarrow{\partial_n} B_{n-1} \to 0, \\
(b) \quad 0 &\to B_n \to Z_n \to H_n \to 0.
\end{align*}
\]

Similarly we define \( Z'_n, B'_n \) and \( H'_n \) for the chain complex \( C'_* \). Evidently these groups also form short exact sequences that we denote by \( (a') \) and \( (b') \).

Since all the chain groups are free abelian it follows from Lemma 19.2 that the subgroups \( Z_n, B_n \) and \( Z'_n \) are also free abelian. In particular the sequences \( (b) \) and \( (b') \) are free resolutions of \( H_n \) respectively \( H'_n \). It follows from Lemma 57.13 that for each \( n \in \mathbb{N}_0 \) there exist homomorphisms \( \beta_n \) and \( \zeta_n \) such that the following diagram commutes:

\[
\begin{array}{ccccccccc}
0 &\to& B_n &\to& Z_n &\to& H_n &\to& 0 \\
\downarrow{\beta_n} & & \downarrow{\zeta_n} & & \downarrow{\gamma_n} & & \\
0 &\to& B'_n &\to& Z'_n &\to& H'_n &\to& 0.
\end{array}
\]
Our goal is to extend the maps $\zeta_n: \mathbb{Z}_n \rightarrow \mathbb{Z}'_n$ to a chain map $f: C_n \rightarrow C'_n$. To do so we consider the following diagram:

\[
\begin{array}{ccccccccc}
0 & \rightarrow & Z_n' & \rightarrow & C_n & \rightarrow & B_{n-1} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & Z'_n & \rightarrow & C'_n & \rightarrow & B'_{n-1} & \rightarrow & 0 \\
\end{array}
\]

Here the top sequence is precisely the short exact sequence (a) and the bottom sequence is the short exact sequence (a'). Here the unlabeled maps are the obvious inclusion and projection maps. It follows immediately from Lemmas 46.1 and 46.2 that there exist isomorphisms $\psi_n: C_n \xrightarrow{\sim} Z_n \oplus B_{n-1}$ and $\psi'_n: C'_n \xrightarrow{\sim} Z'_n \oplus B'_{n-1}$ which make the diagram commute. Now we define $f_n: C_n \rightarrow C'_n$ to be vertical homomorphism given by the diagram, i.e. $f_n = (\psi'_n)^{-1} \circ (\zeta_n \oplus \beta_{n-1}) \circ \psi_n$.

Now we need to show that the maps $f_n$ form a chain map. We consider the diagram

\[
\begin{array}{ccccccc}
C_n & \xrightarrow{\partial} & B_{n-1} & \xleftarrow{f_n} & Z_{n-1} & \xrightarrow{\zeta_{n-1}} & C_{n-1} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
C'_n & \xrightarrow{\partial'} & B'_{n-1} & \xleftarrow{f'_n} & Z'_{n-1} & \xrightarrow{\zeta'_{n-1}} & C'_{n-1} \\
\end{array}
\]

where all unlabeled maps are the obvious inclusion maps. The middle square commutes by the choice of $\beta_{n-1}$ and $\zeta_{n-1}$. We had arranged the maps $f_n, f'_{n-1}$ in such a way that the squares to the left and right commute. This shows that the rectangle commutes. But that was exactly what we needed to do to show that the maps $f_n, n \in \mathbb{N}_0$ form a chain map.

Finally note that it follows easily from the choice of $\zeta_n$ that the chain map $f_n$ induces the given maps $\gamma_n$ on homology. $\blacksquare$

The remainder of this section will be occupied with the proof of Proposition 49.2. As we will see the proof is significantly trickier than the proof of Proposition 49.1. We start out with the following definition.

**Definition.** Let $(C_n, c_n)$ and $(D_n, d_n)$ be two chain complexes and let $\varphi: C_* \rightarrow D_*$ be a chain map. The *algebraic mapping cone* of $\varphi$ is the chain complex $(M(\varphi), \partial_*)$ that is given by the chain groups

\[M(\varphi)_n := \frac{C_{n-1}}{D_n} := C_{n-1} \oplus D_n\]
and the boundary maps
\[ \begin{array}{c|c|c}
| & M(\varphi)_n & M(\varphi)_{n-1} \\
\hline
\partial: & C_{n-1} & C_n \\
\hline
& D_n & D_{n-1} \\
\hline
x \mapsto & -c_{n-1}(x) \\
y \mapsto & \varphi_{n-1}(x) + d_n(y) \\
\end{array} \]
which we write as block matrices
\[
\begin{pmatrix}
-c_{n-1} & 0 \\
\varphi_{n-1} & d_n
\end{pmatrix}
\begin{pmatrix}
C_{n-2} \\
D_{n-1}
\end{pmatrix}
\]

**Remark.** Let \( f: A \to X \) be a map between topological spaces. Recall that on page 701 we defined the corresponding *mapping cone* as
\[
\text{Cone}(f: A \to X) := (A \times [0, 1] \sqcup X)/ \sim
\]
where \((a, 1) \sim f(a)\) for all \(a \in A\) and \((a, 0) \sim (b, 0)\) for all \(a, b \in A\). As an application we showed on page 701 that for an inclusion map \( i: A \to X \) there exists a natural isomorphism
\[
\tilde{H}_n(\text{Cone}(i: A \to X)) \xrightarrow{\cong} H_n(X, A),
\]
i.e. we can reinterpret relative homology groups as reduced homology groups of the corresponding mapping cone. Now suppose that \( A \) and \( X \) are finite CW-complexes and that \( f \) is a cellular map. By Corollary 36.35 (3) we can equip the mapping cone \( \text{Cone}(f: A \to X) \) with a natural CW-structure. In Exercise 49.3 we will show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map \( f^*: C^\text{CW}_*(A) \to C^\text{CW}_*(X) \).

\[ \begin{array}{c}
\text{CW-complex } A \\
\text{cellular map } f \\
\text{CW-complex } X \\
\text{mapping cone } \text{Cone}(f: A \to X)
\end{array} \]

**Figure 804**

**Lemma 49.7.** Let \( \varphi: C_* \to D_* \) be a chain map between two chain complexes \((C_*, c_*)\) and \((D_*, d_*)\). We denote by \( i: D_n \to M(\varphi)_n = C_{n-1} \oplus D_n \) the obvious natural inclusion map and we denote by \( p: M(\varphi)_n = C_{n-1} \oplus D_n \to C_{n-1} \) the obvious natural projection map. Then the following sequence is exact:
\[
\ldots \to H_n(C_*) \xrightarrow{\varphi_*} H_n(D_*) \xrightarrow{i_*} H_n(M(\varphi)) \xrightarrow{p_*} H_{n-1}(C_*) \xrightarrow{\varphi_*} H_{n-1}(D_*) \to \ldots
\]

\[ \text{Note that } \partial_{n-1} \circ \partial_n = \begin{pmatrix} -c_{n-2} & 0 \\ \varphi_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}
\]
since \( \varphi \) is a chain map and \( c_{n-2} \circ c_{n-1} = 0 \) and \( d_{n-1} \circ d_n = 0 \)

This shows that we have indeed defined a chain complex.
Proof. For each \(n \in \mathbb{N}_0\) we consider the following diagram

\[
\begin{array}{ccccccccc}
0 & \to & D_n & \overset{i_n}{\to} & C_{n-1} & \overset{p_n}{\to} & C_{n-1} & \to & 0 \\
& & \downarrow{d_n} & & \downarrow{\partial_n} & & \downarrow{c_n} & & \\
0 & \to & D_{n-1} & \overset{i_{n-1}}{\to} & C_{n-2} & \overset{p_{n-1}}{\to} & C_{n-2} & \to & 0.
\end{array}
\]

We make the following observations:

1. the horizontal sequences are exact,
2. the left-hand square commutes, i.e. the maps \(i_\ast\) define a chain map,
3. the right-hand square commutes up to a minus sign, i.e. we have

\[c_{n-1} \circ p_n = -p_{n-1} \circ \partial_n.\]

Fortunately this minus sign in the above equality does not change the fact that the maps \(p_n\) induce a map between homology groups.

Despite the minus sign in (3) we can use verbatim the same construction as on page 1115 to obtain connecting homomorphisms \(\partial_n : H_n(D_\ast) \to H_n(C_\ast), n \in \mathbb{N}_0\), and verbatim the same proof as in Proposition 43.11 shows that these connecting homomorphisms give rise to a long exact sequence of the form

\[
\cdots \to H_n(C_\ast) \overset{\partial_n}{\to} H_n(D_\ast) \overset{i_\ast}{\to} H_n(M(\varphi)) \overset{p_\ast}{\to} H_{n-1}(C_\ast) \overset{\partial_{n-1}}{\to} H_{n-1}(D_\ast) \to \cdots
\]

It follows easily from the definition of the connecting homomorphism on page 1115 that for each \(n \in \mathbb{N}_0\) we have the equality

\[\partial_n = \varphi_\ast : H_n(C_\ast) \to H_n(D_\ast).\]

We have thus now shown that the sequence in the statement of the lemma is exact. 

\[
\square
\]

The following lemma will be used in the proof of Proposition 49.2.

Lemma 49.8. Let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups such that \(H_n(C_\ast) = 0\) for all \(n \in \mathbb{N}_0\). Then the identity map and the zero map of \(C_\ast\) to itself are chain homotopic.

Proof. For each \(n \in \mathbb{N}_0\) we write as usual

\[Z_n = \ker(\partial_n : C_n \to C_{n-1}) \quad \text{and} \quad B_n = \text{im}(\partial_{n+1} : C_{n+1} \to C_n).\]

By our hypothesis on the homology groups of \(C_\ast\) we have \(B_n = Z_n\) for all \(n \in \mathbb{N}_0\). Thus for each \(n \in \mathbb{N}_0\) we have the short exact sequence

\[0 \to Z_n \to C_n \overset{\partial_n}{\to} Z_{n-1} \to 0.\]

The group \(Z_{n-1} \subset C_{n-1}\) is a subgroup of a free abelian group, thus it is itself a free abelian group by Lemma 19.2. It follows immediately from Lemmas 46.1 and Splitting Lemma 46.2 that for each \(n \in \mathbb{N}_0\) we can find a direct sum decomposition \(C_n = Z_n \oplus A_n\).
such that $\partial_n: A_n \to B_{n-1} = Z_{n-1}$ is an isomorphism. We denote by $\varphi_n: Z_{n-1} \to A_n$ its inverse. Now we define

$$P_n: C_n = Z_n \oplus A_n \to C_{n+1} = Z_{n+1} \oplus A_{n+1}$$

$$z \oplus a \mapsto 0 \oplus \varphi_{n+1}(z).$$

Using the definitions one can now easily verify that for each $n \in \mathbb{N}$ we have

$$P_{n-1} \circ \partial_n + \partial_{n+1} \circ P_n = \text{id}: Z_n \oplus A_n \to Z_n \oplus A_n,$$

i.e. the maps $\{P_n\}_{n \geq 0}$ define the desired chain homotopy from the identity to the zero map. For orientation it might be convenient to keep in mind the following diagram:

\[ C_{n+1} = Z_{n+1} \oplus A_{n+1} \]

\[ C_n = Z_n \oplus A_n \]

\[ C_{n-1} = Z_{n-1} \oplus A_{n-1} \]

This concludes the proof of the lemma.

Now we are finally fully prepared to provide the proof of Proposition 49.2.

**Proof of Proposition 49.2.** Let $\varphi: C_* \to D_*$ be a chain map between chain complexes $(C_*, c_*)$ and $(D_*, d_*)$ of free abelian groups which induces an isomorphism on all homology groups. We need to show that $\varphi$ is in fact a chain homotopy equivalence.

As above we denote by $(M(\varphi)_*, \partial_*)$ the mapping cone of $\varphi$. We consider the long exact sequence from Lemma 49.7:

$$\ldots \to H_n(C_*) \xrightarrow{\varphi_*} H_n(D_*) \xrightarrow{i_*} H_n(M(\varphi)) \xrightarrow{p_*} H_{n-1}(C_*) \xrightarrow{\varphi_*} H_{n-1}(D_*) \to \ldots$$

By our hypothesis the maps $\varphi$ induce isomorphisms of homology groups, thus we see that $H_n(M(\varphi)) = 0$ for all $n \geq 0$. By Lemma 49.8 this means that we have a chain homotopy $\{P_n\}_{n \geq 0}$ from the identity map to the zero map. (Note that here we use that by our hypothesis on $C_*$ and $D_*$ each $M(\varphi)_n = C_{n-1} \oplus D_n$ is a free abelian group.)

Recall that this means that for each $n \in \mathbb{N}$ we have the equality

$$P_{n-1} \circ \partial_n + \partial_{n+1} \circ P_n = \text{id}_{C_{n-1} \oplus D_n}.$$  

Using the obvious matrix notation we write

$$P_n = \begin{pmatrix} p_n^{11} & p_n^{12} \\ p_n^{21} & p_n^{22} \end{pmatrix} : \begin{pmatrix} C_{n-1} \\ D_n \end{pmatrix} = \text{M(\varphi)}_n \to \begin{pmatrix} C_n \\ D_{n+1} \end{pmatrix} = \text{M(\varphi)}_{n+1}.$$
Now we can rewrite the above equality (*) and we obtain that

\[
\begin{pmatrix}
P_{n-1}^{11} & P_{n-1}^{12} \\
P_{n-1}^{21} & P_{n-1}^{22}
\end{pmatrix} \circ \begin{pmatrix}
-c_{n-1} & 0 \\
\varphi_{n-1} & d_n
\end{pmatrix} + \begin{pmatrix}
-c_n & 0 \\
\varphi_n & d_{n+1}
\end{pmatrix} \circ \begin{pmatrix}
P_n^{11} & P_n^{12} \\
P_n^{21} & P_n^{22}
\end{pmatrix} = \begin{pmatrix}
id_{C_{n-1}} & 0 \\
0 & id_{D_n}
\end{pmatrix}.
\]

Looking at the four entries separately we obtain the following four equalities:

(a) \(-P_{n-1}^{11} \circ c_{n-1} + P_{n-1}^{12} \circ \varphi_{n-1} - c_n \circ P_n^{11} = id_{C_{n-1}}, \)
(b) \(P_{n-1}^{12} \circ d_n - c_n \circ P_n^{12} = 0, \)
(c) \(-P_{n-1}^{21} \circ c_{n-1} + P_{n-1}^{22} \circ \varphi_{n-1} + \varphi_n \circ P_n^{11} + d_{n+1} \circ P_n^{21} = 0, \)
(d) \(P_{n-1}^{22} \circ d_n + \varphi_n \circ P_n^{12} + d_{n+1} \circ P_n^{22} = id_{D_n}. \)

We make the following observation:

(1) equation (b) implies that the homomorphisms \(\{P_n^{12} : D_n \to C_n\}_{n \in \mathbb{N}_0}\) define a chain map \(D \to C.\)

Now we claim that the chain map \(\{P_n^{12} \}_{n \in \mathbb{N}_0}\) is a chain homotopy inverse to the chain map \(\varphi.\) We do so with the following two observations:

(2) equation (a) implies that \(P_{n-1}^{12} \circ \varphi \simeq id_{C_{n-1}},\) where the chain homotopy is given by the maps \(P_{n-1}^{11} : C_{n-1} \to C_n,\)
(3) whereas equation (d) implies that \(\varphi \circ P_n^{12} \simeq id_{D_n},\) where the chain homotopy is given by the maps \(P_n^{22} : D_n \to D_{n+1},\)

The last two statements together imply that \(\varphi\) is indeed a chain homotopy equivalence. \(\blacksquare\)

We conclude this section with the proof of Proposition 49.3.

**Proof of Proposition 49.3** Let \(C_\ast\) and \(D_\ast\) be two chain complexes of free abelian groups and let \(\iota : C_\ast \to D_\ast\) be a chain map with the following two properties:

(a) The chain map \(\iota : C_\ast \to D_\ast\) induces an isomorphism of homology groups.
(b) For each \(k \in \mathbb{N}_0\) the map \(\iota : C_k \to D_k\) is a monomorphism and the image is a subsummand of \(D_k.\)

We need to show that there exists a chain map \(\pi : D_\ast \to C_\ast\) with the following two properties:

(1) For each \(k \in \mathbb{N}_0\) we have \(\pi_k \circ \iota_k = id_{C_k}.\)
(2) The maps \(\iota\) and \(\pi\) are chain homotopy homotopy equivalences.

The key to proving the proposition is the following claim:

*Claim.* We set \(C_{-1} = D_{-1} = 0\) and we define \(\pi_{-1}\) to be the zero homomorphism. Let \(k \in \mathbb{Z}_{\geq -1}.\) Suppose that for \(j = -1, \ldots, k\) we are given maps \(\pi_j : D_j \to C_j\) such that for each \(j \in \{0, \ldots, k\}\) we have the following equalities:

(1) \(\pi_j \circ \iota_j = id_{C_j},\)
(2) \(\partial \circ \pi_{j-1} = \pi_j \circ \partial.\)

Then there exists a map \(\pi_{k+1} : D_{k+1} \to C_{k+1}\) such that the maps \(\pi_0, \ldots, \pi_{k+1}\) have the above properties.
First note that by hypothesis we can pick for each $m \in \mathbb{N}$ a submodule $C^t_m$ of $D_m$ such that $D_m = \iota(C_m) \oplus C^t_m$. For orientation it is perhaps convenient to consider the following maps:

\[
\begin{array}{ccc}
D_{k+1} = \iota(C_{k+1}) \oplus C^t_{k+1} & \xrightarrow{\partial_D} & \iota(C_k) \oplus C^t_k = D_k \\
\iota_{k+1} \downarrow & & \iota_k \downarrow \\
C_{k+1} & \xrightarrow{\partial_C} & C_k
\end{array}
\]

Since $C^t_{k+1}$ is a subgroup of the free abelian group $D_{k+1}$ we know by Lemma 19.2 that $C^t_{k+1}$ is also a free abelian group. We pick a basis $T$ for the free abelian group $C^t_{k+1}$. Let $t \in T$. Since $\iota$ induces an isomorphism of homology groups we know that there exists a $c_{k+1} \in C_{k+1}$ such that $t$ and $\iota(c_{k+1})$ are homologous. We calculate that

\[
\pi_k(\partial_D(t_{k+1})) = \pi_k(\partial_D(\iota_{k+1}(c_{k+1}))) = \pi_k(\iota_k(\partial_C(c_{k+1}))) = \partial_C(c_{k+1}).
\]

We set $\pi_{k+1}(t) := c_{k+1}$. Since $T_{k+1}$ is a basis for the free abelian group $C^t_{k+1}$ we obtain a homomorphism $\varphi: C^t_{k+1} \rightarrow C_{k+1}$. It is now straightforward to verify that the map

\[
\pi_{k+1}: D_{k+1} = \iota(C_{k+1}) \oplus C^t_{k+1} \rightarrow C_{k+1} \\
\iota(c_{k+1}) + d_{k+1} \mapsto c_{k+1} + \varphi(d_{k+1})
\]

has all the desired properties. 

Since $C_*$ and $D_*$ are chain complexes of free abelian groups and since $\iota$ induces an isomorphisms of homology groups we know by Proposition 49.2 that $\iota$ is a chain homotopy equivalence. By Property (2) of the claim the maps $\{\pi_n: D_n \rightarrow C_n\}_{n \in \mathbb{N}_0}$ define a chain map. By Property (1) of the claim we have for each $k \in \mathbb{N}_0$ that $\pi_* \circ \iota_* = \text{id}_{\text{H}_k(C_*)}$. Thus we see that the chain map $\pi_*$ also induces isomorphism of the homology groups. So once again we appeal to Proposition 49.2 to conclude that the maps $\pi_*$ form a chain homotopy equivalence. 

49.3. **Singular and cellular chain complexes.** In Chapter 48 we introduced the cellular chain complex and the cellular homology groups of a CW-complex. We saw that cellular homology groups are naturally isomorphic to singular homology groups. At that point we did not say anything about the relationship between the cellular chain complex and the singular chain complex. We will rectify this in this section. The extra information that we gain in this section will stand us in good stead in Section 74.2 when we explore the relationship between cellular cohomology and singular cohomology.

First we recall some definitions and some notation. Let $X$ be a CW-complex.

1. Recall that given $n \in \mathbb{N}_0$ we denote by $X^n$ the $n$-skeleton of $X$, i.e. the union of all cells of dimension $\leq n$.
2. We write $C^\text{CW}_n(X) := H_n(X^n, X^{n-1})$ and we denote by $d_n: C^\text{CW}_n(X) \rightarrow C^\text{CW}_{n-1}(X)$ the cellular boundary map from page 1259.
(3) We refer to
\[ \cdots \xrightarrow{d_{n+2}} \mathbb{C}^{\text{CW}}_{n+1}(X) \xrightarrow{d_{n+1}} \mathbb{C}^{\text{CW}}_n(X) \xrightarrow{d_n} \mathbb{C}^{\text{CW}}_{n-1}(X) \xrightarrow{d_{n-1}} \cdots \]
as the *cellular chain complex*. The corresponding homology groups are denoted by \( H^{\text{CW}}_n(X) \).

In Proposition 48.4 we had seen that, given a CW-complex \( X \) the cellular homology groups \( H^{\text{CW}}_k(X) \) and the singular homology groups \( H_k(X) \) are naturally isomorphic.

In the following we want to relate the cellular chain complex \( C^{\text{CW}}_*(X) \) to the singular chain complex \( C_*^*(X) \). The aforementioned Proposition 48.4 together with the newly acquired Propositions 49.1 and 49.2 gives us immediately the following corollary.

**Corollary 49.9.** Given any CW-complex \( X \) there exists a chain homotopy equivalence \( C_*^*(X) \rightarrow C_*^{\text{CW}}(X) \).

A part of the proof of Corollary 49.9 is pure “algebraic nonsense”, in particular we do not get an explicit chain homotopy equivalence. In fact there is no obvious chain homotopy equivalence, in fact there is not even an obvious “interesting” chain map between these two chain complexes. But as we will see in a minute, it turns out that there is a nice “intermediate” chain complex which maps into both of the above chain complexes:

**Definition.** Given a CW-complex \( X \) and given \( n \in \mathbb{N}_0 \) we define the *intermediate cellular chain complex*

\[ C^{\text{int}}_n(X) := \ker \left( \mathbb{C}_n(X^n) \xrightarrow{\partial} \mathbb{C}_{n-1}(X^n) \rightarrow \mathbb{C}_{n-1}(X^n, X^{n-1}) \right) . \]

The following proposition shows that the intermediate cellular chain complex sits comfortably between the singular and the cellular chain complex. The proposition gives us in particular a more conceptual and satisfying proof of Corollary 49.9.

**Proposition 49.10.** Let \( X \) be a CW-complex. The two natural chain maps

\[ i : C^{\text{int}}_*(X) \hookrightarrow C_*^*(X) \quad \text{and} \quad p : C^{\text{int}}_*(X) \twoheadrightarrow C^{\text{CW}}_*(X), \]

which are given by the obvious inclusion and the obvious projection, are chain homotopy equivalences.

**Remark.** The proof of the proposition is modelled on the proofs provided in [SchubH68 p. 303] or alternatively [Lü89 Lemma 4.2] and [Lü89 p. 263], see also [Wall66a Lemma 1].

**Proof.** By Proposition 49.2 it suffices to show that for each \( n \in \mathbb{N}_0 \) the maps

\[ (1) \ i_* : H_n(C^{\text{int}}_*(X)) \rightarrow H_n(C_*^*(X)) \quad \text{and} \quad (2) \ p_* : H_n(C^{\text{int}}_*(X)) \rightarrow H_n(C^{\text{CW}}_*(X)) \]

are isomorphisms. So let \( n \in \mathbb{N}_0 \). Before we start with showing that the two maps above are isomorphisms we recall that in Lemma 48.1 we proved the following two convenient facts:

(a) We have \( H_{n-1}(X^{n-2}) = 0 \) and \( H_n(X^{n-1}) = 0 \).

\[^{785}\text{It follows almost immediately from the definitions that } C^{\text{int}}_*(X) \text{ is a subcomplex of } C_*^*(X), \text{ in particular it is a chain complex in its own right.}\]
(b) The inclusion \( k: X^n \to X \) induces an isomorphism \( k_*: H_n(X^{n+1}) \cong H_n(X) \).

(c) The inclusion \( k: X^n \to X \) induces an epimorphism \( k_*: H_n(X^n) \to H_n(X) \).

**Claim 1.** Let \( n \in \mathbb{N}_0 \).

(i) The map \( i_*: H_n(C_*^\text{int}) \to H_n(C_*^\text{int}(X)) = H_n(X) \) is a monomorphism.

(ii) The map \( i_*: H_n(C_*^\text{int}) \to H_n(C_*^\text{int}(X)) = H_n(X) \) is an epimorphism.

We consider the following two commutative diagrams

\[
\begin{array}{ccc}
C_{n+1}^\text{int}(X) & \xrightarrow{j} & C_{n+1}(X^{n+1}) \xrightarrow{k} C_{n+1}(X) \\
\downarrow \vartheta & & \downarrow \vartheta \\
C_n^\text{int}(X) & \xrightarrow{j} & C_n(X^{n+1}) \xrightarrow{k} C_n(X) \\
& & \downarrow \vartheta \\
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
C_n^\text{int}(X) & \xrightarrow{j} & C_n(X^n) \xrightarrow{k} C_n(X) \\
\downarrow \vartheta & & \downarrow \vartheta \\
C_{n-1}^\text{int}(X) & \xrightarrow{j} & C_{n-1}(X^n) \xrightarrow{k} C_{n-1}(X) \\
& & \downarrow \vartheta \\
\end{array}
\]

Both statements follow easily from the diagrams together with (b) and (c) above:

(i) Let \( \sigma \in C_n^\text{int}(X) \) be a cycle with the property that \( i(\sigma) \) is null-homologous. It follows from (b) that \( j(\sigma) \) is already null-homologous, i.e. there exists a \( \tau \in C_{n+1}(X^{n+1}) \) with \( \partial \tau = j(\sigma) \). Note that \( j(\sigma) = \sigma \in C_n(X^n) \). Thus we see that \( \tau \) actually lies in \( C_{n+1}^\text{int}(X) \). But this implies that \( \sigma \) is null-homologous in \( C_*^\text{int}(X) \).

(ii) Let \( [\sigma] \in H_n(X) \). By (c) we know that there exists a cycle \( \tau \in C_n(X^n) \) with \( [k(\tau)] = [\sigma] \). Since \( \partial \tau = 0 \) we see that \( \tau \in C_n^\text{int}(X) \). Since the bottom-left horizontal map is a monomorphism we see that \( \tau \in C_n^\text{int}(X) \) is also a cycle. But this shows that \( [\sigma] = [i(\tau)] \).

**Claim 2.** Let \( n \in \mathbb{N}_0 \).

(i) The map \( p_*: H_n(C_*^\text{int}) \to H_n(C_*^\text{CW}(X)) \) is a monomorphism.

(ii) The map \( p_*: H_n(C_*^\text{int}) \to H_n(C_*^\text{CW}(X)) \) is an epimorphism.

For orientation purposes we consider the following commutative diagram:

\[
\begin{array}{cccc}
C_{n+1}^\text{int}(X) & \xrightarrow{\partial} & C_{n+1}(X^{n+1}) & \xrightarrow{p} & C_{n+1}(X^{n+1},X^n) \\
\downarrow \vartheta & & \downarrow \vartheta & & \downarrow d \\
C_n^\text{int}(X) & \xrightarrow{p} & C_n(X^n) & \xrightarrow{\partial} & C_n(X^n,X^{n-1}) \\
\downarrow \vartheta & & \downarrow \vartheta & & \downarrow d \\
C_{n-1}^\text{int}(X) & \xrightarrow{p} & C_{n-1}(X^n) & \xrightarrow{\partial} & C_{n-1}(X^n,X^{n-2}). \\
\end{array}
\]

As we will see, the claim follows from (a) and some chasing around in the above diagram:

(i) Let \( \sigma \in C_n^\text{int}(X) \) be a cycle. Suppose that \( p(\sigma) = 0 \in H_n^\text{CW}(X) \). This means that there exists a \( \mu \in C_{n+1}(X^{n+1},X^n) \) with \( \partial \mu = p(\sigma) \). We pick a \( \tau \in C_{n+1}(X^{n+1}) \) that represents \( \sigma \). Note that \( \partial \tau = \sigma + \alpha \) with \( \alpha \in C_n(X^{n-1}) \). Since \( \partial(\partial \tau) = 0 \) and since \( \partial \sigma = 0 \) we see that \( \partial \alpha = 0 \). From (a) we obtain that there exists a \( \beta \in C_{n+1}(X^{n-1}) \)
with $\partial \beta = \alpha$. Note that $\partial (\tau - \beta) = \partial \tau - \partial \beta = \sigma$. Since $\sigma \in C_n(X^n)$ we conclude that $\tau - \beta \in C^\text{int}_{n+1}(X)$. Thus we have shown that $[\sigma] = 0 \in H_n(C^\text{int}_*(X))$.

(ii) Given a class in $H_n(C^\text{CW}_n(X))$ we pick a representative in $C^\text{CW}_n(X) = C_n(X^n, X^{n-1})$ for which in turn we pick a lift $\sigma \in C_n(X^n)$. Note that $\partial \sigma \in C_{n-1}(X^{n-2})$. But by (a) we know that $H_{n-1}(X^{n-2}) = 0$. Hence there exists a $\mu \in C_n(X^{n-2})$ with $\partial \mu = \partial \sigma$. Note that $\partial (\sigma - \mu) = 0$, in particular $\sigma - \mu$ is a cycle in $C^\text{int}_n(X)$. Furthermore note that $\sigma$ and $\sigma - \mu$ represent the same element in $C_n(X^n, X^{n-1})$.

Exercises for Chapter 49

Exercise 49.1. We consider the following commutative diagram

$$
\begin{array}{cccc}
0 & \to & \mathbb{Z} & \to \mathbb{Z} \\
& & \downarrow^{n \to (0, n)} & \\
0 & \to & \mathbb{Z} \oplus \mathbb{Z} & \to \mathbb{Z} \to 0.
\end{array}
$$

We view the top and bottom sequences as chain complexes $C_*$ respectively $D_*$ and we view the vertical maps as a chain map $f$.

(a) Convince yourself that $f$ induces the zero map on homology.

(b) Is the chain map $f$ chain homotopic to the zero chain map?

Exercise 49.2. Suppose $(C_*, \partial_*)$ and $(C'_*, \partial'_*)$ are two chain complexes. We do not assume that the chain groups are necessarily free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $H_n(C_*)$ and $H_n(C'_*)$ are isomorphic. Does it follow that for each $n \in \mathbb{N}_0$ and any abelian group $G$ the cohomology groups $H^n(C_*; G)$ and $H^n(C'_*; G)$ are also isomorphic?

Exercise 49.3. Let $f: A \to X$ be a map between topological spaces. We define the corresponding mapping cone as

$$\text{Cone}(f: A \to X) := ((A \times [0, 1]) \sqcup X) / \sim$$

where $(a, 1) \sim f(a)$ for all $a \in A$ and $(a, 0) \sim (b, 0)$ for all $a, b \in A$. Now suppose that $A$ and $X$ are finite CW-complexes and that $f$ is a cellular map.

We equip the mapping cone $\text{Cone}(f: A \to X)$ with the natural CW-structure of Corollary 36.35. Show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map $f_*: C^\text{CW}_*(A) \to C^\text{CW}_*(X)$.
50. The Jordan Curve Theorem

We start out with the following proposition.

Proposition 50.1.

1. For every injective map \( h : B^k \to S^n \) we have
   \[
   \tilde{H}_i (S^n \setminus h(B^k)) = 0 \quad \text{for all } i \in \mathbb{N}_0.
   \]

2. For every injective map \( h : S^k \to S^n \) we have
   \[
   \tilde{H}_i (S^n \setminus h(S^k)) \cong \begin{cases} 
   \mathbb{Z}, & \text{if } i = n - k - 1, \\
   0, & \text{otherwise}.
   \end{cases}
   \]

Example.

1. Let \( K \subset S^3 \) be a knot, i.e. let \( K \) be a 1-dimensional submanifold of \( S^3 = \mathbb{R}^3 \cup \{\infty\} \) that is diffeomorphic to \( S^1 \). This means in particular that there exists a smooth embedding \( h : S^1 \to S^3 \) with \( h(S^1) = K \). In Lemma 46.14 we had already determined that \( H_1 (S^3 \setminus K) \cong \mathbb{Z} \). Now we can compute the higher homology groups as well. More precisely, the combination of Proposition 50.1 (2) and Lemma 43.1 says that
   \[
   H_i (S^3 \setminus K) = H_i (S^3 \setminus h(S^1)) \cong \begin{cases} 
   \mathbb{Z}, & \text{if } i = 0, 1, \\
   0, & \text{otherwise}.
   \end{cases}
   \]

2. In Proposition 50.1 we do not assume that \( h \) is in any way smooth. For example there are injective maps \( h : S^1 \to S^2 \) of infinite length, see e.g. \( \text{https://en.wikipedia.org/wiki/Koch_snowflake} \), to which the proposition nonetheless applies. Reduced homology is only defined for non-empty topological spaces. It is implicit in the statement of Proposition 50.1 that \( S^n \setminus h(B^k) \) is not the empty set. Even this statement is not entirely obvious since, as we have pointed out on several occasions, there are non-injective maps \( h : B^1 \to S^n \) that are in fact surjective.

3. In Figure 805 we see the image of an injective map \( \varphi : [0, 1] \to S^3 = \mathbb{R}^3 \cup \{\infty\} \) and we see a closed curve \( C \subset S^3 \setminus \varphi([0, 1]) \). It follows from Proposition 50.1 (1) that \( H_1 (S^3 \setminus \varphi([0, 1])) = 0 \), in particular \( C \) is null-homologous in \( H_1 (S^3 \setminus \varphi([0, 1])) = 0 \). But on \( \text{[Sti93] p. 152} \) it is shown that the curve \( C \) represents in fact a non-trivial element in \( \pi_1 (S^3 \setminus \varphi([0, 1])) \).

To make the exposition more readable we prove the two parts of Proposition 50.1 separately.

Proof of Proposition 50.1 (1). We write \( I = [-1, 1] \). By Proposition 2.52 (2) there exists a homeomorphism \( I^k \cong B^k \). Therefore in the statement of Proposition 50.1 (1) we
image of an injective map $\varphi: [0, 1] \to S^3 = \mathbb{R}^3 \cup \{\infty\}$

trivial in homology but not null-homotopic

the complement of the arc has trivial first homology
but it is not simply connected

Figure 805

can replace $\overline{B^k}$ by $I^k$. So we now want to show that for any injective map $h: I^k \to S^n$ we have

$$\tilde{H}_i(S^n \setminus h(I^k)) = 0 \text{ for all } i \in \mathbb{N}_0.$$  

We will prove this statement by induction on $k$. We start out with $k = 0$. So let $h: I^0 = \{0\} \to S^n$ be an injective map. It follows from the stereographic projection defined in Lemma 2.44 that $S^n \setminus h(\{0\})$ is homeomorphic to $\mathbb{R}^n$. Hence we obtain from Corollary 42.8 (3) that $\tilde{H}_i(S^n \setminus h(\{0\})) = 0$.

Now we do the induction step. We assume we know the desired statement for all injective maps $I^{k-1} \to S^n$. Now let $h: I^k \to S^n$ be an injective map. We suppose that the desired conclusion does not hold, i.e. we suppose that $\tilde{H}_j(S^n \setminus h(I^k)) \neq 0$ for some $j$. We pick a non-trivial element $g_0 \in \tilde{H}_j(S^n \setminus h(I^k))$.

We write $Q = I^{k-1}$, $J_0 = I$ and we write

$$A_1 = S^n \setminus h(Q \times [0, \frac{1}{2}]) \quad \text{and} \quad A_2 = S^n \setminus h(Q \times [\frac{1}{2}, 1]).$$

Since $h$ is injective we have

$$A_1 \cap A_2 = S^n \setminus h(I^k) \quad \text{and} \quad A_1 \cup A_2 = S^n \setminus h(Q \times \{\frac{1}{2}\}).$$

From Lemma 2.40 (3) we know that $A_1$ and $A_2$ are open subsets of $A_1 \cup A_2$. Therefore we can apply the Mayer–Vietoris Theorem 46.5 and we obtain the long exact sequence

$$\ldots \to \tilde{H}_{j+1}(A_1 \cup A_2) \to \tilde{H}_j(A_1 \cap A_2) \to \tilde{H}_j(A_1) \oplus \tilde{H}_j(A_2) \to \tilde{H}_j(A_1 \cup A_2) \to \ldots$$

= 0 by induction

$\tilde{H}_j(A_1 \cap A_2)$

Figure 806. Illustration for the proof of Proposition 50.1 (1).
So we see that the middle map is an isomorphism. Thus there exists an \( i \in \{1, 2\} \) such that the image of \( g_0 \) is non-trivial in \( H_j(A_i) \). If \( i = 1 \), then we set \( J_1 := [0, \frac{1}{2}] \), otherwise we set \( J_1 := \left[ \frac{1}{2}, 1 \right] \). We denote by

\[
\varphi_1 : \tilde{H}_j(S^n \setminus h(Q \times J_0)) \to \tilde{H}_j(S^n \setminus h(Q \times J_1))
\]

the inclusion induced map. By the above exact sequence \( \varphi_1 \) is an epimorphism. We denote by \( \rho_1 \) the inverse of the induced isomorphism

\[
\tilde{H}_j(S^n \setminus h(Q \times J_0)) / \ker(\varphi_1) \to \tilde{H}_j(S^n \setminus h(Q \times J_1)).
\]

Now we iterate this process by running the same argument with \( J_0 \) replaced by \( J_1 \) and so on. For each \( m \in \mathbb{N} \) we can find an interval \( J_m \) of length \( \frac{1}{2^m} \) that is contained in \( J_{m-1} \) such that the image induced homomorphism

\[
\varphi_m : \tilde{H}_j(S^n \setminus h(Q \times J_m)) \to \tilde{H}_j(S^n \setminus h(Q \times J_m))
\]

we have that \( g_m := \varphi_m(g_{m-1}) \) is non-zero. We define \( \rho_m \) the same way from \( \varphi_m \) as we had obtained \( \rho_1 \) from \( \varphi_1 \).

By the definition of the direct limit we have the following commutative diagram\(^{787}\)

\[
\begin{array}{ccc}
\tilde{H}_j(S^n \setminus h(Q \times J_2)) & \xrightarrow{\varphi_2} & \lim_{\longrightarrow} \tilde{H}_j(S^n \setminus h(Q \times J_m)) \\
\tilde{H}_j(S^n \setminus h(Q \times J_1)) & \xrightarrow{\varphi_1} & \tilde{H}_j(S^n \setminus h(Q \times J_0)) \\
\end{array}
\]

Since each \( J_m \) has half the length of \( J_{m-1} \) we conclude that the intersection \( \bigcap_{m \in \mathbb{N}} J_m \) contains a unique point \( t \in [0, 1] \).\(^{788}\) We have

\[
\lim_{\longrightarrow} \tilde{H}_j(S^n \setminus h(Q \times J_m)) \cong \tilde{H}_j \left( \bigcap_{m \in \mathbb{N}} S^n \setminus h(Q \times J_m) \right) = \tilde{H}_j(S^n \setminus h(Q \times \{t\})) = 0.
\]

by Proposition \(47.4\) since the subsets \( S^n \setminus h(Q \times J_m) \) are open

since \( h \) is injective

by induction

since \( Q \times \{t\} \cong I^{k-1} \)

But we have now obtained a contradiction, since the bottom horizontal map of the above commutative diagram has a non-trivial image but it factors through the trivial group. ■

\(^{787}\) Note that we have

\[
\ker(\varphi_1) \subset \ker(\varphi_2 \circ \varphi_1) \subset \ker(\varphi_3 \circ \varphi_2 \circ \varphi_1) \subset \ldots
\]

It follows that the union of these subgroups is again a subgroup.

\(^{788}\) Why does this follow? What results from real analysis do we need to draw that conclusion?
Proof of Proposition 50.1 (2). Recall that we have to show that for every injective map $h: S^k \to S^n$ we have

$$ \tilde{H}_i(S^n \setminus h(S^k)) \cong \begin{cases} \mathbb{Z}, & \text{if } i = n - k - 1, \\ 0, & \text{otherwise.} \end{cases} $$

We prove this statement by induction on $k$. For $k = 0$ we have

$$ \tilde{H}_i(S^n \setminus h(S^0)) \cong \tilde{H}_i(S^{n-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } i = n - 1, \\ 0, & \text{otherwise.} \end{cases} $$

since $S^n \setminus h(S^0)$ is homotopy equivalent to $S^{n-1}$ by Proposition 43.4.

Now suppose we know the statement for some $k \in \mathbb{N}$. Suppose we are given an injective map $h: S^{k+1} \to S^n$. We denote by $S^{k+1}_{\leq 0}$ the lower hemisphere of $S^{k+1}$ and we denote by $S^{k+1}_{\geq 0}$ the upper hemisphere of $S^{k+1}$. Note that $S^{k+1}_{\leq 0} \cap S^{k+1}_{\geq 0} = S^k$. We apply the Mayer–Vietoris Theorem 46.5 to the decomposition of $S^n \setminus h(S^{k+1})$ into the open sets $S^n \setminus h(S^{k+1}_{\leq 0})$ and $S^n \setminus h(S^{k+1}_{\geq 0})$. We obtain a long exact sequence

$$ \cdots \to \tilde{H}_i(S^n \setminus h(S^k)) \to \tilde{H}_i(S^n \setminus h(S^{k+1}_{\leq 0})) \oplus \tilde{H}_i(S^n \setminus h(S^{k+1}_{\geq 0})) \to \tilde{H}_i(S^n \setminus h(S^{k+1})) \to \cdots $$

$= 0$ by part (1) and since $S^{k+1}_{\leq 0} \cong B^{k+1}$

$= 0$ by part (1) and since $S^{k+1}_{\geq 0} \cong B^{k+1}$

Thus we see that

$$ \tilde{H}_i(S^n \setminus h(S^{k+1})) \cong \tilde{H}_{i-1}(S^n \setminus h(S^k)) \cong \begin{cases} \mathbb{Z}, & \text{if } i - 1 = n - k - 1, \\ 0, & \text{otherwise.} \end{cases} $$

by induction.

The following definition is a minute variation on the definition of a Jordan curve given on page 452.

**Definition.** A planar Jordan curve is the image of an injective map $S^1 \to \mathbb{R}^2$.

Now we can formulate the following immediate corollary to Proposition 50.1.

**Corollary 50.2. (Jordan Curve Theorem)** For every planar Jordan curve $C$ the complement $\mathbb{R}^2 \setminus C$ consists of two path-connected components.

**Remark.**

1. The Jordan Curve Theorem 50.2 might appear as “self-evident”. To disabuse the reader of this idea recall that in Proposition 2.60 we saw that there exist planar Jordan curves with non-zero 2-dimensional Lebesgue measure.

2. The Jordan Curve Theorem 50.2 was first proved in 1887 by Camille Jordan. Camille Jordan (1838-1922) was a French mathematician who most readers will already have encountered in linear algebra.

---

789 Can you give a rigorous proof for the statement that the complement of two points in $S^n$ is homotopy equivalent to $S^{n-1}$?

790 Here we use, as in the proof of Proposition 50.1 (1), implicitly the injectivity of $h$. 
Proof. Let \( h: S^1 \to \mathbb{R}^2 \) be an injective map. We use the inclusion \( \mathbb{R}^2 \to \mathbb{R}^2 \cup \{\infty\} = S^2 \) to view \( \mathbb{R}^2 \) as a subset of \( S^2 \). Now we see that
\[
\tilde{H}_0(\mathbb{R}^2 \setminus C) = \tilde{H}_0(\mathbb{R}^2 \setminus h(S^1)) \cong \tilde{H}_0(S^2 \setminus h(S^1)) \cong \mathbb{Z}
\]
see Exercise 46.12 Proposition 50.1 (2)

It follows from Lemma 43.1 (5) that \( \mathbb{R}^2 \setminus C \) has precisely two path-components. 

Proposition 50.1, together with Lemma 43.1, says in particular, that if \( h: S^{n-1} \to S^n \) is an injective map, then
\[
\tilde{H}_i(S^n \setminus h(S^{n-1})) \cong \begin{cases} 
\mathbb{Z}^2, & \text{if } i = 0, \\
0, & \text{otherwise}.
\end{cases}
\]

Put differently, homologically the topological space \( S^n \setminus h(S^{n-1}) \) looks like the disjoint union of two open \( n \)-dimensional balls. One might now suspect that \( S^n \setminus h(S^{n-1}) \) is in fact homeomorphic to the union of two open \( n \)-dimensional balls.

This is in fact true in dimension \( n = 2 \). More precisely Arthur Schönflies\footnote{Arthur Schönflies (1853–1928) was a German mathematician.} proved in 1908 the following theorem. We refer to \cite{Tn92}, Section 3 for a perhaps more readable proof of the theorem.\footnote{More precisely, in \cite{Tn92} Section 3 a proof for the following statement is given: \textit{Let } \( g: S^1 \to \mathbb{R}^2 \) \textit{be an injective map. Then } \( g \) \textit{extends to a homeomorphism of } \mathbb{R}^2. \)

\textbf{Theorem 50.3. (Schönflies Theorem)} Let \( h: S^1 \to S^2 \) be an injective map. Then \( h \) extends to a homeomorphism of \( S^2 \), i.e. there exists a homeomorphism \( H: S^2 \to S^2 \) such that \( H|_{S^1} = h \). In particular both components of \( S^2 \setminus h(S^1) \) are homeomorphic to open disks.

\textbf{Remark.}

(1) The Schönflies Theorem is often also called the Jordan-Schönenflies Theorem.

(2) If \( h: S^1 \to S^2 \) is a smooth embedding, then the conclusion of the Schönflies Theorem 50.3 also follows from the much easier Proposition 23.18.

It is natural to ask whether the conclusion of the Schönflies Theorem also holds in higher dimensions. But this hope breaks down already one dimension higher. More precisely, James Alexander\footnote{James Alexander (1888–1971) was an American mathematician. He also introduced the Alexander polynomial of a knot.} showed in 1924 that there exists an injective map \( S^2 \to \mathbb{R}^3 \) such that one of the two components of the complement of \( h(S^2) \) is not simply connected. The image \( h(S^2) \) is called the \textit{Alexander horned sphere}. It is illustrated in Figure 807. A more detailed description of the Alexander horned sphere and the proof that the complement is not simply connected is given in \cite{Al24} and also \cite{Hat02}, p. 170. In Exercise 50.2 we invite the reader to modify the Example shown in Figure 807 to produce an injective map \( S^2 \to \mathbb{R}^3 \) such that neither of the two components of the complement of \( h(S^2) \) is simply connected.

\textit{Remark.}

(1) The Schönflies Theorem is often also called the Jordan-Schönenflies Theorem.

(2) If \( h: S^1 \to S^2 \) is a smooth embedding, then the conclusion of the Schönflies Theorem 50.3 also follows from the much easier Proposition 23.18.

It is natural to ask whether the conclusion of the Schönflies Theorem also holds in higher dimensions. But this hope breaks down already one dimension higher. More precisely, James Alexander\footnote{James Alexander (1888–1971) was an American mathematician. He also introduced the Alexander polynomial of a knot.} showed in 1924 that there exists an injective map \( S^2 \to \mathbb{R}^3 \) such that one of the two components of the complement of \( h(S^2) \) is not simply connected. The image \( h(S^2) \) is called the \textit{Alexander horned sphere}. It is illustrated in Figure 807. A more detailed description of the Alexander horned sphere and the proof that the complement is not simply connected is given in \cite{Al24} and also \cite{Hat02}, p. 170. In Exercise 50.2 we invite the reader to modify the Example shown in Figure 807 to produce an injective map \( S^2 \to \mathbb{R}^3 \) such that neither of the two components of the complement of \( h(S^2) \) is simply connected.
We have now seen that injective maps $S^2 \to S^3$ can be pretty "wild". The map that defines the Alexander horned sphere is continuous, but it is certainly not smooth. So what happens if we restrict ourselves to smooth maps? In fact in the smooth setting we have the following theorem.

**Theorem 50.4. (Generalized smooth Schönflies Theorem)** Let $h: S^{n-1} \to S^n$ be a smooth embedding. If $n \neq 4$, then there exists an orientation-preserving diffeomorphism $H: S^n \to S^n$ with $H|_{S^{n-1}} = h$.

For $n = 2$ the statement follows fairly easily from the classification of smooth 2-dimensional smooth manifolds that we gave in the Surface Classification Theorem [23,4] see e.g. [Hir76, p. 207]. For $n = 3$ this statement was proved by James Alexander [Al24]. See also [Hat3, Chapter 1] and [Schul14, Theorem 3.2.5] and for an exposition of the proof. For $n \geq 5$ this statement was independently proved by Barry Mazur [Maz59] in 1959 and by Morton Brown [BrownM60] in 1960.

The case $n = 4$ is missing in the Generalized Schönflies Theorem. In fact it is still unknown whether the statement holds for $n = 4$.

**Question 50.5.** Is it true that given any smooth embedding $h: S^3 \to S^4$ there exists a diffeomorphism $H: S^4 \to S^4$ with $H|_{S^3} = h$?

This question is very much open and there is not even a consensus whether one expects the answer to be yes or no. If you can answer this question you would almost certainly obtain a Fields medal.\footnote{But hurry up, you can only get a Fields medal if you are under 40.}

We conclude this section with two more consequences of Proposition 50.1. The following theorem was first proved by Luitzen Brouwer [Brou1911] in 1911. It can be viewed as a significant strengthening of the Smooth Invariant of Domain Theorem [6,19] (1).

**Theorem 50.6. (Topological Invariance of Domain Theorem)** Let $U$ be an open subset of $\mathbb{R}^n$.

1. If $h: U \to \mathbb{R}^n$ is an injective map, then $h(U)$ is also an open subset of $\mathbb{R}^n$.

2. If $h: U \to \mathbb{R}^m$ be an injective map, then $m \geq n$.

\footnote{How can one prove the theorem for $n = 1$ using only the methods from real analysis?}
Remark. The Open Mapping Theorem from complex analysis, see [Lan99, Theorem II.6.2], says that if \( G \subset \mathbb{C} \) is an open subset and if \( f \colon G \to \mathbb{C} \) is a non-constant holomorphic function, then \( f(G) \) is also open. In fact, one can deduce the “Open Mapping Theorem” from the Topological Invariance of Domain Theorem \[50.6\] since by [Jä11, Satz 10] every non-constant holomorphic function on an open subset of \( \mathbb{C} \) is locally the power of an injective function.

In the proof of Theorem \[50.6\] we need the following elementary lemma.

**Lemma 50.7.** Let \( U \subset \mathbb{R}^n \) be a subset. If \( U \) is open in \( \mathbb{R}^n \), then every path-component of \( U \) is also an open subset of \( \mathbb{R}^n \).

**Proof.** Let \( C \) be a path-component of the subset subset \( U \subset \mathbb{R}^n \). Let \( P \in C \). Since \( U \) is open there exists an \( r > 0 \) such that \( B_r(P) \subset U \). But all points in \( B_r(P) \) are path-equivalent to \( P \), hence \( B_r(P) \subset C \). \( \square \)

Now we can provide the proof of Theorem \[50.6\].

**Proof of Theorem 50.6**

(1) Recall that by the homeomorphism from Lemma \[2.44\] we can view \( \mathbb{R}^n \) as an open subset of \( \mathbb{R}^n \cup \{\infty\} = S^n \). So we can view \( h \) as a map from \( U \) to \( S^n \) and we need to show that \( h(U) \) is an open subset of \( S^n \).

Let \( x \in U \). We pick a closed \( n \)-ball \( B \) in \( U \) that contains \( x \) in the interior. It suffices to show that \( h(B \setminus \partial B) \subset h(U) \) is open in \( S^n \). Note that \( S^n \setminus h(\partial B) \) is open by Lemma \[2.40\] (3). By Lemma \[50.7\] it therefore suffices to show that \( h(B \setminus \partial B) \) is a path-component of \( S^n \setminus h(\partial B) \). We will do so in the following claim.

**Claim.** The topological space \( S^n \setminus h(\partial B) \) has precisely two path-components namely the subsets \( h(B \setminus \partial B) \) and \( S^n \setminus h(B) \).

By Proposition \[50.1\] (2) and Lemma \[43.1\] we know that
\[
S^n \setminus h(\partial B) = h(B \setminus \partial B) \cup (S^n \setminus h(B))
\]
has two path-components. It suffices to show that the two sets on the right-hand side are path-connected. The first set \( h(B \setminus \partial B) \) is path-connected since it is the image of the path-connected topological space \( B \setminus \partial B \), while the second set \( S^n \setminus h(B) \) is path-connected by Proposition \[50.1\] (1) and Lemma \[43.1\]. \( \square \)

(2) Let \( h \colon U \to \mathbb{R}^m \) be an injective map with \( m \leq n \). We consider the inclusion given by composing \( h \) with the inclusion \( i \colon \mathbb{R}^m \to (x,0) \to \mathbb{R}^n \). By (1) we know that \( (i \circ h)(U) \) is an open subset. But a subset of \( \mathbb{R}^m \) is open under the inclusion \( i \colon \mathbb{R}^m \to \mathbb{R}^n \) only if \( m = n \). Thus we have shown that \( m \geq n \). \( \square \)

**Corollary 50.8.** Let \( M \) be a non-empty closed \( n \)-dimensional topological manifold and let \( N \) be a connected \( n \)-dimensional topological manifold without boundary. Let \( h \colon M \to N \) be a map.

1. If \( h \colon M \to N \) is locally injective, then \( h \) is also surjective.
2. If \( h \) is injective, then \( h \) is already a homeomorphism.
Example. Corollary 50.8 implies in particular that there exists no injective map from the closed smooth manifold $S^n$ into the smooth manifold $\mathbb{R}^n$. \footnote{How can you show this for $n = 1$, just using methods from real analysis?}

Proof. The second statement of the corollary is an immediate consequence of the first statement and Proposition 2.43 (3). So it suffices to prove the first statement.

Let $h: M \rightarrow N$ be a locally injective map from a non-empty closed $n$-dimensional topological manifold $M$ to a connected $n$-dimensional topological manifold $N$ without boundary.

The image $h(M)$ is closed in $N$ since $M$ is compact and since $N$ is Hausdorff. Since $N$ is connected and since $M$ is non-empty it suffices to show that $h(M)$ is also open in $N$.

So let $Q \in h(M)$. We pick $P \in M$ with $h(P) = Q$. We pick a chart $\Phi: U \rightarrow V$ around $P$ and we pick a chart $\Psi: W \rightarrow X$ around $Q$. After possibly replacing $U$ by $U \cap h^{-1}(W)$ we can assume that $h(U) \subset W$. Since $h$ is locally injective we can, after possibly shrinking $U$ even more, assume that $h|_U$ is injective.

From Theorem 50.6 we know that $(\Psi \circ h \circ \Phi^{-1})(V)$ is an open subset of $\mathbb{R}^n$. Since $\Psi$ is a homeomorphism we see that $h(\Phi^{-1}(V)) = h(U)$ is an open neighborhood of $Q$ that is contained in $h(M)$.

Exercises for Chapter 50

Exercise 50.1. In Figure 810 we see the image of an injective map $\varphi: I \rightarrow S^3 = \mathbb{R}^3 \cup \{\infty\}$ and we see a curve $C \subset S^3 \setminus \varphi(I)$. We know from Proposition 50.1 (1) that $x$ is null-homologous. Show that $x$ is the boundary of an orientable surface $\Sigma$ that is embedded in $S^3 \setminus \varphi(I)$. (In this context this can be seen as the converse to Exercise 48.6.)

Exercise 50.2. Show that there exists an injective map $S^2 \rightarrow \mathbb{R}^3$ such that neither of the two components of the complement of $h(S^2)$ is simply connected.

Remark. You could try to modify the example shown in Figure 807.
the curve $x$ is trivial in homology

Figure 810
51. Topological robotics

In this chapter we will first study the matrix groups $\text{SO}(3)$ and $\text{SU}(2)$, viewed as topological spaces. In particular we will determine $\pi_1(\text{SO}(3))$ and we will use this result to give an application to topological robotics.

51.1. The matrix groups $\text{SO}(3)$ and $\text{SU}(2)$. We recall that Lemma 6.55 implies in particular that we can view $\text{SO}(3)$ and $\text{SU}(2)$ as closed 3-dimensional smooth manifolds. In this section we will see that the smooth manifolds $\text{SO}(3)$ and $\text{SU}(2)$ are diffeomorphic to smooth manifolds we are already very familiar with.

We start out our discussion of $\text{SO}(3)$ and $\text{SU}(2)$ with some definitions. We consider the set of matrices\footnote{Recall that the trace $\text{tr}(A)$ of a matrix is defined as the sum of all the diagonal entries.}

$$T := \{ B \in \text{SL}(2, \mathbb{C}) \mid \text{tr}(B) = 0 \text{ and } B = B^T \}.$$\

Note that $T$ is a 3-dimensional real vector space. We equip it with the basis given by the so-called “Pauli matrices”\footnote{Wolfgang Pauli (1900-1958) was Swiss-American theoretical physicist and one of the pioneers of quantum physics. These matrices were also independently introduced by Paul Dirac. Wikipedia write: “In 1928, building on $2 \times 2$-spin matrices which he [Paul Dirac] discovered independently of Wolfgang Pauli’s work on non-relativistic spin systems, [...] he proposed the Dirac equation as a relativistic equation of motion for the wave function of the electron. This work led Dirac to predict the existence of the positron, the electron’s antiparticle [...].”}\

$$E_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad E_3 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix},$$

and we equip $T$ with the inner product given by

$$\langle A, B \rangle := \frac{1}{2} \text{tr}(AB^T).$$

We consider the isomorphism $\Phi: \mathbb{R}^3 \rightarrow T$ defined by $e_i \mapsto E_i$.\footnote{In the calculation we only have to show that $g(E_i, E_j) = \frac{1}{2} \text{tr}(E_i E_j^T) = \delta_{ij} = \langle e_i, e_j \rangle$ for all choices of $i, j \in \{1, 2, 3\}$. But this can be verified easily.}

It follows from a straightforward calculation that $\Phi$ defines an isometry from $(\mathbb{R}^3, \langle , \rangle)$ to $(T, g)$.\footnote{In the calculation we only have to show that $g(E_i, E_j) = \frac{1}{2} \text{tr}(E_i E_j^T) = \delta_{ij} = \langle e_i, e_j \rangle$ for all choices of $i, j \in \{1, 2, 3\}$. But this can be verified easily.}

It follows immediately from this observation that $\Phi$ induces an isomorphism $\text{SO}(3) \rightarrow \text{SIsom}(T, g)$, where $\text{SIsom}(T, g)$ denotes the group of isometries of $(T, g)$ of determinant $+1$. We use this isomorphism to identify these two groups.

**Lemma 51.1.** The map

$$q: \text{SU}(2) \rightarrow \text{SIsom}(T, g) = \text{SO}(3)$$

$$A \mapsto (B \mapsto ABA^{-1})$$

is a smooth map between smooth manifolds and it is a well-defined group homomorphism. Furthermore for $A, A' \in \text{SU}(2)$ we have

$$q(A) = q(A') \iff A = \pm A'.$$
Example. Given \( t \in \mathbb{R} \) we consider the matrix
\[
A = \begin{pmatrix}
e^{-it} & 0 \\
0 & e^{it}
\end{pmatrix} \in \text{SU}(2).
\]

We want to determine \( q(A) \in \text{SO}(3) \). This means that we have to express the linear map \( T \mapsto T \) that is given by \( B \mapsto ABA^{-1} \) with respect to the ordered basis \( \{E_1, E_2, E_3\} \). A straightforward calculation shows that
\[
AE_1A^{-1} = E_1,
AE_2A^{-1} = \begin{pmatrix} 0 & e^{-2it} \\ e^{2it} & 0 \end{pmatrix} = \cos(2t) \cdot E_2 + \sin(2t) \cdot E_3,
AE_3A^{-1} = \begin{pmatrix} 0 & -ie^{-2it} \\ ie^{2it} & 0 \end{pmatrix} = -\sin(2t) \cdot E_2 + \cos(2t) \cdot E_3.
\]

But this implies that the homomorphism \( T \mapsto T \) given by conjugation with \( A \), with respect to the ordered basis \( \{E_1, E_2, E_3\} \) is given by the matrix
\[
\begin{pmatrix}
1 & 0 & 0 \\
0 & \cos(2t) & -\sin(2t) \\
0 & \sin(2t) & \cos(2t)
\end{pmatrix}, \text{ put differently, we have } q\left( \begin{pmatrix} e^{-it} \\ 0 \\ e^{it} \end{pmatrix} \right) = \begin{pmatrix} 1 & 0 & 0 \\
0 & \cos(2t) & -\sin(2t) \\
0 & \sin(2t) & \cos(2t)\end{pmatrix}.
\]

Proof of Lemma 51.1 (*). First we have to show that for \( A \in \text{SU}(2) \) and \( B \in T \) we also have \( ABA^{-1} \in T \). This is indeed the case since
\[
\text{tr}(ABA^{-1}) = \text{tr}(B) = 0 \quad \text{and} \quad (ABA^{-1})^T = (A^{-1})^T B^T A^T = A B^T A^{-1}.
\]

It follows easily from the definition that \( q \) is a group homomorphism. We also have to show that for \( A \in \text{SU}(2) \) we get indeed an isometry of \( (T, g) \). So let \( B, C \in T \). Then we have indeed
\[
g(q(A)(B), q(A)(C)) = \frac{1}{2} \text{tr}\left(ABA^{-1} \cdot AC^{-1}A^{-T}\right) = \frac{1}{2} \text{tr}\left(A\left(ABA^{-1}\right)^T = \frac{1}{2} \text{tr}(B) \cdot \text{tr}(A)\right)
\]

This shows that \( q \) defines group homomorphism \( \text{SU}(2) \to \text{O}(3) \). By Lemma 2.65 we know that \( \text{SU}(2) \) is path-connected. The image \( q(\text{SU}(2)) \) is a path-connected subset of \( \text{O}(3) \) that contains \( q(\text{id}) = \text{id} \). It follows again Lemma 2.65 that \( q(\text{SU}(2)) \) is contained in \( \text{SO}(3) \).

Finally let \( A, A' \in \text{SU}(2) \). If \( A = -A' \) then we clearly have \( q(A) = q(A') \). Now suppose that conversely we have \( q(A) = q(A') \). We then have in particular \( q(A)(E_i) = q(A')(E_i) \) for \( i = 1, 2, 3 \), i.e. we have \( AE_iA^{-1} = A'E_i(A')^{-1} \) for \( i = 1, 2, 3 \). These equalities give us equations relating the four entries of the matrix \( A \) to the four entries of the matrix \( A' \). An elementary calculation then shows that the only solutions are \( A = \pm A' \). We leave the details to the reader.
This discussion shows that $q$ is a well-defined map and that it is a group homomorphism. After one has unraveled the definitions it will also have become apparent that the map $g$ is indeed a smooth map between smooth manifolds.

The following theorem is the main result of this section.

**Theorem 51.2.** We denote by $q: SU(2) \to S\text{lsom}(T, g) = SO(3)$ the map from Lemma 51.1. Then the following two statements hold:

1. The map $q$ is a 2-fold covering map.
2. There exist diffeomorphisms $f: S^3 \to SU(2)$ and $g: \mathbb{R}P^3 \to SO(3)$ such that the following diagram commutes:

\[
\begin{array}{ccc}
S^3 & \xrightarrow{f} & SU(2) \\
\downarrow{p} & \cong & \downarrow{q} \\
\mathbb{R}P^3 & \xrightarrow{g} & SO(3),
\end{array}
\]

where we denote by $p: S^3 \to \mathbb{R}P^3 = S^3/\pm 1$ the usual projection map.

**Remark.** In Exercise 3.40 we gave a somewhat different homeomorphism between $\mathbb{R}P^3$ and $SO(3)$. In future discussions we will prefer the homeomorphism from Theorem 51.2.

**Convention.** We will use the diffeomorphism from Theorem 51.2 to make the identifications $S^3 = SU(2)$ and $\mathbb{R}P^3 = SO(3)$.

In the proof of Theorem 51.2 we will need the following technical lemma.

**Lemma 51.3.** Let $q: M \to N$ be a map between two $n$-dimensional topological manifolds. Suppose the following conditions are satisfied:

1. the map $q$ is surjective,
2. the map $q$ is locally injective, i.e. for each $P \in M$ there exists a neighborhood $U$ such that $q|_U$ is injective,
3. for each point $Q \in N$ the preimage $q^{-1}(Q)$ is a finite set.

Then $q$ is a covering map.

**Proof (⋆).** Since $q$ is surjective we only have to show that each $Q \in N$ admits an open neighborhood that is uniformly covered. So let $Q \in N$. We denote its preimages by $P_1, \ldots, P_r$. Let $i \in \{1, \ldots, m\}$. It follows easily from (2) and the hypothesis that $M$ is a topological manifold that we can pick a closed ball $B_i$ which is a neighborhood around $P_i$ and such that $q: B_i \to N$ is injective. Since the topological manifold $N$ is in particular Hausdorff it follows from Proposition 2.43 (3) that $q: B_i \to q(B_i)$ is a homeomorphism. It follows from the proof of Corollary 50.8 that $q(B_i) \subset N$ is an open neighborhood of $Q$. It is now straightforward to see that $U := \bigcap_{i=1}^{m} q(B_i)$ is a uniformly covered open neighborhood of $Q$.

Now we can provide the proof of Theorem 51.2.
Proof of Theorem 51.2. Somewhat confusingly the proof of Theorem 51.2 is given in three steps (a), (b) and (c).

(a) One can easily show that the maps

\[ f : S^3 \to SU(2) \quad \text{and} \quad \tilde{f} : SU(2) \to S^3 \]

are inverses to one another and that both maps are smooth. This implies that both maps, in particular \( f \), is a diffeomorphism.

(b) Now we want to show that \( q : SU(2) \to SO(3) \) is a 2-fold covering map. By Lemma 51.1 we know that \( q \) is locally injective. But then it follows from Corollary 50.8 and the fact that \( SU(2) \) and \( SO(3) \) are closed 3-dimensional smooth manifolds and the fact that \( SO(3) \) is connected (which follows from the Lemma 2.65 (1) together with Lemma 2.72) that \( q \) is in fact also a surjection. Since the preimage of each \( A \in SO(3) \) consists of precisely two points in \( SU(2) \) we can apply Lemma 51.3 to deduce that \( q \) is indeed a 2-fold covering map.

(c) For any \((z, w) \in S^3\) we have \( q(f(-z, -w)) = q(-f(z, w)) = q(f(z, w)) \). Thus we see that the map

\[ g : \mathbb{RP}^3 \to SO(3) \]

\[ [(z, w)] \mapsto q(f(z, w)) \]

is well-defined. It follows immediately from the fact, obtained in (b), that \( q \) is surjective, that \( g \) is also surjective. Similarly it is straightforward to show, using (b), that the map \( g \) is injective. Since \( q, f \) and \( p \) are local diffeomorphisms and since locally \( g \) is given by a composition of \( q, f, p \) and their local inverses we see that \( g \) is a local diffeomorphism. But by Lemma 6.23 (3) map between smooth manifolds that is a local diffeomorphism and a bijection is in fact a diffeomorphism.

Finally we note that it follows easily from the definitions that \( g \circ p = q \circ f \), i.e. the diagram given in the theorem commutes.

From Theorem 51.2 and Corollary 16.18 we obtain immediately the following, perhaps initially somewhat surprising, corollary.

Corollary 51.4. We have

\[ \pi_1(SU(2)) = 0 \quad \text{and} \quad \pi_1(SO(3)) \cong \mathbb{Z}_2. \]

In particular \( SU(2) \) is the universal covering of \( SO(3) \). \(^{801}\)

\(^{800}\) In Proposition 60.2 we will see that the map \( f \) arises naturally if we think of \( S^3 \) as the “unit quaternions”.

\(^{801}\) The fact \( SU(2) \) is the universal covering of \( SO(3) \) plays an important role in theoretical physics and it is essential in understanding the notion of “spin” of an electron. At least that is a slogan that I remember from the days when I studied physics.
Remark. We can actually give an explicit description of the non-trivial element in the fundamental group $\pi_1(\text{SO}(3)) \cong \mathbb{Z}_2$. More precisely, we consider the loop

$$\gamma: [0, 1] \to \text{SO}(3)$$

$$t \mapsto \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2\pi t) & \sin(2\pi t) \\ 0 & -\sin(2\pi t) & \cos(2\pi t) \end{pmatrix}$$

at the base point $\text{id} \in \text{SO}(3)$. The calculation on page [1303] shows that a lift of the path $\gamma: [0, 1] \to \text{SO}(3)$ to a path $[0, 1] \to \text{SU}(2)$ to the starting point $\text{id} \in \text{SU}(2)$ is given by

$$\tilde{\gamma}: [0, 1] \to \text{SO}(3)$$

$$t \mapsto \begin{pmatrix} e^{-i\pi t} & 0 \\ 0 & e^{i\pi t} \end{pmatrix}.$$

Note that $\tilde{\gamma}(1) = -\text{id}$, i.e. $\tilde{\gamma}$ is not a loop. Since $q: \text{SU}(2) \to \text{SO}(3)$ is a covering and since $\text{SU}(2)$ is simply connected it follows from Lemma 16.15 that $[\gamma]$ is non-trivial in $\pi_1(\text{SO}(3), \text{id})$.

Corollary 51.4 also raises the following question.

**Question 51.5.** Let $n \geq 4$. What is $\pi_1(\text{SO}(n))$?

We will return to this question later on in Proposition 114.11.

51.2. The belt trick. In this section we will see that one can visualize the non-trivial element in $\pi_1(\text{SO}(3)) \cong \mathbb{Z}_2$ using a belt. We proceed as follows.

1. First of all note that a matrix in $\text{SO}(3)$ is precisely given by an ordered orthonormal basis, i.e. by a choice of an ordered set of three orthogonal vectors $v_1, v_2, v_3$ of length 1 in $\mathbb{R}^3$.
2. We equip $\text{SO}(3)$ with the base point given by the identity matrix, i.e. by the standard basis $\{e_1, e_2, e_3\}$.
3. Now suppose we are given a belt with a buckle, a red edge and a green edge, with a blue top side and a pink lower side.
4. Any point on a twisted belt defines a triple of orthogonal vectors:
   - (a) the first vector lies in the plane defined by the belt and points away from the buckle,
   - (b) the second vector also lies in the plane defined by the belt and points towards the red edge,
   - (c) the third is orthogonal to the belt and it is attached to the top side of the belt.
5. In the remainder of the discussion we fix the buckle in the $xy$-plane such that it points in the $x$-direction, so that to a point at the buckle we assign the identity matrix.
6. We say that the end of the belt is in standard position if it lies in a plane parallel to the plane of the buckle and if it points into the $x$-direction. Put differently, the end of the belt is in standard position precisely if the matrix assigned to it is the identity matrix.

---

802 Recall that Lemma 265 (1) says that $\text{SO}(n)$ is path-connected.
803 What is $\pi_1(\text{SO}(2))$?
(7) When we walk on the middle curve of the belt from the buckle towards the other end of the belt, then we obtain a path \([0, 1] \to \SO(3)\). In particular, if the end of the belt is in standard position, then the path defined by the belt is in fact a loop in \(\SO(3)\) at the base point \(\text{id}\).

![Figure 811](image)

moving along the middle curve of the belt we get a path \([0, 1] \to \SO(3)\)

(8) When we hold the belt tightly without twisting it, then we assign the identity matrix to every point on the belt, i.e. the belt defines the constant loop \(t \mapsto \text{id} \in \SO(3)\).

(9) Now we give the belt, that is still fixed at the buckle, a full twist. As in (7) this defines a loop \(\gamma: [0, 1] \to \SO(3)\), in fact it is straightforward to see that this loop is precisely the loop that we had considered on page \(1306\). In particular we have visualized the non-trivial element \([\gamma] \in \pi_1(\SO(3), \text{id}) \in \mathbb{Z}_2\).

both points define the standard basis of \(\mathbb{R}^3\), i.e. the base point \(\text{id} \in \SO(3)\)

![Figure 812](image)

the path \(\gamma: [0, 1] \to \SO(3)\) defined by the matrices along the middle curve

is a loop and thus defines an element \([\gamma] \in \pi_1(\SO(3), \text{id})\)

(10) The loop \(\gamma \ast \gamma: [0, 1] \to \SO(3)\) is given by performing another full twist along the belt. It follows from Corollary 51.4 that \([\gamma \ast \gamma] = [\gamma]^2\) is trivial in \(\pi_1(\SO(3), \text{id}) \cong \mathbb{Z}_2\), i.e. \(\gamma \ast \gamma\) is null-homotopic.

(10) One can see that the loop \(\gamma \ast \gamma\) is null-homotopic as follows: one can untwist the belt while keeping the end in standard position, put differently, we can find a path-homotopy from the loop \(\gamma \ast \gamma\) to the trivial loop. This homotopy is illustrated in Figure 814.
the double full twist defines the loop $\gamma \ast \gamma$ which represents $[\gamma]^2 \in \pi_1(\text{SO}(3), \text{id})$

The fact that $\pi_1(\text{SO}(3)) \cong \mathbb{Z}_2$ lies at the heart of some other tricks, in particular the “plate trick” and “Dirac’s string trick”. More information and some videos can be found here:

https://en.wikipedia.org/wiki/Plate_trick
https://www.youtube.com/watch?v=JaIR-cWk_-o
https://www.youtube.com/watch?v=JDJKfs3HqRg
https://www.youtube.com/watch?v=1CEIgznuHmg

51.3. **Topological robotics**. In this section we want to discuss a “real-life” application of Corollary 51.4. Let us assume that we are given a solid ball and we are allowed to perform the following operations:

1. first we can rotate the ball around the $z$-axis by an angle $\gamma \in S^1$,
2. then we can rotate the ball around the $y$-axis by an angle $\beta \in S^1$, finally
3. we can rotate the ball around the $x$-axis by an angle $\alpha \in S^1$.

Using these three operations, in that order, we can rotate the ball into any position. More precisely, we have the following lemma:
Lemma 51.6. The map
\[ \Phi: S^1 \times S^1 \times S^1 \to SO(3) \]
\[ (\alpha, \beta, \gamma) \mapsto \text{rotation by } \alpha \text{ around the x-axis} \circ \text{rotation by } \beta \text{ around the y-axis} \circ \text{rotation by } \gamma \text{ around the z-axis} \]
is a surjection.\footnote{The map is also continuous. Why is that?}

Remark. One can use Lemma 51.6 and a variation on the argument on page 1303 to give an alternative proof for the statement that \( q: SU(2) \to SO(3) \) is surjective.

Sketch of proof. Let \( A \in SO(3) \) be matrix with columns \( v_1, v_2, v_3 \). After a rotation around the \( z \)-axis we can assume that \( v_1 \) lies in the \( xz \)-plane. After a rotation around the \( y \)-axis we can then arrange that \( v_1 \) lies in fact on the \( x \)-axis, i.e. we can arrange that \( v_1 = e_1 \). Since \( v_1 = e_1, v_2, v_3 \) is an orthonormal basis we see that \( v_2, v_3 \) lie in the \( yz \)-plane. After a rotation around the \( x \)-axis we can finally arrange that \( v_2 = e_2 \) and \( v_3 = e_3 \). \( \blacksquare \)

This lemma gives rise to the following practical problem: given a matrix \( P \in SO(3) \), can we continuously find parameters \( \alpha(P), \beta(P), \gamma(P) \in S^1 \) such that these parameters give back the matrix \( P \)? More precisely, we have the following question.

Question 51.7. Does there exist a continuous map \( \Psi: SO(3) \to S^1 \times S^1 \times S^1 \) such that \( \Phi \circ \Psi = id_{SO(3)} \) ?

It turns out that the answer is negative. More precisely, we have the following proposition.

Proposition 51.8. There is no continuous map \( \Psi: SO(3) \to S^1 \times S^1 \times S^1 \) such that \( \Phi \circ \Psi = id_{SO(3)} \).

This proposition falls into the area of “topological robotics”, more information on this example and on topological robotics can be found in [Gh14, p. 76]. Other aspects of topological robotics are discussed in the monograph [Far08].

Proof. Let us suppose there exists a continuous map \( \Psi: SO(3) \to S^1 \times S^1 \times S^1 \) such that \( \Phi \circ \Psi = id_{SO(3)} \). Then we get the following commutative diagram

\[
\begin{array}{ccc}
\pi_1(S^1 \times S^1 \times S^1) & \cong \mathbb{Z}^3 \\
\Psi_* \downarrow & & \Phi_* \\
\pi_1(SO(3)) & \cong \mathbb{Z}_2 \\
\downarrow id_* & & \downarrow id_* \\
\pi_1(SO(3)) & \cong \mathbb{Z}_2 \\
\end{array}
\]

By Corollary 51.4 we have that \( \pi_1(SO(3)) \cong \mathbb{Z}_2 \) and from Corollary 16.18 we know that \( \pi_1(S^1 \times S^1 \times S^1) \cong \mathbb{Z}^3 \). Since \( \mathbb{Z}_2 \) is a finite group and since \( \mathbb{Z}^3 \) is torsion-free we see that the homomorphism \( \Psi_*: \pi_1(SO(3)) \to \pi_1(S^1 \times S^1 \times S^1) \) is the trivial map. But that is not possible since the horizontal map is an isomorphism of a non-trivial group. \( \blacksquare \)
51.4. **Linkages**. We conclude this chapter with a somewhat unrelated but fun topic that also appears in topological robotics.

(1) We recall that an undirected abstract graph $G$ is a triple $(V,E,\lambda)$ where $V$ is a non-empty set, $E$ is a set and $\lambda$ is a map

$$\lambda : E \rightarrow \{ \text{subsets of } V \text{ with one or two elements} \}.$$ 

The elements of $V$ are called **vertices** of $G$ and the elements of $E$ are called the **edges** of $G$. Furthermore, given $e \in E$ the points in $\lambda(e)$ are called the **endpoints** of $e$.

(2) Given $n \in \mathbb{N}$ we define the **linear graph of length** $n$ to be the undirected abstract graph $G(n)$ which is given by the vertex set $V = \{0, \ldots, n\}$ and the edge set $\{e_0, \ldots, e_{n-1}\}$ with $\lambda(e_i) = \{i, i + 1\}$ for $i = 0, \ldots, n - 1$. This graph is illustrated in Figure 816.

![Figure 816](image.png)

**Definition.**

(1) A **planar linkage** is a triple $(G = (V, E, \lambda, \psi))$ consisting of a finite undirected abstract graph $G = (V, E)$, a function $\lambda : E \rightarrow \mathbb{R}_{>0}$ and a map $\psi : W \rightarrow \mathbb{C} = \mathbb{R}^2$ where $W$ is a subset of $V$. Put differently, $\lambda$ assigns a length to each edge and $\psi$ represents a subset of the vertices by points in $\mathbb{C}$.

(2) A **configuration** of a planar linkage $(G = (V, E, \lambda, \psi))$ is a map $f : V \rightarrow \mathbb{R}^2 = \mathbb{C}$ such that $f|_W = \psi$ and such that for every edge $e$ the distance between the endpoints of $e$ is $\lambda(e).$

(3) The set $C(G = (V, E, \lambda, \psi))$ of all configurations is called the **configuration space** of the linkage. We have an injective map

$$C(G = (V, E, \lambda, \psi)) \rightarrow \mathbb{C}^{|V|} := \text{maps}(V \rightarrow \mathbb{C})$$

$$f \mapsto (v \mapsto f(v))$$

thus we can view the configuration space $C(G = (V, E, \lambda, \psi))$ as a topological space.

![Figure 817](image.png)

In some cases the topological shape of the configuration space of a planar linkage is easy to describe. More precisely, we have the following lemma which is a straightforward

\footnote{In particular if $e$ has only one endpoint, then we need $\lambda(e) = 0$.}
consequence of the definitions and Proposition 2.43 (3). We leave it to the reader to provide the proof.

**Lemma 51.9.** Let $G(m)$ be the linear graph with $m$ edges. We consider a planar linkage of the form $(G(m), \lambda, \psi(0) = 0)$. For $i = 1, \ldots, m$ we write $r_i = \lambda(e_i)$. Then the map

$$(S^1)^m = S^1 \times \cdots \times S^1 \to C(G(m), \lambda, \psi)$$

$$(z_1, \ldots, z_m) \mapsto \left( \{0, \ldots, m\} \to \mathbb{C} \quad k \mapsto \sum_{i=1}^{k} r_i z_i \right)$$

is a homeomorphism.

![Sketch for the proof of Lemma 51.9](image)

Figure 818. Sketch for the proof of Lemma 51.9

For general linkages the topology of the configuration spaces are much harder to describe than for free planar linkages.

(1) Given $r_1, \ldots, r_m > 0$ we denote by $C(r_1, \ldots, r_m, P, Q)$ the configuration space corresponding to the planar linkage defined by $G(m)$, $\lambda(e_i) = r_i$ and by the conditions that $\psi(0) = P$ and $\psi(m) = Q$.

(a) Using elementary arguments one can easily show that

$$C(r_1, r_2, P, Q) = \begin{cases} \emptyset, & \text{if } r_1 + r_2 < d(P, Q), \\ \text{one point, } & \text{if } r_1 + r_2 = d(P, Q), \\ \text{two points, } & \text{if } r_1 + r_2 > d(P, Q). \end{cases}$$

(b) Kevin Walker [Walkb85, p. 35], see also [Gh14, p. 12], showed in 1985 in his bachelor thesis that the surfaces of genus $0, 1, \ldots, 4$ are homeomorphic to configuration spaces of the type $(r_1, r_2, r_3, r_4, P, Q)$ for suitable values of $r_1, \ldots, r_4$ and points $P$ and $Q$.

![Configurations for the planar linkage](image)

Figure 819

(2) Michael Kapovich and John Millson [KaM02] showed that given any compact smooth manifold $M$ there exists a planar linkage such that each component of the configuration space is homeomorphic to $M$. In particular this shows that any compact smooth manifold can be represented by a 2-dimensional physical object.
Exercises for Chapter 51

Exercise 51.1. Let \( q : \text{SU}(2) \to \text{SO}(3) \) be the homomorphism that we defined in Lemma 51.1. Show that
\[
q\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad q\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad q\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.
\]

Remark. This calculation will actually turn out to be useful in Section 66.4.
52. The Hurewicz Theorem in Dimension One

In this chapter we want to relate the first homology group to the fundamental group of a path-connected topological space $X$. Both are defined by mapping 1-dimensional smooth manifolds into $X$, hence it is reasonable to expect that there is a relationship. But in general these two groups associated to a topological space cannot be the same, since the first homology group is by definition abelian, whereas we saw on many occasions that fundamental groups can be non-abelian.

We start out with the following notation.

**Notation.** Let $X$ be a topological space. Throughout this chapter we denote by $\Phi$ the following bijection:

$$\Phi: \{\text{paths } [0,1] \to X\} \to \{\text{singular 1-simplices in } X\}$$

$$(\gamma: [0,1] \to X) \mapsto \left(\Delta^1 \to X \atop (1-t,t) \mapsto \gamma(t)\right).$$

On many occasions we will use the trivial observation that for any path $\gamma: [0,1] \to X$ we have $\Phi(\overline{\gamma}) = \overline{\Phi(\gamma)}$.

We continue with the following lemma.

**Lemma 52.1.** Let $X$ be a topological space. If $f$ and $g$ are two paths in $X$ such that the endpoint of $f$ agrees with the starting point of $g$, then the singular 1-chains $\Phi(f) + \Phi(g)$ and $\Phi(f \ast g)$ are homologous.

**Proof.** The lemma follows quite easily from Lemma 41.3. We refer to Figure 820 for a sketch of the proof. We leave it to the reader to turn the sketch into a proper proof. ■

![Figure 820. Illustration of the proof of Lemma 52.1](image)

Now we can easily prove the following proposition.
Proposition 52.2. Let $(X, x_0)$ be a pointed topological space.

(1) If $\gamma$ is a loop in $(X, x_0)$, then $\Phi(\gamma) \in C_1(X)$ is a cycle.

(2) The map $\Phi$ induces a well-defined map

$$
\Phi_{(X,x_0)} : \pi_1(X, x_0) \to H_1(X)
$$

$\left[\gamma : [0,1] \to X\right] \mapsto [\Phi(\gamma)]$.

(3) The map $\Phi_{(X,x_0)} : \pi_1(X, x_0) \to H_1(X)$ is a group homomorphism.

(4) Let $\operatorname{PTop}$ be the category of pointed topological spaces and let $\mathcal{G}r$ be the category of groups. The Hurewicz homomorphisms

$$
\Phi_{(X,x_0)} : \pi_1(X, x_0) \to H_1(X)
$$

define a natural transformation from the functor

$$
\operatorname{PTop} \to \mathcal{G}r
$$

$(X,x_0) \mapsto \pi_1(X, x_0)$ to the functor

$$
\operatorname{PTop} \to \mathcal{G}r
$$

$(X,x_0) \mapsto H_1(X)$.

In plain English this means the following, given a map $f : X \to Y$ between topological spaces and given $x_0 \in X$ the following diagram commutes:

$$
\begin{array}{ccc}
\pi_1(X, x_0) & \xrightarrow{f_*} & \pi_1(Y, f(x_0)) \\
\Phi_{(X,x_0)} \downarrow & & \downarrow \Phi_{(Y,f(x_0))} \\
H_1(X) & \xrightarrow{f_*} & H_1(Y).
\end{array}
$$

Proof.

(1) The first statement follows immediately from the definitions and the description of $\partial_1 : C_1(X) \to C_0(X)$ given on page 1076.

(2) We denote by $\sim$ the equivalence relation on $[0,1]$ that is generated by $0 \sim 1$. We denote by $\alpha : \Delta^1 \to [0,1]/\sim$ the map that is given by $\alpha(1-t,t) = \lbrack t \rbrack$. Note that $\alpha$ defines an element in $H_1([0,1]/\sim)$. Now suppose that $f, g : [0,1] \to X$ are two path-homotopic loops in $x_0$. We denote by $\tilde{f}, \tilde{g} : [0,1]/\sim \to X$ the induced maps. Then

$$
[\Phi(f)] = \left[\tilde{f} \circ \alpha\right] = \tilde{f}_*([\alpha]) = \tilde{g}_*([\alpha]) = [\tilde{g} \circ \alpha] = [\Phi(g)].
$$

since $f$ and $\tilde{f}$ are the same map $\Phi(f)$ and $\tilde{f} \circ \alpha$ are homotopic maps $[0,1]/\sim \to X$.

(3) The third statement is an immediate consequence of Lemma 52.1.

(4) The last statement follows easily from the definitions. $lacksquare$

Definition. Given a pointed topological space $(X, x_0)$ we refer to the homomorphism

$$
\Phi_{(X,x_0)} : \pi_1(X, x_0) \to H_1(X)
$$

$\left[\gamma : [0,1] \to X\right] \mapsto [\Phi(\gamma)]$

as the Hurewicz homomorphism.
It is clear that the Hurewicz homomorphism is in general neither injective nor surjective:

1. The Hurewicz homomorphism is in general not injective since $\pi_1(X, x_0)$ is in many cases a non-abelian group whereas $H_1(X)$ is an abelian group, and it is not possible that a non-abelian group is a subgroup of an abelian group.

2. The Hurewicz homomorphism is in general not surjective, since $\pi_1(X, x_0)$ depends only on the path-component of $x_0$, while $H_1(X)$ "sees" all path-components of $X$. But as we will see in the next lemma, this turns out to be the only obstacle to $\Phi$ being surjective.

### Proposition 52.3

Let $X$ be a topological space and let $x_0 \in X$. If $X$ is path-connected, then the Hurewicz homomorphism

$$\Phi_{(X,x_0)} : \pi_1(X, x_0) \rightarrow H_1(X)$$

is surjective.

In the proof of Proposition 52.3 we will need the following lemma.

### Lemma 52.4

Let $X$ be a set and let $x_1, \ldots, x_k$ and $y_1, \ldots, y_l$ be elements in $X$. If

$$\sum_{i=1}^{k} x_i - \sum_{i=1}^{l} y_i = 0 \in \mathbb{Z}^X,$$

then $k = l$ and there exists a permutation $s \in S_k$ such that $y_i = x_{s(i)}$ for $i = 1, \ldots, k$.

**Proof ($\ast$).** Let $X$ be a set and let $x_1, \ldots, x_k$ and $y_1, \ldots, y_l$ be elements in $X$ such that

$$\sum_{i=1}^{k} x_i = \sum_{i=1}^{l} y_i \in \mathbb{Z}^X.$$

It follows from Lemma 19.1 that there exists a unique homomorphism $\psi : \mathbb{Z}^X \rightarrow \mathbb{Z}$ with the property that $\psi(x) = 1$ for all $x \in X$. By definition we have $\psi(a) = k$ and $\psi(b) = l$. So from $a = b$ we deduce that $k = l$.

Note that it follows from applying Lemma 19.1 once again that there exists a unique homomorphism $\psi : \mathbb{Z}^X \rightarrow \mathbb{Z}$ with the property that $\psi(x_k) = 1$ and $\psi(x) = 0$ for all $x \in X \setminus \{x_k\}$. By definition we have $\psi(a) > 0$. From $\psi(b) = \psi(a) > 0$ it follows that there exists an $n \in \{1, \ldots, k\}$ such that $y_n = x_k$. We define $s(k) = n$. We obtain an equality

$$\sum_{i=1}^{k-1} x_i = \sum_{i \in \{1, \ldots, k\} \setminus \{s(k)\}} y_i \in \mathbb{Z}^X$$

and we iterate this procedure to define $s(k-1), \ldots, s(1)$. By construction the map $s : \{1, \ldots, k\} \rightarrow \{1, \ldots, k\}$ is a bijection $\blacksquare$

Now we can provide the proof of Proposition 52.3.

**Proof of Proposition 52.3** We denote by $\Psi$ the inverse of the above bijection

$$\Phi : \{\text{paths }[0,1] \rightarrow X\} \rightarrow \{\text{singular 1-simplices in } X\}$$

---

806Witold Hurewicz (1904-1956) was a Polish mathematician.
We pick a homology class \( z \in H_1(X) \). Let \( c = \sum_{i=1}^k a_i \sigma_i \) be a cycle in \( C_1(X) \) that represents \( z \).

It follows from Lemma 41.3 that, after possibly replacing a singular chain \( \sigma_i \) by \( \overline{\sigma_i} \), we can assume that all the coefficients \( a_i \) are positive. Furthermore, since we do not require that the \( \sigma_i \)'s are different, we can in fact suppose that \( a_1 = \cdots = a_k = 1 \). Next note that we have

\[
0 = \partial_1(c) = \partial_1 \left( \sum_{i=1}^k a_i \sigma_i \right) = \sum_{i=1}^k a_i (0,1) - \sigma_i(1,0) = \sum_{i=1}^k \sigma_i(0,1) + \sum_{i=1}^k -\sigma_i(1,0).
\]

On the right hand side each “positive summand” needs to cancel with a “negative summand”. This means, see also Lemma 52.4, that there exists a permutation \( \theta \in S_k \) such that for each \( i \) the “endpoint” \( \sigma_i(0,1) \) of \( \sigma_i \) is just the “starting point” \( \sigma_{\theta(i)}(1,0) \) of \( \sigma_{\theta(i)} \).

Since \( X \) is path-connected we can choose for each \( i \in \{1, \ldots, k\} \) a path \( p_i \) from the base point \( x_0 \) to the starting point \( \sigma_i(1,0) \) of \( \sigma_i \).

We obtain the following equality in \( H_1(X) \):

\[
c = \sum_{i=1}^k \sigma_i = \sum_{i=1}^k \sigma_i + \sum_{i=1}^k \Phi(p_i) + \sum_{i=1}^k \Phi(\overline{p_i}) = \sum_{i=1}^k \left( \Phi(p_i) + \Phi(\Psi(\sigma_i)) + \Phi(\overline{\sigma_i}) \right) = \Phi \left( \prod_{i=1}^k p_i * \Psi(\sigma_i) * \overline{\sigma_i} \right).
\]

Thus we have shown that \( z = [c] \in \Phi(\pi_1(X,x_0)) \). This concludes the proof that the Hurewicz homomorphism \( \Phi(\pi_1,X,x_0): \pi_1(X,x_0) \to H_1(X) \) is surjective.

In the following we want to study to what degree the Hurewicz homomorphism fails to be injective. Before we can do so we need to recall some definitions and results from Section 21.5.
Definition. Let \( \pi \) be a group.

1. For \( x, y \in \pi \) we denote by \( [x, y] := xyx^{-1}y^{-1} \) the commutator of \( x \) and \( y \).
2. We refer to \( \{[x, y] \mid x, y \in \pi \} \) as the commutator subgroup of \( \pi \).
3. We refer to \( \pi_{ab} := \pi/\langle \langle \{[x, y] \mid x, y \in \pi \} \rangle \rangle \) as the abelianization of \( \pi \).

In Section 21.5 we saw that the abelianization is “the largest abelian quotient” of \( \pi \). More precisely, if \( \alpha: \pi \to H \) is a homomorphism from \( \pi \) to an abelian group \( H \), then Proposition 21.20 says that there exists a unique homomorphism \( \beta: \pi_{ab} = \pi/\langle \langle \{[x, y] \mid x, y \in \pi \} \rangle \rangle \to H \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\pi & \xrightarrow{\alpha} & \pi_{ab} = \pi/\langle \langle \{[x, y] \mid x, y \in \pi \} \rangle \rangle \\
\downarrow \cong & & \downarrow \exists! \beta \\
H & & H.
\end{array}
\]

In particular, given a pointed topological space \((X, x_0)\) the corresponding Hurewicz homomorphism \( \Phi_{(X,x_0)}: \pi_1(X, x_0) \to H_1(X) \) induces a homomorphism \( \pi_1(X, x_0)_{ab} \to H_1(X) \) that we also denote by \( \Phi_{(X,x_0)} \) and that we also refer to as the Hurewicz homomorphism. Now we can formulate the following proposition.

**Theorem 52.5. (Hurewicz Theorem)** Let \((X, x_0)\) be a pointed topological space. If \(X\) is path-connected, then the Hurewicz homomorphism

\[
\Phi_{(X,x_0)}: \pi_1(X, x_0)_{ab} \to H_1(X)
\]

is a natural \(^{807}\) isomorphism.

**Examples.**

1. If we compare our calculations of fundamental groups with our calculations of homology groups, then we see that we had encountered this isomorphism many times.
   a. In Corollary 16.18 we showed that \( \pi_1((S^1)^n) \cong \mathbb{Z}^n \), whereas on page 1235 we saw that \( H_1((S^1)^n) \cong \mathbb{Z}^n \).
   b. For \( n \geq 2 \) we saw in Corollary 16.18 that \( \pi_1(\mathbb{R}P^n) \cong \mathbb{Z}_2 \) and in Lemma 46.9 we had calculated that \( H_1(\mathbb{R}P^n) \cong \mathbb{Z}_2 \).
   c. In Proposition 22.3 we showed that
      \[
      \pi_1(\text{Klein bottle}) \cong \langle x, y \mid yxyx^{-1} \rangle.
      \]
      The abelianization of that group is isomorphic to \( \mathbb{Z} \oplus \mathbb{Z}_2 \) which is isomorphic to the first homology of the Klein bottle that we had determined in Lemma 46.13.
   d. In Proposition 22.3 we showed that for any \( g \in \mathbb{N} \) we have
      \[
      \pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle.
      \]

\(^{807}\)Whenever we write “natural” one needs to work out what the categories and functors are. In this case we consider the category of path-connected topological spaces, the category of groups and the functors \((X, x_0) \to \pi_1(X, x_0)_{ab}\) and \((X, x_0) \to H_1(X)\).
The abelianization of this group is isomorphic to $\mathbb{Z}^2$ which is precisely the first homology group that we had determined in Proposition 48.9.

(e) Let $X$ be a path-connected topological space and let $f: X \to X$ be a homeomorphism. By Lemma 46.23, we know that there exists a short exact sequence

$$0 \to \text{coker}(H_1(X) \xrightarrow{f_* - \text{id}} H_1(X)) \xrightarrow{i} H_1(\text{Tor}(X, f)) \to \mathbb{Z} \to 0.$$ 

On the other hand, it follows from Proposition 24.28 and the remark on page 720 that there exists an isomorphism $\psi: \pi_1(\text{Tor}(X, f)) \cong \pi_1(X) \times \mathbb{Z}$ where the action of $1 \in \mathbb{Z}$ on $\pi_1(X)$ is induced by $f$. Therefore, we can put $\pi_1(\text{Tor}(X, f))$ into a short exact sequence

$$0 \to \pi_1(X) \to \pi_1(\text{Tor}(X, f)) \to \mathbb{Z} \to 0.$$ 

Now we apply the abelianization functor to these groups and homomorphisms. We obtain the exact sequence

$$\pi_1(X)_{ab} \to \pi_1(\text{Tor}(X, f))_{ab} \to \mathbb{Z} \to 0,$$

which, using the Hurewicz Theorem 52.5, we can rewrite as

$$H_1(X) \to H_1(\text{Tor}(X, f)) \to \mathbb{Z} \to 0.$$ 

This is, fortunately, consistent with the above short exact sequence.

(2) Note that we now have a new, and depending on one’s taste, more satisfying proof of Corollary 27.25. The Hurewicz Theorem 52.5 together with Lemma 46.14 implies that given any knot $K \subset S^3$ the abelianization of $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

\textbf{Proof of the Hurewicz Theorem 52.5 (\ast).} Let $(X, x_0)$ be a pointed path-connected topological space. We write $\pi := \pi_1(X, x_0)$. By Proposition 52.2, we know that the Hurewicz homomorphism $\Phi(x, x_0): \pi_{ab} \to H_1(X)$ is surjective. Furthermore, it follows from Proposition 52.3 that the Hurewicz homomorphism $\Phi(x, x_0): \pi_{ab} \to H_1(X)$ is surjective. It remains to show that $\Phi(x, x_0)$ is injective.

In the following we will make the identification $[0, 1] = \Delta^1$ that is given by the homeomorphism $t \mapsto (1 - t, t)$. In particular, we will identify paths $[0, 1] \to X$ with singular 1-simplices $\Delta^1 \to X$.

So let $f: [0, 1] = \Delta^1 \to X$ be a loop in $(X, x_0)$ such that $[f] = 0 \in H_1(X)$. By definition, this means that there exists a 2-chain $\sum_{j=1}^s n_j \sigma_j$ in $X$ whose boundary is the singular 1-simplex $f$. Furthermore, since we do not demand that the $\sigma_j$ are distinct, we can assume that all $n_j$ are either $-1$ or $1$. Given $j \in \{1, \ldots, s\}$ and $k \in \{0, 1, 2\}$ we write

$$\mu_{j,k} := \sigma_j \circ i^2_k: [0, 1] = \Delta^1 \to X \quad \text{and} \quad n_{(j,k)} := (-1)^k \cdot n_j.$$ 

\textit{\textsuperscript{806}In Exercise 21.6, we saw that if $\varphi: A \to B$ is an epimorphism, then the induced map $A_{ab} \to B_{ab}$ is also an epimorphism. We had also seen that there exist monomorphisms $\varphi: A \to B$ such that the induced map $A_{ab} \to B_{ab}$ is not a monomorphism.

\textsuperscript{809}Recall that for $j \in \{0, \ldots, n\}$ we denote by $i_j^n$ the map

$$i^n_j: \Delta^{n-1} \to \Delta^n$$

$$(t_0, \ldots, t_{n-1}) \mapsto (t_0, \ldots, t_{j-1}, 0, t_j, \ldots, t_{n-1}).$$}
We write \( A = \{1, \ldots, s\} \times \{0, 1, 2\} \). We have the following equality in \( C_1(X) \):

\[
f = \partial_1 \left( \sum_{j=1}^{s} n_{j} \sigma_{j} \right) = \sum_{j=1}^{s} \sum_{k=0}^{2} n_{(j,k)} \cdot \mu_{j,k} = \sum_{a \in A} n_{a} \cdot \mu_{a}. \]

By comparing the left and the right-hand side of this equality we see that there exists a \( b \in A \) with \( n_{b} \cdot \mu_{b} = 1 \cdot f \). We write \( A_{\pm} = \{ a \in A \setminus \{b\} \mid n_{a} = \pm 1 \} \). Now we obtain from the above equality that

\[
\sum_{a \in A_{+}} \mu_{a} + \sum_{a \in A_{-}} (-1) \cdot \mu_{a} = 0.
\]

We make the following choices and introduce the following definitions:

1. For each point \( P \) in \( X \) that is a starting or an endpoint of some \( \mu_{a} \) we pick a path \( \beta_{P} \) from \( x_{0} \) to \( P \). For \( P = x_{0} \) we just pick the constant path.
2. Given \( \mu_{(i,j)} : [0, 1] = \Delta^{1} \rightarrow X \) we write

\[
\hat{\mu}_{(i,j)} := \beta_{\text{starting point of } \mu_{(i,j)}} * \mu_{(i,j)} * \beta_{\text{endpoint of } \mu_{(i,j)}}.
\]

Note that \( \hat{\mu}_{(i,j)} \) is a loop in \( (X, x_{0}) \), in particular it defines an element in the group \( \pi = \pi_{1}(X, x_{0}) \) which, by a slight abuse of notation, we denote again by \( \hat{\mu}_{(i,j)} \).

![Figure 822.](image)

We make the following elementary observation: for any \((i, j) \in \{1, \ldots, s\} \times \{0, 1, 2\}\) we have the following equality in \( \pi = \pi_{1}(X, x_{0}) \):

\[
(*) \quad \hat{\mu}_{(i,j)}^{-1} := \beta_{\text{starting point of } \overline{\mu}_{(i,j)}} * \overline{\mu}_{(i,j)} * \overline{\beta}_{\text{endpoint of } \overline{\mu}_{(i,j)}}.
\]
In $\pi_{ab}$ we have the following equalities:

\[
\begin{align*}
\text{loop in the starting point of } \mu(j,0) & \uparrow \\
\prod_{j=1}^k \beta_{\text{starting point of } \mu(j,0)} = & \prod_{j=1}^k (\mu(j,0) * \mu(j,1) * \mu(j,2))^{n_j} * \beta_{\text{starting point of } \mu(j,0)} \\
\text{since } \mu(j,0) * \mu(j,1) * \mu(j,2) \text{ is null-homotopic} & \uparrow \\
= & \prod_{j=1}^k \mu_{(j,0)}^{n_{(j,0)}} * \mu_{(j,1)}^{n_{(j,1)}} * \mu_{(j,2)}^{n_{(j,2)}} = \prod_{a \in \{1, \ldots, k\} \times \{0,1,2\}} \hat{\mu}_a^{n_a}
\end{align*}
\]

follows from inserting null-homotopic paths $\beta_p * \beta_p$ together with the above equality ($*$)

\[
\begin{align*}
= f * \prod_{a \in A_-} \hat{\mu}_a^{n_a} * \hat{\mu}_{\psi(a)}^{n_{\psi(a)}} = f * \prod_{a \in A_-} \hat{\mu}_a^{n_a} * \hat{\mu}_{\psi(a)}^{n_{\psi(a)}} = f.
\end{align*}
\]

since $\{1, \ldots, k\} \times \{0,1,2\} = (1,0) \sqcup A_- \sqcup \psi(A_-)$ for $a \in A_-$ we have $\mu_{\psi(a)} = \mu_a$ and $n_a = -n_a$.

This completes the proof of the proposition.\footnote{In the notation we do not distinguish between loops and elements they represent in $\pi_{ab}$.}

For most topological spaces for which we had computed the fundamental group we had also determined the homology groups. But there is one rather interesting exception, namely the lens spaces. From Corollary \ref{cor:16.18} and the Hurewicz Theorem \ref{thm:52.5} we obtain immediately the following corollary.

**Corollary 52.6.** For any coprime $p, q \in \mathbb{N}$ we have

\[
\begin{align*}
H_1(\text{lens space } L(p,q)) & \cong \mathbb{Z}_p.
\end{align*}
\]

**Remark.** The Hurewicz Theorem \ref{thm:52.5} is perhaps a mixed blessing. On the one hand it allows us to use the techniques that we had developed in earlier chapters to determine first homology groups. On the other hand it tells us that all the information that is contained in the first homology group is already contained in the fundamental group. So we do not get any new information. In particular, as we saw in Corollary \ref{cor:52.6} the first homology group cannot help us in our long-standing goal of distinguishing lens spaces with the same fundamental group.

Calculating (isomorphism types) of homology groups can get quite involved. But what is often even harder is to determine the maps on homology groups induced by maps between topological spaces. Using Proposition \ref{prop:52.2}(4) we can transfer calculations of induced maps on fundamental groups to obtain the corresponding induced maps on homology groups.

For example we have the following lemma, which later on will be used on many occasions.\footnote{Where did we actually use that we work with $\pi_{ab}$ instead of $\pi$?}
Lemma 52.7. Let \( n \in \mathbb{N} \). We denote by \( T = \mathbb{R}^n / \mathbb{Z}^n = (S^1)^n \) the \( n \)-dimensional torus.

1. We denote by \( \sigma \in H_1(S^1) \) the standard generator introduced on page 1174. Given \( i \in \{1, \ldots, n\} \) we denote by
\[
p_i: S^1 \to (S^1)^n
\]
the obvious \( i \)-th inclusion map and we write \( z_i = p_i*(\sigma) \). Then \( e_1, \ldots, e_n \) is a basis of \( H_1(T) \).

2. Let \( A \in \text{GL}(n, \mathbb{Z}) \) be a matrix. We denote by \( T = \mathbb{R}^n / \mathbb{Z}^n \) the \( n \)-dimensional torus. By Lemma 6.35 the map
\[
f(A): T = \mathbb{R}^n / \mathbb{Z}^n \to T = \mathbb{R}^n / \mathbb{Z}^n
\]
\[
[v] \mapsto [A \cdot v]
\]
is a homeomorphism. With respect to the above basis \( e_1, \ldots, e_n \) of \( H_1(T) \) the induced map \( f(A)_*: H_1(T) \to H_1(T) \) is given by multiplication by the matrix \( A \).

Remark.

1. In Exercise 84.6 we will study what self-maps of \( H_2(S^2 \times S^2) \) can be realized by self-maps of \( S^2 \times S^2 \).

2. Exercise 45.20 can be used to give an alternative proof of Lemma 52.7 (2).

Proof.

1. This statement follows easily from the definitions, Theorem 16.16 and the Hurewicz Theorem 52.5.

2. Let \( \Theta: \pi_1(T, 0) \to \mathbb{Z}^n \) be the isomorphism from Theorem 16.16. By Proposition 52.2 (4), Theorem 16.16 and Exercise 16.16 we obtain the following commutative diagram
\[
\begin{array}{ccc}
H_1(T) & \xleftarrow{\Phi(T,0)} & \pi_1(T,0) \\
\downarrow{f(A)} & & \downarrow{f(A)_*} \\
H_1(T) & \xleftarrow{\Phi(T,0)} & \pi_1(T,0)
\end{array}
\]
\[
\begin{array}{ccc}
\pi_1(T,0) & \xrightarrow{\theta} & \mathbb{Z}^n \\
\downarrow{\Phi(T,0)} & & \downarrow{\Phi(T,0) \circ f(A)_*} \\
\pi_1(T,0) & \xrightarrow{\theta} & \mathbb{Z}^n
\end{array}
\]

The desired statement follows from the observation that the horizontal isomorphism
\( \Theta \circ \Phi(T,0): H_1(T) \to \mathbb{Z}^n \) is precisely the one corresponding to the basis \( e_1, \ldots, e_n \). □

As another illustration of Proposition 52.2 (4) we also prove the following corollary.

Corollary 52.8. (*) Let \( p: Y \to X \) be a finite-index covering of path-connected topological spaces. Then the cokernel of the map
\[
p_*: H_1(Y) \to H_1(X)
\]
is finite.

Remark. Let \( p: Y \to X \) be a finite-index covering of path-connected topological spaces. Let \( y_0 \in Y \). By Corollary 16.14 the induced map \( p_*: \pi_1(Y, y_0) \to \pi_1(X, p(y_0)) \) is a monomorphism. On the other hand it is in general not true that the induced homomorphism \( p_*: H_1(Y) \to H_1(X) \) is a monomorphism. For example on page 497 we saw that there
exists a 2-fold covering map \( p: T \to K \) from the torus \( T \) to the Klein bottle \( K \). By Lemmas \ref{lem:covering map torus} and \ref{lem:covering map Klein bottle} we know that \( H_1(T) \cong \mathbb{Z}^2 \) and that \( H_1(K) \cong \mathbb{Z} \oplus \mathbb{Z}_2 \). By Lemma \ref{lem:covering map properties} (2) there is no monomorphism from the group \( \mathbb{Z}^2 \) to \( \mathbb{Z} \oplus \mathbb{Z}_2 \).

**Proof.** We pick a base point \( y_0 \) of \( Y \) and we write \( x_0 = p(y_0) \). We consider the following diagram of maps:

\[
\begin{array}{ccc}
\pi_1(Y, y_0) & \xrightarrow{p_*} & \pi_1(X, x_0) \\
\downarrow \Phi_y & & \downarrow \Phi_X \\
\pi_1(Y, y_0)_{ab} & \xrightarrow{p_*} & \pi_1(X, x_0)_{ab}
\end{array}
\]

Here it follows from the Hurewicz Theorem \ref{thm:hurewicz theorem} that the lower diagonal maps are isomorphisms. The “big rectangle in the back” commutes by Proposition \ref{prop:covering map properties} (4). The upper parallelogram commutes by Proposition \ref{prop:covering map properties} (7). Since the lower diagonal maps are isomorphisms it follows that the lower parallelogram also commutes.

By Lemma \ref{lem:covering map properties} and by our hypothesis that \( p \) is a finite covering we know that \( p_*(\pi_1(Y, y_0)) \) is a finite index subgroup of \( \pi_1(X, x_0) \), i.e. \( p_*: \pi_1(Y, y_0) \to \pi_1(X, x_0) \) has a finite cokernel. It follows\footnote{This can be seen as follows: First we write \( G = \pi_1(X, x_0) \) and \( H = p_*(\pi_1(Y, y_0)) \). Let \( g_1, \ldots, g_k \) be coset representatives for \( G/H \). One can easily verify that the images of \( g_1, \ldots, g_k \) in \( G_{ab} \) have the property that \( G_{ab} = g_1 H_{ab} \cup \cdots \cup g_k H_{ab} \).} that \( p_*: \pi_1(Y, y_0)_{ab} \to \pi_1(X, x_0)_{ab} \) also has a finite cokernel. From the commutativity of the lower parallelogram it immediately follows that the map \( p_*: H_1(Y) \to H_1(X) \) has a finite cokernel as well. \( \blacksquare \)

**Exercises for Chapter 52**

**Exercise 52.1.** Let \( T = S^1 \times S^1 \) be the torus. Let \( \varphi, \psi: S^1 \to T \) be two smooth embeddings such that \( \varphi_*([S^1]) = \psi_*([S^1]) \in H_1(T) \). Show that \( \varphi \) and \( \psi \) are homotopic maps.

**Exercise 52.2.** Let \( A \in \text{SL}(2, \mathbb{Z}) \). Prove the following statements:

(a) If \( \text{tr}(A) = 2 \), then \( A \) is congruent over \( \mathbb{Z} \) to a matrix of the form \( \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \).

(b) If \( \text{tr}(A) = 2 \), then \( A \) is congruent over \( \mathbb{Z} \) to a matrix of the form \( \begin{pmatrix} -1 & * \\ 0 & -1 \end{pmatrix} \).

(c) If \( \text{tr}(A) \in (-2, 2) \), then \( A \) is a matrix of finite order in the group \( \text{SL}(2, \mathbb{Z}) \).

(d) If \( \text{tr}(A) \notin [-2, 2] \), then \( A \) has two real eigenvalues \( \lambda, \lambda^{-1} \) with \( |\lambda| > 1 \).

**Exercise 52.3.** Let \( A \in \text{SL}(2, \mathbb{Z}) \). We consider the map

\[
f(A): \mathbb{R}^2 / \mathbb{Z}^2 \to \mathbb{R}^2 / \mathbb{Z}^2 \\
[v] \mapsto [A \cdot v]
\]
and following the definition on page 711 we consider the corresponding mapping torus
\[ \text{Tor}(\mathbb{R}^2/S^2, f(A)) = ((\mathbb{R}^2/S^2) \times [0, 1])/(x, 0) \sim (f(A)(v), 1). \]
(a) Show that \( \text{Tor}(\mathbb{R}^2/S^2, f(A)) \) is a closed oriented 3-dimensional smooth manifold.
(b) Determine \( \text{rank}(\text{H}_1(\text{Tor}(\mathbb{R}^2/S^2, f(A))) \) and \( \text{H}_2(\text{Tor}(\mathbb{R}^2/S^2, f(A))) \) in terms of the classification of Exercise 52.2.
Remark. You might want to use Proposition 46.21 and Lemma 52.7.

Exercise 52.4. Let \( p: S^1 \times S^1 \to S^1 \) and \( q: S^1 \times S^1 \to S^1 \) be the projection onto the first respectively second factor and let \( \mu: S^1 \times S^1 \to S^1 \) be the multiplication map. Show that the following diagram commutes:
\[
\begin{array}{ccc}
\text{H}_1(S^1 \times S^1) & \xrightarrow{\mu_*} & \text{H}_1(S^1) \\
p_* \oplus q_* & \downarrow & (\varphi, \psi) \mapsto \varphi + \psi \\
\text{H}_1(S^1) \oplus \text{H}_1(S^1) & \xrightarrow{\text{H}_1(S^1) \oplus \text{H}_1(S^1)} & \\
\end{array}
\]

Exercise 52.5. Let \( X \) and \( Y \) be path-connected topological spaces. Let \( x \in X \) and let \( y \in Y \). We denote by \( i: X \to X \times Y \) the inclusion map that is given by \( i(x) = (x, y) \) and similarly we denote by \( j: Y \to X \times Y \) the inclusion map that is given by \( j(y) = (x, y) \). Furthermore we denote by \( p: X \times Y \to X \) and \( q: X \times Y \to Y \) the two natural projections. Show that the map
\[ i_* \oplus j_*: \text{H}_1(X) \oplus \text{H}_1(Y) \to \text{H}_1(X \times Y) \]
is an isomorphism and that the inverse is given by \( p_* \oplus q_* \).
Hint. Use Proposition 40.8.
53. THE HUREWICZ THEOREM IN HIGHER DIMENSIONS

The goal of this chapter is to formulate and prove the high-dimensional analogue of the Hurewicz Theorem \[\text{52.5}\] from Chapter \[\text{52}\]. Furthermore in this chapter and in Chapter \[\text{54}\] we will discuss several applications of the higher-dimensional Hurewicz Theorem.

53.1. The Hurewicz homomorphism in higher dimensions. The Hurewicz Theorem \[\text{52.5}\] evidently raises the question whether there is a connection between higher homotopy groups and higher homology groups. As in the 1-dimensional case we first try to find a promising map from homotopy groups to homology groups.

Throughout the subsequent discussion the following notation is convenient.

**Notation.** We write \( I = [0,1] \).

Next we introduce the following technical definition.

**Definition.** Let \( n \in \mathbb{N}_0 \), let \( \omega \in \text{H}_n(B^n,S^{n-1}) \) be the standard generator as defined on page \[1176\]. Let \( \phi: (I^n, \partial I^n) \rightarrow (B^n,S^{n-1}) \) be the homeomorphism from page \[126\]. We refer to \( \phi_\ast(\omega) \in \text{H}_n(I^n,\partial I^n) \) as the standard generator of \( \text{H}_n(I^n,\partial I^n) \).

Now comes the actual definition we are interested in.

**Definition.** Let \( X \) be a topological space, let \( x_0 \in X \) and let \( n \geq 1 \). We denote by \( \omega \in \text{H}_n(I^n,\partial I^n) \) the standard generator as defined above. We refer to the map

\[
\Phi_{(X,x_0)}: \pi_n(X,x_0) \rightarrow \text{H}_n(X,x_0) \quad [f: (I^n, \partial I^n) \rightarrow (X,x_0)] \mapsto f_\ast(\omega)
\]
as the Hurewicz homomorphism.\[813\]

**Remark.** It follows quite easily from the explicit description of the standard generator of \( \text{H}_1(B^1,S^0) \) on page \[1176\] that for \( n = 1 \) the above definition of the Hurewicz homomorphism agrees with the definition given on page \[1314\].

In the next lemma we show in particular that the Hurewicz homomorphism is in fact a homomorphism.

**Lemma 53.1.**

(1) Let \( X \) be a topological space, let \( x_0 \in X \) and let \( n \geq 1 \). The Hurewicz homomorphism

\[
\Phi_{(X,x_0)}: \pi_n(X,x_0) \rightarrow \text{H}_n(X)
\]
is a homomorphism.

\[813\] It follows from Proposition \[42.5\] that the Hurewicz homomorphism is indeed well-defined.
(2) Let \( X \) be a topological space and let \( n \geq 1 \). Furthermore let \( \gamma : I \to X \) be a path from a point \( x_0 \) to some point \( x_1 \). The following diagram commutes:

\[
\begin{array}{ccc}
\pi_n(X, x_1) & \xrightarrow{\Phi_{(x, x_1)}} & H_n(X) \\
\gamma^* & \downarrow & \downarrow \text{id} \\
\pi_n(X, x_0) & \xrightarrow{\Phi_{(x, x_0)}} & H_n(X).
\end{array}
\]

Here the vertical maps are defined in Propositions 14.11 and 40.5.

(3) As usual let \( \text{PTop} \) be the category of pointed topological spaces and let \( \text{Gr} \) be the category of groups. The Hurewicz homomorphisms define a natural transformation from the functor

\[
\begin{align*}
\text{PTop} & \to \text{Gr} \\
(X, x_0) & \mapsto \pi_n(X, x_0) \\
\text{PTop} & \to \text{Gr} \\
(X, x_0) & \mapsto H_n(X).
\end{align*}
\]

(4) Let \( X \) be a topological space, let \( x_0 \in X \) and let \( n \geq 1 \). If we take the point of view from page 1059, i.e. if we view elements in \( \pi_n(X, x_0) \) as homotopy classes of maps \( (S^n, *) \to (X, x_0) \), then the Hurewicz homomorphism is given by the map

\[
\pi_n(X, x_0) \to H_n(X)
\]

\[
[f : (S^n, *) \to (X, x_0)] \mapsto f_*(\omega)
\]

where \( \omega \in H_n(S^n) \) is the standard generator as defined on page 1174.

Proof. (\( \ast \)).

(1) We denote by \( \omega \in H_n(I^n, \partial I^n) \) the standard generator. We need to show that for any two maps \( f, g : (I^n, \partial I^n) \to (X, x_0) \) we have

\[
[f_*(\omega)] + [g_*(\omega)] = [(f * g)_*(\omega)] \in H_n(X, x_0).
\]

But we showed precisely this equality in Lemma 47.12.

(2) Let \( f : (S^n, *) \to (X, x_1) \) be a map. One easily sees that \( f \) and \( f^* \), viewed as maps \( S^n \to X \) are homotopic. Thus it follows from Proposition 42.5 that \( f_*(\omega) = (f^*)_*(\omega) \).

But this means precisely that the given diagram commutes.

(3) This statement follows immediately from the functoriality of homology groups.

(4) This statement is a straightforward consequence of Proposition 45.5 (3). \( \blacksquare \)

The following lemma gives in particular an affirmative answer to Question 40.17.

**Lemma 53.2.** For every \( n \in \mathbb{N} \) the Hurewicz homomorphism

\[
\Phi : \pi_n(S^n, *) \to H_n(S^n) \cong \mathbb{Z}
\]

sends \( [\text{id}_{S^n} : S^n \to S^n] \in \pi_n(S^n) \) to the standard generator of \( H_n(S^n) \), in particular the Hurewicz homomorphism is an epimorphism.

Proof. We denote by \( \omega \in H_n(S^n) \) the standard generator. By Lemma 53.1 (4) we have

\[
\Phi([\text{id}_{S^n} : S^n \to S^n]) = (\text{id}_{S^n})_*([\omega]) = [\omega].
\]
Thus we see that the standard generator of $H_n(S^n) \cong \mathbb{Z}$ lies in the image of the Hurewicz homomorphism. But this implies that the Hurewicz homomorphism $\Phi: \pi_n(S^n, \ast) \to H_n(S^n)$ is an epimorphism.

The fairly simple-minded Lemma 53.2 actually already turns out to be quite useful. More precisely, we recall that for $A = \mathbb{R}$ or $A = \mathbb{C}$ and $k \leq l$ we can view $\mathbb{A}P^k$ as a submanifold of $\mathbb{A}P^l$. Now we can formulate the following application of Lemma 53.2.

**Lemma 53.3.** For $k < l$ the submanifold $\mathbb{R}P^k$ is not a retract of $\mathbb{R}P^l$.

**Proof.** We have

$$\pi_k(\mathbb{R}P^k) \cong \pi_k(S^k) \neq 0 \quad \text{and} \quad \pi_k(\mathbb{R}P^l) \cong \pi_k(S^l) = 0.$$  

With this calculation, and the fact that $\pi_n$ is functorial, the argument of Lemma 15.7 can be easily modified to show that $\mathbb{R}P^k$ is not a retract of $\mathbb{R}P^l$.

Lemma 53.3 raises the following question.

**Question 53.4.** Let $k < l$. Is the complex projective space $\mathbb{C}P^k$ a retract of $\mathbb{C}P^l$?

At this moment though, it is much more interesting to ask whether, given a path-connected topological space $X$ and $n \geq 2$, the Hurewicz homomorphism

$$\Phi_{(X,x_0)}: \pi_n(X,x_0) \to H_n(X)$$

is necessarily an isomorphism. But browsing through our examples shows that the Hurewicz homomorphism is in general neither a monomorphism nor an isomorphism:

1. In Lemma 46.12 we showed that $H_2(S^1 \times S^1) \cong \mathbb{Z}$ is non-zero, whereas on page 1068 we showed that $\pi_2(S^1 \times S^1) = 0$. This shows that the Hurewicz homomorphism $\pi_2(S^1 \times S^1) \to H_2(S^1 \times S^1)$ is not an epimorphism.
2. Here are two examples that show that in general the Hurewicz homomorphism is not a monomorphism:
   a. We consider $X = \mathbb{R}P^2$. By Proposition 40.13 and Lemma 53.2 we know that $\pi_2(\mathbb{R}P^2) \cong \pi_2(S^2)$ is non-trivial. On the other hand we saw in Lemma 46.9 that $H_2(\mathbb{R}P^2) = 0$.
   b. We consider $X = S^1 \vee S^2$. It follows immediately from Propositions 43.4 and 47.8 that $H_2(S^1 \vee S^2) \cong \mathbb{Z}$. On the other hand we know by Proposition 40.13 and the discussion on page 836 that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\pi_2(\tilde{X})$ where $\tilde{X}$ is the real line “with infinitely many 2-spheres attached”, see e.g. Figure 690 for an illustration. Using the projections onto the various spheres and using Lemma 53.2 one can now show that $\pi_2(\tilde{X})$ admits an epimorphism onto $\mathbb{Z}^\infty$. It follows from Lemma 19.8 (2) that there is no monomorphism from $\pi_2(X) = \pi_2(\tilde{X})$ into $H_2(X) \cong \mathbb{Z}$. In particular the Hurewicz homomorphism $\pi_2(X) \to H_2(X)$, whatever it is precisely, cannot be a monomorphism.

---

814 The proof of this statement is a slight variation on the proof of Exercise 40.3.
The above examples show that we need to put some hypothesis on $X$ for a higher Hurewicz homomorphism to be an isomorphism. This leads us to the following definition.

**Definition.** Let $k \in \mathbb{N}_0$. We say that a topological space $X$ is $k$-connected, if $\pi_i(X) = 0$ for $i = 0, \ldots, k$.

The goal of this chapter is to prove the following theorem which can be viewed as the high-dimensional analogue of the original Hurewicz Theorem 52.5.

**Theorem 53.5. (Hurewicz Theorem)** Let $(X, x_0)$ be a pointed topological space. Furthermore let $n \in \mathbb{N}_{\geq 2}$. If $X$ is $(n-1)$-connected then the following two statements hold:

1. we have $\tilde{H}_k(X; \mathbb{Z}) = 0$ for $k = 0, \ldots, n-1$, and
2. the Hurewicz homomorphism $\Phi_{(X,x_0)} : \pi_n(X,x_0) \to H_n(X; \mathbb{Z})$ is an isomorphism.

**Remark.** On page 1326 we already saw that in general the hypothesis in the Hurewicz Theorem 53.5 that $X$ is $(n-1)$-connected cannot be dropped.

Using the Hurewicz Theorem 53.5 we can now determine some homotopy groups that had been eluding us for a long time.

**Corollary 53.6.**

1. For any $n \in \mathbb{N}$ we have $\pi_n(S^n) \cong \mathbb{Z}$, in fact $\pi_n(S^n, *) = \mathbb{Z} \cdot [id_{S^n}]$.
2. For any $n \in \mathbb{N} \cup \{\infty\}$ we have $\pi_2(\mathbb{C}P^n) \cong \mathbb{Z}$. In fact, if we make the identification $\mathbb{C}P^1 = S^2$ from page 197 and if we use the convention from page 194 to consider $\mathbb{C}P^1 = S^2$ as a subset of $\mathbb{C}P^n$, then $\pi_2(\mathbb{C}P^n, *) = \mathbb{Z} \cdot [id_{\mathbb{C}P^1}]$.

**Proof.**

1. Let $n \in \mathbb{N}$. By Proposition 40.10 we know that $S^n$ is $(n-1)$-connected. Thus the statement follows immediately from the Hurewicz Theorems 52.5 and 53.5 and the fact that $H_n(S^n; \mathbb{Z}) = \mathbb{Z} \cdot [S^n]$.
2. Let $n \in \mathbb{N} \cup \{\infty\}$. We denote by $i : \mathbb{C}P^1 \to \mathbb{C}P^n$ the obvious inclusion. From Lemma 53.1 (3) we obtain the following commutative diagram

\[
\begin{array}{ccc}
\pi_2(\mathbb{C}P^1, *) & \xrightarrow{i_*} & \pi_2(\mathbb{C}P^n, *) \\
\Phi_{(\mathbb{C}P^1, *)} & \downarrow & \Phi_{(\mathbb{C}P^n, *)} \\
H_2(\mathbb{C}P^1; \mathbb{Z}) & \xrightarrow{i_*} & H_2(\mathbb{C}P^n; \mathbb{Z}).
\end{array}
\]

If $n \in \mathbb{N}$, then it follows immediately from Lemma 90.6 that the inclusion induced map $H_2(\mathbb{C}P^1; \mathbb{Z}) \to H_2(\mathbb{C}P^n; \mathbb{Z})$ is an isomorphism. For $n = \infty$ we need to appeal to the discussion on page 1263 to draw the same conclusion. Finally, since $[\mathbb{C}P^1] = [S^2]$

---

815 For example, $X$ is 0-connected if and only if $X$ is path-connected and non-empty. Furthermore, $X$ is 1-connected if and only if it is simply connected.

816 Since a $k$-connected topological space is in particularly 0-connected and thus path-connected we see that we can ignore base points.

817 Recall that by the definition on page 1327 this means that $\pi_i(X) = 0$ for $i = 0, \ldots, n-1$. 

is a generator of $H_2(\mathbb{CP}^1; \mathbb{Z}) = H_2(S^2; \mathbb{Z})$ we obtain that $\pi_2(\mathbb{CP}^n, \ast) = \mathbb{Z} \cdot [\text{id}_{\mathbb{CP}^1}]$ from the above commutative diagram. $
abla$

On several occasions we will also need the following straightforward corollary to the Hurewicz Theorem 53.5.

**Corollary 53.7.** Let $(X, x_0)$ be a pointed topological space and let $n \in \mathbb{N}$. We suppose that $X$ is simply connected. If given every $k \in \{2, \ldots, n\}$ we have $\pi_k(X, x_0) = 0$ or $H_k(X; \mathbb{Z}) = 0$, then the following two statements hold:

1. for $k = 1, \ldots, n$ we have $\pi_k(X, x_0) = H_k(X; \mathbb{Z}) = 0$,  
2. the Hurewicz homomorphism $\pi_{n+1}(X, x_0) \to H_{n+1}(X; \mathbb{Z})$ is an isomorphism.

**Proof.** We prove the corollary by induction on $n$. First consider the case $n = 1$. Since $X$ is simply connected we obtain from the Hurewicz Theorem 52.5 that $H_1(X; \mathbb{Z}) = 0$. Furthermore it follows from the Hurewicz Theorem 53.5 that $\Phi_{(X, x_0)}: \pi_2(X, x_0) \to H_2(X; \mathbb{Z})$ is an isomorphism. 

Now suppose the statement holds for $n - 1$ with $n \geq 2$. Suppose that for every $k \in \{2, \ldots, n\}$ we have $\pi_k(X, x_0) = 0$ or $H_k(X; \mathbb{Z}) = 0$. By induction we know that the homotopy and homology groups vanish up to degree $n - 1$. Thus we can apply the Hurewicz Theorem 53.5 which says that $\pi_n(X)$ and $H_n(X; \mathbb{Z})$ are isomorphic. Since one is zero, both are zero. Hence we can apply the Hurewicz Theorem 53.5 once more to see that the Hurewicz homomorphism $\pi_{n+1}(X, x_0) \to H_{n+1}(X; \mathbb{Z})$ is an isomorphism. $
abla$

As a nice application to Corollary 53.7 we can prove the following lemma.

**Lemma 53.8.** Let $X$ be a 1-dimensional CW-complex and let $x_0 \in X$ be base point. Then $\pi_n(X, x_0) = 0$ for every $n \geq 2$.

The content of this lemma is the same as for Lemma 40.15, the only difference is that this time the proof is more satisfying than before.

**Proof.** Let $X$ be a 1-dimensional CW-complex, let $n \geq 2$ and let $x_0 \in X$ be a base point. If necessary we can replace $X$ by the path-component of $x_0$. In other words, without loss of generality we can assume that $X$ is path-connected. We denote by $\tilde{X}$ the universal covering of $X$. By Proposition 36.37 we know that $\tilde{X}$ is again a 1-dimensional CW-complex. It follows from Proposition 48.5 (1) that $H_n(\tilde{X}) = 0$ for all $n \in \mathbb{N}_{\geq 2}$. Furthermore, by definition of a universal covering we know that $\tilde{X}$ is simply connected. It follows from Corollary 53.7 that $\pi_n(X, x_0) = 0$ for every $n \geq 2$. $
abla$

We conclude this section with the following proposition.

**Proposition 53.9.** Let $n \in \mathbb{N}$ and let $f: S^n \to S^n$ be a homeomorphism with $f(\ast) = \ast$. Then the following equality holds in $\pi_n(S^n, \ast)$:

$[f] = \begin{cases} 
[\text{id}_{S^n}], & \text{if } f \text{ is orientation-preserving}, \\
- [\text{id}_{S^n}], & \text{if } f \text{ is orientation-reversing}.
\end{cases}$

**Remark.** Let $n \in \mathbb{N}$. Proposition 53.9 says that every orientation-preserving self-homeomorphism $f$ of $S^n$ with $f(\ast) = \ast$ is homotopic, rel the base point $\ast$, to the identity. It is not
clear to me whether $f$ is isotopic, rel the base point $*$, to the identity. Put differently, can one find a homotopy $F$ from $f$ to id such that each $F_t: S^n \to S^n$ is also a homeomorphism?

**Proof.** Let $n \in \mathbb{N}$ and let $f: S^n \to S^n$ be a homeomorphism with $f(*) = *$. By the naturality of the Hurewicz homomorphism, see Lemma 53.1 (3), we have the following commutative diagram

$$
\begin{array}{c}
\pi_n(S^n, *) \\
\downarrow \Phi(S^n, *) \\
H_n(S^n; \mathbb{Z})
\end{array}
\xrightarrow{f_*} 
\begin{array}{c}
\pi_n(S^n, *) \\
\downarrow \Phi(S^n, *) \\
H_n(S^n; \mathbb{Z}).
\end{array}
$$

By Proposition 40.10 we know that $S^n$ is $(n-1)$-connected. Therefore the vertical maps are isomorphisms by the Hurewicz Theorems 52.5 and 53.5. The corollary now follows from Proposition 72.2 and the simple observation that $[f] = f_*([id_{S^n}]) \in \pi_n(S^n, *)$. \hfill \blacksquare

Now that we are fully convinced of the value of the Hurewicz Theorem 53.5 we turn to the proof thereof. We will discuss more applications in the Chapter 54.

### 53.2. The group structure on $\pi_n(X, x_0)$.

Before we turn to the formulation of the high-dimensional Hurewicz Theorem we want to recall some conventions regarding higher homotopy groups and we want to introduce a useful approach to understanding the sum operation in the higher homotopy groups.

First we recall some conventions and notations that apply to any $n \in \mathbb{N}$.

1. We write $* = (0, \ldots, 0, 1) \in S^n$.
2. We write $I = [0, 1]$.
3. We denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$.
4. We denote by $\partial I^n$ the boundary of $I^n$ viewed as a subset of $\mathbb{R}^n$.
5. Let $\varphi: (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 126.
6. Let $\psi: (\overline{B}^n, S^{n-1}) \to (S^n, *)$ be the map from page 182 that induces the usual identification $\overline{B}^n/S^{n-1} \to S^n$.
7. As on page 1059 we use $\varphi$ and $\psi$ to make the identifications

$$
\pi_n(X, x_0) = \frac{\text{set (of homotopy classes) of maps } (I^n, \partial I^n) \to (X, x_0)}{\text{set (of homotopy classes) of maps } (S^n, *) \to (X, x_0)} = \frac{\text{set (of homotopy classes) of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0)}{\text{set (of homotopy classes) of maps } (S^n, *) \to (X, x_0)}.
$$

The maps $\varphi$ and $\psi$ are illustrated in Figure 823.
Now let \((X, x_0)\) be a pointed topological space and let \(n \in \mathbb{N}\). Recall that on page 1055 we defined the group structure on \(\pi_n(X, x_0)\) by considering elements in the homotopy groups as homotopy classes of maps \((I^n, \partial I^n) \to (X, x_0)\). Under the above identifications it is at times difficult to see what the group structure actually looks like. We start out with considering inverses of homotopy classes.

**Lemma 53.10.** Let \(n \in \mathbb{N}\) and let \((X, x_0)\) be a pointed topological space.

1. Let \(f: (B^n, S^{n-1}) \to (X, x_0)\) be a map. If \(\rho: B^n \to B^n\) is the reflection in some hyperplane of \(\mathbb{R}^n\), then \(-[f] = [f \circ \rho] \in \pi_n(X, x_0)\).

2. Let \(f: (S^n, \ast) \to (X, x_0)\) be some map. If \(\rho: S^n \to S^n\) is the reflection in some hyperplane of \(\mathbb{R}^{n+1}\) that contains the binormal \(\mathbb{R} \cdot (0, \ldots, 0, 1)\), then we have the equality \(-[f] = [f \circ \rho] \in \pi_n(X, x_0)\).

**Proof** (*).

1. Let \(\varphi: (I^n, \partial I^n) \to (B^n, S^{n-1})\) be the homeomorphism from page 126 that we use to identify the two different points of view regarding the homotopy group \(\pi_n(X, x_0)\). It follows from Proposition 40.1(2) and from considering the definition of \(\rho\) that if \(\rho\) is the reflection in the \((x_2 = 0)\)-hyperplane, then \(-[f] = [f \circ \rho]\). If \(\psi\) is the reflection in some other hyperplane, then it follows from Lemma 18.3 that \(\psi\) and \(\rho\) are homotopic as maps \((B^n, S^{n-1}) \to (B^n, S^{n-1})\). But this observation implies \([f \circ \psi] = [f \circ \rho]\) and thus we see that \([f \circ \psi] = -[f]\).

2. This statement follows easily from statement (1) and from considering the map \(\psi: (B^n, S^{n-1}) \to (S^n, \ast)\) from page 182 that we use to identify the two different points of view regarding the homotopy group \(\pi_n(X, x_0)\).

To consider the group structure on the higher homotopy groups we need the following new and fairly harmless definition.

**Definition.** Let \(n \in \mathbb{N}\) and let \(M\) be an \(n\)-dimensional topological manifold.

1. We say embeddings \(\alpha_1, \ldots, \alpha_m: B^n \to M\) are (weakly) disjoint if the images (of the interiors) do not intersect.

2. Let \(X\) be a topological space and let \(x_0 \in X\). Given weakly disjoint embeddings \(\alpha_1, \ldots, \alpha_m: B^n \to M\) and maps \(f_1, \ldots, f_m: (B^n, S^{n-1}) \to (X, x_0)\) we define \(\Phi(\alpha_1, \ldots, \alpha_m, f_1, \ldots, f_m): M \to X\)

\[
y \mapsto \begin{cases} f_i(z), & \text{if } y = \alpha_i(z) \text{ with } z \in B^n, \\ x_0, & \text{otherwise.} \end{cases}
\]

The definition of this map is illustrated in Figure 824.

The following proposition gives a versatile tool for dealing with the group structure.

---

818 We can only consider such reflections since the point \(\ast = (0, \ldots, 0, 1)\) needs to be fixed.
819 Note that \(\rho(\ast) = \ast\), hence \((f \circ \rho)(\ast) = x_0\).
820 We refer to page 432 for the definition of an embedding. As discussed on page 433, a smooth embedding of a smooth manifold in the sense of the definition on page 342 is indeed an embedding.
821 It follows from Lemmata 2.40 and 2.17, 6.28 and Lemma 2.35(2) that this map is indeed continuous.
Proposition 53.11. Let \((X, x_0)\) be a pointed topological space and let \(n \in \mathbb{N}_{\geq 2}\). Suppose we are given weakly disjoint smooth embeddings \(\bar{B}^n \to S^n\) such that the images of the \(B^n\) lie in \(S^n \setminus \{\ast\}\). Also suppose we are given maps \(f_1, \ldots, f_m : (\bar{B}^n, S^{n-1}) \to (X, x_0)\). Given \(i \in \{1, \ldots, m\}\) we write \(\epsilon_i = 1\) if \(\alpha_i\) is orientation-preserving otherwise we write \(\epsilon_i = -1\). Then we have the following equality in \(\pi_n(X, x_0)\):

\[
\left[ \Phi(\alpha_1, \ldots, \alpha_m, f_1, \ldots, f_m) : (S^n, \ast) \to (X, x_0) \right] = \sum_{i=1}^{m} \epsilon_i \cdot \left[ f_i : (\bar{B}^n, S^{n-1}) \to (X, x_0) \right].
\]

Example. A slight modification of the map \(\bar{B}^2 \to S^1\) given on page 182 provides us with an orientation-preserving smooth embedding \(\alpha_1 : \bar{B}^2 \to S^2\) that sends the disk to the “left hemisphere”. Similarly we also obtain an orientation-preserving smooth embedding \(\alpha_2 : \bar{B}^2 \to S^2\) that sends the disk to the “right hemisphere”. It follows from Proposition 53.11 that for any two maps \(f_1, f_2 : (\bar{B}^2, S^1) \to (X, x_0)\) we have

\[
[\Phi(\alpha_1, \alpha_2, f_1, f_2) : (S^2, \ast) \to (X, x_0)] = [f_1 : (\bar{B}^2, S^1) \to (X, x_0)] + [f_2 : (\bar{B}^2, S^1) \to (X, x_0)].
\]

This situation is illustrated in Figure 825. We obtain basically the same picture as we had already obtained on page 1060.

Remark. The statement of Proposition 53.11 also holds for embeddings, i.e. we do not necessarily need that the embeddings are smooth. But in that case, in the proof below, one needs to replace the mainstream Theorem 8.36 by the surprisingly difficult Theorem 100.10

\(^{822}\)Note that here we work on purpose with “smooth embeddings” instead of “embeddings”.

---

**Figure 824**

**Figure 825**
In particular it is not clear to me what goes into the proof of Theorem 100.10 (does it require the Hurewicz Theorem, are we in danger of using circular logic?). Therefore I prefer to stick to smooth embeddings.\footnote{Recall that the absence of the word “topological” implies in our setup that smooth embeddings are smooth maps.}

In the proof of Proposition 53.11 we need the following lemma which basically says the following: if we isotope the embeddings $\alpha_i$, then the resulting $\Phi$-maps are homotopic.

\textbf{Lemma 53.12. (\ast)} Let $n \in \mathbb{N}$, let $M$ be an $n$-dimensional smooth manifold and let $Z$ be a subset of $M$. Furthermore suppose we are given a topological space $X$, a base point $x_0 \in X$ and maps $f_1, \ldots, f_m: (\overline{B^n}, S^{n-1}) \to (X, x_0)$. Finally suppose that for $i = 1, \ldots, m$ we are given homotopies
\[ \Omega_i: \overline{B^n} \times [0, 1] \to M \setminus Z \]
such that for each $t \in [0, 1]$ the maps $\Omega_{1,t}, \ldots, \Omega_{m,t}: \overline{B^n} \to M$ are weakly disjoint embeddings, then the maps
\[ \Phi(\Omega_{1,0}, \ldots, \Omega_{m,0}, f_1, \ldots, f_m), \Phi(\Omega_{1,1}, \ldots, \Omega_{m,1}, f_1, \ldots, f_m): (M, Z) \to (X, x_0) \]
are homotopic as maps of pairs of topological spaces.

\textbf{Proof (\ast).} As before it follows from Lemmas 2.40 and 2.17 Lemma 6.28 and Lemma 3.10 that the map
\[ H: M \times [0, 1] \to X \]
\[ (P,t) \mapsto \Phi(\Omega_{1,t}, \ldots, \Omega_{m,t}, f_1, \ldots, f_m)(P) \]
is continuous. This map is then the desired homotopy. \hfill \blacksquare

\textbf{Sketch of a proof of Proposition 53.11 (\ast).} Let $(X, x_0)$ be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $f_1, \ldots, f_m: (\overline{B^n}, S^{n-1}) \to (X, x_0)$ be maps. Finally let $\alpha_1, \ldots, \alpha_m: \overline{B^n} \to S^n$ be weakly disjoint smooth embeddings such that the images of the $B^n$ lie in $S^n \setminus \{\ast\}$. We start out with the following observations:

1. Let $\rho: \overline{B^n} \to \overline{B^n}$ be the reflection in some hyperplane of $\mathbb{R}^n$. We replace every pair $(\alpha_i, f_i)$ for which $\alpha_i$ is orientation-reversing by the pair $(\alpha_i \circ \rho, f_i \circ \rho)$. It follows immediately from Lemma 53.10 that the desired equality holds for the new data if and only if it holds for the old data.

2. If the $\alpha_i$ are not disjoint we make them disjoint by shrinking. More precisely, we consider the isotopies
\[ F_i: \overline{B^n} \times [0, 1] \to M \]
\[ (P,t) \mapsto \alpha_i(P \cdot (1 - t)) \]
Since the $\alpha_i$ were weakly disjoint we see that the resulting embeddings are now disjoint.

3. The map $(\overline{B^n}, S^{n-1}) \to (S^n, \{\ast\})$ that we gave on page 182 restricts to a diffeomorphism $\overline{B^n} \to S^n \setminus \{\ast\}$. 
Keeping the above three observations in mind we obtain from Lemma 53.12 that it suffices to prove the following statement.

**Statement.** If \( \alpha_1, \ldots, \alpha_m : B^n \to B^n \) are disjoint orientation-preserving smooth embeddings, then the following equality holds in \( \pi_n(X, x_0) \):

\[
\left[ \Phi(\alpha_1, \ldots, \alpha_m, f_1, \ldots, f_m) : (B^n, S^{n-1}) \to (X, x_0) \right] = \sum_{i=1}^{m} \left[ f_i : (B^n, S^{n-1}) \to (X, x_0) \right].
\]

Perhaps the key observation in the proof is that Theorem 8.36 (where we use our hypothesis that \( n \geq 2 \) and here we use that work with smooth embeddings not just embeddings of balls) together with Lemma 53.12 implies that we only need to prove the statement for a single choice of disjoint orientation-preserving smooth embeddings \( \alpha_1, \ldots, \alpha_m \). Put differently, it remains to prove the following claim.

**Claim.** There are disjoint orientation-preserving smooth embeddings \( \alpha_1, \ldots, \alpha_m : B^n \to B^n \) such that

\[
\left[ \Phi(\alpha_1, \ldots, \alpha_m, f_1, \ldots, f_m) : (B^n, S^{n-1}) \to (X, x_0) \right] = \sum_{i=1}^{m} \left[ f_i : (B^n, S^{n-1}) \to (X, x_0) \right].
\]

By induction it suffices prove the claim for \( m = 2 \). Even your famously verbose author does not feel like spelling out all the details. We leave it to the reader to piece together the argument using Figure 826 and the following observations:

(a) by Proposition 53.11 (or alternatively Lemma 40.2) we can “move cubes” in \( I^n \),
(b) by Lemma 18.2 the map \( \varphi^{-1} : B^n \to I^n \) is isotopic to the identity,
(c) the restriction of the map \( \varphi : I^n \to B^n \) to each open cone on one of the sides of the cube \( I^n \) is smooth.

Using Lemma 53.12 these moves translate into homotopies of the corresponding maps. ■

53.3. **The proof of the Hurewicz Theorem 53.5.** The proof of the Hurewicz Theorem 53.5 requires some preparations.

**Convention.** Let \( k \in \mathbb{N}_0 \). We view \( \Delta^k \) as a CW-complex in the following way. Given \( m \in \{0, \ldots, k\} \) the \( m \)-cells correspond precisely to all the maps

\[
B^m = \Delta^m \to \Delta^k \quad (t_0, \ldots, t_m) \mapsto \sum_{i=0}^{m} t_i e_{\varphi(i)}
\]

where \( \varphi \) is a strictly increasing map \( \varphi : \{0, \ldots, m\} \to \{0, \ldots, k\} \). Note that the \( (k-1) \)-skeleton of \( \Delta^k \) is given by \( \partial \Delta^k \).

**Definition.** Let \((X, x_0)\) be a pointed topological space and let \( n \in \mathbb{N}_0 \). Given \( k \in \mathbb{N}_0 \) we define

\[
C_k^{(n)}(X, x_0) := \text{the subgroup of the relative chain group } C_k(X, \{x_0\}) \text{ generated by all singular simplices } \sigma : \Delta^k \to X \text{ with } \sigma(n\text{-skeleton of } \Delta^k) \subset \{x_0\}.
\]
hit seems reasonable to expect that π-homology groups H_n(X,x) 0 are close to elements in π_n(X,x). In particular it seems reasonable to expect that H_{n-1}(X,x) is a group that “sits between” H_n(X;Z) and π_n(X,x).

Example. In Figure 828 we show a pointed topological space (X,x) and we consider an element σ ∈ C^{(0)}_1(X,x) and an element τ ∈ C^{(1)}_2(X,x). From the pictures it becomes apparent that elements in C^{(n-1)}_n(X,x) are “close” to elements in π_n(X,x). In particular it seems reasonable to expect that H^{(n-1)}_n(X,x) is a group that “sits between” H_n(X;Z) and π_n(X,x).

Note that the notation C^{(n)}_k(X,x) instead of C^{(n)}_k(X,x) is on purpose.
In the following lemma we summarize a few basic facts about these new chain groups.

**Lemma 53.13.** Let \((X,x_0)\) be a pointed topological space and let \(n \in \mathbb{N}_0\). Furthermore let \(k \in \{0, \ldots, n\}\). The following statements hold:

1. We have \(C^{(n)}_k(X,x_0) = 0\),
2. we have \(H^{(n)}_k(X,x_0) = 0\),
3. any element in \(C^{(n)}_{k+1}(X,x_0)\) is a cycle.

**Proof.** Let \(k \in \{0, \ldots, n\}\). Put differently, we have \(k \leq n\). Note that this implies that \(\Delta^k\) is the \(n\)-skeleton of \(\Delta^k\). In particular, by definition, \(C^{(n)}_k(X,x_0)\) is the subgroup of \(C_k(X,\{x_0\})\) generated by the constant maps \(\Delta^k \to \{x_0\}\), but these are zero in the relative chain group \(C_k(X,\{x_0\})\). This concludes the proof of (1). The remaining two statements are immediate consequences of (1).

The following lemma is one of the key ingredients in the proof of the Hurewicz Theorem 53.5

**Lemma 53.14.** Let \((X,x_0)\) be a pointed topological space and let \(n \in \mathbb{N}\). If \(X\) is \(n\)-connected, then the inclusion map

\[
C^{(n)}_*(X,x_0) \to C_*(X,\{x_0\})
\]

is a chain homotopy equivalence. In particular for any \(k \in \mathbb{N}_0\) the induced map

\[
H^{(n)}_k(X,x_0) \to H_k(X,\{x_0\})
\]

is an isomorphism.

**Proof.** Let \((X,x_0)\) be a pointed topological space and let \(n \in \mathbb{N}\). We suppose that \(X\) is \(n\)-connected. We recall the following notation from Lemma 42.6: given \(t = 0\) and \(t = 1\) and \(k \in \mathbb{N}_0\) we denote by

\[
\eta : \Delta^k \to \Delta^k \times [0,1] \\
x \mapsto (x,t)
\]

the obvious inclusion map. We start out with the following claim which basically says that any singular simplices \(\Delta^k \to X\) can be homotopied consistently to a singular simplices that lie in \(C^{(n)}_k(X,x_0)\).

**Claim.** Given any \(k \in \mathbb{N}_0\) and given any singular simplex \(\sigma : \Delta^k \to X\) we can choose a map \(P(\sigma) : \Delta^k \times [0,1] \to X\) such that the following four statements are satisfied:

(a) we have \(P(\sigma) \circ \eta_0 = \sigma : \Delta^k \to X\),
(b) the singular \(k\)-simplex \(P(\sigma) \circ \eta_1 : \Delta^k \to X\) lies in \(C^{(n)}_k(X,x_0)\),
(c) if \(\sigma \in C^{(n)}_k(X,x_0)\), then \(P(\sigma) = \sigma \circ \pi\) where \(\pi : \Delta^k \times [0,1] \to \Delta^k\) is the projection map, and
(d) for any \(j \in \{0, \ldots, k\}\) we have

\[
P(\sigma) \circ (i_j^k \times \text{id}_{[0,1]}) = P(\sigma \circ i_j^k) : \Delta^{k-1} \times [0,1] \to X.
\]
We turn to the proof of the claim. Property (d) already suggests that we should prove the claim by induction on \(k\). It is convenient to view \(k = -1\) as the (trivial) base case. Now let \(k \in \mathbb{N}_0\) and suppose that we have proved the claim for all singular \(i\)-simplices with \(i < k\). Now let \(\sigma : \Delta^k \to X\) be a singular simplex. If \(\sigma \in C^{(n)}_k(X, x_0)\), then we set \(P(\sigma) = \sigma \circ \pi\). In this case it is straightforward to verify that the conditions (a), (b) and (d) are satisfied.

Now consider the case that \(\sigma \notin C^{(n)}_k(X, x_0)\). We distinguish two cases.

1. First we consider the case that \(k \leq n\). By induction the maps \(P(\sigma \circ i^k_j)\) have been defined for all \(j\). We set \(\partial(\Delta^k \times [0, 1]) := (\partial \Delta^k \times [0, 1]) \cup (\Delta^k \times \{0\})\) and we consider the map

\[
Q : \partial(\Delta^k \times [0, 1]) \to X
\]

which is defined via \(\sigma\) on \(\Delta^k \times \{0\}\), via the maps \(P(\sigma \circ i^k_j)\) on \(\partial \Delta^k \times [0, 1]\) and which sends all points in \(\Delta^k \times \{1\}\) to \(x_0\). (We refer to Figure 829 for an illustration of this map.) It follows almost immediately from Proposition 2.52 (2) that the pair \((\Delta^k \times [0, 1], \partial(\Delta^k \times [0, 1]))\) is homeomorphic to \((\overline{B}^{k+1}, S^k)\). Since \(k \leq n\) and since \(X\) is \(n\)-connected we obtain from Lemma 40.4 that there exists an extension of \(Q\) to a map \(\Delta^k \times [0, 1] \to X\). We define \(P(\sigma)\) to be any such extension. We obtain a map \(P(\sigma)\) which is easily seen to have all the desired properties.

\[
\partial(\Delta^k \times [0, 1]) = (\partial \Delta^k \times [0, 1]) \cup (\Delta^k \times \{0\}) \cup (\Delta^k \times \{1\})
\]

![Figure 829](image)

2. Now we consider the case that \(k > n\). Note that in this case condition (b) is satisfied “for free” by any map \(\Delta^k \times [0, 1] \to X\) that satisfies (d). Thus we only have to find a map \(P(\sigma)\) that satisfies (a), (c) and (d). This is much easier than in (1). Indeed, similar to (1) we consider the map

\[
G : (\Delta^k \times \{0\}) \cup (\partial \Delta^k \times [0, 1]) \to X
\]

that is defined via \(\sigma\) on \(\Delta^k \times \{0\}\) and via the maps \(P(\sigma \circ i^k_j)\) on \(\partial \Delta^k \times [0, 1]\). (We refer to Figure 830 for an illustration.) Note that by Lemma 38.3 (together with the homeomorphism \(\overline{B}^k \cong \Delta^k\)) there exists a retraction \(r\) from \(\Delta^k \times [0, 1]\) to the domain of \(G\). Thus combining this retraction \(r\) with \(Q\) we obtain an extension of \(Q\).

---

825 Here we use that we assume that the maps \(P(\mu)\) are defined for simplices of dimension \(< k\).

826 It follows from Lemma 2.35 (2') that this map is indeed continuous.
to map $\Delta^k \times [0,1] \to X$. We define $P(\sigma)$ to be this extension. It follows basically by construction that all the statements are satisfied.

(\partial \Delta^k \times [0,1]) \cup (\Delta^k \times \{0\})

Now we turn to the actual proof of the statement that the inclusion map is a chain homotopy equivalence. To do so we consider the map

$\phi: C_*(X, \{x_0\}) \to C_*(X, \{x_0\})$

that is determined by

$$(\sigma: \Delta^n \to X) \mapsto \phi(\sigma) := P(\sigma) \circ \eta.$$ 

It follows from (b) that $\phi$ does indeed take values in $C_*(X, x_0)$ and it follows easily from (d) that $\phi$ is in fact a chain map. We want to show that $\phi$ is a chain homotopy inverse to $\iota$. By (c) we have $\phi \circ \iota = \text{id}$. Thus it remains to prove the following claim.

Claim. There exists a chain homotopy from $\iota \circ \phi$ to the identity of $C_*(X, \{x_0\})$.

Let $k \in \mathbb{N}_0$. We recall that on page 1099 we introduced the singular $(k+1)$-chain

$$\Omega_k := \sum_{j=0}^k (-1)^j \cdot [v_0, \ldots, v_j, w_j, \ldots, w_k] \in C_{k+1}(\Delta^k \times [0,1])$$

where $v_0, \ldots, v_k, w_0, \ldots, w_k$ denote the vertices of $\Delta^k \times [0,1]$, see page 1099 for details. The key property of these singular chains is that Lemma 42.6 says that for any $k \in \mathbb{N}_0$ we have

$$\partial_{k+1}(\Omega_k) + \sum_{j=0}^k (-1)^j \cdot (i_j^k \times \text{id}_{[0,1]})_* (\Omega_{k-1}) = \eta_{k-1} - \eta_0 \in C_k(\Delta^k \times [0,1]).$$

For any $k \in \mathbb{N}_0$ we consider the map

$D_k: C_k(X, \{x_0\}) \to C_{k+1}(X, \{x_0\})$

that is determined by

$$(\sigma: \Delta^k \to X) \mapsto (\sigma)_* (\Omega_k).$$

---

\[827\] Here and throughout the proof we do not distinguish in the notation between a singular chain in $C_k(X)$ and the element it represents in $C_k(X, \{x_0\})$. 
We claim that these maps define a chain homotopy from \( \iota \circ \phi \) to the identity of \( C_\ast(X, \{x_0\}) \). Thus let \( \sigma : \Delta^k \to X \) be a singular \( k \)-simplex. We need to show that \( \partial D \sigma + D \partial \sigma = \phi(\sigma) - \sigma \).

Indeed we have

\[
\partial_{k+1}(D_k(\sigma)) + D_{k-1}(\partial_k(\sigma)) = \partial_{k+1}(D_k(\sigma)) + D_{k-1}\left( \sum_{j=0}^{k} (-1)^j \cdot \sigma \circ t_j^{k} \right) \\
= \partial_{k+1}(P(\sigma)_* \Omega_k) + \sum_{j=0}^{k} (-1)^j \cdot P(\sigma \circ t_j^{k})_*(\Omega_{k-1}) \\
= P(\sigma)_* \left( \partial_{k+1}(\Omega_k) + \sum_{j=0}^{k} (-1)^j \cdot (t_j^{k} \times \text{id}_{[0,1]})_*(\Omega_{k-1}) \right) \\
\]

in the first summand we used that \( P(\sigma)_* \) is a chain map and in the second summand we used that by (d) we have \( P(t_j^{k} \circ \sigma) = P(\sigma) \circ (t_j^{k} \times \text{id}_{[0,1]}) \).

By the above equality (\( \ast \))

\[
\eta \in \mathcal{A} \\
\therefore \text{let } \phi \text{ to mak e the iden tication} \\
\text{Indeed we ha v e} \\
\text{Note that the comp osition of the rst t w o homeomorphisms is precisely the homeomorphism from} \\
\text{Lemma [41.1]} \\
\text{It follows from Lemma [3.32] (3) that such a matrix exists.} \\
\text{The map } \eta_n \text{ depends on the choice of the matrix } A_n, \text{ this will not affect us at all.} \\
\]

Before we can continue with the proof of the Hurewicz Theorem [53.5] we need to introduce another, slightly different point of view, regarding higher homotopy groups.

So let \( n \in \mathbb{N} \). We consider the homeomorphism \( \eta_n : (\Delta^n, \partial \Delta^n) \to (\overline{B}^n, S^{n-1}) \) that is given by the composition of the following three maps\( \text{[828]} \)

\[
\eta_n : \Delta^n \xrightarrow{\cong} \{(x_1, \ldots, x_n) \in [0,1]^n \left| \sum_{i=1}^{n} x_i \in [0,1] \right\} \xrightarrow{\text{Proposition 2.53 (2)}} \overline{B}^n \xrightarrow{\text{by } A_n} \overline{B}^n \\
(t_0, \ldots, t_n) \mapsto (t_0, \ldots, t_{n-1}) \\
\]

where \( A_n \in O(n) \) is a matrix which is chosen in such a way that we have the equality \( \eta_n((1,0,\ldots,0)) = * := (0,\ldots,0,1) \).\( \text{[829]} \)

We sketch the definition of \( \eta_n \) in Figure [831]

\[ z \quad \Delta^2 \quad \text{projection} \quad \approx \quad y \quad \{ (x,y) \in [0,1]^2 \mid x+y \in [0,1] \} \]

\[ x \]

\[ \xrightarrow{\text{applied to } Q = (\frac{1}{3}, \frac{1}{3})} \]

\[ \xrightarrow{\text{rotation}} \]

\[ \eta_2 \]

\[ \text{Figure 831} \]

We use the homeomorphism \( \eta_n : (\Delta^n, \partial \Delta^n) \to (\overline{B}^n, S^{n-1}) \) to identify these two pairs of topological spaces. In particular we use it to make the identification \( \partial \Delta^n = S^{n-1} \). By a slight abuse of notation we write \( * := (1,0,\ldots,0) \in \Delta^n \). In particular for any \( n \in \mathbb{N}_0 \)
we can extend the identifications from page 1329 to obtain the following identifications

\[
\pi_n(X, x_0) = \text{set (of homotopy classes)} \text{ of maps } (I^n, \partial I^n) \to (X, x_0) = \text{set (of homotopy classes)} \text{ of maps } (S^n, *) \to (X, x_0)
\]

\[
\text{set (of homotopy classes)} \text{ of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0) = \text{set (of homotopy classes)} \text{ of maps } (\partial \Delta^{n+1}, *) \to (X, x_0)
\]

\[
\text{set (of homotopy classes)} \text{ of maps } (\Delta^n, \partial \Delta^n) \to (X, x_0).
\]

As above we will use these identifications to pick at each given moment our most convenient point of view.

As an illustration, under the above identifications Lemma 40.4 translates into the following lemma.

**Lemma 53.15.** Let \((X, x_0)\) be a pointed topological space and let \(n \geq 1\). Furthermore let \(f: (\partial \Delta^{n+1}, *) \to (X, x_0)\) be a map. Then \(f\) represents the trivial element in \(\pi_n(X, x_0)\) if and only if there exists a map \(F: \Delta^{n+1} \to X\) so that \(F|_{\partial \Delta^{n+1}} = f\).

The following lemma is the other key technical ingredient in the proof of the Hurewicz Theorem 53.5.

**Lemma 53.16.** Let \((X, x_0)\) be a pointed topological space and let \(n \in \mathbb{N}_{\geq 2}\). Furthermore let \(\sigma: \partial \Delta^{n+1} \to X\) be a map that sends the \((n-1)\)-skeleton of \(\partial \Delta^{n+1}\) to \(x_0\). Then

\[
[\sigma: (\partial \Delta^{n+1}, *) \to (X, x_0)] = \sum_{j=0}^{n+1} (-1)^j \cdot [\sigma \circ i_{j+1}^n: (\Delta^n, \partial \Delta^n) \to (X, x_0)] \in \pi_n(X, x_0).
\]

We refer to Figure 832 for an illustration for \(n = 1\), even though this case is strictly speaking not allowed.

![Diagram](image-url)

**Figure 832.** Illustration of Lemma 53.16

**Proof (\(*\)).** The reader might already have noticed that the statement of the lemma resembles the statement of Proposition 53.11. Indeed, after some massaging we will be able to deduce the desired statement from Proposition 53.11.

---

\textsuperscript{831}Note that our hypothesis that \(\sigma\) sends the \((n-1)\)-skeleton of \(\partial \Delta^{n+1}\) to \(x_0\) implies in particular that for all \(j \in \{0, \ldots, n+1\}\) we have \((\sigma \circ i_{j+1}^n)(\partial \Delta^n) = \{x_0\}\).

\textsuperscript{832}Also note that by our base point \(*\) is chosen in such a way that it lies on the \((n-1)\)-skeleton of \(\partial \Delta^{n+1}\).
Given any \( k \in \mathbb{N}_0 \), let \( \eta_k : (\Delta^k, \partial\Delta^k) \to (\overline{B}^k, S^{k-1}) \) the homeomorphism from page 1338.

Using our identifications the desired statement is now equivalent to the following statement.

**Statement.** Given \( j \in \{0, \ldots, n+1\} \) we write \( \alpha_i = \eta_{n+1} \circ i_{n+1} \circ \eta_n^{-1} : \overline{B}^n \to S^n = \partial B^{n+1} \) and furthermore we write \( f_j = \sigma \circ i_j \circ \eta^{-1} : \overline{B}^n \to X \). Then we have the following equality in \( \pi_n(X, x_0) \):

\[
\Phi(\alpha_0, \ldots, \alpha_n, f_0, \ldots, f_n) : (S^n, \ast) \to (X, x_0) \]

\[
\in \pi_n(X, x_0)
\]

\[
\sum_{j=0}^{n+1} (-1)^j \cdot [f_j : (\overline{B}^n, S^{n-1}) \to (X, x_0)] \in \pi_n(X, x_0)
\]

We refer to Figure 833 for an illustration.

**Figure 833.** Illustration of the proof of Lemma 53.16

First note that it follows from the discussion on page 2094 that the maps \( \eta_k \) is orientation-preserving if and only if \( k \) is even. Furthermore it is fairly straightforward to see that the maps \( i_{j+1} \) are orientation-preserving if and only if \( j \) is even. In summary, the embedding \( \alpha_j \) is orientation-preserving if and only if \( j \) is odd.

The only reason why we cannot apply Proposition 53.11 immediately is that the maps \( \alpha_j \) are embeddings but they are not smooth, so they are not smooth embeddings. Keeping Lemma 53.11 in mind we see that it suffices to prove the following claim.

**Claim.** The maps \( \alpha_0, \ldots, \alpha_{n+1} : B^n \to S^n \) are isotopic, through weakly disjoint embeddings, to smooth embeddings \( \beta_0, \ldots, \beta_{n+1} \).

For \( j = 0, \ldots, n+1 \) we write \( F_j = i_{n+1} \circ \eta_n^{-1} \) and we write \( \overline{F}_j = i_j \circ \eta^{-1} \). Note that \( F_j \) is an \( n \)-dimensional submanifold of \( \mathbb{R}^{n+1} \), we endow it with the usual orientation where the “normal vector sticks out”. Now this claim can be proved using the following observations:

1. Similar to the discussion on page 1332 we can shrink the weakly disjoint embeddings \( \alpha_j : B^n \to \overline{F}_j \) to disjoint embeddings \( \beta_j : B^n \to F_j \).

---

833 Here we used the deep fact that precisely one out of the numbers \( n, n+1 \) is odd.
(2) Using Lemma 18.2 we can isotope these embeddings \( \beta_j : B^n \to F_j \) to smooth embeddings \( \gamma_i : B^n \to F_j \).

(3) For each \( j \in \{0, \ldots, n+1\} \) the restriction of \( \eta_{n+1} : \partial \Delta^{n+1} \to S^n \) to \( \eta_{n+1} : F_j \to S^n \) is smooth and orientation-preserving.

Together with Figure 834 the reader should have no troubles assembling a full proof of the claim and the lemma using the above observations.

\[ \begin{array}{c}
\xymatrix{ B^2 \ar[r]^{\eta_2^{-1}} \ar[dr]_{i_j^2} & & \Delta \ar[dr]_{\eta_j | \partial \Delta^3} \ar[r] & B^n \ar[r]^{\beta_j} \ar@{..>}[r] & X \ar[r]^f & \Delta^n \ar[r] & S^n }
\end{array} \]

**Figure 834. Illustration of the proof of Lemma 53.16**

Now we can turn to the proof of the Hurewicz Theorem 53.5.

**Proof of the Hurewicz Theorem 53.5.** Let \( n \in \mathbb{N}_{\geq 2} \) and let \( (X, x_0) \) be a pointed topological space. We suppose that \( X \) is \((n-1)\)-connected.

Statement (1) of the theorem can be proved easily. Indeed, let \( k \in \{0, \ldots, n-1\} \). We have

\[ \widetilde{H}_k(X; \mathbb{Z}) \cong H_k(X, \{x_0\}; \mathbb{Z}) = H_k^{n-1}(X, x_0) = 0. \]

Lemma 43.14 by Lemma 53.14 since \( X \) is \((n-1)\)-connected \( k \leq n-1 \)

We turn to the much more interesting proof of statement (2). As a reminder, we want to show that the map

\[ \pi_n(X, x_0) \xrightarrow{\Phi_{(X, x_0)}} H_n(X; \mathbb{Z}) \]

is an isomorphism. The goal again is to bring the homology groups \( H_n^{n-1}(X, x_0) \) into the game. This leads us to the following claim.

**Claim.**

(1) The map

\[ \Psi_{(X, x_0)} : \pi_n(X, x_0) \to H_n^{n-1}(X, x_0) \]

\[ [f : (\Delta^n, \partial \Delta^n) \to (X, x_0)] \mapsto \left[ \tilde{f} : \Delta^n \to X \right] \in C_n^{n-1}(X, x_0) \]

\( \text{Recall that a smooth embedding is by definition smooth.} \)
is well-defined and it is a homomorphism.

(2) The following diagram commutes up to the sign \((-1)^n\):

\[
\begin{array}{ccc}
\pi_n(X, x_0) & \xrightarrow{\Phi(X, x_0)} & H_n(X; Z) \\
\Psi(X, x_0) & & \\
H_n^{(n-1)}(X, x_0) & \xrightarrow{\iota} & H_n(X, \{x_0\}; Z)
\end{array}
\]

where \(\iota\) is induced by the inclusion \(C^{(n-1)}_n(X, x_0) \to C_n(X, \{x_0\})\).

(3) The right-vertical and the bottom-horizontal maps of the diagram in (2) are isomorphisms.

We prove the claim using a somewhat convoluted logic.\footnote{The convoluted logic is forced upon us since proving (1) as a stand-alone statement is actually slightly tricky.} We consider the following diagram

\[
\begin{array}{ccc}
\{\text{set of maps } (\Delta^n, \partial \Delta^n) \to (X, x_0)\} & \xrightarrow{f \mapsto f_*([\Delta^n])} & H_n(X; Z) \\
\downarrow f \mapsto [f] & & \\
H_n^{(n-1)}(X, x_0) & \xleftarrow{\Psi(X, x_0)} & \pi_n(X, x_0) & \xrightarrow{\Phi(X, x_0)} & H_n(X, \{x_0\}; Z) \\
& & \downarrow \cong
\end{array}
\]

We make the following observations:

(a) It follows from \(n \geq 2\) and from the long exact sequence of homology groups of the pair \((X, \{x_0\})\), see Corollary \ref{cor:long-exact-sequence}, that the right-hand vertical map of both diagrams is an isomorphism.

(b) It follows from Lemma \ref{lem:connectedness-of-X} and our hypothesis that \(X\) is \((n - 1)\)-connected that the bottom horizontal map \(\iota\) of both diagrams is an isomorphism.

(c) Let \(f : (\Delta^n, \partial \Delta^n) \to (X, x_0)\) be a map. The \((n - 1)\)-skeleton of \(\Delta^n\) equals \(\partial \Delta^n\), thus the map \(f : \Delta^n \to X\) does indeed define an element in \(C^{(n-1)}_n(X, x_0)\). Furthermore by Lemma \ref{lem:element-in-C} (3) we know that every element in \(C^{(n-1)}_n(X, x_0)\) is a cycle, thus \(f\) defines an element in \(H^{n-1}_n(X, x_0)\). This shows that in the above diagram the left vertical map is well-defined.

(d) It is clear that the “outer rectangle” of the above diagram commutes.

(e) It follows from Proposition \ref{prop:commutation-of-triangles} (2) that the top small triangle in the above diagram commutes up to the sign \((-1)^n\).

(f) We want to show that \(\Psi(X, x_0)\) is well-defined and that it is a homomorphism. By (b) we know that \(\iota\) is an isomorphism. Thus it suffices to show these statements for \(\iota \circ \Psi(X, x_0)\). But these now follow from (d) and (e) and the fact, see Lemma \ref{lem:hurewicz} (1), that the Hurewicz homomorphism \(\Phi(X, x_0)\) is well-defined and a homomorphism. \(\square\)
By the claim it suffices to show that the homomorphism
\[
\Psi_{(X,x_0)} : \pi_n(X,x_0) \to H^{(n-1)}_n(X,x_0) \\
[f : (\Delta^n, \partial\Delta^n) \to (X,x_0)] \mapsto [f : \Delta^n \to X]
\]
is in fact an isomorphism. We will do so by defining an explicit inverse.

\textbf{Claim.}

(1) The map
\[
\Xi_{(X,x_0)} : C^{(n-1)}_n(X,x_0) \to \pi_n(X,x_0)
\]
that is induced by
\[
(\sigma : (\Delta^n, \partial\Delta^n) \to (X,x_0)) \mapsto [\sigma : (\Delta^n, \partial\Delta^n) \to (X,x_0)]
\]
is well-defined.

(2) The map $\Xi_{(X,x_0)}$ from (1) descends to a well-defined map
\[
H^{(n-1)}_n(X,x_0) \to \pi_n(X,x_0).
\]

(3) The map $\Xi_{(X,x_0)}$ is an inverse to $\Psi_{(X,x_0)}$.

Since the end is near we set out with renewed vigor to prove the claim.

(1) Recall that we know from Proposition \[40.3\] and our hypothesis $n \geq 2$ that the group on the right is abelian. Therefore it follows from Lemma \[19.1\] that the map is well-defined.

(2) Let $\sigma : \Delta^{n+1} \to X$ be a singular $(n+1)$-simplex that defines an element in the group $C^{(n-1)}_{n+1}(X,x_0)$. We need to show that $\Xi_{(X,x_0)}(\partial\sigma) = 0$. We calculate that we have the following equality in $\pi_n(X,x_0)$:
\[
\Xi_{(X,x_0)}(\partial\sigma) = \Xi_{(X,x_0)}(\sum_{j=0}^{n+1} (-1)^j \cdot \sigma \circ i^j_0) = \sum_{j=0}^{n+1} (-1)^j \cdot \left[ \sigma \circ i^{n+1}_j \right] = - [\sigma |_{\partial\Delta^{n+1}}] = 0.
\]

by definition of $\Xi_{(X,x_0)}$ Lemma \[53.16\] Lemma \[53.15\]

(3) It follows immediately from the definitions that $\Xi_{(X,x_0)} \circ \Psi_{(X,x_0)}$ is the identity on $\pi_n(X,x_0)$. Furthermore it follows easily from Lemma \[53.13\] and the definitions that $\Psi_{(X,x_0)} \circ \Xi_{(X,x_0)}$ is the identity on a generating set for $H^{(n-1)}_n(X,x_0)$. But by the claim and Lemma \[53.1\] (1) we know that $\Psi_{(X,x_0)}$ and $\Xi_{(X,x_0)}$ are both homomorphisms. Thus we see that $\Psi_{(X,x_0)} \circ \Xi_{(X,x_0)}$ is actually the identity on all of $H^{(n-1)}_n(X,x_0)$.

This concludes the proof of the claim and thus we are done with the proof of the Hurewicz Theorem \[53.3\]

\textbf{Remark.} The most awkward aspect of the proof of the Hurewicz Theorem \[53.3\] is that one needs to go back and forth between the different points of view regarding elements in higher homotopy groups, in particular the fact that we need Proposition \[53.11\] and Lemma \[53.16\] is arguably aesthetically somewhat unpleasant.

---

\[836\text{Put differently, it would be a serious dereliction of duty to use the additive notation for a group structure, if the group was not known to be additive.}\]
In fact there is, in principle, an elegant way around this problem: One could prove the Hurewicz Theorem \[53.5\] using “cubical singular homology” instead of the usual singular homology. As the name suggests, in this theory the “building blocks” are singular cubes, i.e. maps from \([0,1]^n\) to a topological space \(X\). (This theory is developed in \[Mass91\], Chapter VII.2.) Since cubes are also used in the definition of the product structure on higher homotopy groups I would expect that many of the technical issues we had to deal with vanish magically.

The downside is that one still needs to show that “cubical singular homology” is naturally isomorphic to the usual singular homology. This can be shown using the Acyclic Model Theorem \[80.16\].

**Exercises for Chapter 53.** In the following four exercises we need the following definitions.

**Definition.** Let \(X\) be a topological space. We say \(X\) is *aspherical* if \(X\) is path-connected and if all higher homotopy groups \(\pi_n(X), n \geq 2\), vanish.

**Exercise 53.1.** Let \(X\) be a connected 2-dimensional CW-complex with \(\pi_2(X) = 0\). Show that \(X\) is aspherical.

**Exercise 53.2.** Let \(X\) be a topological space and let \(U\) and \(V\) be open subsets of \(X\). Let \(n \in \mathbb{N}_{\geq 2}\). Suppose that \(U\) and \(V\) are \((n-1)\)-connected and that \(U \cap V\) is \(n\)-connected. We pick a base point \(x_0 \in U \cap V\) and we denote by \(i: U \to X\) and \(j: V \to X\) the inclusion maps. Show that the map
\[
i_* \oplus j_*: \pi_n(U,x_0) \oplus \pi_n(V,x_0) \to \pi_1(X,x_0)
\]
is an isomorphism.

**Exercise 53.3.** Let \(X\) be a CW-complex and let \(U\) and \(V\) be path-connected subcomplexes of \(X\). Suppose that \(U \cap V\) is path-connected and furthermore suppose that the inclusion induced maps \(\pi_1(U \cap V) \to \pi_1(U)\) and \(\pi_1(U \cap V) \to \pi_1(V)\) are monomorphisms. Finally suppose that \(U\), \(V\) and \(U \cap V\) are aspherical. Show that \(X\) is also aspherical.

**Hint.** You might want to use Propositions \[21.24, 30.6\] and Proposition \[74.12\].

**Exercise 53.4.** We start out with the following easy-to-digest definition. Let \(X\) be a topological space and let \(k \in \mathbb{N}_0\). We say \(X\) is \(k\)-*connected*, if \(\pi_i(X) = 0\) for \(i = 0, \ldots, k\). Now let \(M\) and \(N\) be two closed oriented \(n\)-dimensional smooth manifolds. Suppose there exists a \(k \in \mathbb{N}\) such that \(M\) and \(N\) are \(k\)-connected. Show that the connected sum \(M \# N\) is also \(k\)-connected.

**Exercise 53.5.** Let \(X\) be an \(n\)-dimensional CW-complex and let \(Y\) be a subcomplex of \(X\) that is homotopy equivalent to \(S^n\). Show that the inclusion induced map \(\pi_n(Y) \to \pi_n(X)\) is a monomorphism.

**Exercise 53.6.** We denote by \(*\) suitable base points of the spheres. Now let \(f: S^n \to S^n\) be a map with \(f(*) = *\). We suppose that \(f\) is a map of degree \(k \in \mathbb{Z}\), i.e. \(f\) is a map such that the induced map \(f_*: H_n(S^n;\mathbb{Z}) \to H_n(S^n;\mathbb{Z})\) is given by multiplication by \(k\).
(a) Let \( g: S^n \to S^m \) be a map. Show that \( [g \circ f] = k \cdot [g] \in \pi_n(S^m) \).

(b) Show that if \( g: S^m \to S^n \) is a map, then it is not necessarily the case that the equality \( [f \circ g] = k \cdot [g] \in \pi_m(S^n) \) holds.

*Hint.* We view \( S^3 \) as a subset of \( \mathbb{C}^2 \) and we make the usual identification \( \mathbb{C}P^1 = S^1 \).

Now consider the following commutative diagram:

\[
\begin{array}{ccc}
S^3 & \xrightarrow{(z,w) \mapsto (z,w)} & S^2 \\
\downarrow (z,w) \mapsto (z,w) & & \downarrow [(z,w) \mapsto (z,w)] \\
S^3 & \xrightarrow{(z,w) \mapsto (z,w)} & S^2.
\end{array}
\]

(c) Let \( g: S^{m-1} \to S^{n-1} \) be map. As usual we denote by \( \Sigma(g): S^m \to S^n \) the suspension of \( g \). Show that \( [f \circ \Sigma(g)] = k \cdot [\Sigma(g)] \in \pi_m(S^n) \).

**Exercise 53.7.** Given \( n \in \mathbb{N} \) we denote by \( L(n, 1) = S^3/\mathbb{Z}_n \) the lens space, as defined on page 502. For which \( n \in \mathbb{N} \) is the Hurewicz homomorphism \( \pi_3(L(n, 1)) \to H_3(L(n, 1); \mathbb{Z}) \) an isomorphism?

**Exercise 53.8.** Let \( X \) be a topological homology \( n \)-sphere, i.e. \( X \) is an \( n \)-dimensional topological manifold such that for any \( k \in \mathbb{N}_0 \) we have \( H_k(X) \cong H_k(S^n) \). We denote by \( \Sigma(X) \) the suspension of \( X \) as defined on page 694. Show that \( \pi_i(\Sigma(X)) = 0 \) for \( i = 1, \ldots, n \).

**Exercise 53.9.** Let \( n \in \mathbb{N} \). Let \( \varphi: S^1 \to S^1 \) be the map that is given by \( z \mapsto z^n \). We consider the topological space \( X := \overline{B}^2 \cup_{\varphi} S^1 \). In other words, \( X \) is the CW-complex obtained by attaching a 2-cell to \( S^1 \) via the attaching map \( \varphi \).

(a) Compute \( \pi_1(X) \).

(b) Compute \( \pi_2(X) \).

**Exercise 53.10.** Let \( \varphi: S^1 \to S^5 \) be a smooth embedding.

(a) Compute \( H_*(S^5 \setminus \varphi(S^1)) \).

(b) Show that \( \pi_3(S^5 \setminus \varphi(S^1)) \neq 0 \).

*Remark.* For (b) you need to use that \( \varphi \) is a smooth embedding, the statement is in general not true, if we only assume that \( \varphi \) is an injective map. More precisely, in [Haj19] it is shown that there exists an injective map \( \varphi: S^1 \to S^5 \) such that \( \pi_3(S^5 \setminus \varphi(S^1)) = 0 \).

**Exercise 53.11.** Show that there exists a closed 3-dimensional smooth manifold \( M \) such that \( \pi_2(M) \) is infinitely generated.

*Hint.* You could try to imitate the topological space \( S^1 \vee S^2 \).

**Exercise 53.12.** Let \( X \) be a 0-connected countable CW-complex. Show that \( \pi_2(X) \) is countable.

*Remark.* This answer Question 40.16 in the affirmative for \( n = 2 \).
54. Applications of the Hurewicz Theorem (∗)

In this chapter we want to spend some more time with the Hurewicz Theorems 52.5 and 53.5. In particular we want to discuss some applications thereof. This chapter is not entirely essential and can also be safely skipped at a first reading.

54.1. The social choice problem. In this section we will consider the real-life problem that \( n \in \mathbb{N}_{\geq 2} \) people have to agree in a democratic and reasonable way on one of the following:

1. The temperature setting of a joint office.
2. A vacation spot in Bavaria.
3. A vacation spot on Earth.

More generally, the \( n \) people are supposed to agree on the following:

4. A point in some topological space \( X \).

One reasonable approach to solving this problem is the following. Each person gets to pick a point in \( X \). We then need a map \( f \) which takes as input the \( n \) choices of points in \( X \) and which turns these choices into a common choice. In other words, we need a map

\[
f : X^{n} = X \times \cdots \times X \rightarrow X.
\]

Our interpretation that the common choice should be chosen “democratically and reasonably” is that the map \( f \) should have the following three properties:

(a) A small change in choices of the people involved should correspond to a small change in the common choice.
(b) If everybody is of the same opinion, then evidently the common choice should be the point everybody picked.
(c) Everybody should be treated fairly, i.e. the social choice should not depend on the ordering of the \( n \) people.

In some cases it is easy to come up with a social choice. For example if \( X \) is a convex subset of some \( \mathbb{R}^{m} \), e.g. if \( X = \mathbb{R}^{m} \) itself, then given any \( n \in \mathbb{N} \) the map

\[
X^{n} \rightarrow X \\
(x_{1}, \ldots, x_{n}) \mapsto \frac{1}{n} \sum_{i=1}^{n} x_{i}
\]

evidently satisfies all of the above conditions. In particular this approach solves the problem for (1). If \( X \) is homeomorphic to a convex subset of some \( \mathbb{R}^{m} \), then we can translate our problem into the previous situation and we can find a solution. In particular, Bavaria being to the best of my knowledge homeomorphic to a closed disk, we see that we have a solution to (2).

\[\text{footnote}{837}\text{It follows easily from the convexity of } X \text{ that the map does indeed take values in } X.\]

\[\text{footnote}{838}\text{For what choices of subsets } X \text{ of } \mathbb{R}^{m} \text{ does the geometric mean } (x_{1}, \ldots, x_{n}) \mapsto (x_{1} \cdot \cdots \cdot x_{n})^{\frac{1}{n}} \text{ define a social choice?}\]

\[\text{footnote}{839}\text{The fact that Bavaria lost the Pfalz in 1946 greatly simplifies finding a solution to (2).}\]
In the following we will now study the third problem in greater detail. At this point it is convenient to introduce the following definition from [Eckm04], which is just a formalization of our wish list above.

**Definition.** Let $X$ be a topological space and let $n \in \mathbb{N}$. A social choice of type $n$ is a map $f : X^n \rightarrow X$

such that the following three axioms are satisfied:

(a) The map $f$ is continuous.
(b) For every $x \in X$ we have $f(x, \ldots, x) = x$.
(c) For every permutation $\sigma \in S_n$ and any $(x_1, \ldots, x_n) \in X^n$ we have $f(x_{\sigma(1)}, \ldots, x_{\sigma(n)}) = f(x_1, \ldots, x_n)$.

We say that a topological space is social, if for every $n \in \mathbb{N}$ it admits a social choice of type $n$.

Thus the question of whether there exists a “democratic and reasonable” way for $n$ people to settle on a vacation spot on earth can be interpreted as the following question.

**Question 54.1.** Does there exist a social choice of type $n$ on $S^2$?

As we will see, this question will be short-lived. The key to answer this question is the following proposition which is the main result of this section.

**Proposition 54.2.**

1. Let $X$ be a 0-connected topological space. If $X$ admits a social choice of type $n$ for some $n \in \mathbb{N}_{\geq 2}$, then given any $k \in \mathbb{N}$ the group $\pi_k(X)$ is abelian, and it is either zero or infinitely generated.

2. Let $X$ be a non-empty connected CW-complex that has the property that for every $k \in \mathbb{N}$ the number of $k$-cells is finite. If for every $n \in \mathbb{N}_0$ the topological space $X$ admits a social choice of type $n \geq 2$, then for every $k \in \mathbb{N}$ we have $\pi_k(X) = 0$.

**Remark.**

1. It follows from the Whitehead Theorem [119.9] that in Proposition 54.2 (2) we can upgrade the conclusion to the statement that $X$ is actually contractible.

---

\footnote{In this section we will only deal with path-connected topological spaces and we will only be interested in the isomorphism type of the higher homotopy groups, thus we will use Proposition 40.5 as an excuse to ignore base points.}
In the context of sociology, Proposition 54.2 was first formulated in 1980 by the mathematical economist Graciela Chichilnisky [Chic80]. It turns out that the proposition was already proved earlier by Beno Eckmann [Eckm54] in 1954. The discussion of this section follows mostly [Eckm04]. For more information and some generalizations we refer to [Eckm04] and [Weinb04].

We are now already in a position to answer Question 54.1 in the negative.

**Corollary 54.3.** Let \( k \in \mathbb{N} \). The sphere \( S^k \) does not admit a social choice for any \( n \in \mathbb{N}_{\geq 2} \).

**Proof.** By Corollary 53.6 we know that \( \pi_k(S^k) \cong \mathbb{Z} \). Since \( \mathbb{Z} \) is neither zero nor infinitely generated we obtain from Proposition 54.2 (1) that \( S^k \) does not admit a social choice for any \( n \in \mathbb{N}_{\geq 2} \). ■

The idea behind the proof of Proposition 54.2 is quite simple. We need to see what effect the existence of a social choice on \( X \) has on the higher homotopy groups. Perhaps not surprisingly, the properties of a social choice give rise to very similar properties of the homotopy groups. This leads us to the following definition.

**Definition.** Let \( G \) be a group and let \( n \in \mathbb{N}_{\geq 2} \). We say a map \( \varphi: G^n \rightarrow G \) is a social homomorphism of type \( n \) if the following conditions are satisfied:

- (a) The map \( \varphi \) is a homomorphism.
- (b) For every \( g \in G \) we have \( \varphi(g, \ldots, g) = g \).
- (c) For every permutation \( \sigma \in S_n \) and any \( (g_1, \ldots, g_n) \in G^n \) we have
  \[ \varphi(g_{\sigma(1)}, \ldots, g_{\sigma(n)}) = \varphi(g_1, \ldots, g_n). \]

**Example.** Evidently, if we consider \( G = (\mathbb{Q}, +) \) or \( G = (\mathbb{R}, +) \), then taking the arithmetic mean defines a social homomorphism.

The following lemma relates social choices on topological spaces to social homomorphisms.

**Lemma 54.4.** Let \( X \) be a path-connected topological space. If \( X \) admits a social choice of some type \( n \geq 2 \), then for every \( k \in \mathbb{N} \) the homotopy group \( \pi_k(X) \) admits a social homomorphism of type \( n \).

**Proof.** To simplify the notation a little bit we only consider the case \( n = 2 \). Thus let \( f: X \times X \rightarrow X \) be a social choice of type 2. Let \( k \in \mathbb{N} \). We fix a base point \( x_0 \in X \). We consider the map

\[
\Theta: \pi_k(X, x_0) \times \pi_k(X, x_0) \rightarrow \pi_k(X \times X, (x_0, x_0))
\]

\[
([\alpha: (S^k, \ast) \rightarrow (X, x_0)], [\beta: (S^k, \ast) \rightarrow (X, x_0)]) \mapsto \left[ (S^k, \ast) \rightarrow (X \times X, (x_0, x_0)) \right],
\]

Next we consider the map

\[
\varphi: \pi_k(X, x_0) \times \pi_k(X, x_0) \xrightarrow{\Theta} \pi_k(X \times X, (x_0, x_0)) \xrightarrow{f_*} \pi_k(X, x_0).
\]

It remains to show that \( \varphi = f_* \circ \Theta \) is a social homomorphism of type 2. We do so in the following three steps.
(a) By Proposition 40.8 (2) we know that the map $\Theta$ is actually a homomorphism. It follows that $\varphi = f_\ast \circ \Theta$ is a homomorphism.

(b) It follows immediately from the fact that for every $x \in X$ we have $f(x, x) = x$ that for every $g \in \pi_k(X)$ we have $\varphi(g, g) = g$.

(c) Similarly it follows immediately from the fact that for every $x, y \in X$ we have $f(x, y) = f(y, x)$ that for every $g, h \in \pi_k(X, x_0)$ we have $\varphi(g, h) = \varphi(h, g)$. ■

In light of Lemma 54.4 we now need to understand, given $n \in \mathbb{N}_{\geq 2}$, which groups admit social homomorphisms of type $n$.

**Definition.** Let $G$ be an abelian group.

1. Let $n \in \mathbb{N}$. We say $G$ is strongly divisible by $n$, if the map $g \mapsto n \cdot g$ is an isomorphism of the group $G$.

2. We say $G$ is strongly divisible, if $G$ is strongly divisible by any $n \in \mathbb{N}$.

**Remark.** Usually an abelian group $G$ is called divisible if for every $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$. This will also be our definition later on page 1863. Clearly a group which is strongly divisible is also divisible. But the converse does not hold, for example the abelian group $(\mathbb{Q}/\mathbb{Z}, +)$ is divisible but it is not strongly divisible.

The following lemma gives a satisfying characterization of groups that admit a social homomorphism of type $n$.

**Lemma 54.5.** Let $G$ be a group and let $n \in \mathbb{N}_{\geq 2}$. The following two statements are equivalent:

1. The group $G$ admits a social homomorphism of type $n$.

2. The group $G$ is abelian and it is strongly divisible by $n$.

**Proof.** In the following let $G$ be a group and let $n \in \mathbb{N}_{\geq 2}$. Since we will shortly see that the groups involved are abelian we will use additive notation throughout the argument.

First we deal with the implication “(2) $\Rightarrow$ (1)”. If $G$ is abelian and if it is strongly divisible by $n$, then evidently the usual “arithmetic mean formula”

$$(g_1, \ldots, g_n) \mapsto \frac{1}{n}(g_1 + \cdots + g_n) := \text{inverse of the isomorphism}$$

$$G \to G \text{ given by } g \mapsto n \cdot g,$$

applied to $g_1 + \cdots + g_n \in G$

defines a social homomorphism of type $n$.

Next we prove the much more interesting implication “(1) $\Rightarrow$ (2)”. Let $\varphi: G^n \to G$ be a social homomorphism of type $n \geq 2$. Throughout the proof we mean by (a), (b) and (c) the three defining properties of a social homomorphism. First note that it follows immediately from (c) that for any $g \in G$ we have the equalities

$$\varphi(g, 0, \ldots, 0) = \varphi(0, g, 0, \ldots, 0) = \varphi(0, \ldots, 0, g) \in G.$$  

We denote this common value by $\psi(g)$. We make the following observations:

(i) It follows immediately from (a) that $\psi: G \to G$ is also a homomorphism.
(ii) For any \( g, h \in G \) we have
\[
\psi(g) + \psi(h) = \psi(g, 0, \ldots, 0) + \varphi(h, 0, \ldots, 0) = \psi(g) + \psi(h).
\]
since \( n \geq 2 \) by (a)

(iii) For any \( g \in G \) we have
\[
\psi(g) + \cdots + \psi(g) = \varphi(g, 0, \ldots, 0) + \cdots + \varphi(g, 0, \ldots, 0) = \varphi(g, \ldots, g) = g.
\]
by definition of \( \psi \)
by (a)
by (c)

(iv) Let \( g, h \in G \). We have
\[
g + h = \psi(g + h) + \cdots + \psi(g + h)
= \psi(h) + \psi(g) + \cdots + \psi(h) + \psi(g) = \psi(h + g) + \cdots + \psi(h + g) = h + g.
\]
by (ii)
by (i)
by (iii)
This shows that \( G \) is abelian.

(v) Since \( G \) is abelian we know that multiplication by \( n \) is a homomorphism of \( G \).

(vi) It follows almost immediately from (i) and (iii) that \( \psi \) is an inverse to the map \( G \to G \) that is given by \( g \mapsto n \cdot g \). Together with (v) this shows that \( g \mapsto n \cdot g \) does indeed define an isomorphism of \( G \).

The following lemma basically tells us which finitely generated abelian groups are strongly divisible by some \( n \in \mathbb{N}_{\geq 2} \).

**Lemma 54.6.** Let \( n \in \mathbb{N}_{\geq 2} \).

1. The group \( \mathbb{Z} \) is not strongly divisible by \( n \).
2. Let \( m \in \mathbb{N} \). The cyclic group \( \mathbb{Z}_m \) is strongly divisible by \( n \) if and only if \( m \) and \( n \) are coprime.
3. If a finitely generated group is strongly divisible by \( n \), then it is isomorphic to a direct sum \( \bigoplus_{i=1}^{k} \mathbb{Z}_{m_i} \) where each \( m_i \) is coprime to \( n \).

**Proof.** The first two statements are basically trivial. Finally the last statement follows from the previous two statements together with the classification of finitely generated abelian groups, see Theorem 19.4.

Now we have assembled everything we need for the proof of Proposition 54.2.

**Proof of Proposition 54.2**

1. Let \( X \) be a 0-connected topological space that admits a social choice of type \( n \) for some \( n \in \mathbb{N}_{\geq 2} \). Let \( k \in \mathbb{N} \). By Lemma 54.4 we know that the group \( \pi_k(X) \) is abelian
and that it is strongly divisible by \( n \). It follows almost immediately from Lemma 54.6 that \( \pi_k(X) \) is either zero or infinitely generated.

(2) Let \( X \) be a non-empty connected CW-complex that has the property that for every \( k \in \mathbb{N} \) the number of \( k \)-cells is finite. We assume that \( X \) is social, i.e. we assume that given any \( n \geq 2 \) there exists a social choice of type \( n \) on \( X \). By Lemma 54.4 we know that every homotopy group \( \pi_k(X) \) is abelian and that it is strongly divisible by \( n \).

Next note that by Proposition 37.13 and our hypothesis that \( X \) has finitely many 1-cells we know that \( \pi_1(X) \) is finitely generated. It follows from the above together with Lemma 54.6 that \( \pi_1(X) = 0 \).

Now suppose that we already know that \( \pi_i(X) = 0 \) for \( i = 1, \ldots, k \). By the Hurewicz Theorem 53.5 we know that \( \pi_{k+1}(X) \cong H_{k+1}(X) \). Since \( X \) has finitely many \((k+1)\)-cells we obtain from Proposition 48.5 that \( \pi_{k+1}(X) \cong H_{k+1}(X) \) is finitely generated. Basically the same argument as above shows that \( \pi_{k+1}(X) = 0 \). Iterating this procedure shows that all homotopy groups of \( X \) vanish. \( \blacksquare \)

We conclude this section with the following question.

**Question 54.7.** Does there exist a non-empty CW-complex that is social but that is not contractible?

We will return to this question later on in Section 120.6.

### 54.2. The degree of a self-map of a sphere \( \Pi \)

Let \( n \in \mathbb{N}_0 \) and let \( f: S^n \to S^n \) be map. On page 1181 we defined the degree of \( f \) as follows:

\[
\deg(f) := \deg \left( f_*: \tilde{H}_n(S^n) \to \tilde{H}_n(S^n) \right).
\]

In Lemma 45.11 (3) we showed that any two homotopic maps \( S^n \to S^n \) have the same degree. Now we have the tools to prove the converse of this statement. In fact we have the following proposition.

**Proposition 54.8.** For any \( n \in \mathbb{N} \) the map

\[
\begin{array}{ccc}
\text{set of homotopy equivalence classes of maps } S^n \to S^n \\
\deg: [S^n, S^n] & \to & \mathbb{Z} \\
[f: S^n \to S^n] & \mapsto & \deg(f)
\end{array}
\]

is an isomorphism. (The set \([S^n, S^n]\) is a monoid through composition of maps.)

**Proof.** First note that we know by Lemma 45.11 (3) and (4) that the degree map is well-defined and that it is a monoid morphism. It remains to show that the degree map is a bijection. Now let \(* \in S^n\) be the standard base point. We consider the following diagram

\[
\begin{array}{ccc}
\langle (S^n, *), (S^n, *) \rangle & \cong & [S^n, S^n] \\
\downarrow & & \downarrow f \mapsto f_*([S^n]) \\
\pi_n(S^n, *) & \cong & H_n(S^n).
\end{array}
\]
We make the following observations and clarifications:

1. By Corollary 38.8 we know that the map \((S^n, \ast), (S^n, \ast) \rightarrow [S^n, S^n]\) is a bijection.
2. By Theorem 53.5 we know that the bottom horizontal map is an isomorphism.
3. The diagonal map is an isomorphism by Proposition 43.4.
4. Finally note that it is clear that the diagram commutes. It follows from this observation and all of the above that the map \(\deg: [S^n, S^n] \rightarrow \mathbb{Z}\) is indeed an isomorphism.

54.3. Paths acting on homotopy groups. In Proposotions 14.11 and 40.5 we already saw that for path-connected topological spaces the isomorphism types of the homotopy groups do not depend on the choice of the base point.

In this section we want to discuss this statement in greater detail. We recall the following definition which appeared already in the proof of Proposition 40.5.

**Definition.** Let \(X\) be a topological space and let \(n \in \mathbb{N}\). Let \(\gamma: [0, 1] \rightarrow X\) be a path from a point \(x_0\) to a point \(x_1\). Given a map \(f: (I^n, \partial I^n) \rightarrow (X, x_1)\) we define the map

\[
\gamma^* : (I^n, \partial I^n) \rightarrow (X, x_0)
\]

\[
(t_1, \ldots, t_n) \mapsto \begin{cases} f(2t_1 - \frac{1}{2}, \ldots, 2t_n - \frac{1}{2}), & \text{if } (t_1, \ldots, t_n) \in \left[\frac{1}{4}, \frac{3}{4}\right]^n, \\ \gamma(t), & \text{if } (t_1, \ldots, t_n) \in \partial(\left[\frac{1}{4}, \frac{3}{4}\right]) \text{ for } t \in [0, 1].
\end{cases}
\]

The definition of \(\gamma^*\) is illustrated in Figure 836.

![Figure 836](image)

**Example.** We consider the case \(n = 1\) in the above definition. In this situation the map \(f: (I, \partial I) \rightarrow (X, x_1)\) is a loop. It follows almost immediately from the definitions that the new loop \(\gamma^*: (I, \partial I) \rightarrow (X, x_0)\) equals, up to an orientation-preserving reparametrization, the loop \(\gamma \ast f \ast \overline{\gamma}\) that is given by the product of the three paths \(\gamma, f\) and \(\overline{\gamma}\). We refer to Figure 837 for an illustration.

![Figure 837](image)

**Remark.** We recall that on pages 1060 and 1329 we saw that we can interpret elements in a homotopy group \(\pi_n(X, x_0)\) as homotopy classes of maps \((S^n, \ast) \rightarrow (X, x_0)\). Now let...
\[ \gamma: [0, 1] \rightarrow X \] be a path from \( x_0 \) to \( x_1 \) and let \( f: (S^n, *) \rightarrow (X, x_1) \) be a map. We define

\[ f^\gamma: S^n \rightarrow X \]

\[
\cos(\varphi) \cdot (1, 0, \ldots, 0) + \sin(\varphi) \cdot (0, v) \\
\varphi \in [0, \pi], v \in \mathbb{R}^{n-1}
\]

\[
\begin{cases}
  f(\cos(2\varphi) \cdot (1, 0, \ldots, 0) + \sin(2\varphi) \cdot (0, v)), & \text{if } \varphi \in [0, \frac{\pi}{2}] \\
  \gamma(2 - \frac{\pi}{2}t), & \text{if } \varphi \in [\frac{\pi}{2}, \pi].
\end{cases}
\]

Of course one should only work with the formula if one is forced to at gun point. It is much more illuminating to look at Figure 838 where we try our best to visualize the map \( f^\gamma: (S^n, *) \rightarrow (X, x_0) \). One can easily verify that, under the various identifications, the map \( f^\gamma \) corresponds to the construction on page 1352.

Before we continue we introduce the following basically self-explanatory definition.

**Definition.** Let \( G \) be a group and let \( A \) be a group (or module or vector space). An action of \( G \) on the group \( A \) (respectively module or vector space) is an action \( G \times A \rightarrow A \) in the sense of the definition on page 1352 such that for each \( g \in G \) the map

\[
A \rightarrow A \\
a \mapsto g \cdot a
\]

is a group homomorphism (respectively module or vector space homomorphism).

The following proposition can be viewed as a more precise version of Proposition 4.5 and as a generalization of Proposition 15.11.

**Proposition 54.9.** Let \( X \) be a topological space and let \( n \in \mathbb{N} \).

1. If \( \gamma: [0, 1] \rightarrow X \) is a path from \( x_0 \) to \( x_1 \), then the map

\[
\gamma_*: \pi_n(X, x_1) \rightarrow \pi_n(X, x_0) \\
[f] \mapsto [f^\gamma]
\]

is a well-defined isomorphism.

2. If \( x_0 \) and \( x_1 \) are two points in \( X \) which lie in the same path-component of \( X \), then \( \pi_n(X, x_0) \) is isomorphic to \( \pi_n(X, x_1) \).

---

\[81\] It follows easily from Lemma 2.35 (2') that this map is continuous.

\[82\] In fact, since multiplication by \( g^{-1} \) is an inverse we see that these maps are actually isomorphisms.
(3) Let \( \varphi: X \to Y \) be a map between topological spaces.

(a) If \( \gamma: [0, 1] \to X \) is a path from \( x_0 \) to \( x_1 \), then the following diagram commutes

\[
\begin{array}{ccc}
\pi_n(X, x_1) & \xrightarrow{\gamma_*} & \pi_n(X, x_0) \\
\varphi_* \downarrow & & \downarrow \varphi_* \\
\pi_n(Y, \varphi(x_1)) & \xrightarrow{(\varphi \circ \gamma)_*} & \pi_n(Y, \varphi(x_0)).
\end{array}
\]

(b) If \( \varphi_*: \pi_n(X, x_0) \to \pi_n(Y, \varphi(x_0)) \) is an isomorphism (epimorphism, monomorphism) for some base point \( x_0 \in X \), then for any other base point \( x_1 \) in the same path component of \( X \) the map \( \varphi_*: \pi_n(X, x_1) \to \pi_n(Y, \varphi(x_1)) \) is also an isomorphism (epimorphism, monomorphism). \(^{843}\)

(4) Let \( \gamma \) and \( \delta \) be two paths in \( X \) from \( x_0 \) to \( x_1 \). If \( \gamma \) and \( \delta \) are path-homotopic in \( X \), then the corresponding maps \( \gamma_* \) and \( \delta_* \) from \( \pi_n(X, x_1) \) to \( \pi_n(X, x_0) \) agree.

(5) If \( \gamma \) is a path in \( X \) from \( x_0 \) to \( x_1 \) and if \( \delta \) is a path in \( X \) from \( x_1 \) to \( x_2 \), then

\[
(\gamma \circ \delta)_* = \gamma_* \circ \delta_* : \pi_n(X, x_2) \to \pi_n(X, x_0).
\]

(6) The map

\[
\pi_1(X, x_0) \times \pi_n(X, x_0) \to \pi_n(X, x_0)
\]

\[
([\gamma], [f]) \mapsto [\gamma] \cdot [f] := [f^\gamma]
\]

defines an action (in the sense of the definition on page 185) of the group \( \pi_1(X, x_0) \) on the group \( \pi_n(X, x_0) \).

(7) Let \( f_0, f_1: S^n \to X \) be two maps. We write \( x_0 = f_0(*) \) and \( x_1 = f_1(*) \). The following statement holds:

\[
f_0 \text{ and } f_1 \text{ are homotopic } \iff \text{ there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \text{ such that } [f^\gamma_1] = [f_0] \in \pi_n(X, x_0).
\]

Remark. Let \( X \) be a topological space, let \( x_0, x_1 \) be two points in \( X \) and let \( \gamma \) and \( \delta \) be two paths from \( x_0 \) to \( x_1 \). If \( X \) is simply connected, then Lemma 14.13 tells us that the two paths \( \gamma \) and \( \delta \) are in fact homotopic. Therefore it follows from Proposition 54.9 (4) that \( \gamma_* = \delta_* : \pi_n(X, x_0) \to \pi_n(X, x_1) \). In other words, if \( X \) is simply connected, then given any two base points \( x_0 \) and \( x_1 \) there exists in fact a natural isomorphism \( \pi_n(X, x_0) \cong \pi_n(X, x_1) \). In particular in this case it is almost always entirely safe to suppress the base point in the notation. By Proposition 14.14 this observation applies in particular to \( X = S^k \) for \( k \geq 2 \).

Proof.

\(^{843}\) For \( n = 1 \) this is basically the content of Proposition 15.11.

\(^{844}\) Here it is worth remembering that by definition, see page 465, the product path \( \gamma \circ \delta \) is given by first traversing \( \gamma \) and then traversing \( \delta \).

\(^{845}\) As always, when the adjective “natural” gets used it is an amusing exercise to figure out what categories and functors are involved.
Let $\gamma: [0,1] \to X$ be a path from $x_0$ to $x_1$. It is straightforward to see that the map

$$\gamma_*: \pi_n(X,x_1) \to \pi_n(X,x_0)$$

$$[f] \mapsto [f \gamma]$$

is well-defined. It is also elementary, albeit potentially slightly painful, to see that $\gamma_*$ is a group homomorphism. (See the corresponding discussion in the proof of Proposition 40.5.)

Recall that in Proposition 14.6 (3) we saw that for any path $\delta$ the composition $\delta * \delta$ is path-homotopic to the constant path. It follows easily from this observation together with (4) and (5) that $\gamma_*$ is a bijection. Together with (0) we see that for any path $\gamma: [0,1] \to X$ from $x_0$ to $x_1$ the induced map $\gamma_*: \pi_n(X,x_1) \to \pi_n(X,x_0)$ is an isomorphism.

This is an immediate consequence of (1)

Statement (a) follows immediately from the definitions. Statement (b) is a consequence of the commutative diagram of (a) and the fact that the horizontal maps are isomorphisms by (1).

It follows immediately from (4) and (5) that the map defines an action of $\pi_1(X,x_0)$ on the set $\pi_n(X,x_0)$. Furthermore (1) implies that this action is in fact an action on the group $\pi_n(X,x_0)$.

The proof of this statement is a moderately complicated generalization of the proof of Proposition 18.33. We leave it to the reader to fill in the details.$\blacksquare$

54.4. **Group rings.** Before we continue with our study of higher homotopy groups it is convenient to introduce the purely algebraic concept of a group ring.

**Definition.** Let $G$ be a group and let $R$ be a commutative ring. We denote the free $R$-module generated by the set $G$ by $R[G]$. Put differently, with the notation from page 580 we have

$$R[G] = \left\{ \sum_{i=1}^{m} r_i g_i \bigg| r_1, \ldots, r_m \in R \text{ and } g_1, \ldots, g_m \in G \right\}.$$ 

We equip $R[G]$ with the multiplication that is given by $846$

$$\left( \sum_{i=1}^{m} r_i g_i \right) \cdot \left( \sum_{j=1}^{n} s_j h_j \right) := \sum_{i=1}^{m} \sum_{j=1}^{n} r_i s_j \cdot (g_i h_j).$$

We refer to $R[G]$ as the **group ring of $G$ with $R$-coefficients.** (For $R = \mathbb{Z}$ we refer to $\mathbb{Z}[G]$ as the **group ring of $G$.**)

The following lemma summarizes a few basic facts about group rings.

---

846 The multiplication is basically given by naive “multiplying out.”
Lemma 54.10. Let $G$ be a group and let $R$ be a commutative ring.

1. The group ring $R[G]$ is an associative ring with a multiplicatively neutral element, namely $1 \cdot e$ where $e$ denotes the trivial element in $G$.
2. The group ring $R[G]$ is commutative if and only if $G$ is an abelian group.
3. If $R$ is a field, then $R[G]$ is evidently an algebra over the field $R$.
4. Given a unit $r \in R$ and an element $g \in G$ the product $r \cdot g$ is a unit in $R[G]$.
5. If $G$ has a torsion element, i.e. if there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$, then $R[G]$ has zero divisors.

Proof. All the statements are verified easily. Perhaps the most interesting statement is (5). We will not rob the reader of the pleasure of proving this in Exercise 54.3.

Examples. Let $R$ be a commutative ring.

1. We consider the infinite cyclic group $(t)$. In this case the group ring $R[(t)]$ is isomorphic to the ring $R[t^\pm]$ of Laurent polynomials, more precisely the “obvious” map

$$R[t^\pm] \rightarrow R[(t)]$$

$$\sum_{i=r}^s a_i t^i \mapsto \sum_{i=r}^s a_i t^i$$

is a ring isomorphism.

2. More generally, if $H$ is a free abelian group of rank $m$, then any choice of a basis $t_1, \ldots, t_m$ for $H$ gives rise to a natural isomorphism from the multivariable Laurent polynomial ring $R[t_1^\pm, \ldots, t_m^\pm]$ to the group ring $R[H]$.

The group rings of free groups are particularly interesting. Therefore we dedicate a lemma to them.

Lemma 54.11. Let $\langle T \rangle$ be the free group on a generating set $T$. Given any ring $S$ and given any map $g: T \rightarrow S$ there exists a unique ring homomorphism $\varphi: \mathbb{Z}[\langle T \rangle] \rightarrow S$ with $\psi(t) = g(t)$ for all $t \in T$.

Remark. Given a commutative ring $R$ the group ring $R[\langle T \rangle]$ is sometimes called the free ring on the set $S$ over the ring $R$.

Proof. It follows immediately from Lemma 19.14 that there exists a unique group homomorphism $\varphi: \langle T \rangle \rightarrow S^* := \{\text{units of } S\}$ that extends the given map $g$. It is now straightforward to verify that the map

$$\mathbb{Z}[\langle T \rangle] \rightarrow S$$

$$\sum_{i=1}^m r_i g_i \mapsto r_i \cdot \varphi(g_i)$$

is a ring homomorphism that extends $g$ and that it is the unique ring homomorphism with this desirable property.

As a side remark we mention the following beautiful conjectures. These say in particular that in some sense the statements of Lemma 54.10 (4) and (5) are optimal.
Conjecture 54.12. (Kaplansky Conjectures) Let $G$ be a torsion-free group and let $F$ be a field.

1. The elements 0 and 1 are the only idempotents of $F[G]$, i.e. they are the only elements in $F[G]$ with $x^2 = x$.
2. The group ring $F[G]$ is a domain, i.e. it has no non-trivial zero divisors.
3. The only units in $F[G]$ are the elements of the form $f \cdot g$ with $f \in F \setminus \{0\}$ and $g \in G$.
4. The group ring $\mathbb{C}[G]$ can be embedded in a skew field.

Remark.

1. The conjectures are named after the Canadian mathematician Irving Kaplansky (1917-2006). The first conjecture is often also referred to as the zero divisor conjecture. They are formulated in [Lu02, Conjecture 10.14], [Lam91, p. 95] and [FrG05, p. 729]. As is pointed out in [Lam91, p. 95], Conjecture (3) implies Conjecture (2). It is elementary to see that Conjecture (4) implies Conjecture (2) and that Conjecture (2) implies Conjecture (1).

2. The Kaplansky Conjectures are very attractive since they are easy to state. But it is usually very very hard to prove non-trivial group-theoretic statements that are valid for all (torsion-free) groups. In particular all of the Kaplansky Conjectures are still wide open. We refer to [Lu09, Chapter 4.5] for a summary of what is known regarding these conjectures.

We continue with the following elementary lemma.

Lemma 54.13. Let $G$ be a group and let $A$ be an abelian group (with additive notation for the group structure). Suppose we are given a $G$-action on the group $A$. Then the map

$$\mathbb{Z}[G] \times A \to A$$

$$\left( \sum_{i=1}^{m} r_i g_i, a \right) \mapsto \sum_{i=1}^{m} r_i \cdot (g_i \cdot a) \in A$$

defines a natural $\mathbb{Z}[G]$-left module structure on $A$.

Proof. The lemma is indeed elementary and trivial. We leave it to the reader to ponder what “natural” might mean in this context.

Before we continue we introduce or recall the following convention:

---

$^817$Here we use a somewhat perilous notation, namely we use the symbol “$\cdot$” with two different meanings. First of all, for $g \in G$ and $a \in A$ we denote by $g \cdot a \in A$ the element defined by the $G$-action on $A$. Secondly, for $r \in \mathbb{Z}$ and $b \in A$ we write, as usual, $r \cdot b = b + \cdots + b$ for $r \geq 0$ and $r \cdot b = -b - \cdots - b$ for $r < 0$.

$^848$If $R$ is a non-commutative ring, then one needs to be a little careful when one talks about “$R$-modules”. More precisely, there are now two different concepts one can consider: Given an abelian group $M$ one can demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = r \cdot (s \cdot m)$ in which case one says that $M$ is an “$R$-left module”. Alternatively one could demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = s \cdot (r \cdot m)$ in which case one says that $M$ is an “$R$-right module”. This discussion is the analogue of the discussion on page 185.
 Convention. If a homotopy group is abelian, then sometimes we use additive notation for the group multiplication instead of the multiplicative notation.

This convention, Lemma 54.13, Propositions 40.3 and Proposition 54.9 lead us to the following lemma.

**Lemma 54.14.** Let \((X,x_0)\) be a pointed topological space. If \(n \geq 2\), then the map

\[
\mathbb{Z}[\pi_1(X,x_0)] \times \pi_n(X,x_0) \to \pi_n(X,x_0)
\]

induced by

\[
([\gamma],[f]) \mapsto [f\gamma]
\]

defines a natural \(\mathbb{Z}[\pi_1(X,x_0)]\)-left module structure on \(\pi_n(X,x_0)\).

54.5. **Homotopy groups of** \(S^1 \vee S^2\). In this section we want to consider the homotopy groups of \(S^1 \vee S^2\) since they are quite instructive. On page 1326 we already saw that \(\pi_2(S^1 \vee S^2)\) is very big, more precisely, we saw that it admits an epimorphism onto \(\mathbb{Z}\infty\). We will now see that if we take the view of Lemma 54.14, i.e. if we view \(\pi_2(S^1 \vee S^2)\) as a module over the group ring \(\mathbb{Z}[\pi_1(S^1 \vee S^2)]\), then the apparently messy group \(\pi_2(S^1 \vee S^2)\) suddenly gets a simple description.

We explicitly construct \(X = S^1 \vee S^2\) by identifying the point \(i \in S^1\) with the point \((0,0,-1) \in S^2\). In the following we evidently use the wedge point as the base point of \(X = S^1 \vee S^2\). We refer to it by \(x_0\). Finally we denote by \(\gamma: [0,1] \to S^1 \subset X\) the obvious counterclockwise loop that starts at \(i\). Furthermore we denote by \(\text{id}_{S^2}: S^2 \to S^2 \subset X\) the obvious inclusion map.

Now we can formulate the following proposition which delivers the promised concise description of \(\pi_2(S^1 \vee S^2)\).

**Proposition 54.15.** To simplify the formulation and the proof of the proposition we use the base point \(* = (0,0,-1)\) for \(S^2\) and we use this base point to define the second homotopy groups. This convention has the advantage that \(\text{id}: (S^0,*) \to (S^1 \vee S^2,x_0)\) is a map of based topological spaces. Using this convention the homomorphism

\[
\Psi: \mathbb{Z}[t^{\pm 1}] \to \pi_2(S^1 \vee S^2,x_0)
\]

that is uniquely determined by

\[
\sum_{i=1}^n a_i \cdot t^i \mapsto \sum_{i=1}^n a_i \cdot [(\text{id}_{S^2})_{\gamma^i}]
\]

is an isomorphism of \(\mathbb{Z}[t^{\pm 1}] = \mathbb{Z}[t] = \mathbb{Z}[\pi_1(S^1 \vee S^2,x_0)]\)-modules. In particular, as an abelian group, \(\pi_2(S^1 \vee S^2)\) is isomorphic to \(\mathbb{Z}\infty\).

**Proof.** It follows immediately from the definitions that the map \(\Psi\) is indeed a homomorphism of \(\mathbb{Z}[t^{\pm 1}] = \mathbb{Z}[t] = \mathbb{Z}[\pi_1(S^1 \vee S^2,x_0)]\)-modules. Thus it remains to show that \(\Psi\) is an isomorphism of abelian groups.
As on page 836 we see that the universal covering of \( X = S^1 \lor S^2 \) is given by the map
\[
p: \left( \mathbb{R} \cup (\mathbb{Z} \times S^2) \right) / n \sim (n, (0, 0, -1)) \to S^1 \lor S^2
\]
\[
P \mapsto \begin{cases} 
e 2\pi i (p + \frac{1}{4}) & \text{if } P \in \mathbb{R} \\ Q & \text{if } P = (n, Q) \text{ with } n \in \mathbb{Z}, Q \in S^2. \end{cases}
\]
We pick the base points \( x_0 = i \in S^1 \subset X \) and \( \widetilde{x}_0 = 0 \in \mathbb{R} \subset \widetilde{X} \). Even though we have seen this covering map on numerous occasions we show it again in Figure 839. We consider the following sequence of maps
\[
(*) \quad \mathbb{Z}[t^{\pm 1}] \xrightarrow{\Psi} \pi_2(X, x_0) \xrightarrow{\Xi} \pi_2(\widetilde{X}, \widetilde{x}_0) \xrightarrow{\Phi(\widetilde{X}, \widetilde{x}_0)} \mathbb{H}_2(\widetilde{X}; \mathbb{Z}) \xrightarrow{\Omega} \mathbb{Z}[t^{\pm 1}].
\]
Here \( \Phi(\widetilde{X}, \widetilde{x}_0) \) denotes the Hurewicz homomorphism. Since \( \widetilde{X} \) is simply connected we obtain from the Hurewicz Theorem 53.5 that it is an isomorphism. The reader will not have failed to notice that we did not define the two maps \( \Xi \) and \( \Omega \) yet. We will do so now.

1. First we recall that given a map \( g: (S^2, *) \to (X, x_0) \) there exists by Proposition 29.2 a unique lift \( \widetilde{g}: (S^2, *) \to (\widetilde{X}, \widetilde{x}_0) \). Now we consider the map
\[
[ g: (S^2, *) \to (X, x_0) ] \mapsto [ \widetilde{g}: (S^2, *) \to (\widetilde{X}, \widetilde{x}_0) ].
\]
By Proposition 40.13 we know that \( \Xi \) is well-defined and that it is an isomorphism.

2. Given \( i \in \mathbb{Z} \) we denote by \( f_i: S^2 \to X \) the “obvious” \( i \)-th inclusion map. In Lemma 47.7 we saw that the map
\[
\Omega: \mathbb{Z}[t^{\pm 1}] \to \mathbb{H}_2(\widetilde{X}; \mathbb{Z})
\]
\[
\sum_{i=r}^s a_i \cdot t^i \mapsto \sum_{i=r}^s a_i \cdot f_i([S^2])
\]
is an isomorphism.

We see in particular that in (\( *) \) the three maps to the right are isomorphisms. Therefore it suffices to show that the maps \( \Omega^{-1} \circ \Phi(\widetilde{X}, \widetilde{x}_0) \circ \Xi \circ \Psi \) is the identity. In other words, it suffices to show the following claim.

**Claim.** For any \( n \in \mathbb{Z} \) we have
\[
(\Phi(\widetilde{X}, \widetilde{x}_0) \circ \Xi \circ \Psi)(t^n) = \Omega(t^n) \in \mathbb{H}_2(\widetilde{X}; \mathbb{Z}).
\]
So let \( n \in \mathbb{Z} \). It follows immediately from the definitions of the various maps that the desired statement is equivalent to the statement that
\[
\left( \left( \tilde{\text{id}}_{S^2} \right)^\gamma \right)_* [S^2] = \left( f_n \right)_* ([S^2]) \in H_2(\tilde{X}; \mathbb{Z}).
\]
Thus by Proposition 42.5 it suffices to show that the two maps \((\text{id}_{S^2})^\gamma\) and \(f_n\) are homotopic maps from \(S^2\) to \(\tilde{X}\). For those readers who are still awake this should be basically obvious. As a digestion aid we illustrate both maps in Figure 839.

![Figure 839](image_url)

**Figure 840.** Second illustration for the proof of Proposition 54.15.

In Proposition 48.5 we saw that the homology groups of a finite CW-complex are finitely generated abelian groups. Since the discussion on page 1326 we had known that the corresponding statement is not true for homotopy groups. But we now also know that one should really view the homotopy groups of a pointed topological space \((X, x_0)\) as modules over the group ring \(\mathbb{Z}[\pi_1(X, x_0)]\). Thus the following question arises.

**Question 54.16.** Let \(X\) be a finite CW-complex. Are the homotopy groups \(\pi_n(X, x_0)\), \(n \geq 2\), finitely generated \(\mathbb{Z}[\pi_1(X, x_0)]\)-modules?

It turns out that the answer is yes if \(X\) is simply connected. More precisely, Jean-Pierre Serre [Ser53] proved the following theorem.

**Theorem 54.17.** (Serre) If \(X\) is a simply-connected topological space such that all homology groups are finitely generated (for example \(X\) could be a compact topological manifold or a finite CW-complex), then all homotopy groups are also finitely generated abelian groups.

---

849 In fact this follows from the “\(\Leftarrow\)”-direction of Proposition 54.9 (7).

850 Jean-Pierre Serre (*1926) is a French mathematician. He was, and remains, the youngest person ever to be awarded the Fields Medal.

851 It follows immediately from the Hurewicz Theorem 33.5 that \(\pi_2(X)\) is finitely generated. The fact that the higher homotopy groups are also finitely generated is much stronger.
Example. It follows in particular from Serre’s Theorem 54.17 that the homotopy groups of spheres are finitely generated. Even this statement is highly non-trivial. In particular it is much better than our only result in this direction, namely Corollary 62.10, which says that homotopy groups of spheres are countable.

Nonetheless, it turns out that the answer to Question 54.16 is negative. In fact, one does not need to wander off particularly far to find such an example:

Proposition 54.18. The group $\pi_3(S^1 \vee S^2)$ is not finitely generated over the group ring $\mathbb{Z}[\pi_1(S^1 \vee S^2)] = \mathbb{Z}[t^{\pm 1}]$.

A proof for the proposition is for example sketched in [Hat02, Chapter 4.2, Exercise 38].

Remark. The Hilton-Milnor theorem, see [Hilt55, Theorem A], [Miln72] or [WhdG78, Chapter XI], gives a calculation of the homotopy groups of a finite wedge of spheres, more precisely, these homotopy groups are computed in terms of the homotopy groups of the spheres involved. Unfortunately, at least at a first glance, it is not so clear how the module structure over the group ring can be read off from the Hilton-Milnor theorem.

Exercises for Chapter 54.

Exercise 54.1. Let $X$ be a topological space that admits a social choice of some type $n \geq 2$. Is $X$ necessarily connected?

Exercise 54.2. Let $(X, x_0)$ be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. We consider the Hurewicz homomorphism $\Phi : \pi_n(X, x_0) \to H_n(X; \mathbb{Z})$. Show that for any $g \in \pi_1(X, x_0)$ and any $\sigma \in \pi_n(X, x_0)$ we have

$$\Phi(g \cdot \sigma) = \Phi(\sigma) \in H_n(X; \mathbb{Z}).$$

Exercise 54.3. Let $G$ be a group and let $R$ be a commutative ring. Suppose there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$. Show that $R[G]$ has a zero divisor, i.e., show that there exist non-zero elements $p, q \in R[G]$ with $p \cdot q = 0$.

Hint. First consider the case that $G = \langle t \mid t^n \rangle$ is a finite cyclic group with $n \geq 2$ elements.

Exercise 54.4. Is the ring $M(3 \times 3, \mathbb{R})$ of real $(3 \times 3)$-matrices isomorphic, as a ring, to the real group ring $\mathbb{R}[G]$ of some group $G$?

Exercise 54.5. Let $G$ be a finite group. We view $\mathbb{Q}[G]$ as a $\mathbb{Q}[G]$-left module via left multiplication. Show that $\mathbb{Q}[G]$ admits a submodule $V \neq 0$ with $V \neq \mathbb{Q}[G]$ that is isomorphic to the trivial $\mathbb{Q}[G]$-module $\mathbb{Q}$ where every $g \in G$ acts via the identity on $\mathbb{Q}$.

Exercise 54.6. Let $G$ be a finite group. Show that there exists a monomorphism from $G$ to some unitary group $U(n)$.

Exercise 54.7. We consider the ring $M(2, \mathbb{R})$. Does there exist a finite set $T$ and an epimorphism from the free ring $\mathbb{R}[(T)]$ onto $M(2, \mathbb{R})$?
Exercise 54.8. Let $G$ be a group that acts on an abelian group $A$. Show that the set
\[
\{ g \cdot a - a \mid g \in G \text{ and } a \in A \} \subset A
\]
is in fact a subgroup of $A$.

Exercise 54.9. Let $X$ be a simply connected topological space and let $f : X \to X$ be a self-homeomorphism. Recall that on page 711 we introduced the mapping torus
\[
M := (X \times [0, 1])/(x, 0) \sim (f(x), 1).
\]
Express the $\mathbb{Z}[\pi_1(M)]$-module $\pi_2(M)$ in terms of the homology groups of $X$ and the action by $f$ on the homology groups of $X$.

Exercise 54.10. Show that there exists a closed smooth manifold $M$ such that $\pi_2(M)$ is infinitely generated as an abelian group.
55. The Euler characteristic

55.1. The Euler characteristic and homology groups. Let $X$ be a finite CW-complex, i.e. let $X$ be a CW-complex with finitely many cells. Recall that on page 983 we defined the Euler characteristic $\chi(X)$ as follows:

$$\chi(X) = \sum_n (-1)^n \cdot \text{number of } n\text{-cells}.$$  

A short glance on the examples in Figure 599 shows that the three different CW-structures for the torus provided in that figure have the same Euler characteristic. The following proposition explains why this is not a coincidence.

**Proposition 55.1.** Let $X$ be a finite CW-complex, then

$$\chi(X) = \sum_n (-1)^n \cdot \text{rank}(H_n(X)).$$

**Examples.**

1. It follows either from the CW-structure of the $n$-dimensional sphere $S^n$ with one 0-cell and one $n$-cell given on page 935 or from the calculation of the homology groups in Proposition 43.4 that

$$\chi(S^n) = 1 + (-1)^n = \begin{cases} 0, & \text{if } n \text{ is odd,} \\ 2, & \text{if } n \text{ is even.} \end{cases}$$

2. Let $n \in \mathbb{N}_0$. We want to determine the Euler characteristic of $B^n$. One could of course write down a CW-structure for $B^n$ but with our knowledge it is quicker to point out that follows immediately from Proposition 55.1 and Corollary 42.8 (3) that $\chi(B^n) = 1$.

3. Given any $k, n \in \mathbb{N}_0$ we deduce from Corollary 42.8, Proposition 43.4 and Proposition 55.1 that $\chi(S^k \times B^n) = \chi(S^k) = 1 + (-1)^k$.

4. It follows either from the obvious generalizations of CW-structure provided in Figure 841 or alternatively from Proposition 48.9 that for the surface $\Sigma_g$ of genus $g$ and that for the non-orientable surface $N_k$ of genus $k$ we have

$$\chi(\Sigma_g) = 2 - 2g \quad \text{and} \quad \chi(N_k) = 2 - k.$$

---

852 As a reminder, if $G$ is a finitely generated abelian group, then it follows from the classification of finitely generated abelian groups, see Theorem 19.4, that $G$ is isomorphic to $\mathbb{Z}^r \oplus T$, where $T$ is finite. We then call $r$ the rank of $G$. Put differently, let $T \subset G$ be the torsion subgroup, then $G/T$ is isomorphic to $\mathbb{Z}^r$ for an $r$, and this $r$ is just the rank of $G$.

853 The statement that $\chi(S^2) = 2$ was proved, in a different language, by Leonhard Euler [Eul1758, p. 119]. This equality was already noted before by Francesco Maurolico [Friedm18, p. 71] in 1537 and René Descartes [Rabo10, p. 447] in 1628.

854 What is the “simplest” CW-structure you can find for $B^n$?
surface $\Sigma_g$ of genus $g=2$ non-orientable surface $N_k$ of genus $k=3$

\[
\begin{array}{|c|c|c|c|}
\hline
& \text{number of 0-cells} & \text{number of 1-cells} & \text{number of 2-cells} \\
\hline
2g & 1 & k & 1 \\
\hline
2-2g & \text{Euler characteristic} & 2-k & \\
\hline
\end{array}
\]

\textbf{Figure 841}

(5) It follows immediately from the CW-structures provided in Lemma 36.1 that for any $n \in \mathbb{N}_0$ we have

\[\chi(\mathbb{R}P^n) = \begin{cases} 
0, & \text{if } n \text{ is odd}, \\
1, & \text{if } n \text{ is even} 
\end{cases}\quad \text{and} \quad \chi(\mathbb{C}P^n) = n + 1.\]

Before we turn to the proof of Proposition 55.1 we draw the following corollary.

\textbf{Corollary 55.2.} \textit{Let }$X$\textit{ and }$Y$\textit{ be finite CW-complexes. If }$X$\textit{ and }$Y$\textit{ are homotopy equivalent, then }$\chi(X) = \chi(Y)$.\textit{ }

\textbf{Proof.} The corollary is an immediate consequence of Proposition 55.1 together with Corollary 42.8(2).

\textbf{Example.} On page 672 we introduced two examples of closed orientable 2-dimensional smooth manifolds for which we found it difficult to determine the genus. We show the same surfaces also in Figure 842. Let us first consider the surface on the left: it is given identifying opposite sides of the hexagon $E_6$. The obvious CW-structures on the hexagon $H_6$ descend to a CW-structure on $E_6/\sim$. We make the following observations:

1. the single 2-cell on $E_6$ defines a 2-cell for $E_6/\sim$,
2. we identify every 1-cell of $E_6$ with the opposite 1-cell, thus $E_6/\sim$ has three 1-cells,
3. we identify all 0-cells that differ by an even number of vertices, thus $E_6/\sim$ has precisely two 0-cells.

Summarizing we see that $E_6/\sim$ has Euler characteristic $2 - 3 + 1 = 0$. We had just seen on page 1363 that the surface of genus $g$ has Euler characteristic $2 - 2g$. Thus we obtain from the Surface Classification Theorem 23.4 that $E_6/\sim$ is diffeomorphic to the surface of genus zero, i.e. the torus.

The same argument shows that $E_{10}/\sim$ has Euler characteristic $2 - 5 + 1 = -2$ and that it is diffeomorphic to the surface of genus two. Evidently the same argument shows that if we take a regular $(4g + 2)$-gon and if we identify opposite sides, then we obtain the surface of genus $g$.

It is a great mental exercise to visualize that the surface on the left is a torus and that the surface on the right is a surface of genus two.

The key step in the proof of Proposition 55.1 is the following purely algebraic lemma.
hexagon with opposite sides identified dodecagon with opposite sides identified

in each case there are two equivalence classes of vertices: red and blue

\textbf{Figure 842}

**Lemma 55.3.** Let

\[ C_\ast := 0 \rightarrow C_k \xrightarrow{\partial_k} C_{k-1} \xrightarrow{\partial_{k-1}} \ldots C_1 \xrightarrow{\partial_1} C_0 \rightarrow 0 \]

be a chain complex of finitely generated abelian groups. Then the following equality holds:

\[
\sum_{n=0}^{k} (-1)^n \cdot \text{rank } C_n = \sum_{n=0}^{k} (-1)^n \cdot \text{rank } H_n(C_\ast).
\]

The same statement holds if the \( C_i \) are vector spaces over a field and if we replace ranks by dimensions.

**Proof.** For the above chain complex \((C_n, \partial_n)\) we write for each \( n \in \mathbb{N}_0 \)

\[ Z_n := \ker(\partial_n), \quad B_n := \text{im}(\partial_{n+1}) \quad \text{and} \quad H_n = Z_n / B_n. \]

These groups form the following two types of short exact sequences

\begin{align*}
\text{(a)} & \quad 0 \rightarrow Z_n \rightarrow C_n \xrightarrow{\partial_n} B_{n-1} \rightarrow 0, \\
\text{and} & \\
\text{(b)} & \quad 0 \rightarrow B_n \rightarrow Z_n \rightarrow H_n \rightarrow 0.
\end{align*}

\footnote{It is a common notation to call these groups \( Z_n \) and \( B_n \), the names go back to the German words “Zykel” and “Bild”.
}
Now we see that
\[
\sum_{n=0}^{k} (-1)^n \cdot \text{rank } C_n = \sum_{n=0}^{k} (-1)^n \cdot (\text{rank } Z_n + \text{rank } B_{n-1})
\]
by (a) and Lemma \ref{lem:rank} (2) we know that
\[
\text{rank } C_n = \text{rank } Z_n + \text{rank } B_{n-1}
\]
\[
= \sum_{n=0}^{k} (-1)^n \cdot (\text{rank } B_n + \text{rank } H_n + \text{rank } B_{n-1})
\]
by (b) and Lemma \ref{lem:rank} (2) we know that
\[
\text{rank } Z_n = \text{rank } B_n + \text{rank } H_n + \text{rank } B_{n-1}
\]
\[
= \sum_{n=0}^{k} (-1)^n \cdot (\text{rank } H_n + \sum_{n=0}^{k-1} (-1)^n \cdot \text{rank } B_n) + \sum_{n=0}^{k-1} (-1)^n \cdot \text{rank } B_m
\]
we do the substitution \(m = n - 1\) and we use that \(B_k = 0\) and \(B_0 = 0\)
\[
= \sum_{n=0}^{k} (-1)^n \cdot \text{rank } H_n.
\]
Basically the same proof also applies if the \(C_i\) are vector spaces over a field and if we replace ranks by dimensions.

Now we can easily provide the proof of Proposition \ref{prop:chi}.

**Proof of Proposition \ref{prop:chi}** Let \(X\) be a finite \(k\)-dimensional CW-complex. We have
\[
\chi(X) = \sum_{n=0}^{k} (-1)^n \cdot \text{number of } n\text{-cells} = \sum_{n=0}^{k} (-1)^n \cdot \text{rank}(C_n^{\text{CW}}(X))
\]
\[
= \sum_{n=0}^{k} (-1)^n \cdot \text{rank}(H_n^{\text{CW}}(X)) = \sum_{n=0}^{k} (-1)^n \cdot \text{rank}(H_n(X)).
\]
\[
\text{Lemma } \ref{lem:rank} \quad \text{Proposition } \ref{prop:rank}
\]

Using Lemma \ref{lem:rank} we can also easily prove the following lemma which will be useful on several occasions.

**Lemma \ref{lem:exact_sequence}** Let
\[
0 \to A_k \to A_{k-1} \to \ldots \to A_1 \to A_0 \to 0
\]
be an exact sequence of finitely generated abelian groups. Then
\[
\sum_{n=0}^{k} (-1)^n \cdot \text{rank } A_n = 0.
\]

**Proof.** We can view this exact sequence of finitely generated abelian groups as a chain complex whose homology groups vanish. The lemma is therefore an immediate consequence of Lemma \ref{lem:rank}.

**Definition.**

1. Given a topological space \(X\) and \(n \in \mathbb{N}_0\) such that \(H_n(X)\) is a finitely generated abelian group we refer to
\[
b_n(X) := \text{rank}(H_n(X))
\]
as the \textit{n-th Betti number} of $X$.\footnote{These numbers are named after the Italian mathematician Enrico Betti (1823-1892) who had studied an early version of homology groups.}

(2) Let $X$ be a topological space. If all homology groups are finitely generated and if $\sum b_n(X)$ is finite, then we define the \textit{Euler characteristic} of $X$ to be

$$\chi(X) := \sum_n (-1)^n \cdot b_n(X).$$

It follows from Proposition 55.1 that this new definition of the Euler characteristic of a finite CW-complex agrees with the earlier definition.

\textbf{Example.} Using Proposition 46.21 and using Lemma 55.4 several times we will prove the following statement in Exercise 55.3. Let $X$ be a topological space that is homotopy equivalent to a finite CW-complex. Then for any self-homeomorphism $f$ of $X$ we have

$$\chi(\text{Tor}(X, f)) = 0.$$ 

\section*{55.2. Properties of the Euler characteristic.} The Euler characteristic is an invariant which "sees less" than the homology groups. On the other hand we will now see that it behaves better than the homology groups under several natural operations.

The following lemma makes it possible to determine the Euler characteristic of a CW-complex from suitable decompositions.

\textbf{Lemma 55.5.} Let $X = Y \cup Z$ be a decomposition of a finite CW-complex $X$ into two subcomplexes $Y$ and $Z$. Then the following equality holds

$$\chi(X) = \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure843}
\caption{Figure 843}
\end{figure}

\footnote{http://de.wikipedia.org/wiki/Enrico_Betti}
Proof. We give two proofs for the lemma:

1. Given $n \in \mathbb{N}_0$ and given a subset $W$ we denote by $n(W)$ the number of open $n$-cells that are contained in $W$. In our case we have

$$n(X) = n(Y) + n(Z) - n(Y \cap Z).$$

since every open $n$-cell of $X$ lies in $Y$ or $Z$, the $n$-cells that lie in $Y \cap Z$ get counted twice in $n(Y) + n(Z)$, so we have to subtract $n(Y \cap Z)$.

By performing the alternating sum over all $n$ we obtain immediately that

$$\chi(X) = \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

We have thus proved the desired equality.

2. The lemma also follows from applying Lemma 55.4 and Proposition 55.1 to the long exact sequence of homology groups that we obtain by applying the Mayer–Vietoris Theorem for CW-complexes to the decomposition $X = Y \cup Z$. ■

In the following we provide two examples to which we already know the answer by other means. Nonetheless, the approach using Lemma 55.5 gives particularly short and pleasing arguments.

Example. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem there exists a tubular map $\Phi: B^2 \times K$. We set $X_K := S^3 \setminus \Phi(B^2 \times K)$. By Theorem 64.5 there exists a CW-structure for $S^3$ such that $X_K$ and $\Phi(B^2 \times S^1)$ are subcomplexes. We see that

$$0 = \chi(S^3) = \chi(X_K \cup \Phi(B^2 \times S^1)) = \chi(X_K) + \chi(B^2 \times S^1) - \chi(\partial B^2 \times S^1) = \chi(X_K).$$

Of course this calculation also follows from Lemma 68.16.

Example. As usual, given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface $\Sigma_g$ of genus $g$ minus $n$ open disks. Now we want to determine the Euler characteristic $\chi(\Sigma_{g,n})$. We could do so by using Propositions 55.1 and 48.9. But here we use an alternative approach. By Theorem 64.5 there exists a CW-structure on $\Sigma_g$ such that $\Sigma_{g,n}$ and the closed disks that we remove are subcomplexes. It now follows that

$$2 - 2g = \chi(\Sigma_g) = \chi(\Sigma_{g,n} \cup \bigcup_{i=1}^n B^2) = \chi(\Sigma_{g,n}) + \sum_{i=1}^n \chi(B^2) - \sum_{i=1}^n \chi(\partial B^2) = \chi(\Sigma_{g,n}) + n.$$

Thus we see that $\chi(\Sigma_{g,n}) = 2 - 2g - n$.

We record the above example in a lemma.

Lemma 55.6.

1. Let $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$. If we denote by $\Sigma_{g,n}$ the surface $\Sigma_g$ of genus $g$ minus $n$ open disks, then $\chi(\Sigma_{g,n}) = 2 - 2g - n$.

2. Let $\Sigma$ and $\Sigma'$ be two compact orientable connected 2-dimensional smooth manifolds. If $\Sigma$ and $\Sigma'$ have the same number of boundary components and if $\chi(\Sigma) = \chi(\Sigma')$, then $\Sigma$ and $\Sigma'$ are diffeomorphic.
Proof.

(1) We proved this statement in the example preceding the lemma.
(2) This statement follows immediately from (1) and the classification of compact orientable connected 2-dimensional smooth manifolds, see the Surface Classification Theorem 23.4.

We continue with a calculation of the Euler characteristic of a connected sum.

**Lemma 55.7.** If $M$ and $N$ are two compact connected $n$-dimensional smooth manifolds. We have the following equality:

$$\chi(M \# N) = \chi(M) + \chi(N) + \begin{cases} -2, & \text{if } n \text{ is even,} \\ 0, & \text{if } n \text{ is odd.} \end{cases}$$

**Proof (†).** We perform the following straightforward calculation:

$$\chi(M \setminus B^n) = \chi(M) - \chi(B^n) + \chi(S^{n-1}) = \chi(M) + (-1)^{n-1}.$$  

**Lemma 55.8** since $\chi(B^n) = 1$ and $\chi(S^{n-1}) = 1 + (-1)^{n-1}$.

The same way we also see that $\chi(N \setminus B^n) = \chi(N) + (-1)^{n-1}$. It then follows, using the same type of arguments, that

$$\chi(M \# N) = \chi(M \setminus B^n) + \chi(N \setminus B^n) - \chi(S^{n-1})$$  

$$= \chi(M) + (-1)^{n-1} + \chi(N) + (-1)^{n-1} - (1 + (-1)^{n-1})$$  

$$= \chi(M) + \chi(N) - 1 + (-1)^{n-1}.$$  

For completeness sake we point out that in Proposition 68.13 we will calculate the homology groups of the connected sum of two closed oriented smooth manifolds. Together Proposition 55.1 this gives an alternative proof of the above equality.

**Examples.**

(1) In Figure 220 we saw that the connected sum of two tori is the surface of genus two. By Lemma 55.7 we obtain that

$$\chi(\text{surface of genus two}) = \chi(\text{torus}) + \chi(\text{torus}) - 2 = -2.$$  

We had obtained the same result on page 1363 using a different method.

(2) Note that from the CW-structure for $\mathbb{R}P^2$ that we gave in Figure 600 we read off that $\chi(\mathbb{R}P^2) = 1$. It follows from Lemma 55.7 that for any $k \in \mathbb{N}$ we have

$$\chi(k \cdot \mathbb{R}P^2) = 1 - k.$$  

Using the same argument as in Lemma 55.6 one can also show that

$$\chi(k \cdot \mathbb{R}P^2 \text{ minus } n \text{ open disks}) = 1 - k - n.$$  

---

857 Strictly speaking, if $M$ and $N$ are both orientable, then we need to assume that $M$ and $N$ are oriented to get a well-defined connected sum.

858 How many arguments can you find in the lecture notes that show that the Euler characteristic of the torus is zero?
In the following we work our way through more constructions of CW-complexes and the effect on Euler characteristics. First we remind the reader of the following lemma.

**Lemma 37.5.** Let $X$ be a finite CW-complex and let $A$ be a subcomplex. We equip the quotient $X/A$ with the CW-structure given by Lemma 36.32 (3). Then

$$
\chi(X/A) = \chi(X) - \chi(A) + 1.
$$

Next let $X$ and $Y$ be two finite CW-complexes. On page 961 we introduced the product CW-structure which by Proposition 36.23 is indeed a CW-structure for the topological space $X \times Y$. The following lemma relates the Euler characteristics of $X$, $Y$ and $X \times Y$ in an appealing way.

**Lemma 55.8.** Let $X$ and $Y$ be two finite CW-complexes, then

$$
\chi(X \times Y) = \chi(X) \cdot \chi(Y).
$$

**Example.** For any finite CW-complex $X$ we have $\chi(S^1 \times X) = \chi(S^1) \cdot \chi(X) = 0$.

**Proof.** Let $X$ and $Y$ be two finite CW-complexes. Given $k \in \mathbb{N}_0$ we denote by $c_k$ the number of $k$-cells of $X$ and we denote by $d_l$ the number of $k$-cells of $Y$.

We equip $X \times Y$ with the product CW-structure from page 961. By construction we have

$$
\#n\text{-cells of } X \times Y = \sum_{k+l=n} \#k\text{-cells of } X \cdot \#l\text{-cells of } Y = \sum_{k+l=n} c_k \cdot d_l.
$$

It follows that

$$
\chi(X) \cdot \chi(Y) = \left(\sum_k (-1)^k \cdot c_k\right) \cdot \left(\sum_l (-1)^l \cdot d_l\right) = \sum_n (-1)^n \sum_{k+l=n} c_k \cdot d_l = \chi(X \times Y).
$$

Now let $p: \tilde{X} \to X$ be a $k$-fold covering of path-connected topological spaces. We saw in Corollary 16.14 that the induced map $p_*: \pi_1(\tilde{X}) \to \pi_1(X)$ is a monomorphism and we saw in Lemma 16.15 (3) that $p_*(\pi_1(\tilde{X}))$ is a subgroup of index $k$ of $\pi_1(X)$. There is no analogous statement for homology groups. For example the projection map $p: S^2 \to S^2/\sim = \mathbb{R}P^2$ is a 2-fold covering, but $H_2(S^2) = \mathbb{Z}$ and $H_2(\mathbb{R}P^2) = 0$, which shows that the induced map on homology is in general not a monomorphism.

It is therefore perhaps surprising that we already saw in Proposition 37.4 that the Euler characteristic behaves well under finite coverings. For convenience we recall, a slightly simplified version, of the statement of Proposition 37.4.

**Proposition 37.4.** Let $p: \tilde{Y} \to Y$ be a finite covering of a finite connected CW-complex $Y$. Then $\tilde{Y}$ is also a finite CW-complex with

$$
\chi(\tilde{Y}) = [\tilde{Y} : Y] \cdot \chi(Y).
$$

Note that the lemma also gives an affirmative answer to the question posed in Exercise 37.2.
Example. We consider again the 2-fold covering \( p : S^2 \to \mathbb{RP}^2 \). In this case we have by the calculation on page 1216 or alternatively in Proposition 48.10 that

\[
\begin{align*}
    H_0(S^2) &\cong \mathbb{Z}, \\
    H_1(S^2) &\cong 0, \\
    H_2(S^2) &\cong \mathbb{Z}, \\
    H_i(S^2) &\cong 0, \text{ for } i \geq 3,
\end{align*}
\]

and

\[
\begin{align*}
    H_0(\mathbb{RP}^2) &\cong \mathbb{Z}, \\
    H_1(\mathbb{RP}^2) &\cong \mathbb{Z}_2, \\
    H_2(\mathbb{RP}^2) &\cong 0, \\
    H_i(\mathbb{RP}^2) &\cong 0, \text{ for } i \geq 3.
\end{align*}
\]

Thus we see that the homology groups are quite different. Nonetheless we observe that \( \chi(S^2) = 2 \) is indeed twice \( \chi(\mathbb{RP}^2) = 1 \), as we had determined on page 1364.

In Question 30.7 we asked how the genus of a surface changes if we take finite covers. We had answered this question already in Proposition 31.6 (1). The proof of the following lemma is arguably more conceptual and easier to remember.

Lemma 55.9. Let \( \Sigma \) be the surface of genus \( g \) and let \( \tilde{\Sigma} \to \Sigma \) be a \( k \)-fold connected covering. Then

\[
\text{genus}(\tilde{\Sigma}) = k \cdot (g - 1) + 1.
\]

Example. In Figure 549 we illustrate a 3-fold covering of the surface of genus 4 over the surface of genus 2.

Remark. We had given an alternative proof of Lemma 55.9 in Exercise 31.6. The new proof using Euler characteristics is surely much more instructive than our previous proof.

Proof. We denote by \( \tilde{g} \) the genus of \( \tilde{\Sigma} \). The lemma follows immediately from the following two facts:

1. By the remark on page 1363 we have \( \chi(\Sigma) = 2 - 2g \) and \( \chi(\tilde{\Sigma}) = 2 - 2\tilde{g} \).
2. By Proposition 37.4 we have \( \chi(\tilde{\Sigma}) = k \cdot \chi(\Sigma) \).

Now we can also give a new proof of the following proposition.

Proposition 31.17. If \( g \geq 1 \), then the group

\[
\pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] : \cdots : [x_g, y_g] \rangle
\]

is not isomorphic to the free group \( F_{2g} \) on \( 2g \) generators.

Proof. Let \( \Sigma \) be a surface of genus \( g \geq 1 \). We write \( \pi = \pi_1(\Sigma) \). Suppose that there exists an isomorphism \( \varphi : \pi \to F \) where \( F \) is the free group on \( 2g \) generators. Let \( \alpha : \pi \to \mathbb{Z}_k \) be an epimorphism for some \( k \geq 2 \). We denote by \( p : \tilde{\Sigma} \to \Sigma \) the covering which satisfies \( p_*(\pi_1(\Sigma)) = \ker(\alpha) \) which is given by Proposition 29.5. By Lemma 16.15 (3) this is a \( k \)-fold

---

\[860\text{Recall that by the Surface Classification Theorem 23.4 there exists precisely one } \tilde{g} \text{ such that the closed, oriented 2-dimensional smooth manifold } \tilde{\Sigma} \text{ is diffeomorphic to precisely the surface of genus } \tilde{g}.\]

\[861\text{Why does such an epimorphism exist?}\]
covering. We get the following commutative diagram:

\[
\begin{array}{cccccc}
\pi & \xrightarrow{\cong} & \ker(\alpha) & \xrightarrow{\cong} & \pi_1(\Sigma_k(g-1)+1) & \xrightarrow{\text{abelianization}} & \mathbb{Z}^{2k(g-1)+2} \\
\phi & \cong & \phi & \cong & \cong & \cong & \cong \\
F & \xrightarrow{\cong} & \ker(\alpha \circ \phi^{-1}) & \xrightarrow{\cong} & F_k(2g-1)+1 & \xrightarrow{\text{abelianization}} & \mathbb{Z}^{k(2g-1)+1} \\
\end{array}
\]

It follows from \(k \geq 2\) that \(2k(g-1)+2 \neq k(2g-1)+1\), hence the two groups on the right cannot be isomorphic. We have thus obtained a contradiction. ■

55.3. Groups acting on spheres and surfaces. We recall that on page 185 we said that a group \(G\) acts freely on a topological space \(X\) if for every \(g \neq e\) and every \(x \in X\) we have \(g \cdot x \neq x\). For example for each \(k \in \mathbb{N}\) the action

\[
\mathbb{Z}_k \times S^1 \to S^1, \quad (l, z) \mapsto e^{2\pi il/k} \cdot z
\]

is free. We can easily generalize this example. More precisely, let \(S^{2n-1}\) be an odd-dimensional sphere. We view \(S^{2n-1}\) as subset of \(\mathbb{R}^{2n} = \mathbb{C}^n\). Then it is straightforward to show that

\[
\mathbb{Z}_k \times S^{2n-1} \to S^{2n-1}, \quad (l, (z_1, \ldots, z_n)) \mapsto (e^{2\pi il/k} z_1, \ldots, e^{2\pi il/k} z_n)
\]

is a free and continuous action of \(\mathbb{Z}_k\) on \(S^{2n-1}\).

It is less clear what finite groups can act freely and continuously on even-dimensional spheres. The group \(\mathbb{Z}_2 \cong \{\pm 1\}\) acts of course freely and continuously on any sphere. The following proposition says that \(\mathbb{Z}_2\) is in fact the only finite non-trivial group that can act freely and continuously on an even-dimensional sphere. This proposition and the above example give a complete answer to Question 16.8.

**Proposition 55.10.** If a finite group \(G\) acts freely and continuously on \(S^{2n}\), then \(G\) is either trivial or \(G \cong \mathbb{Z}_2\).

**Proof.** Let \(G\) be a finite group that acts freely and continuously on \(S^{2n}\). By Lemma 16.5 the action is also discrete. By Proposition 16.9 the projection map \(S^{2n} \to S^{2n}/G\) is a covering of degree \(|G|\). We obtain the equalities

\[
2 = \chi(S^{2n}) = |G| \cdot \chi(S^{2n}/G).
\]

If follows that \(|G|\) divides two, i.e. \(|G| = 1\) or \(|G| = 2\). In first case the group \(G\) is the trivial group and in the second case we have \(G \cong \mathbb{Z}_2\) ■

We already gave a different proof of Proposition 55.10 in Exercise 45.21. But whereas the approach of Exercise 45.21 made very much use of the topology of spheres, the approach taken in the above proof generalizes to many other settings:

\[\text{Why is every group with two elements isomorphic to } \mathbb{Z}_2?\]
**Proposition 55.11.** Let \( g \in \mathbb{N}_0 \). If a finite group \( G \) acts freely and continuously on the surface \( \Sigma \) of genus \( g \), then the order of \( G \) divides \( \chi(G) = 2 - 2g \).

**Proof.** The proof of Proposition 55.11 is verbatim the same as the proof of Proposition 55.10. The only change is that we need to use the fact, shown on page 1363, that \( \chi(\Sigma) = 2 - 2g \).

**Example.** Let \( \Sigma \) be the surface of genus four. By the remark on page 1363 we know that \( \chi(\Sigma) = -6 \). By Proposition 55.10 we know that the order of any finite group acting freely and continuously on \( \Sigma \) has to have an order that divides 6. In Figure 844 we sketch a free and continuous action of the group \( \mathbb{Z}_3 \) on \( \Sigma \). In Exercise 55.10 we will see that given any \( n \) with \( n|\chi(\Sigma) \) the cyclic group \( \mathbb{Z}_n \) admits a free and continuous action on \( \Sigma \).

![Figure 844](image)

55.4. **Topological graphs** (*). Using the results of this chapter we can now easily prove the following lemma:

**Lemma 55.12.** Let \( G \) be a connected topological graph with \( v \) vertices and \( e \) edges. Then

\[
H_0(G) \cong \mathbb{Z}, \quad H_1(G) \cong \mathbb{Z}^{e-v+1} \quad \text{and} \quad H_i(G) = 0 \text{ for } i \geq 2.
\]

**Example.** In Figure 845 we see a connected topological graph \( G \) with 22 vertices and 24 edges. It follows from Lemma 55.12 that its first homology group is isomorphic to \( \mathbb{Z}^3 \). In Figure 845 we sketched three cycles which represent a generating set for \( H_1(G) \cong \mathbb{Z}^3 \).

![Figure 845](image)

**Proof.** Let \( G \) be a connected topological graph with \( v \) vertices and \( e \) edges. Recall that by the discussion on page 332 we can view \( G \) as a 1-dimensional CW-complex with \( v \) 0-cells and \( e \) 1-cells.
Now that we have developed so many techniques for computing homology groups it is perhaps not surprising that we can provide three different proofs for the lemma.

1) First of all, from Proposition 41.5 together with Proposition 36.10 (7) it follows immediately that $H_0(G) \cong \mathbb{Z}$. Furthermore, from Proposition 48.5 it follows that $H_i(G) = 0$ for $i \geq 2$ and that $H_1(G)$ is torsion-free.

From Proposition 55.1 we obtain that

$$\chi(X) = \sum_i (-1)^i \cdot \text{rank}(H_i(X)).$$

Putting everything together we see that

$$1 - \text{rank}(H_1(G)) = \chi(X) = \#0\text{-cells} - \#1\text{-cells} = v - e.$$

Since $H_1(G)$ is torsion-free we obtain that $H_1(G) \cong \mathbb{Z}^{e-k+1}$.

2) We can also modify the argument of (1) as follows: instead of calculating $H_1(G)$ using the Euler characteristic, we could also have determined that $H_1(G) \cong \mathbb{Z}^{e-k+1}$ by combining the calculation of the fundamental group in Proposition 20.5 with the isomorphism of the Hurewicz Theorem 52.5.

3) An alternative proof for Lemma 55.12 is given as follows: we have

$$\tilde{H}_j(G) \cong \tilde{H}_j(\text{wedge of } 1 - \chi(G) \text{ circles}) \cong \bigoplus_{i=1}^{1-\chi(G)} \tilde{H}_j(S^1) \cong \begin{cases} \mathbb{Z}^{1-\chi(G)}, & \text{if } j = 1, \\ 0, & \text{else.} \end{cases}$$

It is a matter of taste which of the three proofs is the nicest.

---

Exercises for Chapter 55

Exercise 55.1. Show that every CW-structure for the torus with one 0-cell has precisely one 2-cell.

Exercise 55.2.

(a) Let $k \in \mathbb{N}$. By Proposition 17.3 we know that the non-orientable surface $N_k$ admits an essentially unique 2-fold covering $\Sigma \to N_k$ that is orientable. What is the genus of $\Sigma$?

(b) Let $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$. By Proposition 17.3 we know that the non-orientable surface $N_{k,m}$ admits an essentially unique 2-fold covering $\Sigma \to N_{k,m}$ that is orientable. What is the genus of $\Sigma$ and what is the number of boundary components of $\Sigma$?

Remark. You could use Exercise 17.2.

Remark. These are precisely the same questions as in Exercise 23.11. But this time you can give a different, shorter proof using Euler characteristics.

Exercise 55.3. Let $X$ be a topological space and let $f : X \to X$ be a homeomorphism. In Proposition 46.21 we showed that for any $n \in \mathbb{N}_0$ there exists a short exact sequence

$$0 \to \text{coker}(H_n(X) \xrightarrow{f_* - \text{id}} H_n(X)) \to H_n(\text{Tor}(X, f)) \to \ker(H_{n-1}(X) \xrightarrow{f_* - \text{id}} H_{n-1}(X)) \to 0.$$
(a) Let $T = \mathbb{R}^2/\mathbb{Z}^2$ be the torus. Given $A \in \text{SL}(2, \mathbb{Z})$ we consider the homeomorphism

$$f(A): \mathbb{R}^2/\mathbb{Z}^2 \to \mathbb{R}^2/\mathbb{Z}^2$$

$$[v] \mapsto [Av].$$

Determine the homology groups of $\text{Tor}(T,f(-\text{id})).$

Remark. You can use the fact that under the usual identification $H_1(T) = \mathbb{Z}^2$ the induced map $f(A)_* \text{ is given by multiplication by } A^{563}.$

(b) Does there exist a matrix $A \in \text{SL}(2, \mathbb{Z})$ such that $H_1(\text{Tor}(T,f(A))) \cong \mathbb{Z}^2$?

(c) Let $X$ be a topological space that is homotopy equivalent to a finite CW-complex. Show that for any self-homeomorphism $f$ of $X$ we have

$$\chi(\text{Tor}(X,f)) = 0.$$

**Exercise 55.4.** For a topological space $X$ and $n \in \mathbb{N}_0$ we denote by $b_n(X) \in \mathbb{N}_0 \cup \{\infty\}$ the rank of $H_n(X).$ Does there exist a topological space $X$ such that $b_1(X) < \infty$ but such that for a finite cover $\tilde{X}$ of $X$ we have $b_1(\tilde{X}) = \infty$?

**Exercise 55.5.** Given $g, n, \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface of genus $g$ minus $n$ open disks. Let $g, k, m, n \in \mathbb{N}_0.$ Suppose there exists a smooth embedding $\Sigma_{g,m} \to \Sigma_{k,n}.$ Show that $g \leq k.$

*Hint.* Use Proposition 6.30.

**Figure 846.** Rather schematic illustration of Exercise 66.14

**Exercise 55.6.** Let $\Sigma$ be a 2-dimensional smooth manifold. A *curve system* is a collection of disjoint curves (i.e., closed connected 1-dimensional smooth manifolds) $C_1, \ldots, C_n$ on $\Sigma$ with the following two properties:

1. None of the $C_i$ is the boundary of a disk on $\Sigma$.
2. There is no annulus on $\Sigma$ such that the boundary is the union of two curves.

In Figure 847 on the right we see a curve system on the surface of genus two consisting of three curves.

(a) Is there a curve system consisting of four curves on the surface of genus two?

(b) Given $g \in \mathbb{N}_0,$ what is the maximal number of curves in a curve system on the surface of genus $g$?

**Exercise 55.7.** We consider the topological graph $G$ together with the map $f: G \to G$ shown in Exercise 55.7. Determine the determinant and the trace of the induced map $f_*: H_1(G) \to H_1(G).$

---

863 Why does this hold?
Remark. In the proof of Lemma 55.12 we gave three different, more or less explicit, isomorphisms $\varphi: H_1(G) \cong \mathbb{Z}^2$. The challenge now is to find an isomorphism $\varphi$ that is explicit enough so that one can calculate the map $\varphi \circ f \circ \varphi^{-1} : \mathbb{Z}^2 \to \mathbb{Z}^2$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure847.png}
\caption{Figure 847. Illustration of Exercise 55.12.}
\end{figure}

Exercise 55.8. Let $M$ be a compact orientable connected 2-dimensional smooth manifold.

(a) Show that there exists a $g \in \mathbb{N}_0$ such that $M$ admits $g$ disjoint curves such that the complement is connected, but such that any $g + 1$ disjoint curves disconnect $M$.

(b) Show that $g$ equals the genus of $M$, as defined on page 672.

Remark. This exercise gives an intrinsic definition of the genus of a compact orientable connected 2-dimensional smooth manifold.

Exercise 55.9. Let $M$ be a closed non-orientable connected 2-dimensional smooth manifold. We define $k(M) \in \mathbb{N}_0$ to be the maximum $k \in \mathbb{N}_0 \cup \{\infty\}$ such that there exist $k$ smooth embeddings of the Möbius band into $M$ with the following two properties: the images are disjoint and the complement of images is connected.

(a) Let $K$ be the Klein bottle. Show that $k(M) \geq 2$.

(b) Let $M$ be a closed non-orientable connected 2-dimensional smooth manifold.

(i) Show that $k(M)$ is finite.

(ii) Show that $k(M)$ equals the genus of $M$, as defined on page 672.

Remark. This exercise gives an intrinsic definition of the genus of a compact non-orientable connected 2-dimensional smooth manifold.

Exercise 55.10.

(a) Let $N_3 = \mathbb{RP}^2 \# \mathbb{RP}^2 \# \mathbb{RP}^2$ be the non-orientable surface of genus three. Show that given any even $n \in \mathbb{N}$ there exists a connected orientable covering $p: \Sigma \to N_3$ of degree $n$.

(b) Let $\Sigma$ be the surface of genus $g$. Show that given any $k \in \mathbb{N}$ that divides $\chi(\Sigma)$ there exists a continuous and free action by the cyclic group $\mathbb{Z}_n$ on $\Sigma$.

Remark. This exercise gives in particular a more systematic solution to Exercise 3.33.
Exercise 55.11. Let $\Sigma$ be the torus minus one open disk. Furthermore let $\alpha, \beta: S^1 \to \Sigma$ be two disjoint embeddings with $\alpha_*([S^1]) = \beta_*([S^1]) \in H_1(\Sigma)$. We denote this homology class by $x$.

(a) Suppose that $x \neq 0$. Show that $\alpha$ is isotopic to $\beta$.
(b) Show that the conclusion of (a) does not necessarily hold, if we drop the hypothesis that $x \neq 0$.

Exercise 55.12. The two player game of “Brussels sprouts” works as follows:

(1) Initially one draws $n$ disjoint crosses on a 2-dimensional smooth manifold.
(2) The two players take turns to do the following move: Join two free ends with a curve, without crossing any existing curve, and then put a short stroke across the new curve to create two new free ends.

Such a game with $n = 2$ is illustrated in Figure 849.

(a) Suppose that the game takes place on the plane $\mathbb{R}^2$. Show that if $n$ is odd, then the first player will always win and show that if $n$ is even, then the second player invariably wins.
(b) Show that the conclusion of (a) also holds if the game takes place on a closed orientable 2-dimensional smooth manifold.

Remark. The game of “Brussels sprouts” is a variation on the more interesting game “sprouts” introduced by John Conway and Michał Paterson in the 1967. More information on “Sprouts” and “Brussels sprouts” can be found in [FiG91, Chapter 6] and [Gar89, Chapter 1].
56. Applications of the Euler characteristic (*)

In this chapter we show that the fairly simple concept of the Euler characteristic can be used to give answers to several questions about 3-dimensional objects. The reader is warned in that in this chapter at times we will sacrifice complete notational rigor for readability.

56.1. Building a leather football. In this section we will discuss the shapes of footballs and the platonic solids. The results of this section will not be used later on and we will present some of the material in a slightly informal, somewhat less rigorous style.

First we recall that an $n$-gon on the 2-dimensional sphere $S^2$ is called regular if the isometry group of the sphere acts transitively on the set of vertices and the set of faces of the $n$-gon. In particular all interior angles are the same. For example the classical leather football, see Figure 850, is made out of regular pentagons and hexagons.

![regular pentagon and hexagon](image)

**Figure 850**

Now we want to determine how many pentagons and hexagons are required to make a football. So suppose a football is made out of $p$ spherical regular pentagons and $h$ spherical regular hexagons where the vertices of the pentagons are precisely the vertices of hexagons. This endows $S^2$ with a CW-structure. We first note that each 1-cell bounds two 2-cells. Furthermore, elementary spherical geometry, see e.g. [Bon09] p. 53 or [Fen01] p. 260, says that the interior angle of a spherical pentagon and a spherical hexagon are larger than the corresponding Euclidean angles. Therefore we see that interior angles are larger than $\pi - \frac{2\pi}{5} = \frac{3\pi}{5}$. So at any vertex there are not more than three hexagons and pentagons that meet, which of course implies that there are precisely three hexagons and pentagons that meet. Therefore we see that

\[
\begin{align*}
\#2\text{-cells} &= p + h \\
\#1\text{-cells} &= \frac{1}{2}(5p + 6h) \\
\#0\text{-cells} &= \frac{1}{3}(5p + 6h).
\end{align*}
\]

By Proposition 55.1 and the above calculation of the Euler characteristic of $S^2$ we now have

\[
2 = \chi(S^2) = \sum_{n=0}^{2} (-1)^n \cdot \#n\text{-cells} = \frac{1}{3}(5p + 6h) - \frac{1}{2}(5p + 6h) + (p + h) = \frac{1}{6}p.
\]

Thus we see that a football has to have precisely 12 pentagons. On the other hand, the number of hexagons is not fixed. For example, the standard football has 20 hexagons, as pictured in Figure 851 on the left. But in principle one could also build a football with zero hexagons, see Figure 852 on the right, and one obtains a spherical dodecahedron. One

---

Where does that formula come from?
could also build with many hexagons, but they would be much less round since they would have bigger flat parts.

The 1-skeleton of this CW-structure were in fact already “invented by nature”, more precisely, there exists a molecule, called the Buckminsterfullerene $C_{60}$, built out of 60 carbon atoms, which has exactly the same shape as a football. More information can be found at

56.2. **Platonic solids**. Recall that on page 123 we defined the *convex hull* of a subset $S \subset \mathbb{R}^n$ as the intersection of all convex subsets of $\mathbb{R}^k$ that contain $S$. Since the intersection of convex sets is again convex we see that the convex hull of $S$ is a convex subset of $\mathbb{R}^k$.

*Definition.*

1. A *convex polyhedron* is the convex hull of finitely many points in $\mathbb{R}^k$.
2. The *dimension of a convex polyhedron* is defined as the minimal dimension of an affine subspace of $\mathbb{R}^k$ that contains the convex polyhedron.

We leave the task of providing a proof of the following lemma to the meticulous reader.

---

\[\sum_{i=1}^n t_i P_i \mid t_1, \ldots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^n t_i = 1\].
**Lemma 56.1.** If $P$ is a convex polyhedron in $\mathbb{R}^k$, then there exists a unique finite set $V$ such that $P$ is the convex hull of $V$, but such that for any proper subset $W$ of $V$, $P$ is not the convex hull of $W$.

**Definition.** Let $P$ be a convex polyhedron in $\mathbb{R}^k$.

1. We refer to the finite set of Lemma 56.1 as the *vertices of the convex polyhedron* $P$.
2. If $P$ is a $k$-dimensional convex polyhedron, then an *edge* of the convex polyhedron is the convex hull of two vertices that has the property that it lies on $\partial P$.
3. If $P$ is a $k$-dimensional convex polyhedron, then an *$m$-dimensional face* of the convex polyhedron is the convex hull of $m$ vertices that has the property that it lies on $\partial P$. (In particular, by definition a 1-dimensional face is exactly the same as an edge.)
4. An edge is a 1-dimensional face and sometimes we refer to a 2-dimensional face just as a *face*, without specifying the dimension.
5. The *valence* of a vertex is defined as the number of edges that contain the vertex.

**Example.** The notion of a vertex, an edge, a face and the valence of a vertex are illustrated in Figure 854.

**Proposition 56.2. (Euler’s Formula)** Let $P$ be a $k$-dimensional convex polyhedron in $\mathbb{R}^k$.

1. The interior $\hat{P}$ of $P$ is non-empty and all faces of $P$ are of dimension $\leq k - 1$.
2. The boundary $\partial P$ admits a CW-structure such that for each $j \in \mathbb{N}_0$ the $j$-cells are precisely the $j$-dimensional faces of $P$.

---

Here $\partial P$ is the boundary of $P$ viewed as a subset of $\mathbb{R}^k$. 

---

**Figure 853.** Illustration of Lemma 56.1.

**Figure 854.**
56. APPLICATIONS OF THE EULER CHARACTERISTIC (*)

(3) We have
\[ \sum_{j=0}^{k-1} (-1)^j \cdot \#j\text{-dimensional faces} = 1 + (-1)^{k-1}. \]

**Remark.** The 3-dimensional version of Proposition 56.2 gives us that for the boundary of a 3-dimensional convex polyhedron in \( \mathbb{R}^3 \) we have
\[
\text{number of vertices} - \text{number of edges} + \text{number of faces} = 2.
\]

This equality is known as Euler’s Formula and was first formulated Leonhard Euler in 1752. Arguably Euler’s Formula is historically the first result in topology. A famous book by Imre Lakatos [Lak76] is dedicated to the challenge of finding a rigorous proof of Euler’s Formula without employing the technical machinery, namely singular homology, that we used.

**Proof.** We leave the pleasure of proving the first two statements to the reader as Exercise 56.1. Now we calculate that
\[
\sum_{j=0}^{k-1} (-1)^j \cdot \#j\text{-dimensional faces} \overset{\uparrow}{=} \chi(\partial P) \overset{\uparrow}{=} \chi(S^{k-1}) \overset{\uparrow}{=} 1 + (-1)^{k-1}.
\]
by (1) and (2) Proposition 2.52 (2) see page 1363

We move on to the next definitions.

**Definition.**

1. Let \( P \) be a convex \( m \)-dimensional polyhedron in \( \mathbb{R}^k \).
   a. A rotational symmetry of \( P \) in \( \mathbb{R}^k \) is a matrix \( A \in \text{SO}(k) \) such that \( A \cdot P = P \).
   The rotational symmetry group \( \text{Sym}(P) \subset \text{SO}(k) \) is defined as the group of all rotational symmetries of \( P \).
   b. A flag of \( P \) is a sequence \( F_0 \subset F_1 \subset \cdots \subset F_{m-1} \) of faces of \( P \) such that each \( F_i \) is \( i \)-dimensional.
   c. A convex polyhedron \( P \) is called regular if the rotational symmetry group \( \text{Sym}(P) \) acts transitively on the set of flags of \( P \).
2. Two convex polyhedra \( P \) and \( Q \) in \( \mathbb{R}^k \) are called equivalent if there exists an \( r > 0 \), a point \( v \in \mathbb{R}^k \), and an orthogonal matrix \( A \in \text{SO}(k) \) with \( P = A \cdot (r \cdot Q) + v \).

\[ \begin{align*}
\text{three flags in the regular tetrahedron } T
\end{align*} \]

**Figure 855**

**Examples.**

1. Let \( T \) be the 3-dimensional polyhedron in \( \mathbb{R}^3 \) that has four 2-dimensional faces, each of which is an equilateral triangle. We show \( T \) together with three flags in Figure 855. Some elementary geometry shows that \( T \) is, up to equivalence, uniquely defined and it is regular. We refer to \( T \) as the regular tetrahedron.
(2) The standard \( n \)-simplex \( \Delta^n \) is an \( n \)-dimensional convex polyhedron in \( \mathbb{R}^{n+1} \) with vertex set \( \{(1,0,\ldots,0),(0,1,0,\ldots,0),\ldots,(0,\ldots,0,1)\} \). Each vertex has valence \( n \). It is straightforward to see that \( \Delta^n \) is regular.

(3) Let \( n \in \mathbb{N}_{\geq 3} \) and \( r > 0 \). The convex hull of the points \( r, re^{2\pi i/n}, \ldots, re^{2\pi i(n-1)/n} \) in \( \mathbb{C} = \mathbb{R}^2 \) is a regular convex polyhedron with vertices \( r, re^{2\pi i/n}, \ldots, re^{2\pi i(n-1)/n} \), where each vertex has valence 2. We leave it to the reader to show that, up to equivalence, these are all regular 2-dimensional convex polyhedra in \( \mathbb{R}^2 \). We refer to Figure 856 for an illustration.

(4) The convex polyhedron spanned by \( \{(\pm 1,0,0),(0,\pm 1,0),(0,0,\pm 1)\} \) is a regular 3-dimensional convex polyhedron where each vertex has valence 4. This convex polyhedron is usually called the *regular octahedron*. We refer to Figure 856 for an illustration.

\[ \text{convex hull of } 1, e^{2\pi i/5}, \ldots, e^{2\pi i/5} \]

\[ \text{convex hull of } \{(\pm 1,0,0),(0,\pm 1,0),(0,0,\pm 1)\} \]

\[ \text{regular convex polyhedron in } \mathbb{R}^2 \]

\[ \text{regular octahedron} \]

\[ \text{Figure 856} \]

(5) We consider the cube \([-1,1]^3 \subset \mathbb{R}^3\). In [Arm88, p. 38] it is shown that \( \text{Sym}([-1,1]^3) \) is isomorphic to \( S_4 \). More precisely, we denote by \( D \) the set of the diagonals in the cube, i.e. the segments in \( \mathbb{R}^3 \) spanned by opposite vertices of the cube. Note that \( D \) has precisely four elements. We refer to Figure 857 for an illustration. Then the map

\[ \text{Sym}([-1,1]^3) \rightarrow S_4 \cong \text{permutation group of } D \]

\[ A \mapsto \begin{pmatrix} D & \rightarrow & D \\ d & \mapsto & A \cdot d \end{pmatrix} \]

is shown in [Arm88, p. 38] to be an isomorphism.\(^{869}\) It is clear that the cube is a regular convex polyhedron. Since it has six sides it is in our context also referred to as *regular hexahedron*.

\[ \text{Figure 857. The four diagonals in a cube.} \]

(6) Let \( z := 1 + \frac{\sqrt{5}}{2} \) be the golden ratio. We denote by \( D \) the polyhedron that is spanned by the 20 vertices

\[ (\pm 1,\pm 1,\pm 1), \quad (0,\pm z,\pm \frac{1}{z}), \quad (\pm \frac{1}{z},0,\pm z), \quad \text{and} \quad (\pm z,\pm \frac{1}{z},0). \]

\(^{869}\) It is a good exercise to verify this statement.
It is illustrated in Figure 858. By [Cox48, p. 53] this is a regular polyhedron. We refer to it as the *regular dodecahedron*. Note that it has 12 faces and 20 vertices. We can inscribe five cubes $C_1, \ldots, C_5$ into the regular dodecahedron. In [Arm88, p. 40] it is shown that the map
\[
\text{Sym}(D) \to A_5 \cong \text{positive permutations of } \{C_1, \ldots, C_5\}
\]
\[
A \mapsto (C_i \mapsto A \cdot C_i)
\]
is an isomorphism.

![Regular dodecahedron, cube inscribed into the regular dodecahedron, five diagonals of a face correspond precisely to one inscribed cube](image)

**Figure 858**

(7) Let $z := 1 + \frac{\sqrt{5}}{2}$ be the golden ratio. We denote by $I$ the polyhedron that is spanned by the 12 vertices

\[
(0, \pm 1, \pm z), \quad (\pm z, 0, \pm 1) \quad \text{and} \quad (\pm 1, \pm z, 0).
\]

By [Cox48, p. 52] this is a regular polyhedron. We refer to it as the *regular icosahedron*. Note that the regular dodecahedron has 20 vertices and 12 faces whereas the regular icosahedron has 12 vertices and 20 faces. In fact the regular icosahedron is dual to the regular dodecahedron in the following sense: up to a scaling factor and a rotation, the regular icosahedron is spanned by the centers of the faces of the regular dodecahedron and vice-versa. We refer to Figure 859 for an illustration of this fact. It follows that the symmetry group of the regular icosahedron $I$ is in a suitable sense equal to the symmetry group of the regular dodecahedron $D$. In particular the group Sym($I$) is isomorphic to $A_5$.

![Regular dodecahedron, regular icosahedron](image)

**Figure 859**

The following definition is one of the oldest in the history of mathematics.

*Definition.* A *Platonic solid* is a regular 3-dimensional convex polyhedron in $\mathbb{R}^3$. 

---

56. APPLICATIONS OF THE EULER CHARACTERISTIC (*) 1383
Theorem 56.3. Up to rotation and stretching the only regular convex 3-dimensional polyhedra in \( \mathbb{R}^3 \) are the platonic solids illustrated in Figure 860. They have the following types of faces and valences and they have the following rotational symmetry groups:

<table>
<thead>
<tr>
<th></th>

<td>( A_5 )</td>
</tr>
</tbody>
</table>

Figure 860. The five platonic solids.

Sketch of proof. We will not provide a full proof for the theorem. We refer to [Cox48, Section 6.7] for a full proof that the list of five platonic solids is indeed complete. Furthermore we refer to [Arm88, p. 40] or alternatively to [Aa08, Chapter 5.5] for a proof of the statement regarding the rotational symmetry groups.

In the following we will show that any platonic solid fits into the table of the theorem. Put differently, we will show that given any platonic solid the number of faces, the shape of faces and the valence of a vertex corresponds to one of the five columns in the above table.

Thus let \( P \) be a regular convex 3-dimensional polyhedron in \( \mathbb{R}^3 \). We make the following observations:

1. It follows easily from the definition of a regular polyhedron that there exists an \( m \) such that each face of \( P \) is a regular \( m \)-gon.
2. The number of faces that meet a vertex is the same for every vertex and it is at least three.

The following claim tells us the possible values for \( m \) and the number of faces that meet at a vertex.

Claim.

<table>
<thead>
<tr>
<th>possible values for ( m )</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>faces that meet at a vertex</td>
<td>3, 4, 5</td>
<td>4</td>
<td>3</td>
</tr>
</tbody>
</table>

We had sketched the proofs for the regular hexahedron, the regular dodecahedron and the regular icosahedron.
First note that after a translation we can assume that the sum of all vertices is in the origin. Next we shrink the convex polyhedron so that it fits into the sphere $S^2$. Then we consider the projection of the vertices and edges of the convex polyhedron onto the sphere, see Figure 861. Recall that the spherical interior angle of a regular $m$-gon is greater than the Euclidean angle of a regular $m$-gon. So it follows that in our case the interior angle is greater than the angle of a regular $m$-gon in $\mathbb{R}^3$, i.e. it is greater than $\pi - \frac{2\pi}{m}$ Since at any vertex at least three faces meet we obtain the restriction that $3(\pi - \frac{2\pi}{m}) < 2\pi$. It is now straightforward to see that we obtain the stated table.

Now we treat the cases $m = 3, 4, 5$ separately. We start out with the case $m = 3$, i.e. we assume that all the faces of the convex polyhedron are equilateral triangles. Let us first consider the case that three triangles meet at a vertex. Then we have

$$
\#\text{faces} = k, \quad \#\text{edges} = \frac{1}{2} \cdot 3k \quad \text{and} \quad \#\text{vertices} = \frac{1}{3} \cdot 3k.
$$

Now we see that

$$
2 = \#\text{vertices} - \#\text{edges} + \#\text{faces} \quad \uparrow \quad \text{Euler's Formula 56.2}
$$

$$
= k - \frac{3}{2}k + k = \frac{1}{2}k.
$$

It follows that $k = 4$. Almost the same calculation shows that if four triangles meet at a vertex, then $k - \frac{3}{2}k + \frac{4}{2}k = 2$, i.e. $k = 8$. Finally by the above claim it remains to consider the case that five triangles meet at a vertex. In this case we see that $k - \frac{3}{2}k + \frac{5}{2}k = 2$, i.e. $k = 20$.

Next we consider the case $m = 4$, i.e. each face is a square. The same argument as above shows that the valence of a vertex can only be three and the same calculation shows that there have to be precisely six faces. Finally if $m = 5$, i.e. if each face is a regular pentagon, then as above we see that the valence of a vertex can only be three and that there have to be precisely twelve faces.

On page 1382 we had just seen that there exist infinitely many equivalence classes of regular convex polyhedra in $\mathbb{R}^2$. On the other hand we have just seen in Theorem 56.3 that in $\mathbb{R}^3$ there are only finitely many, namely precisely five equivalence classes of regular convex polyhedra in $\mathbb{R}^3$. This begs the question, what is the number in higher dimensions? It turns out that in $\mathbb{R}^4$ there are six equivalence classes of regular convex polyhedra, whereas in all higher dimensions there are only three equivalence classes of convex polyhedra.
nice exposition of these facts is given on the following website:

http://math.ucr.edu/home/baez/platonic.html

56.3. **Planar graphs**. On pages 221 and 226 we defined the notions of an (ordered) abstract graph. By Lemma 4.4 and the discussion on page 480 we know that they have homeomorphic topological realizations. In this section we will mostly deal with undirected abstract graphs. Since this name is rather unwieldy we will refer to them just as graphs. For the convenience of the reader we recall the definition.

**Definition.** An *(undirected abstract) graph* $G$ is a triple $(V, E, \varphi)$ where $V$ is a non-empty set, $E$ is a set and $\varphi$ is a map

$$\varphi: E \to \{\text{subsets of } V \text{ with one or two elements}\}.$$  

The elements of $V$ are called *vertices of $G$* and the elements of $E$ are called the *edges of $G$*.

**Examples.**

(1) For $n \in \mathbb{N}$ we define the *complete graph* $K_n$ as the abstract graph with vertex set $V = \{v_1, \ldots, v_n\}$ and edge set $E = \{\{v_i, v_j\} \mid i, j \in \{1, \ldots, n\} \text{ with } i \neq j\}$. Furthermore we define $\varphi: E \to V$ via $\varphi(e) = e$. Put differently, the complete graph $K_n$ has $n$ vertices and each vertex is connected to any other vertex by precisely one edge. In Figure 863 we show topological realizations of the complete graphs $K_1, K_2, K_3, K_4$ and $K_5$.

![Figure 862](image)

(2) For every choice of $m, n \in \mathbb{N}$ we define the *complete bipartite graph* $K_{m,n}$ as the abstract graph which is defined by the vertex set $V = \{x_1, \ldots, x_m\} \cup \{y_1, \ldots, y_n\}$, the edge set $E = \{\{x_i, y_j\} \mid i \in \{1, \ldots, m\} \text{ and } j \in \{1, \ldots, n\}\}$ and the map $\varphi: E \to V$ via $\varphi(e) = e$. Put differently, the complete bipartite graph $K_{m,n}$ consists of $m$ “red-colored” vertices, $n$ “green-colored” vertices and each “red-colored” vertex is connected to any “green-colored” vertex by precisely one edge. In Figure 863 we show topological realizations of the complete bipartite graphs $K_{2,3}, K_{1,5}$ and $K_{3,3}$.

![Figure 863](image)

Let $G = (V, E, \varphi)$ be a graph. On page 222 we introduced its topological realization $\lvert G \rvert$. It follows from Lemma 4.4 and the discussion on page 932 that $\lvert G \rvert$ is naturally a
1-dimensional CW-complex where the 0-cells correspond to the vertices and the 1-cells correspond to the edges.

Let $G$ be a finite graph. On page 224 we had already mentioned that there exists an embedding of its topological realization $|G|$ into $\mathbb{R}^3$. In Question 4.3 we asked, without really expecting a positive answer, whether one can always find an embedding of $|G|$ into $\mathbb{R}^2$. This leads us to the following dimension.

Definition. We say a finite graph $G$ is planar if its topological realization $|G|$ admits an embedding $|G| \to \mathbb{R}^2$.

Examples.

(1) The above graphs $K_1, K_2, K_3$ and $K_{1,5}$ are planar. The above topological realizations of $K_4$ and $K_{2,3}$ are not planar. But as we see in Figure 864 both graphs admit planar realizations.

![topological realizations of $K_4$ and $K_{2,3}$](image)

Figure 864

(2) One can easily verify that given an $m \in \mathbb{N}$ the bipartite graph $K_{2,m}$ is planar.

Now the following question arises.

Question 56.4. Are the graphs $K_5$ and $K_{3,3}$ also planar?

If this question sounds too abstract and bipartite graphs sound too otherworldly let me reformulate the question regarding $K_{3,3}$.

Question 56.5. Suppose we are in charge of finding efficient bus routes in a given city. Furthermore suppose the city has three main employers $A, B$ and $C$. After work the employees, naturally, either want to go to the train station $\alpha$, or the swimming pool $\beta$, or the shopping mall $\gamma$. Is it possible to find bus routes which connect each of the three employers with each of the three destinations such that the bus routes do not intersect?\(^{872}\)

![bus routes](image)

Figure 865

To answer that question we need a few more definitions.

\(^{872}\)It follows easily from Proposition 8.29 that the answer to this question does not depend on the precise location of $A, B, C$ and $\alpha, \beta, \gamma$, as long as they are distinct.
Definition. Let $G$ be a graph.

1. Given $n \in \mathbb{N}$ we denote by $X_n$ the “circular graph with $n$ vertices and $n$ edges”, more precisely, $X_n$ is the graph with

$$V(X_n) = \{1, \ldots, n\} \quad \text{and} \quad E(X_n) = \{(1, 2), \{2, 3\}, \ldots, \{n-1, n\}, \{n, 1\}\}.$$

2. A cycle of length $n$ in $G$ is an injective map $\varphi : X_n \to G$ of graphs in the sense of the definition given in Exercise 15.4.

3. The girth of $G$ is the shortest length of a cycle in $G$. If $G$ has no cycles, then we define its girth as $\infty$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure866}
\caption{Figure 866}
\end{figure}

Examples.

1. The girth of the graph shown in Figure 866 to the right is one, since it has an edge where the two endpoints agree.
2. For any $n \geq 3$ the girth of the complete graphs $K_n$ equals three.
3. For any $n, m \geq 2$ the girth of the complete bipartite graphs $K_{n,m}$ equals four.

The following gives an obstruction to a graph being planar.

Proposition 56.6. Let $G$ be a graph with $v$ vertices and $e$ edges. We denote by $g$ the girth of $G$. If $G$ is planar and if $g < \infty$, then

$$e \leq \frac{g}{g-2} \cdot (v-2).$$

Sketch of proof. Let $G$ be a graph with $v$ vertices and $e$ edges. We suppose that the girth $g$ of $G$ is finite. Furthermore we suppose that $G$ is planar, i.e., we suppose that there exists an embedding $\varphi : |G| \to \mathbb{R}^2$. We write $X = \varphi(|G|)$. Without loss of generality we can assume that $X$ lies in $B^2$.

Now we view $X$ as a subset of the sphere $S^2 = B^2/S^1$. We refer to the closures of the components of $S^2 \setminus X$ as faces and we denote by $f$ the number of faces. We refer to Figure 867 for an illustration. We make the following observation:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure867}
\caption{Figure 867}
\end{figure}

(2) We make the following two observations:  

(a) The boundary of each face is a cycle. By the definition of the girth each face is bounded by at least $g$ edges.

(b) Each edge lies in the boundary of at most two faces.  

Now we deduce that 

$$g \cdot f \leq \sum_{\text{faces } f} \text{number of edges in the boundary of } f = \sum_{\text{edges } e} \text{number of faces that contain } e \text{ in the boundary} \leq 2e.$$  

Here the first inequality follows from (a) and the last inequality follows from (b). Summarizing we see that $g \cdot f \leq 2e.$

Now we see that  

$$2 = \chi(S^2) = v - e + f \leq v - e + \frac{2}{g}e = v - \frac{g - 2}{g}e.$$  

Solving for $e$ we get the desired inequality $e \leq \frac{g}{g - 2} \cdot (v - 2).$  

The following proposition gives in particular a negative answer to Question 56.4.

**Proposition 56.7.** If a graph $G$ contains the complete graph $K_3$ or the complete bipartite graph $K_{3,3}$ as a subgraph, then $G$ itself cannot be planar.  

**Proof.**

(1) Let $m \in \mathbb{N}_{\geq 3}$. It is straightforward to see that the complete graph $K_m$ has $m$ vertices and $\frac{1}{2}m(m - 1)$ edges. Furthermore the girth is three. It is straightforward to verify that the inequality of Proposition 56.6 is only satisfied for $m = 3$ and $m = 4$.

(2) Let $m, n \in \mathbb{N}_{\geq 2}$. Again it easy to verify that the complete bipartite graph $K_{m,n}$ has $m + n$ vertices and $m \cdot n$ edges. Furthermore, as we pointed out above, the girth is four. It is straightforward to verify that the inequality of Proposition 56.6 is only satisfied if $m = 2$ or $n = 2$.

(3) The Proposition now follows from (1) and (2) and the observation that if a graph is planar, then any subgraph is also planar.  

**Remark.** Let $G$ be a graph that contains the complete graph $K_7$. By Proposition 56.7 the graph $G$ cannot be planar. John Conway and Cameron Gordon proved in 1984 the following interesting variation: given any embedding $\varphi : |G| \to \mathbb{R}^3$ such that image is a polygon (i.e. it is the union of finitely many line segments) the image $\varphi(|G|)$ contains a non-trivial polygonal knot. More precisely, there exists a closed polygon $C$ in $\varphi(|G|)$ such

---

873 Here is the reason why it is the sketch of a proof: we do not prove that each face is in fact homeomorphic to a closed disk. This statement is “clear from the picture” and it can be proved using the Schönflies Theorem 50.3. But we will not attempt to give a rigorous proof.
that \( \pi_1(\mathbb{R}^3 \setminus C) \) is not isomorphic to \( \mathbb{Z} \). We refer to \cite{CoG83} for the precise formulation of the theorem and the proof.

Now we will consider the question, to what degree the converse to Proposition 56.7 holds. First we need to introduce the notion of a subdivision of a graph. From Figure 868 it should become clear what is meant be a subdivision. As so often, the formal definition is a little cumbersome.

**Definition.** Let \( G = (V, E, \varphi : E \to \mathcal{P}(V)) \) be a graph.

1. Let \( e \in E \) be an edge. We say that a graph \( G' = (V', E', \varphi' : E' \to \mathcal{P}(V')) \) is a subdivision of \( G \) at \( e \) if \( V' = V \sqcup \{w\} \) and \( E' = (E \setminus \{e\}) \sqcup \{f_1, f_2\} \) with \( w \not\in V \) and \( f_1, f_2 \not\in E \) such that \( \varphi'(e') = e \) for \( e' \in E \setminus \{e\} \), \( \varphi'(f_1) = \{v_1, *\} \) and \( \varphi'(f_2) = \{v_2, *\} \) where \( \varphi(e) = \{v_1, v_2\} \).
2. We say a graph \( G' \) is a subdivision of \( G \) if \( G' \) is obtained from \( G \) by a finite sequence of subdivisions along edges.

The following lemma says in particular that “planarity” is unaffected by subdivisions.

**Lemma 56.8.** Let \( G \) be a graph. If \( G' \) is a subdivision of \( G \), then the topological realizations of \( G' \) and \( G \) are homeomorphic.

**Proof.** We leave it to the reader to provide the elementary proof of this lemma.

We move on to the final definition of this section.

**Definition.** We say a graph is simple if its girth is at least three.

Put differently, a graph \( G \) is simple if the following two conditions are satisfied:

1. \( G \) has no loops, i.e. if there is no edge where the two endpoints agree,
2. \( G \) does not have multiple edges, i.e. there are no two edges with the same endpoints.
In the remainder of this section we restrict ourselves to graphs that are simple. We start out with the following observations.

(1) If a simple graph $G$ admits a vertex $v$ of valence one, then $v$ is the endpoint of a single edge $e$. If we delete $v$ and $e$ we obtain a new graph $G'$. An argument as in the proof of Proposition 18.31 shows that the topological realization of $G'$ is homotopy equivalent to the topological realization of $G$. It is straightforward to see that $G$ is planar if and only if $G'$ is planar.

(2) If a simple graph admits a vertex $v$ of valence two, then $v$ is the endpoint of two edges $e_1$ and $e_2$. We can combine $e_1$ and $e_2$ into one edge and eliminate $v$. This way we obtain a new graph with a homeomorphic topological realization.

This shows that for the most part we can restrict ourselves to simple graphs where every vertex has valence at least three.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure870.png}
\caption{Theorem 56.9: Kuratowski’s Reduction Theorem.}
\end{figure}

If we restrict ourselves to simple graphs such that every vertex has valence at least three, then the graphs $K_5$ and $K_{3,3}$ turn out to be the only obstruction to being planar. More precisely the following theorem was proved by Kuratowski in 1930. We refer to [BoM08 Chapter 10.5] for a proof.

**Theorem 56.9. (Kuratowski’s Reduction Theorem)** Let $G$ be a finite simple graph such that every vertex has valence at least three. Then the following statements are equivalent:

1. The graph $G$ is planar.
2. The $G$ contains neither a subdivision of $K_5$ nor a subdivision of $K_{3,3}$ as a subgraph.

---

**Exercises for Chapter 56**

**Exercise 56.1.**

(a) Let $P$ be a $k$-dimensional convex polyhedron in $\mathbb{R}^k$. Show that the interior $\hat{P}$ of $P$ is non-empty.

(b) Let $Q$ be a $k$-dimensional convex polyhedron in some $\mathbb{R}^n$. Show that $Q$ is homeomorphic to $B^k$.

_Hint._ Use (a) and Proposition 2.52 (2).

(c) Let $P$ be a $k$-dimensional convex polyhedron in some $\mathbb{R}^n$. Show that $P$ admits a CW-structure such that the boundary $\partial P$ is a subcomplex and such that for each $j \in \mathbb{N}_0$ the $j$-cells in $\partial P$ are precisely the $j$-dimensional faces of $P$.

---

871 Recall that the _valence_ of a vertex is defined as the number of edges that contain the vertex.

872 Kazimierz Kuratowski (1896-1980) was a Polish mathematician.
Exercise 56.2.
(a) Show that there exist injective maps \(K_5 \to S^1 \times S^1\) and \(K_{3,3} \to S^1 \times S^1\).
(b) Let \(n \in \mathbb{N}_{>0}\). What is the smallest \(g\) that you can find such that there exists an injective map from \(K_n\) to the surface of genus \(g\)?

Exercise 56.3. In his last will, a farmer, who owns a rectangular plot, wants to distribute his land among his sons as follows:

1. every son gets a connected compact field with non-empty area,
2. every son should be the neighbor of every other son.

What is maximal number of sons for which the farmer’s last will can be fulfilled?

Remark. On the margin of the last will the farmer insists that the new distribution should give a CW-structure for the rectangular plot.

![Illustration of Exercise 56.3](image)

Figure 871. Illustration of Exercise 56.3

Exercise 56.4. Find an embedded loop on the edges of the dodecahedron that covers all vertices.

Remark. This is known as Hamilton’s “icosian game”. This puzzle was actually marketed in the 19th century as a board game.

![Illustration of Exercise 56.4](image)

Figure 872. Illustration of Exercise 56.4
57. Homology with coefficients

In this chapter we will introduce the homology groups of a topological space $X$ with coefficients in a ring $R$. These homology groups will have many applications, for example they will be essential in relating the homology groups of a smooth manifold $M$ to the de Rham cohomology groups of $M$. They will also be essential in proving theoretic statements, for example we will need to work with $\mathbb{F}_2$-coefficients to prove the higher-dimensional analogue of the Borsuk-Ulam Theorem [16.22]. Before we can introduce the homology groups with coefficients we will need to introduce or recall some basic algebraic concepts.

57.1. The tensor product of abelian groups. The key to defining homology groups with coefficients is the notion of the tensor product of two abelian groups.

Definition. Let $A$ and $B$ be abelian groups. We define the tensor product $A \otimes B$ to be the following abelian group:

$$A \otimes B := \left\{ \text{free abelian group which is generated by all symbols of the form } a \otimes b \text{ with } a \in A, b \in B \right\} / N(A, B)$$

where $N(A, B)$ is the subgroup generated by the elements of the form

$$(a + a') \otimes b - (a \otimes b + a' \otimes b) \quad \text{and} \quad a \otimes (b + b') - (a \otimes b + a \otimes b')$$

with $a, a' \in A$ and $b, b' \in B$. For $a \in A$ and $b \in B$ we denote, by a slight abuse of notation, the image of $a \otimes b$ in $A \otimes B$ again by $a \otimes b$.

We summarize some elementary properties of the tensor product of two abelian groups in the following lemma.

Lemma 57.1. Let $A$ and $B$ be two abelian groups.

1. For any $a, a' \in A$ and $b, b' \in B$ we have

$$(a + a') \otimes b = a \otimes b + a' \otimes b \in A \otimes B$$

$$(a \otimes (b + b')) = a \otimes b + a \otimes b' \in A \otimes B.$$  

2. For any $a \in A$, $b \in B$ and $m \in \mathbb{Z}$ we have

$$(m \cdot a) \otimes b = a \otimes (m \cdot b) = m \cdot (a \otimes b).$$

3. Any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} a_i \otimes b_i$.

4. Let $n \in \mathbb{N}$. For any $c \in A \otimes \mathbb{Z}_n$ we have $n \cdot c = 0 \in A \otimes \mathbb{Z}_n$.

Proof. Let $A$ and $B$ be two abelian groups.

1. This statement is an immediate consequence of the definition of the tensor product.

2. Let $a \in A$ and $b \in B$. We first consider the case that $m > 0$. We have

$$(m \cdot a) \otimes b = \left( \sum_{i=1}^{m} a \right) \otimes b = \sum_{i=1}^{m} a \otimes b = m \cdot (a \otimes b) = \ldots = a \otimes (m \cdot b).$$

by (1) \hspace{1cm} \text{same argument backwards}
It follows easily from (1) that $0 \otimes b = a \otimes 0 = 0$ and that $( -a ) \otimes b = a \otimes ( -b ) = -a \otimes b$. Using these observations we get statement (2) for $m = 0$ and we can easily reduce the case $m < 0$ of (2) to the case $m > 0$ of (2).

(3) It follows immediately from the definition of the tensor product, together with the notational convention of “formal linear combinations” that we introduced on page 580 that any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} r_i \cdot ( a_i \otimes b_i )$. But by (2) we know that $r_i \cdot ( a_i \otimes b_i ) = ( r_i \cdot a_i ) \otimes b_i$ thus we get the desired result.

(4) Let $n \in \mathbb{N}$ and let $c \in A \otimes \mathbb{Z}_n$. By (3) we can write $c = \sum_{i=1}^{m} a_i \otimes r_i$ with $a_1, \ldots, a_m \in A$ and $r_1, \ldots, r_m \in \mathbb{Z}_n$. Then

$$n \cdot c = n \cdot \left( \sum_{i=1}^{m} a_i \otimes r_i \right) = \sum_{i=1}^{m} a_i \otimes n \cdot r_i = 0.$$  

by statement (2) $\blacksquare$

**Definition.** Let $A,B$ and $C$ be abelian groups. We say that a map $f: A \times B \rightarrow C$ is **bilinear**, if for all $a, a' \in A$, $b, b' \in B$ the following equalities hold:

$$f(a + a', b) = f(a, b) + f(a', b) \quad \text{and} \quad f(a, b + b') = f(a, b) + f(a, b').$$

We leave it to the reader to provide the elementary proof of the following lemma.

**Lemma 57.2.** Let $A$ and $B$ be abelian groups.

(1) The map

$$f: A \times B \rightarrow A \otimes B$$

$$(a, b) \mapsto a \otimes b$$

is bilinear.

(2) Given any abelian group $G$ and any bilinear map $g: A \times B \rightarrow G$ there exists a unique homomorphism $\varphi: A \otimes B \rightarrow G$ such that the following diagram commutes:

$$
\begin{array}{ccc}
A \times B & \xrightarrow{f} & A \otimes B \\
g \downarrow & & \downarrow \varphi \\
G & & \\
\end{array}
$$

(3) Given any abelian group $G$ the map

$$\text{Hom}(A \otimes B, G) \rightarrow \text{set of bilinear maps } A \times B \rightarrow G$$

$$(\varphi: A \otimes B \rightarrow G) \mapsto (A \times B \xrightarrow{f} A \otimes B \xrightarrow{\varphi} G)$$

is a bijection.

**Remark.** One can show quite easily that if a homomorphism $g: A \times B \rightarrow H$ is bilinear and if this homomorphism satisfies the universal property of Lemma 57.2 (2), then there exists an isomorphism $H \cong A \otimes B$. We will not make use of this observation.

Before we state a few more properties of the tensor product it is convenient to introduce the following definition.
**Definition.** Let \( f: A \to A' \) and \( g: B \to B' \) be homomorphisms between abelian groups. We define \( f \otimes g \) to be the homomorphism that is given by

\[
\sum_{i=1}^n a_i \otimes b_i \mapsto \sum_{i=1}^n f(a_i) \otimes g(b_i)
\]

Now we can continue with the promised lemma on properties of the tensor product. On many occasions we will make use of it without explicitly referring to it.

**Lemma 57.3.** Let \( A, B, C \) and \( A_i, i \in I \) be abelian groups.

1. The maps

\[
A \otimes B \to B \otimes A \quad \text{and} \quad \left( \bigoplus_{i \in I} A_i \right) \otimes B \to \bigoplus_{i \in I} A_i \otimes B
\]

are well-defined and they are natural isomorphisms.

2. The map

\[
\left( A \otimes B \right) \otimes C \to A \otimes \left( B \otimes C \right)
\]

is well-defined and it is a natural isomorphism.

3. Let \( k \in \mathbb{N} \). The maps

\[
\mathbb{Z}_k \otimes A \to A/kA \quad \text{and} \quad \mathbb{Z} \otimes A \to A
\]

are well-defined and they are natural isomorphisms.

4. Suppose \((I, \leq)\) is an ordered set and \( \{(A_i)_{i \in I}, \{\varphi_{ij}\}_{i \leq j}\} \) is a direct system of abelian groups. Then the map

\[
\lim \to (A_i \otimes B) \xrightarrow{\cong} (\lim \to A_i) \otimes B
\]

that is induced by the maps \( A_i \to \lim A_i \) is a natural isomorphism.

**Proof.** We refer to [Lan93] Corollary XVI.2.2 for a proof for the distributivity in (1). The other statements in (1) to (3) follow fairly easily from the definitions and Lemma 57.1. We refer to [Mun84] Chapter 50 for details. A proof of the last statement is given in [Bon07] Chapter II.6.3 or alternatively in [Mats89] Theorem A1. 

**Remark.**

1. As we mentioned in the statement of Lemma 57.3, all the isomorphisms are natural, in the sense that they define natural transformations between appropriate functors. For

---

\(876\) It is straightforward to verify that the map \( f \otimes g \) is indeed well-defined and that it is a homomorphism.

\(877\) Note that for an abelian group \( A \) and \( k \in \mathbb{Z} \) the set \( kA := \{k \cdot a \mid a \in A\} \) is a subgroup of \( A \) and we can thus form the quotient \( A/kA \).
example if we denote by \(\text{AbGr}\) the category of abelian groups, then the isomorphisms of Lemma 57.3 (3) define a natural transformation between the two functors

\[
\text{AbGr} \to \text{AbGr} \quad \text{and} \quad \text{AbGr} \to \text{AbGr},
\]

\[
A \mapsto A \quad \text{and} \quad A \mapsto \mathbb{Z} \otimes A.
\]

As an example, for every \(k \in \mathbb{N}\) and any abelian group \(A\) we get a commutative diagram

\[
\begin{array}{ccc}
\mathbb{Z} \otimes A & \xrightarrow{\cong} & A \\
\downarrow \scriptstyle{k \otimes \text{id}} & & \downarrow \scriptstyle{k} \\
\mathbb{Z} \otimes A & \xrightarrow{\cong} & A \\
\end{array}
\]

(2) We use these natural isomorphisms from Lemma 57.3 to identify the various groups. Note that Lemma 57.3 (2) allows us to write the tensor product \(A \otimes B \otimes C\) unambiguously without having to worry about parentheses.

(3) In Lemma 57.3 we saw that the tensor product commutes with forming direct sums. The analogous statement is not true if we replace direct sums by direct products. More precisely, in Exercise 57.11 we will see that

\[
\left( \prod_{n \in \mathbb{N}} \mathbb{Z}_n \right) \otimes \mathbb{Q} \neq 0 \quad \text{but} \quad \prod_{n \in \mathbb{N}} (\mathbb{Z}_n \otimes \mathbb{Q}) = 0, \text{by Lemma 57.3 (3)}
\]

Examples.

(1) Let \(m, n \in \mathbb{N}\). We write \(r = \gcd(m, n)\) and \(s = m/r\). Then

\[
\mathbb{Z}_m \otimes \mathbb{Z}_n \cong \mathbb{Z}_n/m \mathbb{Z}_n = \mathbb{Z}_n/rs \mathbb{Z}_n = \mathbb{Z}_n/r \cdot (s \mathbb{Z}_n) \cong \mathbb{Z}_n/r \mathbb{Z}_n \iff \mathbb{Z}_r = \mathbb{Z}_{\gcd(m, n)}.
\]

Lemma 57.3 (3) since \(s\) is coprime to \(n\)

(2) Let \(A\) be a finitely generated abelian group of rank \(r\). By the classification of finitely generated abelian groups, see Theorem 19.4, we have \(A \cong \mathbb{Z}^r \oplus \bigoplus_{i=1}^n \mathbb{Z}_{a_i}\) where \(a_1, \ldots, a_n\) are non-zero natural numbers. For \(S = \mathbb{Q}, \mathbb{R}\) or \(S = \mathbb{C}\) we have

\[
A \otimes S \cong \left( \mathbb{Z}^r \oplus \bigoplus_{i=1}^n \mathbb{Z}_{a_i} \right) \otimes S = (\mathbb{Z} \otimes S)^r \oplus \left( \bigoplus_{i=1}^n \mathbb{Z}_{a_i} \otimes S \right) \cong S^r \oplus \bigoplus_{i=1}^n S/\mathbb{Z}_{a_i} S = S^r.
\]

Lemma 57.3 (1) Lemma 57.3 (3) since \(a_i \neq 0\) in \(S = \mathbb{Q}, \mathbb{R}, \mathbb{C}\)

(3) Let \(A\) be an abelian group, then

\[
\ker \left( \begin{array}{c}
A \\
A \otimes \mathbb{Q} \\
\end{array} \right) \quad \text{all torsion elements of } A.
\]

If \(A\) is finitely generated, then this follows easily from the classification of finitely generated abelian groups together with Lemma 57.3. If \(A\) is infinitely generated, then we can view it as the direct limit of finitely generated abelian groups and using Lemma 57.3 the statement can be reduced to the finitely generated case. We leave the details to the reader.
(4) Recall that given a set $W$ we denote by $Z(W)$ the free abelian group generated by $W$. Let $A$ and $B$ be two sets. We then have
\[
Z(A) \otimes Z(B) = \left( \bigoplus_{a \in A} \mathbb{Z} \cdot a \right) \otimes \left( \bigoplus_{b \in B} \mathbb{Z} \cdot b \right) \cong \bigoplus_{a \in A, b \in B} \mathbb{Z} \cdot (a, b) = Z(A \times B).
\]

(5) Let $A$ and $B$ be two finitely generated abelian groups. Using examples (1) and (2), the classification of finitely generated abelian groups and Lemma 57.3 (1) and (4) one can now easily show that
\[
\text{rank}(A \otimes B) = \text{rank}(A) \cdot \text{rank}(B).
\]

For future reference we record the following lemma:

**Lemma 57.4.** Let $f: A \to A'$ and $f': A' \to A''$ be homomorphisms and let $g: B \to B'$ and $g': B' \to B''$ be homomorphisms between abelian groups. Then we have
\[
(f' \otimes g') \circ (f \otimes g) = (f' \circ f) \otimes (g' \circ g).
\]

**Proof.** The statement follows immediately from the definitions. \[\square\]

The following elementary lemma will play a major role.

**Lemma 57.5.** Let $R$ be a commutative ring.

1. Given any abelian group $A$ the map
\[
\left( \sum_{i=1}^{n} a_i \otimes b_i, r \right) \mapsto \sum_{i=1}^{n} a_i \otimes b_i r
\]
defines an $R$-module structure on $A \otimes R$.

2. If $f: A \to B$ is a homomorphism of abelian groups, then the map
\[
f \otimes \text{id}: A \otimes R \to B \otimes R
\]
\[
\sum_{i} a_i \otimes r_i \mapsto \sum_{i} f(a_i) \otimes r_i
\]
is a homomorphism of $R$-modules.

3. The map
\[
A \mapsto A \otimes R
\]
\[
(f: A \to B) \mapsto (f \otimes \text{id}: A \otimes R \to B \otimes R)
\]
defines a functor from the category of abelian groups to the category of $R$-modules.

**Proof.** Once again the statements follow immediately from the definitions. \[\square\]

Lemma 57.5 shows that tensoring with a commutative ring “turns” an abelian group into a module. In particular if we tensor with a field, we obtain a vector space. This is very convenient since sometimes it allows us to reduce problems about abelian groups into problems about vector spaces that we can handle with techniques from linear algebra.

For example we can now give a meaningful definition of the rank of any abelian group.
Definition. The rank of an abelian group $A$ is defined as
\[ \text{rank}(A) := \dim_{\mathbb{Q}}(A \otimes \mathbb{Q}). \]

Remark.

(1) Previously, on page 585 we introduced the rank of finitely generated abelian groups.
It follows from the discussion on page 1396 that for finitely generated abelian groups
the two definitions of rank agree. Put differently, the above definition is an extension
of the earlier notion of rank to all abelian groups.

(2) Let $A$ be an abelian group. We can view $A$ as a $\mathbb{Z}$-module and the above definition
of the rank of the abelian group equals the rank of the corresponding $\mathbb{Z}$-module as
introduced on page 82.

We conclude this section with the following lemma.

**Lemma 57.6.** Let
\[ 0 \rightarrow A \overset{i}{\rightarrow} B \overset{p}{\rightarrow} C \rightarrow 0 \]
be a short exact sequence and let $G$ be an abelian group. If the short exact sequence splits,
then
\[ 0 \rightarrow A \otimes G \overset{i \otimes \text{id}}{\rightarrow} B \otimes G \overset{p \otimes \text{id}}{\rightarrow} C \otimes G \rightarrow 0 \]
is also a short exact sequence and it also splits.

Remark. In most applications we will consider a short exact sequence
\[ 0 \rightarrow A \overset{i}{\rightarrow} B \overset{p}{\rightarrow} C \rightarrow 0 \]
where $C$ is a free abelian group. It then follows from Lemma 46.1 that the short exact
sequence splits, which then implies by Lemma 57.6 that for any abelian group $G$ the sequence
\[ 0 \rightarrow A \otimes G \overset{i \otimes \text{id}}{\rightarrow} B \otimes G \overset{p \otimes \text{id}}{\rightarrow} C \otimes G \rightarrow 0 \]
is also a short exact sequence which furthermore splits.

Proof. According to Splitting Lemma 46.2 we can without loss of generality suppose that
the short exact sequence is of the form
\[ 0 \rightarrow A \overset{a \mapsto (a,0)}{\rightarrow} A \oplus C \overset{(a,c) \mapsto c}{\rightarrow} C \rightarrow 0. \]
If we tensor this short exact sequence with $G$, then using $(A \oplus C) \otimes G = A \otimes G \oplus C \otimes G$ we obtain the sequence
\[
\begin{align*}
0 \rightarrow A \otimes G & \overset{\sum a_i \otimes g_i \mapsto \left( \sum a_i \otimes g_i, 0 \right)}{\rightarrow} A \otimes G \oplus C \otimes G \\
& \overset{\left( \sum c_j \otimes g_j \right) \mapsto \sum c_j \otimes g_j}{\rightarrow} C \otimes G \rightarrow 0,
\end{align*}
\]
which is evidently exact. It is also clear that the short exact sequence splits. $\blacksquare$
57.2. The homology groups of a topological space with coefficients. Let
\[ \ldots \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \ldots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \rightarrow 0 \]
be an algebraic chain complex and let \( G \) be an abelian group. We tensor the chain complex with \( G \), i.e. we consider the following sequence of homomorphisms:
\[ \ldots \rightarrow C_n \otimes G \xrightarrow{\partial_n \otimes \text{id}} C_{n-1} \otimes G \xrightarrow{\partial_{n-1} \otimes \text{id}} \ldots \xrightarrow{\partial_2 \otimes \text{id}} C_1 \otimes G \xrightarrow{\partial_1 \otimes \text{id}} C_0 \otimes G \rightarrow 0. \]
For all \( i \) we have
\[ (\partial_{i-1} \otimes \text{id}) \circ (\partial_i \otimes \text{id}) = (\partial_{i-1} \circ \partial_i) \otimes \text{id} = 0 \otimes \text{id} = 0, \]
i.e. the above sequence of maps is again a chain complex. We denote the corresponding homology groups by \( H_n(C; G) := H_n(C_\ast \otimes G, \partial_\ast \otimes \text{id}) \). If we tensor the chain complex \( C_\ast \) with a commutative ring \( R \), then it follows from the discussion in the previous section that we obtain a chain complex of \( R \)-modules, i.e. all chain groups are \( R \)-modules and all chain maps are \( R \)-homomorphisms. In particular also all homology groups are \( R \)-modules.

**Remark.** Most of the results which we have proved for chain complexes of abelian groups hold, with the obvious modifications, also for chain complexes of \( R \)-modules. In particular one can easily convince oneself that Lemma 41.7, Lemma 42.2, Corollary 42.3 and Propositions 43.11 and Lemma 43.10 also hold in this more general context. In the remainder of the course we will use these generalizations without further comment.

Now we are ready to define the homology groups of a topological space with coefficients in an abelian group \( G \).

**Definition.** Let \( X \) be a topological space. For an abelian group \( G \) we define
\[ C_\ast(X; G) := C_\ast(X) \otimes G. \]
As discussed above, we obtain a chain complex and we denote by
\[ H_k(X; G) := H_k(C_\ast(X; G), \partial \otimes \text{id}) \]
the corresponding homology groups. We call \( H_k(X; G) \) the \( k \)-th homology group of \( X \) with \( G \)-coefficients. We define the notions of “cycle”, “homologous” and “null-homologous” in exactly the same way as on page 1081.

**Example.** We consider an electric circuit as a finite undirected abstract graph \( X \) where at the vertices we have resistors or capacitors. Kirchhoff’s current rule, see e.g.

states that

- at any node (vertex) in an electrical circuit, the sum of currents flowing into that node is equal to the sum of currents flowing out of that node,

or equivalently

- the algebraic sum of currents in a network meeting at a point is zero.

\[ \text{Note that if } G \text{ has also the structure of a commutative ring, then this becomes a chain complex of } G\text{-modules.} \]
Put differently, a current defines a 1-cycle in $C_1(X; \mathbb{R})$.

![Electric circuit diagram](image)

**Figure 873**

We start out with the following three observations. Let $X$ be a topological space.

1. If the coefficients are given by a commutative ring $R$, e.g. if $R = \mathbb{Z}_n$ or $R = \mathbb{Q}, \mathbb{R}, \mathbb{C}$, then, as we pointed out above, each $C_n(X; R) = C_n(X) \otimes R$ is an $R$-module, each boundary map is an $R$-module homomorphism, and each homology group $H_n(X; R)$ is also an $R$-module.

2. From Lemma 57.3 (3) it follows immediately that we have natural isomorphisms $C_* (X; \mathbb{Z}) \cong C_* (X)$ and $H_* (X; \mathbb{Z}) \cong H_* (X)$. In the following we will identify these groups and we will go back and forth between these two notations, depending on which one is more convenient.

3. Let $G$ be an abelian group. Given any singular $k$-simplex $\sigma$, given any $a \in \mathbb{Z}$ and any $g \in G$ we have by definition of the tensor product that $a\sigma \otimes g = \sigma \otimes ng$. From this observation it follows that any element in $C_k(X; G)$ can be written as

$$\sum_{i=1}^{n} \sigma_i \otimes g_i$$

where $\sigma_1, \ldots, \sigma_n$ are singular $k$-simplices and $g_1, \ldots, g_n \in G$.

Most results for homology groups of topological spaces carry over, with the obvious modifications, to the theory of homology groups with $G$-coefficients. For example, given an abelian group $G$ we have the following statements:

1. A map $f : X \to Y$ between two topological spaces $X$ and $Y$ induces a chain map

$$f_* \otimes \text{id} : C_* (X; G) \to C_* (Y; G)$$

which in turn, for each $k \in \mathbb{N}_0$, induces a homomorphism

$$(f_* \otimes \text{id})_* : H_k (X; G) \to H_k (Y; G).$$

To simplify the notation we usually denote this induced map on homology groups also by $f_*$.  

2. The $k$-th homology group with $G$-coefficients defines a functor from the category of topological spaces to the category of abelian groups.

3. If $R$ is a commutative ring, then a map $f : X \to Y$ between topological spaces induces a chain map of $R$-homomorphisms $C_* (X; R) \to C_* (Y; R)$ and $R$-homomorphisms $f_* : H_k (X; R) \to H_k (Y; R)$. Furthermore the $k$-th homology group with $R$-coefficients defines a functor from the category $\text{Top}$ of topological spaces to the category $R - \text{Mod}$ of $R$-modules.

---

879 This observation and the figure are due to Ghrist’s excellent book on applied topology [Ch14].
(4) The augmentation map \(\epsilon: H_0(X;G) \to G\) is defined almost the same way as in Lemma 41.4. More precisely, it is given by the map
\[
\epsilon_X: H_0(X;G) \to G, \quad \left[ \sum_{i=1}^k \sigma_i \otimes g_i \right] \mapsto \sum_{i=1}^k g_i.
\]
If \(X\) is path-connected, then the argument of Proposition 41.5 implies immediately that the augmentation map \(\epsilon: H_0(X;G) \to G\) is an isomorphism. At times we will use this natural isomorphism to make the identification \(H_0(X;G) = G\).

(5) Precisely as on page 1105 we can use the augmentation map \(\epsilon\) to define reduced homology groups \(\tilde{H}_k(X;G)\) with \(G\)-coefficients.

(6) We saw in Proposition 42.3 that if \(f, g: X \to Y\) are two homotopic maps between topological spaces, then the induced maps \(f_*, g_*: C_*(X) \to C_*(Y)\) are chain homotopic. By tensoring the chain homotopies we see that the corresponding induced maps \(C_*(X) \otimes G \to C_*(Y) \otimes G\) are also chain homotopic, and we see that for any \(n \in \mathbb{N}_0\) we have
\[
f_* = g_*: H_n(X;G) \to H_n(Y;G).
\]
In particular, if \(X\) and \(Y\) are homotopy equivalent topological spaces, then for any \(n \in \mathbb{N}_0\) we have an isomorphism
\[
H_n(X;G) \xrightarrow{\cong} H_n(Y;G).
\]

(7) Given a pair \((X, A)\) of topological spaces we can tensor the relative chain complex \(C_*(X, A)\) with \(G\). We obtain the \textit{relative chain complex} \(C_*(X, A; G) := C_*(X, A) \otimes G\). The corresponding homology groups are the \textit{relative homology groups} \(H_k(X, A; G)\).

(8) Let \((X, B, A)\) be a triple of topological spaces. As pointed out on page 1120 the relative chain groups \(C_n(X, B; G)\) are free abelian groups. Thus it follows from the discussion on page 1398 that we obtain a short exact sequence of chain complexes
\[
0 \to C_*(X, A; G) \to C_*(X, A; G) \to C_*(X, B; G) \to 0.
\]
By applying the obvious generalization of Proposition 43.11 to this short exact sequence we obtain the following long exact sequence of homology groups with \(G\)-coefficients:
\[
\ldots \to H_n(B, A; G) \xrightarrow{i_*} H_n(X, A; G) \xrightarrow{p_*} H_n(X, B; G) \xrightarrow{\partial} H_{n-1}(B, A; G) \to \ldots
\]

(9) We have an obvious version of the Mayer–Vietoris Theorem 46.5 for homology groups with \(G\)-coefficients. The proof is basically identical to the proof of Theorem 46.5, we only have to note that when we consider the exact sequence
\[
0 \to C_*(A \cap B) \xrightarrow{i_*} C_*(A) \oplus C_*(B) \xrightarrow{i_* + i_*} C_*(A, B) \to 0,
\]
then it is a consequence of the discussion on page 1398 that the corresponding sequence with \(G\)-coefficients is also exact.

(10) We also have an obvious versions of the Excision Theorems 43.19 and 43.20, the proof for \(G\)-coefficients is almost verbatim the same as before.

(11) For a CW-complex \(X\) we can also consider the corresponding cellular chain complex \(C_*^{CW}(X; G) := C_*^{CW}(X) \otimes G\) and the corresponding cellular homology groups
$H^*_{CW}(X; G)$. Then, as in Proposition 48.4, one can show that there exists a natural isomorphism $H_*(X; G) \cong H^*_a(X; G)$. We can draw the following conclusions:

(a) If $X$ is an $n$-dimensional CW-complex, then $H_i(X; G) = 0$ for $i \geq n + 1$.
(b) If $X$ has only finitely many $n$-cells, then given any field $F$ the vector space $H_n(X; F)$ is finite-dimensional.

(12) Let $X$ be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \ldots$ be a sequence of subsets such that $X = \bigcup_{i \in \mathbb{N}} X_i$ and such that one the following three conditions holds:

(a) every compact subset of $X$ is already contained in one of the $X_i$, or
(b) each $X_i$ is open in $X$, or
(c) $X$ is a CW-complex and each $X_i$ is a subcomplex.

Then a modest modification of the proof of Proposition 47.4 shows that for any $n \in \mathbb{N}_0$ the inclusion induced maps $H_n(X_i; G) \to H_n(X; G)$ induce an isomorphism

$$\lim_{\rightarrow} H_n(X_i; G) \cong H_n(X; G).$$

(13) If $X$ is a finite CW-complex and if $F$ is a field, then the argument of Proposition 55.1 shows that

$$\chi(X) = \sum_i (-1)^i \cdot \dim_F(H_i(X; F)).$$

Examples.

(1) Let $n \in \mathbb{N}$. As on page 935 we equip $S^n$ with the CW-structure with one 0-cell and one $n$-cell. For any abelian group $G$ it follows from (10), and similar to the discussion on page 1260 that

$$H_k(S^n; G) = H^*_k(S^n; G) \cong \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise}. \end{cases}$$

The same result holds for reduced homology with $G$-coefficients except that in this case we have $\tilde{H}_0(S^n; G) = 0$.

(2) We want to determine homology groups of the real projective plane $\mathbb{R}P^2$ with $\mathbb{F}_2$-coefficients. As usual we equip $\mathbb{R}P^2$ with the CW-structure with one 0-cell, one 1-cell and one 2-cell that we introduced on page 1276. In the proof of Proposition 48.10 we saw that the cellular chain complex is given by

$$0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z} \to 0,$$

i.e. $H_2(\mathbb{R}P^2) = 0$, $H_1(\mathbb{R}P^2) = \mathbb{Z}_2$ and $H_0(\mathbb{R}P^2) = \mathbb{Z}$. On the other hand, if we tensor the above cellular chain complex with $\mathbb{F}_2$, then using Lemma 57.3 (3) we obtain the chain complex

$$0 \to \mathbb{F}_2 \xrightarrow{2=0} \mathbb{F}_2 \to \mathbb{F}_2 \to 0.$$

Using the isomorphism between cellular and singular homology with $\mathbb{F}_2$-coefficients we obtain that $H_2(\mathbb{R}P^2; \mathbb{F}_2) = \mathbb{F}_2$, $H_1(\mathbb{R}P^2; \mathbb{F}_2) = \mathbb{F}_2$ and $H_0(\mathbb{R}P^2; \mathbb{F}_2) = \mathbb{F}_2$.

Note that even though the homology groups of $\mathbb{R}P^2$ with $\mathbb{Z}$-coefficients and $\mathbb{F}_2$-coefficients are quite different, in both cases the alternating sums of the dimensions
and ranks give, as promised in Proposition 55.1 and in (10) above, the Euler characteristic. Indeed, we have
\[
\text{rank}(H_0(X)) - \text{rank}(H_1(X)) + \text{rank}(H_2(X)) = 1 - 0 + 0 = 1,
\]
and
\[
\dim_{\mathbb{F}_2}(H_0(X;\mathbb{F}_2)) - \dim_{\mathbb{F}_2}(H_1(X;\mathbb{F}_2)) + \dim_{\mathbb{F}_2}(H_2(X;\mathbb{F}_2)) = 1 - 1 + 1 = 1.
\]

(3) Basically the same argument as in (3) shows that for any \( n \in \mathbb{N} \) we have
\[
H_k(\mathbb{R}P^n;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}
\]
Furthermore, it is not difficult to see that for \( m < n \) the inclusion induced maps
\[
H_k(\mathbb{R}P^m;\mathbb{F}_2) \to H_k(\mathbb{R}P^n;\mathbb{F}_2)
\]
are isomorphisms for \( k = 0, \ldots, m \). It follows that for any \( k \in \mathbb{N}_0 \) we have
\[
H_k(\mathbb{R}P^\infty;\mathbb{F}_2) = \lim_{\to} H_k(\mathbb{R}P^n;\mathbb{F}_2) = \mathbb{F}_2.
\]

Remark. Why should we study the homology groups of a topological space with \( G \)-coefficients? There are several answers one can give:

(1) At times it is easier to work over a field instead of working over the ring \( \mathbb{Z} \). For example, if we only want to determine the Euler characteristic of a CW-complex we can now use a field, even a very simple one like \( \mathbb{F}_2 \), instead of working with the integers.

(2) If we work over the field \( \mathbb{F}_2 \) then many calculations become particularly simple, since we do not need to worry about signs. Even in the previous example we already saw that working with \( \mathbb{F}_2 \)-coefficients can simplify calculations.

(3) Recall that given a smooth manifold \( M \) and \( k \in \mathbb{N}_0 \) we denote its de Rham cohomology groups \( H^k_{\text{dR}}(M) \), which is in fact a real vector space. For each \( k \) we can now also study the homology groups \( H_k(M;\mathbb{R}) \) which are also real vector spaces. The notations \( H^k_{\text{dR}}(M) \) and \( H_k(M;\mathbb{R}) \) look similar and the names “de Rham cohomology” and “homology” also sound similar. We will study the relationship between these two objects later on in Chapters 75 and 79.

We conclude this section with the following elementary lemma which follows immediately from the definitions.

**Lemma 57.7.**

(1) Let \( X \) be a topological space and let \( R \) be a commutative ring with neutral element \( 1_R \). The maps
\[
\varphi_*: C_*(X) \to C_*(X;R) \quad \left[ \sum_{i=1}^k a_i \cdot \sigma_i \right] \mapsto \left[ \sum_{i=1}^k a_i \cdot \sigma_i \otimes 1_R \right]
\]
form a chain map, in particular for each \( n \in \mathbb{N}_0 \) we obtain an induced map
\[
\varphi_*: H_n(X) \to H_n(X;R).
\]
(2) Let \( X \) be a topological space and let \( \varphi : A \to B \) be a homomorphism of abelian groups. Then the maps
\[
\varphi_* : C_*(X; A) \to C_*(X; B)
\]
form a chain map, in particular for each \( n \in \mathbb{N}_0 \) we obtain an induced map
\[
\varphi_* : H_n(X; A) \to H_n(X; B).
\]

(3) Given a topological space \( X \) and \( n \in \mathbb{N}_0 \) the maps \( A \mapsto H_n(X; A) \) from (1) define a covariant functor from the category of abelian groups \( \text{AbGr} \) to itself.

(4) The maps from (1) define a natural transformation from “homology with \( A \)-coefficients” to “homology with \( B \)-coefficients”, i.e. given a map \( f : X \to Y \) of topological spaces we get a commutative diagram
\[
\begin{array}{ccc}
H_n(X; A) & \xrightarrow{f_*} & H_n(Y; A) \\
\downarrow{\varphi_*} & & \downarrow{\varphi_*} \\
H_n(X; B) & \xrightarrow{f_*} & H_n(Y; B).
\end{array}
\]

The above statements also generalize in an obvious way to pairs of topological spaces.

57.3. **Exact functors.** The following question naturally arises from the discussion in the previous section:

**Question 57.8.** Given a topological space \( X \) and an abelian group \( G \), what is the relationship between the usual homology groups of \( X \) and the homology groups with \( G \)-coefficients?

The example on page 1402 shows that for better or worse the naive guess that perhaps \( H_k(X; G) \cong H_k(X) \otimes G \) is in general not correct. More precisely, we saw that
\[
\mathbb{F}_2 = H_2(\mathbb{R}P^2; \mathbb{F}_2) \neq H_2(\mathbb{R}P^2) \otimes \mathbb{F}_2 = 0.
\]

In the following section we will see that, despite this sobering example, one can always deduce the homology groups \( H_*(X; G) \) of a topological space \( X \) from the usual homology groups \( H_*(X) \). But the connection between these homology groups will turn out to be less naive than one might have thought initially.

Before we can hope to answer Question 57.8 we have to introduce many more definitions and algebraic tools. We start out with the following definition from category theory.

**Definition.** Let \( F : \text{AbGr} \to \text{AbGr} \) be a covariant functor from the category \( \text{AbGr} \) of abelian groups to itself.

1. We say \( F \) is **left-exact**, if for every exact sequence
\[
\begin{array}{c}
0 \to A \xrightarrow{i} B \xrightarrow{j} C
\end{array}
\]
of abelian groups the sequence
\[
\begin{array}{c}
0 \to F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C)
\end{array}
\]
is also exact.
(2) We say $F$ is \textit{right-exact}, if for every exact sequence
\begin{align*}
A \xrightarrow{i} & B \xrightarrow{j} C \to 0 \\
F(A) \xrightarrow{F(i)} & F(B) \xrightarrow{F(j)} F(C) \to 0
\end{align*}
of abelian groups the sequence
\begin{align*}
F(A) \xrightarrow{F(i)} & F(B) \xrightarrow{F(j)} F(C) \to 0
\end{align*}
is also exact.

(3) We say $F$ is \textit{exact} if it is left-exact and right-exact, put differently, the functor $F$ is exact, if for every exact sequence
\begin{align*}
0 \to & A \xrightarrow{i} B \xrightarrow{j} C \to 0 \\
0 \to & F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \to 0
\end{align*}
of abelian groups the sequence
\begin{align*}
0 \to & F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \to 0
\end{align*}
is also exact.

\textbf{Remark.} Let $\varphi: A \to B$ be a homomorphism between two abelian groups. Furthermore let $F: \text{AbGr} \to \text{AbGr}$ be a covariant functor from the category $\text{AbGr}$ of abelian groups to itself.

(1) If $F$ is a left-exact functor, then “taking $F$” commutes with “taking kernels”, more precisely, if $\varphi: A \to B$ is a homomorphism, then by applying $F$ to the exact sequence $0 \to \ker(\varphi) \to A \to B$ we see that $F(\ker(\varphi)) = \ker(\varphi_*: F(A) \to F(B))$.

(2) Similarly, if $F$ is right-exact, then “taking $F$” commutes with “taking cokernels”, i.e. if $\varphi: A \to B$ is a homomorphism, then by applying $F$ to the exact sequence $A \to B \to \coker(\varphi) \to 0$ we see that $F(\coker(\varphi)) = \coker(\varphi_*: F(A) \to F(B))$.

\textbf{Lemma 57.9.} Let $G$ be an abelian group. If $G$ is free abelian, then tensoring with $G$ is exact.

\textbf{Proof.} Let
\begin{align*}
0 \to & A \xrightarrow{\varphi} B \xrightarrow{\psi} C \to 0 \\
0 \to & F(A) \xrightarrow{F(\varphi)} F(B) \xrightarrow{F(\psi)} F(C) \to 0
\end{align*}
be a short exact sequence and let $G \cong \mathbb{Z}^{|S|}$ be a free abelian group. It follows from Lemma 57.3 (1) and (3) that tensoring the above short exact sequence with $G \cong \mathbb{Z}^{|S|}$ results in an exact sequence that is isomorphic to the direct sum of $S$ copies of the original sequence, hence it is again exact.

\textbf{Example.} In contrast to the previous lemma we will now see that tensoring with an abelian group $G$ is in general not a \textit{left-exact} functor. For example for any $k \in \mathbb{N}_{\geq 2}$ the sequence
\begin{align*}
0 \to & \mathbb{Z} \xrightarrow{k} \mathbb{Z} \to \mathbb{Z}_k \\
0 \to & \mathbb{Z}_k \xrightarrow{k=0} \mathbb{Z}_k \to \mathbb{Z}_k
\end{align*}
is exact, but after tensoring with $\mathbb{Z}_k$ we obtain, using Lemma 57.3 (3), the sequence
\begin{align*}
0 \to & \mathbb{Z}_k \xrightarrow{k} \mathbb{Z}_k \to \mathbb{Z}_k \\
0 \to & \mathbb{Z}_k \xrightarrow{k=0} \mathbb{Z}_k \to \mathbb{Z}_k
\end{align*}
that is not exact.

In contrast to the previous example we will now see that tensoring with an abelian group $G$ is a \textit{right-exact} functor.
Lemma 57.10. As usual we denote by \( \text{AbGr} \) the category of abelian groups. For every abelian group \( G \) the functor
\[
\text{AbGr} \to \text{AbGr}
\]
\[
A \mapsto A \otimes G
\]
is right-exact.

Proof. Let
\[
A \xrightarrow{i} B \xrightarrow{j} C \to 0
\]
be an exact sequence of abelian groups and let \( G \) be an abelian group. We have to show that the sequence
\[
A \otimes G \xrightarrow{i \otimes \text{id}} B \otimes G \xrightarrow{j \otimes \text{id}} C \otimes G \to 0
\]
is also exact.

(a) Since \( j: B \to C \) is an epimorphism it follows immediately from Lemma 57.1 (3) that the homomorphism
\[
j \otimes \text{id}: B \otimes G \to C \otimes G
\]
\[
\sum_{i=1}^{n} b_i \otimes g_i \mapsto \sum_{i=1}^{n} j(b_i) \otimes g_i
\]
is also an epimorphism.

(b) By Lemma 57.4 we have \( (j \otimes \text{id}) \circ (i \otimes \text{id}) = (j \circ i) \otimes \text{id} = 0 \), i.e. we have
\[
\text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G) \subset \ker(j \otimes \text{id}: B \otimes G \to C \otimes G).
\]

(c) By (b) it remains to show that
\[
\ker(j \otimes \text{id}: B \otimes G \to C \otimes G) \subset \text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G).
\]
Put differently it remains to show that the homomorphism
\[
\Psi: B \otimes G / \text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G) \to C \otimes G
\]
that is induced by \( j \otimes \text{id} \), i.e. that is given by
\[
[b \otimes g] \mapsto j(b) \otimes g,
\]
is a monomorphism. We will do so by providing a left-inverse for \( \Psi \), i.e. we will provide a map \( \Phi \) with \( \Phi \circ \Psi = \text{id} \).

Claim. The map
\[
\varphi: C \times G \to B \otimes G / \text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G)
\]
\[
(c, g) \mapsto b \otimes g \quad \text{where } b \in B \text{ is an element with } j(b) = c.
\]
is well-defined.

Let \((c, g) \in C \times G\). Since \( j \) is by hypothesis surjective we know that there exists a \( b \in B \) with \( j(b) = c \). We have to show that \( \varphi(c, g) \) is independent of the choice of \( b \). So let \( b, b' \in B \) with \( j(b) = j(b') = c \), i.e. with \( j(b - b') = 0 \). From the exactness

---

Note that it is a consequence of (b) that \( \Psi \) is well-defined.
of the original short exact sequence at $B$ it follows that $b - b' = i(a)$ for an $a \in A$. Then we obtain that

$$b \otimes g - b' \otimes g = (b - b') \otimes g = i(a) \otimes g \in \text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G).$$

Thus we have proved that $\varphi$ is well-defined.

The map $\varphi$ is easily seen to be bilinear. It follows from Lemma 57.2 (2) that $\varphi$ induces a well-defined map

$$\Phi: C \otimes G \to B \otimes G / \text{im}(i \otimes \text{id}: A \otimes G \to B \otimes G)$$

where

$$\sum_{i=1}^{k} c_i \otimes g_i \mapsto \sum_{i=1}^{k} \varphi(c_i, g_i).$$

By construction we have $(\Phi \circ \Psi)([b \otimes g]) = [b \otimes g]$ for all $b \in B$ and $g \in G$. But the elements $b \otimes g$ generate $B \otimes G$, hence $\Phi \circ \Psi = \text{id}$, i.e. the map $\Phi$ is indeed a right-inverse to the map $\Psi$. ■

57.4. The $G$-torsion of an abelian group. Our final goal is to relate the homology groups $H_*(C)$ of a chain complex to the homology groups $H_*(C; G)$ of the same chain complex with $G$-coefficients. To state the theorem relating these groups we need to introduce the $G$-torsion of an abelian group.

We start our discussion with the definition of a free abelian group that we already gave on page 580, we also recall some basic facts regarding free abelian groups, and we introduce one new definition.

1. Let $S$ be a non-empty set. We refer to

$$\mathbb{Z}^{(S)} := \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S$$

as the free abelian group generated by $S$.

2. A group $G$ is called free abelian if there exists a set $S$ and also an isomorphism $G \cong \mathbb{Z}^{(S)}$.

3. It follows easily from the definitions that a group $G$ is free abelian if and only if there exists a subset $B = \{b_i\}_{i \in I} \subset G$ with the following property: For any abelian group $A$ and each choice of elements $a_i \in A, i \in I$ there exists a unique homomorphism $\varphi: G \to A$ such that $\varphi(b_i) = a_i$ for all $i \in I$. As on page 582 we call such a subset $B$ a basis of $G$.

4. A free resolution of an abelian group $H$ is an exact sequence

$$\ldots \to F_3 \xrightarrow{f_3} F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

where the $F_i$ are free abelian groups. If there exists an $n \in \mathbb{N}_0$ with $F_n \neq 0$ but $F_m = 0$ for $m > n$, then we refer to $n$ as the length of the resolution. If no such $n$ exists, then we say that the length of the resolution is infinite.

Examples.

1. Let $m \in \mathbb{N}$, then a free resolution for $H = \mathbb{Z}_m$ is given by

$$0 \to \mathbb{Z} \xrightarrow{m} \mathbb{Z} \to \mathbb{Z}_m \to 0.$$
(2) Let $G$ be a finitely generated abelian group. By the classification of finitely generated abelian groups, see Theorem 19.4, there exists an $r \in \mathbb{N}_0$, non-zero natural numbers $a_1, \ldots, a_k$ and an isomorphism

$$\Phi: G \xrightarrow{\cong} \mathbb{Z}^r \oplus \bigoplus_{i=1}^k \mathbb{Z}_{a_i}.$$ 

Thus we obtain a free resolution$^{881}$

$$0 \oplus \begin{pmatrix} a_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & a_k \end{pmatrix} \rightarrow \mathbb{Z}^r \oplus \mathbb{Z}^k \rightarrow \mathbb{Z}^r \oplus \bigoplus_{i=1}^k \mathbb{Z}_{a_i} \rightarrow 0.$$

In most cases, when we want to work with explicit examples, this type of free resolution will turn out to be the most useful free resolution.

(3) We recall the following basic fact: if $M$ is an abelian group, then by Lemma 19.1 there exists a unique homomorphism $\alpha(M): \mathbb{Z}^{(M)} \rightarrow M$ such that for each $m \in M$ we have $\alpha(M)(m) = m$. Evidently this map is an epimorphism. Now let $H$ be an abelian group. We consider

$$\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \rightarrow 0.$$ 

The group $\mathbb{Z}^{(H)}$ is free abelian and $\alpha(H)$ is an epimorphism. In particular the sequence is exact. We set $H_1 := \ker (\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H)$. Then

$$H_1 \rightarrow \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \rightarrow 0$$

is exact. Now we consider

$$\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H_1)} \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \rightarrow 0.$$ 

This sequence is exact and both the groups $\mathbb{Z}^{(H_1)}$ and $\mathbb{Z}^{(H)}$ are free abelian. Now we set $H_2 := \ker (\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H)} H)$ and we iterate this procedure. This way we obtain a free resolution of $H$ as the canonical free resolution of $H$.

The last example provides the proof for the following lemma.

**Lemma 57.11.** Every abelian group (not necessarily finitely generated) admits a canonical free resolution.

The following definition is one of the key definitions in homological algebra.

**Definition.** Let $G$ and $H$ be abelian groups. We denote by

$$\ldots \rightarrow F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \rightarrow 0$$

$^{881}$Note that the homomorphism to the left is a monomorphism since $a_1, \ldots, a_k$ are non-zero.

$^{882}$Note that this procedure does not stop, i.e. it produces an infinite free resolution.
The canonical free resolution from page 1408. We define the \( n \)-th \( G \)-torsion group of \( H \) as

\[
\text{Tor}_n(H, G) := H_n(F_* \otimes G).
\]

The following proposition is the key to calculating torsion-groups.

**Proposition 57.12.** Let \( G \) and \( H \) be abelian groups and let

\[
\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0
\]

be a free resolution of \( H \). Then there exists a natural isomorphism

\[
\text{Tor}_n(H, G) \cong H_n(F_* \otimes G).
\]

**Example.** In many situations we are only interested in determining the isomorphism type of \( \text{Tor}_n(H, G) \) where \( H \) is a given finitely generated abelian group. In such situations it is usually much more convenient to work with the free resolution given on page 1408. For example, let \( m, n \in \mathbb{N} \). We want to determine the isomorphism type of \( \text{Tor}_i(\mathbb{Z}_m, \mathbb{Z}_n) \) for \( i \in \mathbb{N}_0 \). We will do so by doing the following three step process:

1. We pick the free resolution \( 0 \to \mathbb{Z} \xrightarrow{m} \mathbb{Z} \to \mathbb{Z}_m \to 0 \).
2. We tensor this free resolution of \( \mathbb{Z}_m \) with \( \mathbb{Z}_n \) and from Lemma 57.3 (3) we obtain the sequence \( 0 \to \mathbb{Z}_n \xrightarrow{m} \mathbb{Z}_n \to \mathbb{Z}_m \otimes \mathbb{Z}_n \to 0 \).
3. We drop the term to the right and we compute the homology groups.

Now using an argument as in the calculation of the tensor product \( \mathbb{Z}_m \otimes \mathbb{Z}_n \) on page 1396 we see that

\[
\text{Tor}_1(\mathbb{Z}_m, \mathbb{Z}_n) = H_1(0 \to \mathbb{Z}_n \xrightarrow{m} \mathbb{Z}_n \to 0) = \ker(\mathbb{Z}_n \xrightarrow{m} \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}
\]

and

\[
\text{Tor}_0(\mathbb{Z}_m, \mathbb{Z}_n) = H_0(0 \to \mathbb{Z}_n \xrightarrow{m} \mathbb{Z}_n \to 0) = \coker(\mathbb{Z}_n \xrightarrow{m} \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}.
\]

We will fill in the details in Exercise 57.10.

The proof of Proposition 57.12 will require some effort. We start out with the following definition.

**Definition.** Let \( \alpha : H \to H' \) be a homomorphism between abelian groups. Furthermore let \( F_* \) be a free resolution of \( H \) and let \( F'_* \) be a free resolution of \( H' \). An extension of \( \alpha \) to the free resolutions \( F_* \) and \( F'_* \) is a sequence of homomorphisms \( \alpha_i : F_i \to F'_i \), \( i \in \mathbb{N}_0 \) such that the following diagram commutes:

\[
\begin{array}{cccccccccc}
\ldots & \to & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \to & 0 \\
\downarrow{\alpha_2} & & \downarrow{\alpha_1} & & \downarrow{\alpha_0} & & \downarrow{\alpha} & \\
\ldots & \to & F'_2 & \xrightarrow{f'_2} & F'_1 & \xrightarrow{f'_1} & F'_0 & \xrightarrow{f'_0} & H' & \to & 0.
\end{array}
\]

Note that the horizontal exact sequences on top and bottom are in particular chain complexes and the maps \( \alpha_i \) define a chain map from one complex to the other.

The following lemma shows in particular that extensions of homomorphisms between abelian groups always exist.
Lemma 57.13. Let $\alpha: H \to H'$ be a homomorphism between abelian groups. Furthermore let $F_*$ be a free resolution of $H$ and let $F'_*$ be a free resolution of $H'$.

1. There exists an extension of $\alpha$ to the free resolutions $F_*$ and $F'_*$.
2. Any two extensions $\alpha_*$ and $\alpha'_*$, viewed as chain maps, are chain homotopic.
3. Let $\alpha_n: F_n \to F'_n$, $n \in \mathbb{N}_0$ be an extension of $\alpha: H \to H$ and let $G$ be an abelian group. The map

$$\alpha_n \otimes \text{id}: H_n(F_\ast \otimes G) \to H_n(F'_\ast \otimes G)$$

$$\left[\sum_{i=1}^{k} c_i \otimes g_i\right] \mapsto \left[\sum_{i=1}^{k} \alpha_n(c_i) \otimes g_i\right]$$

is well-defined and it is independent of the choice of the extension.

Proof. Let $F_*$ be a free resolution of $H$ and let $F'_*$ be a free resolution of $H'$. Statements (1) and (2) are both a straightforward consequence of some mild diagram chasing and the flexibility which Lemma 19.1 provides for defining homomorphisms starting from a free abelian group. In the following we fill in all the details.

1. We have to show that there exists a sequence $\{\alpha_i\}_{i \in \mathbb{N}_0}$ of homomorphisms such that the following diagram commutes:

$$\begin{array}{ccccccc}
\cdots & \to & F_2 & \to & F_1 & \to & F_0 & \to & H & \to & 0 \\
\downarrow{\alpha_2} & & \downarrow{\alpha_1} & & \downarrow{\alpha_0} & & \downarrow{\alpha} & & \\
\cdots & \to & F'_2 & \to & F'_1 & \to & F'_0 & \to & H' & \to & 0
\end{array}$$

First we define the homomorphism $\alpha_0$. We choose a basis $B_0$ of the free abelian group $F_0$. For each $x_i \in B_0$ we choose an $x'_i \in F'_0$ with $f'_0(x'_i) = \alpha(f_0(x_i))$. This is possible, since $f'_0$ is surjective. By Lemma 19.1 there exists a unique homomorphism $\alpha_0: F_0 \to F'_0$ with $\alpha_0(x_i) = x'_i$ for all $i \in I$. It is now evident that the right square commutes.

Now we turn to the definition of the map $\alpha_1$. We choose a basis $B_1$ of the free abelian group $F_1$. Let $x_i \in B_1$. It follows from the commutativity of the square on the right that

$$f'_0((\alpha_0 \circ f_1)(x_i)) = \alpha((f_0 \circ f_1)(x_i)) = 0.$$  

Since the lower sequence is exact there exists an $x'_i \in F'_1$ with $f'_1(x'_i) = (\alpha_0 \circ f_1)(x_i)$. Again by Lemma 19.1 there exists a unique homomorphism $\alpha_1: F_1 \to F'_1$ such that $\alpha_1(x_i) = x'_i$ for all $i \in I$. It is now evident that the “second square from the right” also commutes. It is now clear how inductively we can construct the homomorphisms $\alpha_2, \alpha_3, \ldots$.

2. Now let $\alpha_i, \alpha'_i: F_i \to F'_i$, $i \in \mathbb{N}_0$ be two extensions of $\alpha$ to the free resolutions $F_*$ and $F'_*$. We have to find a chain homotopy from the chain map $\alpha_i$ to the chain map $\alpha'_i$. The maps $\beta_i = \alpha_i - \alpha'_i$ are an extension of the zero map $\beta = 0: H \to H'$. Therefore it suffices to find a chain homotopy $\lambda$ from $\beta_i = \alpha_i - \alpha'_i$ to the zero chain map. The construction of the chain homotopy is very similar to the construction of the maps $\alpha_i$ in the first part of the proof.
Recall that we have to find a sequence of homomorphisms \( \lambda_i, \ i \in \mathbb{N}_0 \) such that for any \( i \in \mathbb{N}_0 \) we have

\[
f_{i+1}' \circ \lambda_i + \lambda_{i-1} \circ f_i = \beta_i.
\]

In the following discussion it is convenient to keep an eye on the following diagram that contains all the homomorphisms that we are given and that we need to construct:

\[
\begin{array}{ccccccccccccccc}
\cdots & \rightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \rightarrow & 0 \\
& \downarrow{\lambda_2} & & \downarrow{\beta_2} & & \downarrow{\beta_1} & & \downarrow{\beta_0} & & \downarrow{\lambda_{-1}} & & \downarrow{\beta_{-1} = 0} & \\
\cdots & \rightarrow & F_2' & \xrightarrow{f_2'} & F_1' & \xrightarrow{f_1'} & F_0' & \xrightarrow{f_0'} & H' & \rightarrow & 0.
\end{array}
\]

We put \( \lambda_{-1} = 0 \). Next we need to find a map \( \lambda_0: F_0 \rightarrow F_1' \) such that \( \beta_0 = f_1' \circ \lambda_0 \). For each \( x \in B_0 \) we choose an \( x' \in F_1' \) with \( f_1'(x') = \beta_0(x) \). The existence of such \( x' \) follows from the observation that \( f_0'(\beta_0(x)) = \beta(f_0(x)) = 0 \) and from the exactness of the lower sequence.

Now we suppose that we have already found maps \( \lambda_0, \ldots, \lambda_{i-1} \) which have the desired property that

\[
(*) \quad f_j' \circ \lambda_{j-1} + \lambda_{j-2} \circ f_{j-1} = \beta_{j-1} \quad \text{for} \quad j = 0, \ldots, i.
\]

We choose again a basis \( B_i \) of the free abelian group \( F_i \). We have to assign to \( x \) an element \( x' \in F_{i+1}' \) which satisfies the equation

\[
f_{i+1}'(x') = \beta_i(x) - \lambda_{i-1}(f_i(x)).
\]

From the exactness of the lower sequence it follows that \( \text{im}(f_{i+1}') = \ker(f_i') \). Thus it suffices to show that \( f_i' \circ (\beta_i - \lambda_{i-1} \circ f_i) = 0 \). It turns out that indeed we have

\[
f_i' \circ (\beta_i - \lambda_{i-1} \circ f_i) = f_i' \circ \beta_i - f_i' \circ \lambda_{i-1} \circ f_i = \beta_{i-1} \circ f_i - f_i' \circ \lambda_{i-1} \circ f_i
\]

since the \( \beta_i \)'s are a chain map, i.e. \( f_i' \circ \beta_i = \beta_{i-1} \circ f_i \)

\[
= (\beta_{i-1} - f_i' \circ \lambda_{i-1}) \circ f_i = \lambda_{i-2} \circ f_{i-1} \circ f_i = 0.
\]

by \( (*) \) since \( f_{i-1} \circ f_i = 0 \)

(3) It is straightforward to verify that the map is well-defined. It follows from (2) and Lemma 42.2 that any two extensions induce the same map on the homology groups.

Using Lemma 57.13 we can now prove the following lemma.

**Lemma 57.14.** Let

\[
\begin{array}{ccccccccccc}
\cdots & \rightarrow & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \rightarrow & 0
\end{array}
\]

and

\[
\begin{array}{ccccccccccc}
\cdots & \rightarrow & F_2' & \xrightarrow{f_2'} & F_1' & \xrightarrow{f_1'} & F_0' & \xrightarrow{f_0'} & H & \rightarrow & 0
\end{array}
\]
be two free resolutions of an abelian group $H$. We pick an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\text{id}: H \to H$ to the free resolutions $F_s$ and $F'_s$.

1. The maps $\alpha_*$ form a chain homotopy equivalence between the two chain complexes $F_s$ and $F'_s$.
2. Let $G$ be an abelian group. The 
   
   $$H_n(F_s \otimes G) \cong H_n(F'_s \otimes G)$$ 
   
   from Lemma 57.13 (3) is an isomorphism.

**Remark.** The statement of Lemma 57.14 (1) is sometimes called the fundamental theorem of homological algebra, see e.g. [Lü05 Satz 6.3].

**Proof.** We pick an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\text{id}: H \to H$.

1. We apply Lemma 57.13 to the free resolutions $F'_s$ and $F_s$ (i.e. we swap the roles of the free resolutions) and we obtain maps $\{\beta_i\}_{i \in \mathbb{N}_0}$ that give us the lower half of the following commutative diagram.

   $\begin{array}{cccccc}
   \ldots & \to & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \to & 0 \\
   \downarrow{\alpha_2} & & \downarrow{\alpha_1} & & \downarrow{\alpha_0} & & \downarrow{\text{id}} & & & & \\
   \ldots & \to & F'_2 & \xrightarrow{f'_2} & F'_1 & \xrightarrow{f'_1} & F'_0 & \xrightarrow{f'_0} & H & \to & 0 \\
   \downarrow{\beta_2} & & \downarrow{\beta_1} & & \downarrow{\beta_0} & & \downarrow{\text{id}} & & & & \\
   \ldots & \to & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \to & 0. \\
   \end{array}$

   The maps $\beta_i \circ \alpha_i$ now provide us with the following commutative diagram:

   $\begin{array}{cccccc}
   \ldots & \to & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \to & 0 \\
   \downarrow{\beta_2 \circ \alpha_2} & & \downarrow{\beta_1 \circ \alpha_1} & & \downarrow{\beta_0 \circ \alpha_0} & & \downarrow{\text{id}} & & & & \\
   \ldots & \to & F_2 & \xrightarrow{f_2} & F_1 & \xrightarrow{f_1} & F_0 & \xrightarrow{f_0} & H & \to & 0. \\
   \end{array}$

   This shows that the maps $\beta_i \circ \alpha_i$ define an extension of $\text{id}: H \to H$ to the free resolutions $F_i$ and $F'_i$. But the identity maps also define an extension. By Lemma 57.13 the extensions $\{\beta_i \circ \alpha_i\}_{i \in \mathbb{N}_0}$ and $\{\text{id}\}_{i \in \mathbb{N}_0}$ are chain homotopic. The same way one shows that the extensions $\{\alpha_i \circ \beta_i\}_{i \in \mathbb{N}_0}$ and $\{\text{id}\}_{i \in \mathbb{N}_0}$ are chain homotopic.

2. We had just shown that $\alpha_*: F_s \to F'_s$ is a chain homotopy equivalence. One easily verifies that $\alpha_* \otimes \text{id}: F_s \otimes G \to F'_s \otimes G$ is also a chain homotopy equivalence. The statement now follows from Corollary 42.3. \[\square\]

We are now also in a position to prove Proposition 57.12.

**Proof.** Let $G$ and $H$ be abelian groups and let $(F_s, f_s)$ be a free resolution of $H$. We denote by $(F'_s, f'_s)$ the canonical free resolution of $H$. Then by Lemma 57.14 we have a canonical isomorphism

$$\text{Tor}_n(H, G) = H_n(F'_s \otimes G) \cong H_n(F_s \otimes G).$$

\[\square\]
Remark. Using Lemma 57.13 we can now show that the torsion groups $\text{Tor}_n(G, H)$ are “covariantly functorial in both entries”. More precisely the following two statements hold:

1. We fix a group $G$. Let $\beta : H \to H'$ be a homomorphism between two abelian groups. It follows from Lemma 57.13 (3) applied to the canonical free resolutions of $H$ and $H'$ that $\beta$ induces for each $n$ a canonical homomorphism

$$\beta_\ast : \text{Tor}_n(H, G) \to \text{Tor}_n(H', G).$$

One can now easily show that the maps given by

$$H \mapsto \text{Tor}_n(H, G)$$

$$(\beta : H \to H') \mapsto (\beta_\ast : \text{Tor}_n(H, G) \to \text{Tor}_n(H', G))$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

2. We fix a group $H$. Let $\alpha : G \to G'$ be a homomorphism between two abelian groups. Let $F_\ast$ be the canonical free resolution of $H$. Then $\text{id} \otimes \alpha$ defines a chain map from $F_\ast \otimes G$ to $F_\ast \otimes G'$ and we get an induced map

$$\alpha_\ast : \text{Tor}_n(H, G) \to \text{Tor}_n(H, G').$$

One can now easily show that the maps given by

$$G \mapsto \text{Tor}_n(H, G)$$

$$(\alpha : G \to G') \mapsto (\alpha_\ast : \text{Tor}_n(H, G) \to \text{Tor}_n(H, G'))$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

The following lemma shows that the 0-th torsion groups are objects that we are already familiar with.

Lemma 57.15. Let $G$ and $H$ be abelian groups, then there exists a natural isomorphism

$$\text{Tor}_0(H, G) \cong H \otimes G.$$

In the remainder of this course we will use the isomorphism from Lemma 57.13 to identify the groups $\text{Tor}_0(H, G)$ and $H \otimes G$.

Proof. Let $G$ and $H$ be abelian groups. Let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be the canonical free resolution of $H$. We know from Lemma 57.10 that the sequence

$$F_1 \otimes G \xrightarrow{f_1 \otimes \text{id}} F_0 \otimes G \xrightarrow{f_0 \otimes \text{id}} H \otimes G \to 0$$

Note that “natural isomorphism” means in this context that given an abelian group $G$ we have natural isomorphisms from the functor $H \mapsto \text{Tor}_0(H, G)$ to the functor $H \mapsto H \otimes G$ and also from the functor $G \mapsto \text{Tor}_0(H, G)$ to the functor $G \mapsto H \otimes G$.  

---

\[\text{Note that “natural isomorphism” means in this context that given an abelian group } G \text{ we have natural isomorphisms from the functor } H \mapsto \text{Tor}_0(H, G) \text{ to the functor } H \mapsto H \otimes G \text{ and also from the functor } G \mapsto \text{Tor}_0(H, G) \text{ to the functor } G \mapsto H \otimes G.\]
is exact. Now we obtain the following isomorphism

by definition

\[
\text{Tor}_0(H, G) \cong H_0 \left( \cdots \rightarrow F_1 \otimes G \xrightarrow{f_1 \otimes \text{id}} F_0 \otimes G \rightarrow 0 \right)
\]

\[
= \text{coker} \left( F_1 \otimes G \xrightarrow{f_1 \otimes \text{id}} F_0 \otimes G \right) \xrightarrow{f_0 \otimes \text{id}} H \otimes G. \]

isomorphism since \((*)\) is exact

It is straightforward to verify that these isomorphisms define in fact a natural isomorphism from the functor \(H \mapsto \text{Tor}_0(H, G)\) to the functor \(H \mapsto H \otimes G\) and also from the functor \(G \mapsto \text{Tor}_0(H, G)\) to the functor \(G \mapsto H \otimes G\). ■

The following lemma shows that we do not need to worry about higher torsion groups for abelian groups.

**Lemma 57.16.**

1. Every abelian group \(H\) admits a free resolution of length 1.
2. For any two abelian groups \(H\) and \(G\) we have \(\text{Tor}_n(H, G) = 0\) for \(n \geq 2\).

**Proof.**

(1) Let \(H\) be an abelian group. If \(H\) is finitely generated, then we already saw on page 1408 that \(H\) admits a free resolution of length 1. Now suppose that \(H\) is any abelian group. We have the exact sequence

\[
0 \rightarrow \text{ker} \left( \alpha(H) : \mathbb{Z}^{(H)} \rightarrow H \right) \rightarrow \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \rightarrow 0
\]

where \(\alpha(H)\) is defined as in the proof of Lemma 57.11. It follows from Lemma 19.2 that the group \(\text{ker} \left( \alpha(H) : \mathbb{Z}^{(H)} \rightarrow H \right)\), as the subgroup of the free abelian group \(\mathbb{Z}^{(H)}\), is itself free abelian. So in this general case we also found a free resolution of length 1.

(2) Let \(G\) and \(H\) be abelian groups. By (1) there exists a free resolution of length 1, i.e. of the form

\[
0 \rightarrow F_1 \rightarrow F_0 \rightarrow H \rightarrow 0.
\]

It follows immediately from Proposition 57.12 that \(\text{Tor}_n(H, G) \cong H_n(F_+ \otimes G) = 0\) for \(n \geq 2\). ■

**Definition.** Given two abelian groups \(H\) and \(G\) we now write \(\text{Tor}(H, G) := \text{Tor}_1(H, G)\) and we refer to this group as as the \(G\)-torsion of \(H\).

**Remark.** For many purposes the long discussion of \(G\)-torsion groups can be summarized in the following statement: it follows from Proposition 57.12 that for a free resolution \(0 \rightarrow F_1 \xrightarrow{i} F_0 \xrightarrow{j} H \rightarrow 0\) of an abelian group \(H\) we have

\[
\text{Tor}(H, G) \cong \text{ker} \left( F_1 \otimes G \xrightarrow{i \otimes \text{id}} F_0 \otimes G \right).
\]

Now we summarize several properties of the torsion groups \(\text{Tor}(H, G)\) in the following lemma.
Lemma 57.17. Let $G, H, \{H_i\}_{i \in I}$ and $\{G_j\}_{j \in J}$ be abelian groups. Then the following holds:

1. There exists a natural isomorphism $\text{Tor} \left( \bigoplus_i H_i, G \right) \cong \bigoplus_i \text{Tor}(H_i, G)$.
2. There exists a natural isomorphism $\text{Tor} \left( H, \bigoplus_j G_j \right) \cong \bigoplus_j \text{Tor}(H, G_j)$.
3. If $H$ is a torsion-free abelian group, then $\text{Tor}(H, G) = 0$.
4. If $G$ is a torsion-free abelian group, then $\text{Tor}(H, G) = 0$.
5. If $T$ denotes the torsion subgroup of $H$, then $\text{Tor}(H, G) = \text{Tor}(T, G)$.
6. For all $n \in \mathbb{N}$ we have a natural isomorphism $\text{Tor}(\mathbb{Z}_n, G) \cong \ker \left( G \rightarrow \mathbb{Z}_n \right)$.
7. For all $n, m \in \mathbb{N}$ we have $\text{Tor}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n, m)}$.
8. Given any two finitely generated abelian groups $G$ and $H$ the corresponding torsion group $\text{Tor}(H, G)$ is finite.

Remark. Using this lemma one can usually determine the $G$-torsion of an abelian group $H$ without any problems. For example the groups $(\mathbb{Q}, +)$, $(\mathbb{R}, +)$ and $(\mathbb{C}, +)$ are torsion-free abelian groups. Thus it follows immediately from Lemma 57.17 (4) that for every abelian group $H$ we have $\text{Tor}(H, \mathbb{Q}) = \text{Tor}(H, \mathbb{R}) = \text{Tor}(H, \mathbb{C}) = 0$.

Proof.

1. For each $i \in I$ we choose a free resolution $F_i^* = \text{Tor}(H_i, G)$.
2. There exists a natural isomorphism $\text{Tor} \left( F_i^* \otimes G \right) \cong F_i^* \otimes G$.
3. If $H$ is a free abelian group, then $\text{Tor}(H, G) = 0$.
4. By Lemma 57.16 (1) we can pick a free resolution $0 \rightarrow F_0 \rightarrow H$ of length 1 for $H$. First we consider the case that $G$ is a free abelian group. In this case we have $\text{Tor}(H, G) = 0$.

884 The torsion subgroup of an abelian group is defined as the subgroup of all elements of finite order.
885 This fact explains the name “torsion group”.
886 Note that in Lemma 19.9 we saw that the abelian group $(\mathbb{Q}, +)$ is not free abelian.
\[ G \cong \bigoplus_{I} \mathbb{Z} \text{ for an index set } I. \] It follows that

\[
\text{Tor}(H, G) = \text{Tor}(H, \bigoplus_{I} \mathbb{Z}) = \bigoplus_{I} \text{Tor}(H, \mathbb{Z}) \cong \bigoplus_{I} H_1(0 \to F_1 \otimes \mathbb{Z} \to F_0 \otimes \mathbb{Z} \to 0) = 0.
\]

by (1) Proposition 57.12

Now we no longer suppose that \( G \) is free abelian, we just suppose that \( G \) is an abelian group that is torsion-free. We denote by \( \{G_i\}_{i \in I} \) the set of finitely generated subgroups of \( G \). It follows from Theorem 19.4 that each \( G_i \) is a free abelian group. We write \( i \leq j \) if and only if \( G_i \subset G_j \). Together with the inclusion maps the groups \( \{G_i\}_{i \in I} \) form a direct system. We leave it to the reader to verify that

\[
G = \lim_{\rightarrow} G_i.
\]

We have

\[
\text{Tor}(H, G) = \text{Tor}(H, \lim_{\rightarrow} G_i) = H_1(0 \to \lim_{\rightarrow} F_1 \otimes G_i \to \lim_{\rightarrow} F_0 \otimes G_i \to 0)
\]

by Lemma 57.3 (4)

\[
= \lim_{\rightarrow} H_1(0 \to F_1 \otimes G_i \to F_0 \otimes G_i \to 0) = 0.
\]

Lemma 47.6 = 0, by the above, since \( G_i \) is a free abelian group

(5) If \( H \) is a finitely generated abelian group, then it follows from Theorem 19.4 that we can write \( H \) as a direct sum \( F \oplus T \), where is \( T \) the torsion subgroup and where \( F \) is a free abelian group. It follows from (1) and (2) that

\[
\text{Tor}(H, G) \cong \text{Tor}(F \oplus T, G) \cong \text{Tor}(F, G) \oplus \text{Tor}(T, G) = \text{Tor}(T, G).
\]

For the proof in the case that \( H \) is not finitely generated we once again refer to [Hat02] p. 265 for a proof.

(6) We consider the free resolution

\[
0 \to \mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}_n \to 0
\]

for \( H = \mathbb{Z}_n \). After tensoring with the abelian group \( G \), and using Lemma 57.3 we obtain the sequence

\[
0 \to G \to \mathbb{Z}_n \otimes G \to 0.
\]

It follows from Proposition 57.12 that \( \text{Tor}(\mathbb{Z}_n, G) = \ker (G \to G) \).

(7) We showed this isomorphism on page 1409. Alternatively one can deduce the statement using (6).

\[887] The same argument, together with Lemma 57.13 can be used to give a proof of Lemma 57.3 (3), which back then was perhaps shoved under the carpet a little too quickly.
(8) Let $G$ and $H$ be two finitely generated abelian groups. It is a straightforward consequence of the classification of finitely generated abelian groups, see Theorem 19.4, together with all of the above statements that the corresponding torsion group $\text{Tor}(H, G)$ is finite.

57.5. The Universal Coefficient Theorem. Before we can state the Algebraic Universal Coefficient Theorem we need to introduce the following definition.

**Definition.** Let $(C_\ast, \partial_\ast)$ be a chain complex and let $G$ be an abelian group. Throughout this chapter, given $n \in \mathbb{N}_0$, we denote by $\mu$ the natural homomorphism

$$\mu: H_n(C_\ast) \otimes G \to H_n(C_\ast \otimes G)$$

$$\sum_{i=1}^m [c_i] \otimes g_i \mapsto \left[ \sum_{i=1}^m c_i \otimes g_i \right].$$

Now we can formulate and prove the following theorem which is the key result of the whole chapter.

**Theorem 57.18. (The Algebraic Universal Coefficient Theorem)** Let $(C_n, \partial_n)$ be a chain complex of free abelian groups and let $G$ be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a natural homomorphism $p: H_n(C; G) \to \text{Tor}(H_{n-1}(C), G)$ such that the following sequence is exact:

$$0 \to H_n(C) \otimes G \xrightarrow{\mu} H_n(C; G) \xrightarrow{p} \text{Tor}(H_{n-1}(C), G) \to 0.$$

**Remark.** The fact the homomorphisms $\mu$ and $p$ are natural implies that given a chain map $f: C \to D$ and a homomorphism $\varphi: G \to G'$ between abelian groups the diagram

$$
\begin{array}{ccc}
0 & \to & H_n(C) \otimes G \\
\downarrow & & \downarrow \\
H_n(C; G) & \xrightarrow{\mu} & H_n(D; G') \\
\downarrow & & \downarrow \\
\text{Tor}(H_{n-1}(C), G) & \xrightarrow{p} & \text{Tor}(H_{n-1}(D), G') \\
\end{array}
$$

commutes. Here the vertical maps are all induced by the chain map $f: C \to D$ and the homomorphism $\varphi: G \to G'$.

**Proof.** Let $(C_n, \partial_n)$ be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \text{im}(\partial_{n+1})$. Note that it follows from Lemma 19.2 that $B_n$ and $Z_n$ are free abelian groups.

---

\footnote{Here “natural” means that for a chain map $f_\ast: C_\ast \to D_\ast$ and a homomorphism $\varphi: G \to G'$ between abelian groups the following diagram commutes:

$$
\begin{array}{ccc}
H_n(C_\ast) & \xrightarrow{\mu} & H_n(C_\ast \otimes G) \\
\downarrow & & \downarrow \\
H_n(D_\ast) & \xrightarrow{\mu} & H_n(D_\ast \otimes G')
\end{array}
$$

where the vertical maps are induced by $f$ and $\varphi$ in the, hopefully, obvious way.}

\footnote{It is straightforward to show that the map is well-defined. We will discuss in Exercise 57.4 whether the “obvious converse” is also well-defined.}
We consider the following diagram

\[
\begin{array}{c}
\cdots \cdots \cdots \\
0 \rightarrow Z_n \rightarrow C_n \rightarrow B_{n-1} \rightarrow 0 \\
\downarrow 0 \downarrow \partial_n \downarrow 0 \\
0 \rightarrow Z_{n-1} \rightarrow C_{n-1} \rightarrow B_{n-2} \rightarrow 0 \\
\downarrow \downarrow \downarrow \downarrow \\
\cdots \cdots \cdots \\
\end{array}
\]

One sees easily that this diagram is commutative and that the horizontal sequences are exact. We can and will view the left and the right vertical columns as chain complexes. In other words, the above diagram is a short exact sequence of chain complexes. Recall that the groups \(B_n\) are free abelian groups, thus it follows from Lemmas 46.1 that each of the horizontal sequences splits.

Now let \(G\) be an abelian group. We tensor the above short exact sequence of chain complexes with \(G\) and we obtain the following diagram:

\[
\begin{array}{c}
\cdots \cdots \cdots \\
0 \rightarrow Z_n \otimes G \rightarrow C_n \otimes G \rightarrow B_{n-1} \otimes G \rightarrow 0 \\
\downarrow 0 \downarrow \partial_n \otimes \text{id} \downarrow 0 \\
0 \rightarrow Z_{n-1} \otimes G \rightarrow C_{n-1} \otimes G \rightarrow B_{n-2} \otimes G \rightarrow 0 \\
\downarrow \downarrow \downarrow \downarrow \\
\cdots \cdots \cdots \\
\end{array}
\]

This is again a sequence of chain complexes.

Since the original short exact sequences split it follows from Lemmas 37.6 that the horizontal sequences obtained from tensoring with \(G\) are still exact. Therefore we can apply Proposition 43.11 to obtain a long exact sequence of homology groups. Since the vertical boundary maps on the left and on the right are the zero maps, we obtain the following long exact sequence

\[
\ldots \rightarrow B_n \otimes G \xrightarrow{d_n} Z_n \otimes G \rightarrow H_n(C; G) \xrightarrow{\partial_n} B_{n-1} \otimes G \xrightarrow{d_{n-1}} Z_{n-1} \otimes G \rightarrow \ldots
\]

where the maps \(d_n\) are the connecting homomorphisms of the long exact sequence. It follows easily from the definition that the connecting homomorphism \(d_n: B_n \otimes G \rightarrow Z_n \otimes G\) is the map that is given by \(i_n \otimes \text{id}: B_n \otimes G \rightarrow Z_n \otimes G\) where \(i_n: B_n \rightarrow Z_n\) denotes the obvious inclusion map.\(^{800}\)

\(^{800}\)Why is this the case?
Using Lemma \[46.4\] the above discussion implies that we obtain the following short exact sequence

\[ 0 \to \text{coker} \left( B_n \otimes G \xrightarrow{i_n \otimes \text{id}} Z_n \otimes G \right) \to H_n(C; G) \to \ker \left( B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \text{id}} Z_{n-1} \otimes G \right) \to 0. \]

We still have to show that the expressions left and right coincide with the desired expressions. We have natural isomorphisms

\[ \text{coker} \left( B_n \otimes G \xrightarrow{i_n \otimes \text{id}} Z_n \otimes G \right) \cong \text{Tor}_0(H_n(C), G) \cong H_n(C) \otimes G \]

by Proposition \[57.12\] since \( B_n \xrightarrow{i_n} Z_n \to H_n(C) \) is a free resolution of \( H_n(C) \).

Similarly we have a natural isomorphism

\[ \ker \left( B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \text{id}} Z_{n-1} \otimes G \right) \cong \text{Tor}(H_{n-1}(C), G). \]

We have thus shown the existence of the desired short exact sequences. The statement that the homomorphism \( p \) is natural follows easily from the definitions and Lemma \[57.13\] \( (2) \). We leave the verification of the details to the reader. \( \square \)

The following theorem is for us the main application of the Universal Coefficient Theorem \[57.18\].

**Theorem 57.19. (Universal Coefficient Theorem)** Let \((X, A)\) be a pair of topological spaces and let \(G\) be an abelian group. Then for each \(n \in \mathbb{N}_0\) there exists a natural homomorphism \( H_n(X, A; G) \to \text{Tor}(H_{n-1}(X, A), G) \) such that the following sequence is exact:

\[ 0 \to H_n(X, A) \otimes G \xrightarrow{\mu} H_n(X, A; G) \to \text{Tor}(H_{n-1}(X, A), G) \to 0. \]

**Remark.** Note that the naturality of the maps implies for every map \( f: (X, A) \to (Y, B) \) between pairs of topological spaces and any homomorphism \( \varphi: G \to G' \) between abelian groups we obtain the following commutative diagram of short exact sequences:

\[
\begin{array}{c}
0 \rightarrow H_n(X, A) \otimes G \xrightarrow{\mu} H_n(X, A; G) \rightarrow \text{Tor}(H_{n-1}(X, A), G) \rightarrow 0 \\
\downarrow \quad \downarrow \quad \downarrow \\
0 \rightarrow H_n(Y, B) \otimes G' \xrightarrow{\mu'} H_n(Y, B; G') \rightarrow \text{Tor}(H_{n-1}(Y, B), G') \rightarrow 0,
\end{array}
\]

where the vertical maps are the obvious (?) ones induced by \( f \) and \( \varphi \).

**Proof.** Let \((X, A)\) be a pair of topological spaces and let \(G\) be an abelian group. As we pointed out on page \[1120\] the chain groups \( C_n(X, A), n \in \mathbb{N}_0\), are free abelian groups. Thus we can apply the Universal Coefficient Theorem \[57.18\] and we immediately obtain the desired short exact sequence. \( \square \)

Before we consider a few examples let us jot down the following almost immediate corollary.
Corollary 57.20. Let \( f : (X, A) \to (Y, B) \) be a map between pairs of topological spaces and let \( G \) be an abelian group. Then

\[
\begin{align*}
\text{the induced map} & \quad f_* : H_n(X, A) \to H_n(Y, B) \quad \text{is an isomorphism for all } n \in \mathbb{N}_0 \\
\text{the induced map} & \quad f_* : H_n(X, A; G) \to H_n(Y, B; G) \quad \text{is an isomorphism for all } n \in \mathbb{N}_0.
\end{align*}
\]

Proof. The corollary follows immediately from the naturality of the short exact sequence of the Universal Coefficient Theorem together with the Five-Lemma.

Examples.

(1) We consider again the real projective space \( \mathbb{R}P^n \). In Proposition 48.10 we saw that

\[
H_k(\mathbb{R}P^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = 0, \\
\mathbb{Z}_2, & \text{if } k \text{ is odd and } k < n, \\
0, & \text{if } k \text{ is even and } 0 < k \leq n, \\
0, & \text{if } k > n, \\
\mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd}.
\end{cases}
\]

It follows from the Universal Coefficient Theorem, the discussion on page 1396 and Lemma 57.17 (7) that for any even number \( 2k \in \{0, \ldots, n\} \) we have a short exact sequence

\[
0 \to H_{2k}(\mathbb{R}P^n) \otimes \mathbb{F}_2 \xrightarrow{\mu} H_{2k}(\mathbb{R}P^n; \mathbb{F}_2) \to \text{Tor}(H_{2k-1}(\mathbb{R}P^n), \mathbb{F}_2) \to 0
\]

whereas for \( 2k + 1 \in \{0, \ldots, n\} \) an odd number we have a short exact sequence

\[
0 \to H_{2k+1}(\mathbb{R}P^n) \otimes \mathbb{F}_2 \xrightarrow{\mu} H_{2k+1}(\mathbb{R}P^n; \mathbb{F}_2) \to \text{Tor}(H_{2k}(\mathbb{R}P^n), \mathbb{F}_2) \to 0.
\]

Also it follows easily that \( H_k(\mathbb{R}P^n) = 0 \) for \( k > n \). Summarizing we obtain the following result

\[
H_k(\mathbb{R}P^n; \mathbb{F}_2) \cong \begin{cases} 
\mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\
0, & \text{otherwise}.
\end{cases}
\]

Fortunately this calculation agrees with the calculation on page 1403.

(2) As on pages 182 and 196 we make the usual identifications \( S^2 = B^2/S^1 \) and \( \mathbb{R}P^2 = B^2/z \sim -z \) where \( z \in S^1 \). We denote by \( f \) the obvious projection map

\[
f : \mathbb{R}P^2 = B^2/z \sim -z \to S^2 = B^2/S^1.
\]

As in Figure 600 we equip \( \mathbb{R}P^2 \) with the CW-structure with one 0-cell, one 1-cell and one 2-cell and as on page 935 we equip \( S^2 \) with the CW-structure with one 0-cell and one 2-cell. With these CW-structures the above map \( f \) is given by collapsing the \(^{891}\) Note that this is not a covering map and that this map has nothing to do with the more familiar projection map \( S^2 \to \mathbb{R}P^2 \).
1-cell to the unique 0-cell of $S^2$, in particular $f$ is a cellular map. By Proposition 48.4 and the discussion on page 1402 we obtain the following commutative diagram

$$
\begin{array}{c}
H_2(\mathbb{R}P^2; \mathbb{F}_2) \xrightarrow{f_*} H_2(S^2; \mathbb{F}_2) \\
\phi_{\mathbb{R}P^2} \cong \downarrow \phi_{S^2} \\
H_2^{CW}(\mathbb{R}P^2; \mathbb{F}_2) \xrightarrow{f_*} H_2^{CW}(S^2; \mathbb{F}_2).
\end{array}
$$

As we saw on page 1402, the 2-cell is a generator of $H_2^{CW}(S^2; \mathbb{F}_2)$ and it gets sent to the 2-cell in $S^2$ which is, as we saw on page 1261, a generator of $H_2^{CW}(\mathbb{R}P^2; \mathbb{F}_2)$. Thus we see that the bottom map is an isomorphism, it follows that the top map is also an isomorphism. Summarizing the short exact sequences of the Universal Coefficient Theorem 57.19 give us the following commutative diagram:

$$
\begin{array}{cccc}
0 & \xrightarrow{=0} & H_2(\mathbb{R}P^2) \otimes \mathbb{F}_2 & \xrightarrow{=\mathbb{F}_2} \mu & H_2(\mathbb{R}P^2; \mathbb{F}_2) & \xrightarrow{=\mathbb{F}_2} \mu & H_2(S^2) \otimes \mathbb{F}_2 & \xrightarrow{=0} H_2(S^2; \mathbb{F}_2) & \xrightarrow{=0} \mu & H_2(S^2) \otimes \mathbb{F}_2 & \xrightarrow{=\mathbb{F}_2} \mu & H_2(S^2; \mathbb{F}_2) & \xrightarrow{=0} \mu & H_2(S^2; \mathbb{F}_2) & 0.
\end{array}
$$

Note that the two vertical maps to the left and right are the zero map, whereas the middle map is actually an isomorphism. This slightly weird fact will play a role in Proposition 57.26.

In the following corollary we give two instances where the Tor-terms in the Universal Coefficient Theorem 57.19 are zero, i.e. two instances where we can “pull out” the coefficients.

**Corollary 57.21.**

1. Let $(X,A)$ be a pair of topological spaces and let $G$ be a subgroup of $(\mathbb{C},+)$. Then for each $n \in \mathbb{N}_0$ the map

$$
\mu: H_n(X,A; \mathbb{Z}) \otimes G \to H_n(X,A; G)
$$

is a natural isomorphism.

2. Let $(X,A)$ be a pair of topological spaces and let $\mathbb{F}$ be a subfield of $\mathbb{C}$. Then for each $n \in \mathbb{N}_0$ we have $\text{rank}(H_n(X,A)) = \dim_\mathbb{F}(H_n(X,A; \mathbb{F}))$.

**Example.** It follows immediately from Proposition 48.10 together with Corollary 57.21 and Lemma 57.3 (3) that

$$
H_k(\mathbb{R}P^{2n+1}; \mathbb{R}) \cong \begin{cases} 
\mathbb{R}, & \text{if } k = 0, 2n + 1, \\
0, & \text{otherwise}
\end{cases}
$$

and

$$
H_k(\mathbb{R}P^{2n}; \mathbb{R}) \cong \begin{cases} 
\mathbb{R}, & \text{if } k = 0, \\
0, & \text{otherwise}
\end{cases}
$$

**Proof.**

1. This statement is an immediate consequence of the Universal Coefficient Theorem 57.19 and the fact, obtained in Lemma 57.17 (4), that the torsion-groups are zero for any subgroup of $(\mathbb{C},+)$. 

(2) To shorten the notation we consider only the case \( A = \emptyset \). We have

\[
\text{rank}(H_n(X)) = \dim_{\mathbb{Q}}(H_n(X) \otimes \mathbb{Q}) = \dim_{\mathbb{Q}}(H_n(X)) \otimes \mathbb{Q} = \dim_{\mathbb{F}}(H_n(X)) \otimes \mathbb{F}.
\]

by the definition on page 1398 by (1) follows fairly easily from \( \mathbb{Q} \subset \mathbb{F} \)

Remark.

(1) Let \((X, A)\) be a pair of topological spaces and let \( R \) be a subring of \( \mathbb{C} \). Since the map \( \mu: H_n(X, A; \mathbb{Z}) \otimes R \rightarrow H_n(X, A; R) \) is natural we can and we will in the following identify the groups \( H_n(X, A; \mathbb{Z}) \otimes R \) and \( H_n(X, A; R) \) using the isomorphism from Corollary 57.21.

(2) Given a pair \((X, A)\) of topological spaces and \( n \in \mathbb{N}_0 \) we refer to

\[
b_n(X, A) := \text{rank}(H_n(X, A))
\]

as the \( n \)-th Betti number of \((X, A)\). For \( A = \emptyset \) we write of course \( b_n(X) := b_n(X, \emptyset) \).

Note that it follows from Corollary 57.21 that for any subfield \( \mathbb{F} \) of \( \mathbb{C} \) we have \( b_n(X, A) = \dim_{\mathbb{F}}(H_n(X, A; \mathbb{F})) \).

(3) Let \( R \) be a subring of \( \mathbb{C} \). Lemma 57.17 (4) and the Universal Coefficient Theorem 57.18 show that taking the tensor product with \( R \) is an exact functor in the sense of the definition on page 1405.

We conclude this section with the following lemma which we will need later on in the generalization of the Borsuk-Ulam Theorem 16.22 to higher dimensions.

**Lemma 57.22.** Let \( f: S^n \rightarrow S^n \) be a map and let \( k \in \mathbb{N} \). Then the induced map

\[
f_* : H_n(S^n; \mathbb{Z}_k) \rightarrow H_n(S^n; \mathbb{Z}_k)
\]

is given by multiplication by \( \deg(f) \).

**Proof (\#).** Let \( f: S^n \rightarrow S^n \) be a map and let \( k \in \mathbb{N} \). Since the short exact sequence of the Universal Coefficient Theorem 57.19 is natural we obtain the following commutative diagram

\[
\begin{array}{ccccccccc}
0 & \rightarrow & H_n(S^n) \otimes \mathbb{Z}_k & \rightarrow & H_n(S^n; \mathbb{Z}_k) & \rightarrow & \text{Tor}(H_{n-1}(S^n); \mathbb{Z}_k) & \rightarrow & 0 \\
\downarrow f_* \otimes \text{id} & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \\
0 & \rightarrow & H_n(S^n) \otimes \mathbb{Z}_k & \rightarrow & H_n(S^n; \mathbb{Z}_k) & \rightarrow & \text{Tor}(H_{n-1}(S^n); \mathbb{Z}_k) & \rightarrow & 0.
\end{array}
\]

Note that \( H_{n-1}(S^n) \) is torsion-free, hence \( \text{Tor}(H_{n-1}(S^n); \mathbb{Z}_k) = 0 \) by Lemma 57.17. It follows from the exactness of the horizontal sequences that the horizontal maps \( \mu \) on the left are isomorphisms. By definition the map \( f_* : H_n(S^n) \rightarrow H_n(S^n) \) is given by multiplication by \( \deg(f) \), hence \( f_* \otimes \text{id} \) is also given by multiplication by \( \deg(f) \). It now follows that the middle vertical map is also given by multiplication by \( \deg(f) \). \qed

\[802]\ recalls that on page 1398 we defined the rank of an arbitrary abelian group.
57. HOMOLOGY WITH COEFFICIENTS

57.6. Splittings of the Universal Coefficient Theorem. Our goal had been to determine the homology groups \( H_n(C; G) \) only in terms of the original groups \( H_k(C) \) and the abelian group \( G \). The Algebraic Universal Coefficient Theorem 57.18 gave us a short exact sequence

\[
0 \to H_n(C) \otimes G \xrightarrow{\mu} H_n(C; G) \xrightarrow{\rho} \text{Tor}(H_{n-1}(C), G) \to 0.
\]

But in general, as we already saw on page 1205, given a short exact sequence, it is not possible to determine the middle group of a short exact sequence from the groups to the left and the right. But we saw in Splitting Lemma 46.2 that if a short exact sequence of abelian groups

\[
0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0
\]
splits, then the middle group \( B \) is the direct sum of the “outer” groups \( A \) and \( C \). The question arises, whether the short exact sequence in the Universal Coefficient Theorem 57.18 splits. This is fortunately the case:

**Proposition 57.23.** Let \((C_n, \partial_n)\) be a free chain complex\(^{803}\) and let \( G \) be an abelian group. Then for any \( n \in \mathbb{N}_0 \) the short exact sequence

\[
0 \to H_n(C) \otimes G \xrightarrow{\mu} H_n(C; G) \to \text{Tor}(H_{n-1}(C), G) \to 0
\]
of the Algebraic Universal Coefficient Theorem 57.18 splits. In particular there exists an isomorphism

\[
H_n(C; G) \cong H_n(C) \otimes G \oplus \text{Tor}(H_{n-1}(C), G).
\]

**Proof.** Let \((C_n, \partial_n)\) be a chain complex of free abelian groups and furthermore let \( G \) be an abelian group. According to Splitting Lemma 46.2 it suffices to construct a homomorphism \( \eta : H_n(C; G) \to H_n(C) \otimes G \) such that \( \eta \circ \mu \) is the identity on \( H_n(C) \otimes G \).

For each \( n \in \mathbb{N}_0 \) we write as always \( Z_n := \ker(\partial_n) \) and \( B_n := \text{im}(\partial_{n+1}) \). We consider the short exact sequence

\[
0 \to Z_n \hookrightarrow C_n \xrightarrow{\partial_n} B_{n-1} \to 0.
\]

The group \( B_{n-1} \subset C_{n-1} \) is a subgroup of a free abelian group, thus it is itself a free abelian group by Lemma 19.2. Therefore we can deduce from Lemma 46.1 that the above short exact sequence splits. In particular, according to Splitting Lemma 46.2 for each \( n \in \mathbb{N}_0 \) there exists a homomorphism \( p_n : C_n \to Z_n \) such that \( p_n \) is the identity on \( Z_n \subset C_n \).

\(^{803}\)A chain complex \((C_n, \partial_n)\) is called free, if all the groups \( C_n \) are free abelian groups.
Claim. The following diagram commutes:

\[ \cdots \to C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \cdots \]

\[ Z_{n+1} \quad \xrightarrow{p_{n+1}} \quad Z_n \quad \xrightarrow{p_n} \quad Z_{n-1} \]

\[ \cdots \to H_{n+1}(C) \xrightarrow{0} H_n(C) \xrightarrow{0} H_{n-1}(C) \xrightarrow{0} \cdots \]

where the maps \( q_n \) are just the obvious projection maps.

We start at \( C_{n+1} \). If we go down and then right, then we end up with the zero map to \( H_n(C) \). On the other hand, if we first go right, then we end up in \( B_n \subset Z_n \), but then the projection \( q_n \) to \( H_n(C) = Z_n/B_n \) is also the zero map. \( \Box \)

The top and the bottom horizontal sequences of the claim are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

Now we tensor the top and the bottom horizontal sequences with \( G \) and we obtain the following diagram of chain complexes.

\[ \cdots \to C_{n+1} \otimes G \xrightarrow{\partial_{n+1} \otimes \text{id}} C_n \otimes G \xrightarrow{\partial_n \otimes \text{id}} C_{n-1} \otimes G \xrightarrow{\partial_{n-1} \otimes \text{id}} \cdots \]

\[ H_{n+1}(C) \otimes G \xrightarrow{0} H_n(C) \otimes G \xrightarrow{0} H_{n-1}(C) \otimes G \xrightarrow{0} \cdots \]

The induced maps on the homology of these two chain complexes give us a homomorphism

\[ \eta: H_n(C; G) = H_n(C \otimes G) \to H_n(\text{lower sequence}) = H_n(C) \otimes G. \]

It remains to prove the following claim.

Claim. The composition \( \eta \circ \mu \) is the identity on \( H_n(C) \otimes G \).

Let \( [\sigma] \otimes g \in H_n(C) \otimes G \) where \( \sigma \in Z_n \). Then

\[ (\eta \circ \mu)([\sigma] \otimes g) = \eta(\sigma \otimes g) = (q_n(p_n(\sigma))) \otimes g = q_n(\sigma) \otimes g = [\sigma] \otimes g. \]

The following immediate corollary to Proposition 57.23 shows in particular that the homology groups with \( G \)-coefficients of a topological space \( X \) are completely determined by the usual homology groups of \( X \) and the abelian group \( G \).

**Theorem 57.24.** Let \((X, A)\) be a pair of topological spaces and let \( G \) be an abelian group. Then for each \( n \in \mathbb{N}_0 \) the short exact sequence

\[ 0 \to H_n(X, A) \otimes G \xrightarrow{\cdot g} H_n(X, A; G) \to \text{Tor}(H_{n-1}(X, A), G) \to 0 \]
from the Universal Coefficient Theorem 57.19 splits. In particular there exists an isomorphism
\[ H_n(X, A; G) \cong H_n(X, A) \otimes G \oplus \text{Tor}(H_{n-1}(X, A), G). \]

The following is an immediate corollary to Theorem 57.24.

**Corollary 57.25.** Let \((X, A)\) and \((Y, B)\) be topological spaces and let \(G\) be an abelian group. Then
\[ H_n(X, A) \text{ and } H_n(Y, B) \text{ are isomorphic for all } n \in \mathbb{N}_0 \implies H_n(Y, B; G) \text{ and } H_n(X, A; G) \text{ are isomorphic for all } n \in \mathbb{N}_0. \]

**Remark.**

(1) Corollary 57.25 is in some sense a disappointment, it shows that homology groups with coefficients are not better at distinguishing topological spaces than ordinary homology groups.

(2) Corollary 57.25 is also an almost immediate consequence of Propositions 49.1 and 49.2.

The question now arises, whether given an abelian group \(G\) there exists in fact a natural isomorphism
\[ H_n(X; G) \cong H_n(X) \otimes G \oplus \text{Tor}(H_{n-1}(X), G). \]

The discussion on page 490 already shows that this sounds like a dubious idea. Indeed, the following proposition says that such a natural isomorphism does not exist for \(G = \mathbb{F}_2\).

**Proposition 57.26.** It is not possible assign to each topology space \(X\) an isomorphism
\[ \Phi_X : H_n(X; \mathbb{F}_2) \to H_n(X) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_{n-1}(X), \mathbb{F}_2) \]
such that for any map \(f : X \to Y\) between topological spaces the following diagram commutes:
\[
\begin{array}{ccc}
H_n(X; \mathbb{F}_2) & \xrightarrow{\Phi_X} & H_n(X) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_{n-1}(X), \mathbb{F}_2) \\
\downarrow f_* & & \downarrow f_* \\
H_n(Y; \mathbb{F}_2) & \xrightarrow{\Phi_Y} & H_n(Y) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_{n-1}(Y), \mathbb{F}_2).
\end{array}
\]

**Proof.** So suppose instead that such a map \(\Phi_X\) exists for every topological space \(X\). We consider the map
\[ f : \mathbb{R}P^2 = B^2/\sim - z \to S^2 = B^2/S^1 \]
from page 1420. We obtain the following diagram:
\[
\begin{array}{ccc}
H_2(\mathbb{R}P^2; \mathbb{F}_2) & \xrightarrow{\Phi_{\mathbb{R}P^2}} & H_2(\mathbb{R}P^2) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_1(\mathbb{R}P^2), \mathbb{F}_2) \\
\downarrow f_* & & \downarrow f_* \\
H_2(S^2, \mathbb{F}_2) & \xrightarrow{\Phi_{S^2}} & H_2(S^2) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_1(S^2), \mathbb{F}_2).
\end{array}
\]
The horizontal maps are by hypothesis isomorphisms. We saw on page 1420 that the vertical map on the left is an isomorphism. On the other hand the two vertical maps on the right are zero since either the domain or the target is zero. Thus this diagram cannot possibly commute. We have thus found a contradiction to our assumption.

57.7. **Homological algebra over an arbitrary commutative ring (⋆).** A lot of the algebra that we had studied in the previous sections can be generalized from the case of abelian groups, i.e. the case of \( \mathbb{Z} \)-modules, to modules over a commutative ring. We will not make use of the generalizations that we discuss in this short section.

Throughout this section let \( R \) be a commutative ring. Let \( V \) and \( W \) be two \( R \)-modules. We say that an \( R \)-homomorphism \( f: V \times W \to X \) to an \( R \)-module \( X \) is **\( R \)-bilinear**, if for all \( v, v' \in V \), \( w, w' \in W \) and \( r \in R \) the following holds:

\[
\begin{align*}
    f(v + v', w) &= f(v, w) + f(v', w), \\
    f(rv, w) &= rf(v, w) \\
    f(v, w + w') &= f(v, w) + f(v, w') \\
    f(v, rw) &= rf(v, w).
\end{align*}
\]

We say an \( R \)-bilinear map \( f: V \times W \to X \) has the **universal \( R \)-bilinear property**, if for every \( R \)-bilinear map \( g: V \times W \to Y \) there exists a unique \( R \)-homomorphism \( \varphi: X \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
V \times W & \xrightarrow{f} & X \\
\downarrow{g} & & \downarrow{\varphi \text{ unique}} \\
Y & &
\end{array}
\]

Using a variation on the definition of the tensor product of abelian groups that we gave on page 1393, one can now fairly easily prove that there exists an \( R \)-bilinear map \( f: V \times W \to X \) which has the universal \( R \)-bilinear property.

A variation on the usual "universal property" argument shows that if \( f: V \times W \to X \) and \( f': V \times W \to X' \) are maps that both have the universal \( R \)-bilinear property, then there exists a unique isomorphism \( \varphi: X \to X' \) of \( R \)-modules such that \( \varphi(f(v, w)) = f'(v, w) \) for all \( v \in V \) and \( w \in W \).

We denote by \( V \otimes_R W \) the \( R \)-module that satisfies satisfies the above property. (By the universal property we see that \( V \otimes_R W \) is uniquely determined up to isomorphism.) Note that \( V \otimes_R W \) comes with an \( R \)-bilinear map \( V \times W \to V \otimes_R W \). Given \( v \in V \) and \( w \in W \) we denote the image of \((v, w)\) by \( v \otimes w \). If \( R = \mathbb{Z} \), then it follows from the remark after Lemma 57.2 that \( V \otimes_{\mathbb{Z}} W \) is isomorphic to \( V \otimes W \).

As before we see that given an \( R \)-module \( W \) the map \( V \mapsto V \otimes_R W \) defines a functor from the category of \( R \)-modules to the category of \( R \)-modules. The proof of Lemma 57.10 shows that this functor is right-exact.

We define a **free \( R \)-module** precisely the same way as we defined a free abelian group. A **free resolution** of an \( R \)-module \( M \) is an exact sequence

\[
\cdots \to F_2 \overset{f_2}{\to} F_1 \overset{f_1}{\to} F_0 \overset{f_0}{\to} M \to 0
\]

where each \( F_i \) is a free \( R \)-module. We can construct the canonical free resolution of an \( R \)-module \( M \) the same way as we did on page 1408.
Given two $R$-modules $M$ and $N$ we can define the torsion $R$-modules $\text{Tor}_n^R(M, N)$ as before. More precisely, we take the canonical free resolution

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} M \to 0$$

and we define

$$\text{Tor}_n^R(M, N) := H_n(F_\ast \otimes_R N).$$

Here the following statements hold:

1. As in Proposition 57.12 one can show that the isomorphism type of $\text{Tor}_n^R(M, N)$ can be determined using any free resolution for $M$.
2. The argument of page 1413 shows that for each $n \in \mathbb{N}_0$ the $R$-torsion module $\text{Tor}_n^R(M, N)$ is covariantly functorial in both entries.
3. The proof of Lemma 57.15 can also be generalized to show that given any two $R$-modules $M$ and $N$ we have a natural isomorphism $\text{Tor}_0^R(M, N) \cong M \otimes_R N$.
4. The obvious analogues of Lemma 57.17 (1) and (2) also hold in the more general context. Furthermore the obvious analogues of Lemma 57.17 (3) and (4) hold if we replace “torsion-free abelian group” by “free $R$-module”. In general there are no analogues of Lemma 57.17 (5), (6) and (7).
5. For general commutative rings it is no longer true though that $\text{Tor}_i^R(M, N) = 0$ for $i \geq 2$. For example for $R = \mathbb{Q}[t_1, \ldots, t_k]$ the $R$-torsion modules can be non-zero for $i = 1, \ldots, k$ and they are only zero for $i > k$. We refer to [Mac75, Chapter VII.4] for details.

Now let $(C_\ast, \partial_\ast)$ be a chain complex of $R$-modules. Furthermore let $M$ be another $R$-module. We consider the chain complex $C_\ast \otimes_R M$ of $R$-modules. It is natural to ask whether one can again determine the homology groups of $C_\ast \otimes_R M$ from the torsion groups $\text{Tor}_i^R(H_i(C), M)$ with $k \in \mathbb{N}_0$. If $R$ is a principal ideal domain (usually abbreviated by PID), then almost the same statement as in the Universal Coefficient Theorem 57.18 holds. On the other hand, if $R$ is not a principal ideal, then as we pointed out above, the higher torsion groups are in general non-zero and the problem becomes much more subtle. The torsion-terms and the homology with $M$-coefficients are then related by a “spectral sequence”, see e.g. [Rot09, Theorem 10.90] for details.

57.8. The Eilenberg-Steenrod axioms for homology $(\ast)$. In this section we give a very short introduction to the concept of (co-) homology theories which was introduced in the seminal book of Eilenberg–Steenrod [ES52].

Before we can do so we introduce the following definition.

**Definition.** Let $R$ be a commutative ring and let $S$ be a set.

1. An $S$-graded $R$-module is defined as an $R$-module $M$ together with a direct sum decomposition $M = \bigoplus_{s \in S} M_s$ into $R$-modules $M_s$, $s \in S$. If $x \in M$ lies in some $M_s$, then we call $x$ homogeneous and we refer to $\deg(x) := s$ as the degree of $x$.\footnote{Note that in general “$R$-torsion free module” is not going to be strong enough.}
(2) A morphism $f: M \to N$ between $S$-graded $R$-modules $M$ and $N$ is an $R$-module homomorphism such that for each $s \in S$ we have $f(M_s) \subseteq N_s$. Equivalently, it is a family of $R$-module homomorphisms $\{f_s: M_s \to N_s\}_{s \in S}$.

(3) The category $S$-Grad$\text{-}\text{Mod}_R$ of $S$-graded $R$-modules is the category where the objects are $S$-graded $R$-modules and the morphisms are the ones described in (2).

(4) Since abelian groups are for all intents and purposes the same as $\mathbb{Z}$-modules we define the category $S$-Grad$\text{-}\text{Ab}$ of $S$-graded abelian groups to be the category of $\mathbb{N}_0$-graded $\mathbb{Z}$-modules.

**Example.** Given a pair of topological spaces $(X, Y)$ and an abelian group $G$ we write

$$H_*(X, Y; G) := \bigoplus_{n \in \mathbb{N}_0} H_n(X, Y; G)$$

and we view $H_*(X, Y; G)$ as an $\mathbb{N}_0$-graded $\mathbb{Z}$-module.

The following definition goes back to [ES52] and [Miln62b].

**Definition.** A homology theory is a covariant functor

$$\mathcal{H}: \text{category \ PairTop of pairs of topological spaces} \to \text{category \ } \mathbb{N}_0\text{-GradAb of } \mathbb{N}_0\text{-graded abelian groups}$$

that satisfies the following axioms:

1. (Homotopy invariant) If $f, g: (X, A) \to (Y, B)$ are homotopic maps between pairs of topological spaces, then $f_* = g_*$.  
2. (Connecting homomorphism) Given any pair $(X, A)$ of topological spaces and any $n \in \mathbb{N}$ there exists a natural connecting homomorphism $\partial: \mathcal{H}_n(X, A) \to \mathcal{H}_{n-1}(A)$ such that the sequence

$$\ldots \to \mathcal{H}_{n+1}(X, A) \xrightarrow{\partial} \mathcal{H}_n(A) \to \mathcal{H}_n(X) \to \mathcal{H}_n(X, A) \xrightarrow{\partial} \mathcal{H}_{n-1}(A) \to \ldots$$

is exact.

3. (Excision) If $U$ and $A$ are subsets of a topological space $X$ with $U \subseteq A$, then for each $n \in \mathbb{N}_0$ the map $\mathcal{H}_n(X \setminus U, A \setminus U) \to \mathcal{H}_n(X, A)$ is an isomorphism.

4. (Additivity) Let $\{(X_j, A_j)\}_{j \in J}$ be a family of pairs of topological spaces. We write $X = \bigsqcup_{j \in J} X_j$ and $A = \bigsqcup_{j \in J} A_j$. If given $j \in J$ we denote by $i_j: (X_j, A_j) \to (X, A)$ the obvious inclusion map, then for any $k \in \mathbb{N}_0$ the induced map

$$\bigoplus_{j \in J} i_{j*}: \bigoplus_{j \in J} \mathcal{H}_k(X_j, A_j) \to \mathcal{H}_k(X, A)$$

is an isomorphism.

5. (Dimension axiom) We denote by $\star$ the topological space that consists of a single point. For $n \neq 0$ we have $H_n(\star) = 0$.

---

805 The axioms are usually called Eilenberg-Steenrod axioms.
806 Here we use the obvious notation that for a topological space $Y$ we write $\mathcal{H}_n(Y) := \mathcal{H}_n(Y, \emptyset)$. 

Example. It follows from Proposition 43.17, Corollary 43.16, the Excision Theorem 43.19, the obvious generalization of Lemma 41.14 and Lemma 41.6 that singular homology is indeed a homology theory.

We conclude this chapter with a uniqueness theorem of homology theories. To formulate the theorem we need the following definition.

Definition. We call the category \( \text{FullPairCW} \)
\[
\text{Ob}(\text{FullPairCW}) := \text{all pairs of CW-complexes},
\]
\[
\text{Mor}((X, A), (Y, B)) := \text{all continuous maps } f: X \to Y \text{ with } f(A) \subseteq B,
\]
together with the usual composition of maps the \textit{full category of pairs of CW-complexes}.\(^{897}\)

Now we can formulate the following uniqueness statement for homology theories.

**Theorem 57.27.** Let \( \mathcal{H} \) and \( \mathcal{H}' \) be two homology theories and let \( \varphi: \mathcal{H}_0(\ast) \to \mathcal{H}_0'(\ast) \) be an isomorphism. Then there exists a natural isomorphism between \( \mathcal{H} \) and \( \mathcal{H}' \) viewed as functors
\[
\text{full category FullPairCW of pairs of CW-complexes} \rightarrow \text{category } \mathcal{N}_0\text{-GradAb of } \mathcal{N}_0\text{-graded abelian groups.}
\]

**Sketch of a proof.** Let \( G \) be an abelian group. We start our proof with the following observation: Given a pair \( (X, A) \) of CW-complexes we saw in Corollary 36.35 (3) that we can equip the mapping cone \( \text{Cone}(i: A \to X) \) of the inclusion map with a natural CW-structure. Given \( n \in \mathbb{N}_0 \) we define the \( n \)-th cellular homology \( \mathcal{H}^{\text{CW}}_n(X, A; G) \) as the reduced cellular homology with \( G \)-coefficients of the mapping cone.

Proposition 48.4, together with Lemma 46.16, Proposition 48.4 and the discussion on page 1402 shows that for pairs of CW-complexes there exists a natural isomorphism between singular homology with \( G \)-coefficients and cellular homology with \( G \)-coefficients. Closer inspection of the proof shows that we can prove this statement only using the above Eilenberg-Steenrod axioms and the fact that \( \mathcal{H}_0(\ast; G) \cong G \).

Now let \( \alpha: \mathcal{H}_0(\ast) \to G \) be an isomorphism. By the above one can show that there exists a natural isomorphism from \( \mathcal{H} \) to \( \mathcal{H}^{\text{CW}}_n(\ast; G) \). The same applies to \( \mathcal{H}' \) and we obtain the theorem as long as \( \varphi \) is an isomorphism. This approach to the proof is developed in more detail in [TD08] Chapter 12.2].

**Remark.**

(1) Closely related results are also proved in [ES52] p. 100 and [Hu66] p. 52, see also [GH81] p. 138.

(2) The axioms of a cohomology theory are defined basically the same way with the obvious modifications and the analogue of Theorem 57.27 also holds in this context, see [DaK01] Theorem 1.31.

(3) If one drops the dimension axiom, then there are other (co-) homology theories, for example “topological K-theory”. We refer to [Karo08] for details.

\(^{897}\)Note that we consider all continuous maps, we do not restrict ourselves to cellular maps. Thus \( \text{FullPairCW} \) is a full subcategory of the category \( \text{PairTop} \) of pairs of topological spaces.
Exercises for Chapter 57

Exercise 57.1. Show that the abelianization functor from the category of groups to the category of abelian groups is right-exact and that it is not left-exact.

Exercise 57.2. Let $C$ be the category of finitely generated abelian groups. Given an abelian group $A$ we denote by $\text{Tor}(A)$ as usual its torsion subgroup and furthermore we denote by $FA := A/\text{Tor}(A)$ the maximal torsion-free quotient. We consider the following two covariant functors:

$$F: C \mapsto C \quad \text{and} \quad \text{Tor}: C \mapsto C, \quad A \mapsto \text{Tor}(A).$$

(a) Show that the functor $F$ is left-exact.
(b) Show that the functor $F$ is not right-exact.
(c) Is the functor $\text{Tor}$ left-exact?
(d) Is the functor $\text{Tor}$ right-exact?

Exercise 57.3. Let $A$ be an $(m \times n)$-matrix over $\mathbb{Z}$ and let $R$ be a commutative ring. Let $\varphi: \mathbb{Z} \to R$ be the ring homomorphism given by $\varphi(n) = n \cdot 1_R$. Finally let $\Theta_k: \mathbb{Z}^m \otimes R \to R^m$ and $\Theta_n: \mathbb{Z}^n \otimes R \to R^n$ be the natural isomorphisms provided by Lemma 57.3. Show that the following diagram commutes:

$$\begin{array}{ccc}
\mathbb{Z}^n \otimes R & \xrightarrow{(w \mapsto Av) \otimes \text{id}_R} & \mathbb{Z}^m \otimes R \\
\Theta_n \downarrow & & \downarrow \Theta_m \\
R^n & \xrightarrow{w \mapsto \varphi(A)w} & R^m.
\end{array}$$

Exercise 57.4. Let $(C_*, \partial_*)$ be a chain complex and let $G$ be an abelian group. We consider the following map:

$$H_n(C_* \otimes G) \to H_n(C_*) \otimes G,$$

$$\left[\sum_{i=1}^{n} c_i \otimes g_i\right] \mapsto \sum_{i=1}^{n} \left[c_i\right] \otimes g_i.$$

Is this map well-defined?

Exercise 57.5. What are the isomorphism types of the homology groups of $\mathbb{R}P^5$ with $\mathbb{F}_3$-coefficients?

Exercise 57.6. Let $A \to B \to C$ be a short exact sequence of abelian groups and let $G$ be an abelian group. Show that there exists an exact sequence of the form

$$0 \to \text{Tor}(A, G) \to \text{Tor}(B, G) \to \text{Tor}(C, G) \to A \otimes G \to B \otimes G \to C \otimes G \to 0.$$ 

Hint. Use the Snake Lemma 43.9

Remark. This exact sequence is sometimes called the six-term sequence in homological algebra.
Exercise 57.7. Let \( n \in \mathbb{N} \). Let \( G \) be an abelian group (which is not necessarily finitely generated). Suppose \( G \) admits an element of order \( g \), i.e. \( n \cdot g = 0 \) and \( m \cdot g \neq 0 \) for \( m = 1, \ldots, n - 1 \). Show that \( \text{Tor}(G, \mathbb{Z}_n) \neq 0 \).

Remark. You could make use of Exercise 57.6.

Exercise 57.8.

(a) Let \( C_* \) be a chain complex. (We do not assume that the chain groups \( G_k \) are finitely generated.) Suppose that for every \( k \in \mathbb{N}_0 \) and every prime \( p \in \mathbb{N} \) we have \( H_k(C_*; \mathbb{Q}) = 0 \) and \( H_k(C_*; \mathbb{Z}_p) = 0 \). Show that for every \( k \in \mathbb{N}_0 \) we have \( H_k(C_*) = 0 \).

Remark. You might want to use Exercise 57.7.

(b) Let \( f: C_* \to D_* \) be a chain map between two chain complexes. (We do not assume that the chain groups are finitely generated.) Suppose that for every \( k \in \mathbb{N}_0 \) and every prime \( p \in \mathbb{N} \) the maps \( H_k(C_*; \mathbb{Q}) \to H_k(D_*; \mathbb{Q}) \) and \( H_k(C_*; \mathbb{Z}_p) \to H_k(D_*; \mathbb{Z}_p) \) are isomorphisms. Show that for every \( k \in \mathbb{N}_0 \) the map \( H_k(C_*) \to H_k(D_*) \) is an isomorphism.

Hint. Use the algebraic mapping cone that we introduced on page 1284.

Exercise 57.9. Determine \( \text{Tor}(\mathbb{Z}_n, \mathbb{Q}/\mathbb{Z}) \).

Exercise 57.10. Let \( m, n \in \mathbb{N} \). Show that

\[
\text{Tor}(\mathbb{Z}_m, \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}.
\]

Exercise 57.11. Show that

\[
\left( \prod_{n \in \mathbb{N}} \mathbb{Z}_n \right) \otimes \mathbb{Q} \neq 0.
\]

Exercise 57.12. Let \( k \in \mathbb{Z} \setminus \{0\} \) and let \( \varphi_k: \Delta^1 \to S^1 \) be the map given by \((1 - t, t) \mapsto e^{k \cdot 2\pi t i}\). Furthermore let \( i: H_1(S^1) \to H_1(S^1; \mathbb{R}) \) be the homomorphism from Lemma 57.7 (1) that is induced by \( \sigma \mapsto \sigma \otimes 1 \). Show that

\[
\left[ \frac{1}{n} \otimes \varphi \right] = \frac{1}{n} \cdot i_*(\sigma(\Delta^1)) \in H_1(S^1; \mathbb{R}).
\]

We refer to Figure 874 for an illustration.

\[\Delta^1 \xrightarrow{\varphi_k} S^1\]

\text{FIGURE 874. Illustration for Exercise 57.12.}

Exercise 57.13. Let \( T = S^1 \times S^1 \) and let \( K \) be the Klein bottle.

(a) Does there exist a map \( f: K \to T \) such that \( f_*: H_2(K; \mathbb{F}_2) \to H_2(T; \mathbb{F}_2) \) is an isomorphism?

(b) Does there exist a map \( g: T \to K \) such that \( g_*: H_2(T; \mathbb{F}_2) \to H_2(K; \mathbb{F}_2) \) is an isomorphism?
Exercise 57.14. Let $g \in \mathbb{N}$. We denote by $N_g$ the non-orientable surface of genus $g$ as defined on page 206. As a reminder, note that by Lemma 8.33 we know that $N_g$ is diffeomorphic to the connected sum of $g$ copies of $\mathbb{R}P^2$. Show that

$$H_i(N_g; \mathbb{F}_2) \cong \begin{cases} 0, & \text{if } i > 2, \\ \mathbb{F}_2, & \text{if } i = 0 \text{ or } i = 2, \\ \mathbb{F}_2^g, & \text{if } i = 1. \end{cases}$$

Remark. We calculated $H_*(N_g)$ in Proposition 48.9.
58. The Künneth Theorem

In this chapter we want to study the following question:

**Question 58.1.** Let $X$ and $Y$ be two topological spaces. What is the connection between the homology groups of $X$ and $Y$ on the one hand and the homology groups of the product topological space $X \times Y$ on the other hand?

58.1. The tensor product of chain complexes. First we want to find some connection between the chain complexes of $X$, $Y$ and $X \times Y$. To do so we need the notion of the tensor product of chain complexes. Therefore we start out with a short excursion into homological algebra, i.e. into the study of chain complexes.

**Lemma 58.2.** Let $C = (C_*, \partial_*)$ and $C' = (C'_*, \partial'_*)$ be two chain complexes. Given $n \in \mathbb{N}_0$ we define

$$(C \otimes C')_n := \bigoplus_{p+q=n} C_p \otimes C'_q.$$  

The consider the maps

$$d: (C \otimes C')_n \rightarrow (C \otimes C')_{n-1}$$

which are uniquely determined by

$$c_p \otimes c'_q \mapsto \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q$$

for $c_p \in C_p$ and $c'_q \in C'_q$. The maps turn $C \otimes C'$ into a chain complex, called the tensor product $C \otimes C'$ of the chain complexes $C$ and $C'$.

We illustrate the definition of the tensor product of chain complexes in the following diagram:

$\begin{array}{cccc}
C_0 \otimes C'_2 & \xleftarrow{\partial_1 \otimes \text{id}} & C_1 \otimes C'_2 & \xleftarrow{\partial_2 \otimes \text{id}} & C_2 \otimes C'_2 \\
\downarrow \text{id} \otimes \partial'_2 & & \downarrow \text{id} \otimes \partial'_2 & & \downarrow \text{id} \otimes \partial'_2 \\
C_0 \otimes C'_1 & \xleftarrow{\partial_1 \otimes \text{id}} & C_1 \otimes C'_1 & \xleftarrow{\partial_2 \otimes \text{id}} & C_2 \otimes C'_1 \\
\downarrow \text{id} \otimes \partial'_1 & & \downarrow \text{id} \otimes \partial'_1 & & \downarrow \text{id} \otimes \partial'_1 \\
C_0 \otimes C_0' & \xleftarrow{\partial_1 \otimes \text{id}} & C_1 \otimes C_0' & \xleftarrow{\partial_2 \otimes \text{id}} & C_2 \otimes C_0'
\end{array}$

**Proof.** We still have to show that the maps $d$ are indeed boundary maps of a chain complex, i.e. we have to verify that $d \circ d = 0$. This is the case since for any $c_p \in C_p$ and $c'_q \in C'_q$ we have

$$d(d(c_p \otimes c'_q)) = d(\partial c_p \otimes c'_q + d((-1)^p \cdot c_p \otimes \partial' c'_q))$$

$$= \partial \partial c_p \otimes c'_q + (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot c_p \otimes \partial' \partial' c'_q$$

$$= (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q - (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q = 0.$$
Thus we have shown that \((\mathcal{C} \otimes \mathcal{C}', d)\) is indeed a chain complex. □

**Example.** Let

\[
\mathcal{C} = \cdots \rightarrow C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} C_{n-2} \rightarrow \cdots \quad \text{and} \quad \mathcal{C}' = 0 \rightarrow G \rightarrow 0
\]

be two chain complexes where the second consists of a single abelian group. In this case we have

\[
(\mathcal{C} \otimes \mathcal{C}')_n = C_{n-k} \otimes G,
\]

i.e. the tensor product is just given by tensoring the chain groups of \(\mathcal{C}\) by \(G\) and shifting the degrees by \(-k\).

We conclude this section with the following lemma.

**Lemma 58.3.** Let \(\mathcal{C}\) and \(\mathcal{D}\) be two chain complexes.

1. **Given two chain maps** \(f: \mathcal{C} \rightarrow \mathcal{D}\) and \(f': \mathcal{C}' \rightarrow \mathcal{D}'\) the induced map

\[
f \otimes f': \mathcal{C} \otimes \mathcal{C}' \rightarrow \mathcal{D} \otimes \mathcal{D}'
\]

\[
\sum_{i=1}^{n} c_i \otimes c'_i \mapsto \sum_{i=1}^{n} f(c_i) \otimes f'(c'_i)
\]

is also a chain map.

2. **If** \(f, g: \mathcal{C} \rightarrow \mathcal{D}\) and \(f', g': \mathcal{C}' \rightarrow \mathcal{D}'\) are chain homotopic maps, then the induced maps

\[
f \otimes f', g \otimes g': \mathcal{C} \otimes \mathcal{C}' \rightarrow \mathcal{D} \otimes \mathcal{D}'
\]

are also chain homotopic.

3. **If** \(f: \mathcal{C} \rightarrow \mathcal{D}\) and \(f': \mathcal{C}' \rightarrow \mathcal{D}'\) are homotopy equivalences, then the induced map

\[
f \otimes f': \mathcal{C} \otimes \mathcal{C}' \rightarrow \mathcal{D} \otimes \mathcal{D}'
\]

is also a homotopy equivalence.

**Proof.** The proof of the lemma is elementary. For completeness’ sake and for a good conscience we provide the proof of the first statement. So let \(\mathcal{C}\) and \(\mathcal{D}\) be two chain complexes and let \(f: \mathcal{C} \rightarrow \mathcal{D}\) and \(f': \mathcal{C}' \rightarrow \mathcal{D}'\) be chain maps. Let \(c \in C_n\) and \(c' \in C'_n\), then

\[
\partial(f(c) \otimes f'(c')) = \partial f(c) \otimes f'(c') + (-1)^k \cdot f(c) \otimes \partial f'(c') = f(\partial c) \otimes f'(c') + (-1)^k \cdot f(c) \otimes f'(\partial c')
\]

\[
\uparrow
\]

since \(\deg(f(c)) = \deg(c) = k \quad \text{since } f \text{ and } f' \text{ are chain maps}
\]

\[
= (f \otimes f')(\partial c \otimes c' + (-1)^k \cdot c \otimes \partial c') = (f \otimes f'')(\partial(c \otimes c')).
\]

58.2. **The Eilenberg-Zilber Theorem.** The following theorem, which was first proved in 1953, relates the singular chain complex \(C_*(X \times Y)\) of the product of two topological spaces \(X\) and \(Y\) to the tensor product \(C_*(X) \otimes C_*(Y)\) of the two individual chain complexes.

\[\text{Note that in the calculation we made use of the extra-term } (-1)^p \text{ in the definition of the boundary map. If we defined the boundary map "naively" as } d(c_p \otimes c'_q) = \partial c_p \otimes c'_q + c_p \otimes \partial c'_q, \text{ then the result would not have been a chain complex.}\]
Theorem 58.4. (Eilenberg-Zilber) Let \( X \) and \( Y \) be topological spaces. There exist natural chain maps
\[
\Upsilon: C_*(X) \otimes C_*(Y) \to C_*(X \times Y)
\]
and
\[
\Theta: C_*(X \times Y) \to C_*(X) \otimes C_*(Y),
\]
with the following three properties:

1. The maps are chain homotopy-inverses of one another. In particular, by Corollary 42.3, for each \( n \in \mathbb{N}_0 \) we have a natural isomorphism
\[
H_n(X \times Y) \xrightarrow{\Theta_*} H_n(C_*(X) \otimes C_*(Y)).
\]

2. For any \( x \in X \) and any singular \( k \)-chain \( \sigma: \Delta^k \to Y \) the singular chain \( \Upsilon(\{x\} \otimes \sigma) \) equals the singular simplex \( \Delta^k \to X \times Y \) that is given by \( P \mapsto (x, \sigma(P)) \).

3. The same statement as in (2) also holds with the roles of \( X \) and \( Y \) swapped.

Proof. We postpone this technically intricate proof to Section 80.2. In that section the above statement follows from Theorem 80.2 together with the proof of the Eilenberg-Zilber Theorem provided on page 1962. □

Since we just postponed the proof of the Eilenberg-Zilber to significantly later let us prove a partial result that is much weaker, but that is good enough for many purposes. Namely we will prove an analogous statement for CW-complexes which will be sufficient for the calculations of homology groups that we want to do in this chapter. The proof of this special case is significantly easier to digest than the proof of the general case of the Eilenberg-Zilber Theorem.

Proposition 58.5. Let \( X \) and \( Y \) be two CW-complexes with finitely many cells in each dimension. Then there exists a natural isomorphism
\[
C_*^{CW}(X \times Y) \xrightarrow{\cong} C_*^{CW}(X) \otimes C_*^{CW}(Y)
\]
of chain complexes.

Remark. Recall that, following the convention of page 1096, given two chain complexes \( C_* \) and \( D_* \) we write \( C_* \simeq D_* \) if they are homotopy equivalent. Suppose that \( X \) and \( Y \) are

---

\[899\] Here “natural” means that for maps \( f: X \to X' \) and \( g: Y \to Y' \) of topological spaces we obtain commutative diagrams
\[
\begin{align*}
C_*(X) \otimes C_*(Y) & \xrightarrow{\Upsilon} C_*(X \times Y) \\
\downarrow f_* \otimes g_* & \downarrow (f \times g)_* \quad \text{and} \quad C_*(X \times Y) \xrightarrow{\Theta} C_*(X) \otimes C_*(Y) \\
C_*(X') \otimes C_*(Y') & \xrightarrow{\Upsilon} C_*(X' \times Y') \\
\downarrow f_* \otimes g_* & \downarrow (f \times g)_* \\
C_*(X') \otimes C_*(Y') & \xrightarrow{\Theta} C_*(X') \otimes C_*(Y').
\end{align*}
\]

\[900\] Here the notion “natural” means “natural” in the category of CW-complexes, i.e. the isomorphisms \( \Phi_{XY} \) are only natural with respect to cellular maps \( X \to X' \) and \( Y \to Y' \), i.e. the commutative diagram from Footnote 899 only exists for such cellular maps.
CW-complexes which have only finitely many cells in each dimension. Then we have
\[ C_*(X \times Y) \simeq C_*^{CW}(X \times Y) \xrightarrow{\simeq} C_*^{CW}(X) \otimes C_*^{CW}(Y) \simeq C_*(X) \otimes C_*(Y). \]

Corollary 49.9 and Lemma 58.3 Proposition 58.5 Corollary 49.9 and Lemma 58.3

For such \( X \) and \( Y \) this argument proves the existence of the chain homotopies in the statement of the Eilenberg-Zilber Theorem 58.4. But note that the chain homotopy equivalences of Lemma 58.3 are not natural, hence the above chain equivalences are not natural.

**Proof.** Let \( X \) and \( Y \) be two CW-complexes with finitely many cells in each dimension. On page 960 we introduced a CW-structure on \( X \times Y \) where the \( n \)-cells of \( X \times Y \) are precisely of the form \( e \times f \) where \( e \) is a \( p \)-cell of \( X \) and \( f \) is an \((n-p)\)-cell of \( Y \). We quickly recall the definition of the product CW-structure on \( X \times Y \):

1. Using the homeomorphism from Proposition 2.53 (2) we identify the \( n \)-dimensional closed ball \( B^n \) with the \( n \)-dimensional cube \( I^n = [0, 1]^n \).
2. We put \((X \times Y)^0 = X^0 \times Y^0 \).
3. Now we suppose that the \((n-1)\)-skeleton \((X \times Y)^{(n-1)}\) has already been defined. We consider a \( p \)-cell \( e \) in \( X \) which is given by a characteristic map \( \varphi : I^p \to X^p \) and an \((n-p)\)-cell \( f \) in \( Y \) which is given by a characteristic map \( \psi : I^{n-p} \to Y^{n-p} \). Then we denote by \( e \times f \) the \( n \)-cell in \( X \times Y \) which is given by the attaching map
\[
\partial(I^n) = (\partial I^p \times I^{n-p}) \cup (I^p \times \partial I^{n-p}) \to (X \times Y)^{n-1}
\]
\[
(x,y) \mapsto (\varphi(x), \psi(y)).
\]

All these \( n \)-cells together define the \( n \)-skeleton of \( X \times Y \).

Since \( X \) and \( Y \) have only finitely many cells in each dimension the above construction does indeed define a CW-structure on \( X \times Y \).

Given \( n \in \mathbb{N}_0 \) we consider the map
\[
C_n^{CW}(X \times Y) \to C_p^{CW}(X) \otimes C_{n-p}^{CW}(Y)
\]
which is induced by the property that for any \( p \)-cell \( e \) of \( X \) and any \((n-p)\)-cell \( f \) of \( Y \) we have\(^{01}\)
\[
[e \times f] \mapsto [e] \otimes [f].
\]

As on page 1397 one can show that this map is an isomorphism. It remains to prove that the above maps form a chain map. This statement in turn is equivalent to the following claim.

**Claim.** For any \( p \)-cell \( e \) of \( X \) and any \( q \)-cell \( f \) of \( Y \) we have
\[
\partial(e \times f) = \underbrace{\partial e \otimes f}_{\in C^{CW}_{p+q-1}(X \times Y)} + (-1)^p \cdot \underbrace{e \otimes \partial f}_{\in C^{CW}_{p-1}(X) \otimes C^{CW}_q(Y)}
\]

It is possible to prove this formula using the description of the cellular boundary map in Proposition 48.7 and by doing a very careful sign-analysis. We illustrate this argument in Figure 875.\(^{01}\)We follow the convention of page 1267 where saw that cells naturally give rise to a basis of the cellular chain complex.
It remains to show that $\epsilon = 1$ for all $p$. Now let $e$ be a $p$-cell of a CW-complex $K$ and let $f$ be a $q$-cell of a CW-complex $L$. We denote by $\tau$ the set of $(p-1)$-cells of $K$ and we denote by $\phi$ the set of $(q-1)$-cells of $L$. We compute that

$$\partial(e \times f) = \sum_{\tau} [\tau \times f : e \times f] \cdot (\tau \times f) + \sum_{\phi} [e \times \phi : e \times f] \cdot (e \times \phi) = \sum_{\tau} [\tau : e] \cdot (\tau \times f) + \sum_{\phi} \epsilon_{p,q} [\phi : f] \cdot (e \times \phi) = (\partial e) \times f + \epsilon_{p,q} \cdot e \times f.$$

It remains to show that $\epsilon_{p,q} = (-1)^p$. We will prove this indirectly. More precisely, since we know that $\partial^2 = 0$ in the cellular chain complex we obtain that

$$0 = \partial(\partial(e \times f)) = (\partial \partial e) \times f + \epsilon_{p-1,q} \cdot (\partial e) \times (\partial f) + \epsilon_{p,q} \cdot (\partial e) \times (\partial f) + \epsilon_{p,q} \cdot \epsilon_{p,q} \cdot e \times (\partial \partial f) \overset{=0}{=} \epsilon_{p-1,q} \cdot (\partial e) \times f + \epsilon_{p,q} \cdot (\partial e) \times f \overset{=0}{=} (\epsilon_{p-1,q} + \epsilon_{p,q}) \cdot (\partial e) \times f.$$

But this equality can hold for all CW-complexes $K$ and $L$ only if $\epsilon_{p,q} = -\epsilon_{p-1,q}$. Since $\epsilon_{0,q} = 1$ we obtain iteratively that $\epsilon_{p,q} = (-1)^p$. 

58.3. The Künneth Theorem for chain complexes. Our goal is to determine the homology groups of the product $X \times Y$ of two topological spaces in terms of the homology groups of $X$ and $Y$. In light of the Eilenberg-Zilber Theorem, or alternatively, considering Proposition 58.5 we have to find a connection between the homology groups of two chain complexes $C, C'$ and the corresponding tensor product $C \otimes C'$.

We start out with the following elementary lemma.
Lemma 58.6. Let $C$ and $C'$ be two chain complexes. The map
\[
\Omega: H_p(C) \otimes H_q(C') \rightarrow H_{p+q}(C \otimes C')
\]
is well-defined and it is natural with respect to the chain complexes $C$ and $C'$.

**Proof.** Let $C = (C_n, \partial_n)$ and $C' = (C'_n, \partial'_n)$ be two chain complexes. First note that if $c_i \in C_p$ and $c'_i \in C_q$ are cycles, then
\[
d(c_i \otimes c'_i) = \partial c_i \otimes c'_i + (-1)^p c_i \otimes \partial c'_i = 0
\]
i.e. $c_i \otimes c'_i \in C \otimes C'$ is indeed a cycle. Second, if $c_i + \partial e_i$ is an other representative of $[c_i]$ then
\[
[(c_i + \partial e_i) \otimes c'_i] = [c_i \otimes c'_i + d(e_i \otimes c'_i)] = [c_i \otimes c'_i].
\]
The same way one can show that the value of $\Omega$ does not depend on the choice of representative of the class in $H_q(C')$. It is straightforward to verify that $\Omega$ is in fact a natural map. \(\blacksquare\)

**Example.** In some instances the homomorphism $\Omega$ from Lemma 58.6 is an isomorphism. For example let $C = (C_n, \partial_n)$ be a chain complex of free abelian groups such that all boundary maps $C_n \rightarrow C_{n-1}$ in $C$ are the zero map. In this case we have for any chain complex $C'$ that
\[
\bigoplus_{n \in \mathbb{N}_0} H_p(C) \otimes H_{n-p}(C') = \bigoplus_{n \in \mathbb{N}_0} C_p \otimes H_n(C'_*) = \bigoplus_{n \in \mathbb{N}_0} H_n(C_p \otimes C'_*) = H_n(C \otimes C').
\]
using all boundary maps in $C$ are zero, by Theorem 57.18, and Lemma 57.17(3) since $C$ is a direct sum of trivial chain complexes.

Now we can formulate the following proposition which is the key algebraic result of this chapter.

**Theorem 58.7. (Künneth Theorem for Chain Complexes)** Let $C$ and $C'$ be two chain complexes. If $C$ is free, i.e. if all chain groups of the chain complex $C$ are free abelian groups, then there exists a natural short exact sequence
\[
0 \rightarrow \bigoplus_{p+q=n} H_p(C) \otimes H_q(C') \xrightarrow{\Omega} H_n(C \otimes C') \rightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(C), H_q(C')) \rightarrow 0.
\]
If $C'$ is a free chain complex, then this short exact sequence splits.

**Remark.**

\([\text{Hermann Künneth (1892-1975) was a German mathematician.}]\)
58. THE KÜNNETH THEOREM 1439

(1) The adjective “natural” means in this context that if \( f : C \to D \) and \( f' : C' \to D' \) are chain maps, then we obtain a commutative diagram of short exact sequences:

\[
0 \to \bigoplus_{p+q=n} H_p(C) \otimes H_q(C') \xrightarrow{\Omega} H_n(C \otimes C') \to \bigoplus_{p+q=n} \text{Tor}(H_p(C), H_q(C')) \to 0
\]

\[
0 \to \bigoplus_{p+q=n} H_p(D) \otimes H_q(D') \xrightarrow{\Omega} H_n(D \otimes D') \to \bigoplus_{p+q=n} \text{Tor}(H_p(D), H_q(D')) \to 0.
\]

Here the middle map is given by Lemma 58.3 (1) and the map on the right is given by the functoriality of the torsion-groups that we had discussed on page 1413.

(2) If \( C' \) is a chain complex which consists of a single abelian group \( G \), i.e. if it is of the form \( 0 \to G \to 0 \) with \( G \) in degree 0, then \( H_0(C') = G \) and all other homology groups are zero. The Künneth Theorem together with the example on page 1434 thus gives us the short exact sequence

\[
0 \to H_n(C) \otimes G \to H_n(C \otimes C') \to \text{Tor}(H_{n-1}(C), G) \to 0,
\]

i.e. we recover the Universal Coefficient Theorem 57.18 as a special case of the Künneth Theorem. In fact, as we will see, the proof of the Künneth Theorem is quite similar to the proof of the Universal Coefficient Theorem 57.18.

(3) The fact that the short exact sequence of the Künneth Theorem splits implies that the middle group is isomorphic to the direct sum of the two groups to the left and right. But, as we saw in the discussion of the Universal Coefficient Theorem 57.18, see Proposition 57.26, this isomorphism is not natural.

Proof. Let \( C = (C_n, \partial_n) \) and \( C' = (C'_n, \partial'_n) \) be two chain complexes such that all \( C_n \) are free abelian groups. As we will see, the proof of the theorem is quite similar to the proof of the Universal Coefficient Theorem 57.18.

For \( p \in \mathbb{N}_0 \) we consider again

\[
Z_p := \ker(\partial_p : C_p \to C_{p-1}) \quad \text{and} \quad B_p := \text{im}(\partial_{p+1} : C_{p+1} \to C_p).
\]

We denote by \( i : Z_p \to C_p \) the inclusion map. Furthermore we denote by \( Z \) the chain complex which is given by the groups \( Z_p \) where all the boundary maps are the zero map. The same way we obtain from the groups \( B_p \) a chain complex \( B \).

Claim. The sequence

\[
0 \to Z \otimes C' \xrightarrow{i \otimes \text{id}} C \otimes C' \xrightarrow{\partial \otimes \text{id}} B \otimes C' \to 0
\]

is a sequence of chain maps and it is exact at each degree.

It follows easily from the definitions of the boundary maps in the various chain complexes, see also the diagram on page 1418, that the homomorphisms \( i \otimes \text{id} : Z \otimes C' \to C \otimes C' \) and \( \partial \otimes \text{id} : C \otimes C' \to B \otimes C \) are chain maps. It remains to show that the sequence is
exact at each degree. The argument is exactly the same as on page 1418. For the reader’s convenience we recall the argument. First note that by definition the sequences

$$0 \to Z_p \overset{i}{\to} C_p \overset{\partial}{\to} B_{p-1} \to 0$$

are exact. Also recall that by hypothesis each $C_n$ is a free abelian group. It follows from Lemma [9.2] that each $B_n$ is also free abelian. By Lemma [46.1] this means that the above short exact sequence splits. But then it follows from Lemma [57.6] that the sequence stays exact even after tensoring it with any $C'_q$. The claim is an immediate consequence of these observations.

From Proposition [43.11] and the claim we thus obtain the following long exact sequence:

$$\cdots \to H_n(B \otimes C') \overset{d_n}{\to} H_n(Z \otimes C') \to H_n(C \otimes C') \to H_{n-1}(B \otimes C') \overset{d_{n-1}}{\to} H_{n-1}(Z \otimes C') \to \cdots$$

The connecting homomorphism $d_n : H_n(B \otimes C') \to H_n(Z \otimes C')$ from Proposition [43.11] is hereby, as in the proof of the Universal Coefficient Theorem [57.18] induced by the map $i \otimes \text{id}$ where $i$ denotes the inclusion $B \to Z$.

Since the boundary maps in the chain complexes $B$ and $Z$ are the zero maps it follows from the example on page [1438] that we obtain the following long exact sequence:

$$\cdots \overset{i \otimes \text{id}}{\to} \bigoplus_{p+q=n} Z_p \otimes H_q(C') \to H_n(C \otimes C') \to \bigoplus_{p+q=n-1} B_p \otimes H_q(C') \overset{i \otimes \text{id}}{\to} \bigoplus_{p+q=n-1} Z_p \otimes H_q(C') \to \cdots$$

From Lemma [46.4] we obtain a short exact sequence

$$0 \to \bigoplus_{p+q=n} \ker \left( B_p \otimes H_q(C') \overset{i \otimes \text{id}}{\to} Z_p \otimes H_q(C') \right) \to H_n(C \otimes C') \to \bigoplus_{p+q=n-1} \ker \left( B_p \otimes H_q(C') \overset{i \otimes \text{id}}{\to} Z_p \otimes H_q(C') \right) \to 0.$$  

This proves the existence of the short exact sequence. Using Lemma [57.13] one can show that this short exact sequence is natural. We leave it to the reader to verify the details.

Finally we suppose that $C'_*$ is also a free chain complex. We leave it again to the reader to adapt the argument of the proof of Proposition [57.25] to show that the above short exact sequence splits. Alternatively we refer to [Mun84, Chapter 58] for details. 

58.4. The Künneth Theorem for topological spaces. Now we return to our initial Question [58.1] of the chapter, namely, what is the relationship between the homology groups of the topological spaces $X, Y$ and $X \times Y$? The following theorem gives a comprehensive answer.

---

903 The index goes down by one in the map $H_n(C \otimes C') \to H_{n-1}(B \otimes C')$, since the map is induced by the short exact sequence $0 \to Z_p \to C_p \to B_{p-1} \to 0$. 
Theorem 58.8. (Künneth Theorem for Topological Spaces) Let $X$ and $Y$ be topological spaces. Then there exists a short exact sequence

$$0 \to \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \xrightarrow{\partial} H_n(X \times Y) \to \bigoplus_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) \to 0$$

with the following four properties:

1. Both maps are natural with respect to the topological spaces $X$ and $Y$.
2. For $p = 0$ the map $\Omega: H_0(X) \otimes H_q(Y) \to H_q(X \times Y)$ is the “obvious” map, namely for a point $x \in X$ and a singular cycle $\sigma$ the image of $[x] \otimes [\sigma] \in H_0(X) \otimes H_q(Y)$ under $\Omega$ equals the image of $[\sigma]$ under the map $H_q(Y) \to H_q(\{x\} \times Y) \to H_q(X \times Y)$, where the first map is induced by the natural homeomorphism and the second map is induced by the inclusion.
3. The analogue of (2) also holds for $q = 0$.
4. The above short exact sequence splits.$^{[004]}$

Remark. Both maps in the short exact sequence of the Künneth Theorem 58.8 for Topological Spaces are difficult to describe explicitly. At least for the former map we will partly get a nice description in Proposition 80.10.

Proof. We consider the following maps:

$$0 \to \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \xrightarrow{\Omega} H_n(C_*(X) \otimes C_*(Y)) \to \bigoplus_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) \to 0$$

Here the sequence on the top is exact and natural by the Künneth Theorem 58.7 for Chain Complexes. The vertical map is a natural isomorphism by the Eilenberg-Zilber Theorem 58.4 together with Corollary 42.3. We obtain the desired short exact sequence from replacing the upper middle term by the lower middle term $H_n(C_*(X \times Y)) = H_n(X \times Y)$. One can easily verify that this short exact sequence has all the desired properties. ■

Examples.

1. Let $X$ be a topological space. We want to determine the homology groups of $S^1 \times X$. The homology groups of $S^1$ are of course $\mathbb{Z}$ in the dimensions 0 and 1. For any abelian group $A$ we have by Lemma 57.3 a natural isomorphism $\mathbb{Z} \otimes A = A$ and by Lemma 57.17 we have $\text{Tor}(\mathbb{Z}, A) = 0$. It follows from the Künneth Theorem 58.8 for topological spaces that there exists a natural isomorphism

$$H_n(S^1 \times X) \xrightarrow{\cong} H_{n-1}(X) \oplus H_n(X).$$

This is of course precisely the same result as in Lemma 46.22.$^{[004]}$But as in the case of the Universal Coefficient Theorem 57.18 see Proposition 57.26 the splitting is not natural.
It follows fairly easily from Statement (2) that the map $H_n(X) \to H_n(S^1 \times X)$ is the map induced by the projection $S^1 \times X \to X$. It is less clear what the map $H_n(S^1 \times X) \to H_{n-1}(X)$ should be. Some more effort shows that this map is precisely the map that we had described in detail in Exercise 44.5.

(2) Let $n \in \mathbb{N}$ and let $m \in \mathbb{N}$. We want to determine the homology groups of the generalized torus $(S^m)^n$. In fact using the Künneth Theorem 58.8 for topological spaces one can easily show that for any $k \in \mathbb{N}_0$ there exists an isomorphism

$$H_i((S^m)^n) \cong \begin{cases} \mathbb{Z} & \text{if } i = km \text{ with } k \in \{0, \ldots, n\}, \\ 0 & \text{otherwise.} \end{cases}$$

In particular we have

$$H_i((S^m)^2) \cong \begin{cases} \mathbb{Z} & \text{if } i = 0, 2m, \\ \mathbb{Z} \oplus \mathbb{Z} & \text{if } i = m, \\ 0 & \text{otherwise.} \end{cases}$$

We will fill in the details in Exercise 58.1.

(3) Let $X$ and $Y$ be two path-connected topological spaces. Then we have isomorphisms

$$H_1(X \times Y) \cong H_1(X) \otimes H_0(Y) \oplus H_0(X) \otimes H_1(Y) = H_1(X) \oplus H_1(Y).$$

Künneth Theorem 58.8 for topological spaces Proposition 41.5 and Lemma 57.3

This is consistent with the product formula for fundamental groups proved in Proposition 16.20 and with the isomorphism of the Hurewicz Theorem 52.5.

Now we discuss the product $S^2 \times S^4$ in slightly more detail. It follows easily from the Künneth Theorem 58.8 for topological spaces, Proposition 43.4 Proposition 41.5 Lemma 57.3 and Lemma 57.17 that

$$H_k(S^2 \times S^4) \cong \begin{cases} \mathbb{Z} & \text{if } k = 0, 2, 4, 6, \\ 0 & \text{otherwise.} \end{cases}$$

But by the calculation on page 1262 these are precisely the homology groups of the complex projective space $\mathbb{C}P^3$. Furthermore it follows from Propositions 14.14 and 16.20 that $S^2 \times S^4$ is simply connected and it follows from the discussion on page 997 that $\mathbb{C}P^3$ is also simply connected. So all the invariants we are aware of, and that we know how to compute, agree for $S^2 \times S^4$ and $\mathbb{C}P^3$. This raises the following question which we will answer in Corollary 90.9.

**Question 58.9.** Are the topological spaces $S^2 \times S^4$ and $\mathbb{C}P^3$ homeomorphic?

\footnote{As of right now we do not know the higher homotopy groups of these two smooth manifolds, but these will not turn out to be very useful.}
Exercises for Chapter 58

Exercise 58.1. Let \( n \in \mathbb{N} \) and let \( m \in \mathbb{N} \). Show that for every \( k \in \mathbb{N}_0 \) there exists an isomorphism

\[
H_i((S^m)^n) \cong \begin{cases} 
\mathbb{Z} \binom{n}{k} = \mathbb{Z}^{k! (n-k)!} & \text{if } i = km \text{ with } k \in \{0, \ldots, n\}, \\
0, & \text{otherwise}.
\end{cases}
\]

Exercise 58.2. Let \( n \in \mathbb{N}_0 \). Show that

\[
\sum_{k=0}^{n} (-1)^k \cdot \binom{n}{k} = 0.
\]

Remark. There are many ways to prove this equality, one fun way of doing this is by computing the Euler characteristic of the \( n \)-dimensional torus in two different ways.
59. Applications of homology groups

59.1. Persistent homology. In this section we outline the idea behind “persistent homology”. Persistent homology was introduced by Gunnar Carlsson [Carl09] about ten years ago. More information and a much more careful treatment of persistent homology can for example be found in [EdH10]. Some extra information can also be found in [Gh14].

We consider Figure 876. What do we see? If we forget about topology for a second, then we would say that we see a set $X$ of dots that form a loop.

![Figure 876](image)

dots that appear to the eye to form a loop

Figure 876

If we view $X$ as a topological space, then it is just a finite discrete subset of $\mathbb{R}^2$. In particular its homology groups are non-zero only in dimension 0. So how can we use the mathematical machine that we have developed over the last two semesters to “see the loop”?

Given $r \in [0, \infty)$ we denote by $X(r)$ the subset of $\mathbb{R}^2$ that is given by replacing each point $x \in X$ by the closed ball $B_r(x)$ of radius $r$ around $x$. The homeomorphism type of $X(r)$ changes with the radius $r$. For example in Figure 877 we see that at $r = 1$ all but one ball are joined up and we see that $H_1(X(1)) \cong \mathbb{Z}^3$. We show three cycles $c_1, c_2, c_3$ in $X(1)$ which form a basis for $H_1(X(1))$. Two of the generators, namely $c_1, c_2$ are formed “by accident”, namely they arise from balls which are close by. This gets captured by the fact that they become null-homologous in $H_1(X(2))$ whereas $c_3$ represents a non-trivial element for “much longer”, i.e. for much larger values of $r$. Put differently, $c_3$ is a persistent element in homology, hence it captures global information.

Summarizing, given a subset $X$ of $\mathbb{R}^2$ we can study the topological spaces $X(r)$ for any $r \in [0, \infty)$ and furthermore for any $r < s$ we can study the inclusion induced map $H_n(X(r)) \to H_n(X(s))$. If there is a non-zero element in $H_n(X(r))$ which stays non-zero for a “long time”, then we say it is persistent and we hope that it captures something interesting.

The same approach can be applied to any finite subset of some $\mathbb{R}^n$. Pretty much any data one has in practice, e.g. blue pixels of a picture, measurements in an experiment, statistical data and so on, can be viewed as a finite subset of some $\mathbb{R}^n$, so in principle one can study its persistent homology. The real question is, whether one captures something significant or not. For example persistent homology was applied in [SHP16]906 to study...

---

906 Here is an easy way to tell that that paper was not written by mathematicians: In a mathematics paper the authors are invariably listed according to the alphabetic order of their last names. In most other sciences this is not the case.
the “The topological shape of Brexit”. It is perhaps debatable whether one can really obtain anything meaningful about the politics of Brexit using persistent homology.

59.2. The transfer map. Before we can give the next application of homology theory, namely the Borsuk-Ulam Theorem in higher dimensions, we need to introduce and study the transfer map in homology corresponding to a finite covering.

Let \( p: \tilde{X} \to X \) be a \( k \)-fold covering of a topological space \( X \). Let \( \sigma: \Delta^n \to X \) be a singular simplex. Since \( \Delta^n \) is simply connected\(^\text{[29.2]}\), it follows from Proposition 29.2 that there exist precisely \( k \) different lifts of \( \sigma \) to \( \tilde{X} \), i.e. there exist precisely \( k \) different singular simplices \( \tilde{\sigma}_1, \ldots, \tilde{\sigma}_k: \Delta^n \to \tilde{X} \) with \( p \circ \tilde{\sigma}_i = \sigma \) for \( i = 1, \ldots, k \). We write

\[
p^*(\sigma) := \sum_{i=1}^{k} \tilde{\sigma}_i.
\]

Given any commutative ring \( R \) we refer to the map

\[
p^*: C_*(X; R) \to C_*(\tilde{X}; R)
\]

\[
\sum_{i=1}^{n} \sigma_i \otimes r_i \mapsto \sum_{i=1}^{n} p^*(\sigma_i) \otimes r_i
\]

as the **transfer map** of the covering. It is straightforward to verify that the transfer map is in fact a chain map. In particular it induces a map

\[
p^*: H_*(X; R) \to H_*(\tilde{X}; R).
\]

Finally suppose we are given a subset \( A \subset X \). We write \( \tilde{A} := p^{-1}(A) \). One easily verifies that the transfer map \( p^*: C_*(X; R) \to C_*(\tilde{X}; R) \) induces a chain map

\[
p^*: H_*(X; A; R) \to H_*(\tilde{X}, \tilde{A}; R).
\]

\(^{907}\)To be precise, we also use that \( \Delta^n \) is locally path-connected.
**Proposition 59.1.** Let $p: \tilde{X} \to X$ be a covering of degree $k \in \mathbb{N}$ of a topological space $X$ and let $n \in \mathbb{N}_0$. Then the following hold:

1. For any commutative ring $R$ the transfer map $p^*: C_n(X; R) \to C_n(\tilde{X}; R)$ is a monomorphism.
2. For any commutative ring $R$ the map $p_* \circ p^*: H_n(X; R) \to H_n(X; R)$ is given by multiplication by $k$.
3. The projection map $p_*: H_n(\tilde{X}; \mathbb{Q}) \to H_n(X; \mathbb{Q})$ is an epimorphism.

The analogous statements also hold in the relative setting.

**Remark.**

1. If $p: \tilde{X} \to X$ is a finite covering of path-connected topological spaces, then we saw in Corollary 52.8 that the map $p_*: H_1(\tilde{X}) \to H_1(X)$ has finite cokernel. This implies in particular that $p_*: H_1(\tilde{X}; \mathbb{Q}) \to H_1(X; \mathbb{Q})$ is an epimorphism. Therefore we can view Proposition 59.1 (3) as a generalization of Corollary 52.8.
2. The conclusion of Proposition 59.1 (3) does not hold if we drop the condition that the covering is finite. For example, we have an infinite covering $p: \mathbb{R} \to S^1$ but $0 = H_1(\mathbb{R}; \mathbb{Q}) \xrightarrow{p_*} H_1(S^1; \mathbb{Q}) = \mathbb{Q}$ is not an epimorphism.

**Proof.** Let $p: \tilde{X} \to X$ be a $k$-fold covering of a topological space $X$.

1. Let $c \in C_n(X; R)$ be non-trivial. We write $c = \sum_{i=1}^n \sigma_i \otimes r_i$ where $\sigma_1, \ldots, \sigma_n$ are pairwise different singular simplices in $X$ and where $r_1, \ldots, r_n$ are all non-zero. Since each $\sigma_i$ lifts to $k$ different singular simplices and since for $i \neq j$ the lifts of $\sigma_i$ and $\sigma_j$ differ we see immediately from the definition that $p^*(\sigma)$ is also non-zero.
2. Let $R$ be a commutative ring. We denote by $p^*: C_n(X; R) \to C_n(\tilde{X}; R)$ the transfer map. Let $\sigma: \Delta^m \to X$ be a singular simplex. We denote the corresponding lifts by $\tilde{\sigma}_1, \ldots, \tilde{\sigma}_k$. Then

$$ (p_* \circ p^*)(\sigma) = p_*(\tilde{\sigma}_1 + \cdots + \tilde{\sigma}_k) = \underbrace{p \circ \tilde{\sigma}_1 + \cdots + p \circ \tilde{\sigma}_k}_{k \text{ summands}} = \underbrace{\sigma + \cdots + \sigma}_{k \text{ summands}} = k \cdot \sigma. $$

Why does this follow?
We thus see that $p_* \circ p^* : C_m(X) \to C_m(X)$ is multiplication by $k$ for any $m$. It follows easily that the map

$$H_n(X; R) \xrightarrow{p^*} H_n(\widetilde{X}; R) \xrightarrow{p_*} H_n(X; R)$$

is also given by multiplication by $k$.

(3) Since multiplication by $k \neq 0$ is an isomorphism of any rational vector space we obtain from (1) that $p_* \circ p^*: H_n(X; \mathbb{Q}) \to H_n(X; \mathbb{Q})$ is an isomorphism. In particular the second map, namely $p_*$, is an epimorphism.

The proofs in the relative setting are basically identical to the above. ■

**Proposition 59.2.** Let $p: \widetilde{X} \to X$ be a 2-fold covering. Then there exists a natural long exact sequence of the form

$$\ldots \to H_n(X; \mathbb{F}_2) \xrightarrow{p^*} H_n(\widetilde{X}; \mathbb{F}_2) \xrightarrow{p_*} H_n(X; \mathbb{F}_2) \xrightarrow{\partial} H_{n-1}(X; \mathbb{F}_2) \to \ldots$$

Here “natural” means that if we are given a commutative diagram

$$\begin{array}{ccc}
\widetilde{X} & \xrightarrow{\tilde{f}} & \widetilde{Y} \\
P & & \downarrow{q} \\
X & \xrightarrow{f} & Y
\end{array}$$

where $p: \widetilde{X} \to X$ and $q: \widetilde{Y} \to Y$ are 2-fold coverings, then the following diagram commutes:

$$\begin{array}{ccc}
\ldots & \xrightarrow{p^*} & \ldots \\
\downarrow{f} & \xrightarrow{\tilde{f}} & \downarrow{q} \\
\ldots & \xrightarrow{p_*} & \ldots \\
\downarrow{\partial} & \xrightarrow{\partial} & \downarrow{\partial} \\
\ldots & \xrightarrow{\partial} & \ldots
\end{array}$$

**Remark.** Note that it follows from Lemma [25.16](3) a 2-fold covering $p: \widetilde{Y} \to Y$ together with a map $f: X \to Y$ of topological spaces naturally give rise to a commutative diagram as in Proposition [59.2](3).

**Example.** Now we will see that we can use Proposition [59.2](3) to calculate the homology groups $H_k(\mathbb{RP}^n; \mathbb{F}_2)$ just using the following basic facts:

1. By the discussion on page [1402](1) we know that

$$H_k(S^n; \mathbb{F}_2) \cong \begin{cases} 
\mathbb{F}_2, & \text{if } k = 0 \text{ or } k = n, \\
0, & \text{otherwise}
\end{cases}$$

2. By the obvious generalization of Proposition [41.5](4) we know that $H_0(\mathbb{RP}^n; \mathbb{F}_2) = \mathbb{F}_2$.

3. Since $\mathbb{RP}^n$ is an $n$-dimensional CW-complex we know from the discussion on page [1402](3) that $H_k(\mathbb{RP}^n; \mathbb{F}_2) = 0$ for $k > n$. 

In the following discussion we write $F = F_2$ for space reasons. Applying Proposition \textbf{59.2} to the 2-fold covering $p: S^n \to \mathbb{R}P^n$ we obtain the following long exact sequence:

$$
\begin{align*}
H_{n+1}(\mathbb{R}P^n; F) &\xrightarrow{\partial} H_n(\mathbb{R}P^n; F) \xrightarrow{p^*} H_n(S^n; F) \xrightarrow{\partial} H_n(\mathbb{R}P^n; F) \xrightarrow{\partial} H_{n-1}(\mathbb{R}P^n; F) \xrightarrow{p^*} H_{n-1}(S^n; F) \\
&= 0
\end{align*}
$$

which continues all the way to

$$
\ldots \to H_1(\mathbb{R}P^n; F) \xrightarrow{p^*} H_1(S^n; F) \xrightarrow{\partial} H_0(\mathbb{R}P^n; F) \xrightarrow{p^*} H_0(S^n; F) \xrightarrow{\partial} H_0(\mathbb{R}P^n; F) \to 0.
$$

Now we can make the following observations:

1. If we work our way upward through the long exact sequence we see that the connecting homomorphisms give us isomorphisms

$$
H_{n-1}(\mathbb{R}P^2; F) \xrightarrow{\partial} H_{n-2}(\mathbb{R}P^2; F) \xrightarrow{\partial} \ldots \xrightarrow{\partial} H_1(\mathbb{R}P^2; F) \xrightarrow{\partial} H_0(\mathbb{R}P^2; F) \cong F.
$$

2. Now that we know that $H_{n-1}(\mathbb{R}P^n; F) \cong F$ we obtain from the upper end of the long exact sequence that

$$
H_n(\mathbb{R}P^n; F) \xrightarrow{p^*} H_n(S^n; F) \quad \text{and} \quad H_n(\mathbb{R}P^n; F) \xrightarrow{\partial} H_{n-1}(\mathbb{R}P^n; F)
$$

are also isomorphisms.

Summarizing we have shown that

$$
H_k(\mathbb{R}P^n; F) \cong \begin{cases} F, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}
$$

This agrees of course with the result that we had obtained on page 1403.

**Proof of Proposition \textbf{59.2}** Let $p: \tilde{X} \to X$ be a 2-fold covering. First we want to show that the promised long exact sequence in homology exists. By Proposition \textbf{43.11} it suffices to show that the following sequence of chain maps

$$
0 \to C_*(X; F) \xrightarrow{p^*} C_*(\tilde{X}; F) \xrightarrow{\partial} C_*(X; F) \to 0
$$

is in fact exact. As in Lemma \textbf{16.4} we consider the continuous map

$$
f: \tilde{X} \to \tilde{X}
$$

$$
x \mapsto \text{the unique other element of } p^{-1}(p(x)).
$$

Using Proposition \textbf{29.2} we pick for each singular cell $\sigma$ of $X$ a lift $\tilde{\sigma}$ to $\tilde{X}$. We make the following observations which follow easily from the definitions and Proposition \textbf{29.2}

(a) given any singular $n$-simplex $\sigma$ we have $p_* (\tilde{\sigma}) = \sigma$,

(b) given any singular $n$-simplex $\sigma$ we have $p^*(\sigma) = \tilde{\sigma} + f_*(\tilde{\sigma})$,

(c) given any singular simplex $\mu$ of $\tilde{X}$ we have $p_*(f_*(\mu)) = p_*(\mu)$,

(d) any singular singular $n$-simplex $\mu$ of $\tilde{X}$ is of the form $\mu = \tilde{\sigma}$ or $\mu = f_*(\tilde{\sigma})$ for some singular $n$-simplex $\sigma$ of $X$.

\textbf{903} Why does this follow, why are there no other possibilities?
Now we turn to the proof of the exactness of the above sequence.

(1) We first show that the map \( p_* : C_n(\tilde{X}; \mathbb{F}) \to C_n(X; \mathbb{F}) = C_n(X) \otimes \mathbb{F} \) is surjective. So let \( c = \sigma_1 \otimes b_1 + \cdots + \sigma_k \otimes b_k \in C_n(X) \otimes \mathbb{F} \). It follows from (a) that

\[
p_*(\tilde{\sigma}_1 \otimes b_1 + \cdots + \tilde{\sigma}_k \otimes b_k) = \sigma_1 \otimes b_1 + \cdots + \sigma_k \otimes b_k = c.
\]

(2) By Proposition \[59.1\] we know that the transfer map \( p^* \) is a monomorphism.

(3) Next we show that \( \text{im}(p^*) \subset \ker(p_*) \). For any singular \( n \)-simplex \( \sigma \) of \( \tilde{X} \) we have by (c) above that \((p_* \circ p^*)(\sigma) = p_*(\tilde{\sigma} + f_*(\tilde{\sigma})) = 2\sigma \), but it follows from Lemma \[57.1\] (4) that any multiple of two is zero in \( C_*(X; \mathbb{F}) = C_*(X) \otimes \mathbb{F} \).

(4) Finally we have to show that \( \ker(p_*) \subset \text{im}(p^*) \). So let \( c \in \ker(p_*) \). By (d) we can write

\[
c = (\tilde{\sigma}_1 \otimes a_1 + f_*(\tilde{\sigma}_1) \otimes b_1) + \cdots + (\tilde{\sigma}_k \otimes a_k + f_*(\tilde{\sigma}_k) \otimes b_k)
\]

where \( \sigma_1, \ldots, \sigma_k \) are pairwise different and where \( a_1, \ldots, a_k, b_1, \ldots, b_k \in \mathbb{F} \). By (c) we have

\[
p(c) = \sigma_1 \otimes (a_1 + b_1) + \cdots + \sigma_k (a_k + b_k).
\]

But this implies that \( a_i = -b_i \) for \( i = 1, \ldots, k \). But since we work over \( \mathbb{F} \) we actually have \( a_i = b_i \) for \( i = 1, \ldots, k \). It follows from (b) that

\[
c = p^*(\sigma_1 \otimes a_1 + \cdots + \sigma_k \otimes a_k),
\]

as desired.

The fact the long exact sequence is indeed natural follows easily from the definitions and the naturality of the connecting homomorphism, see Lemma \[43.10\] (2). \[\blacksquare\]

59.3. The Borsuk-Ulam Theorem. Our goal in this section is to prove the following generalization of Theorem \[16.22\] from the 2-dimensional case to the higher-dimensional situation.

**Theorem 59.3. (Borsuk-Ulam)** Let \( n \in \mathbb{N}_0 \). For every map \( f : S^n \to \mathbb{R}^n \) there exists a pair of antipodal points \( x \) and \(-x\) on \( S^n \) with \( f(x) = f(-x) \).

**Example.** If our universe happens to be diffeomorphic to \( S^3 \), then there are two antipodal points where the temperature, distance to the Kneitinger and strength of the magnetic field agree.

**Remark.**

(1) The statement was conjectured by Stanislaw Ulam\footnote{That is of course basically the same argument as in the proof of Proposition \[59.1\].} see \cite{Bor33} p. 178. The theorem was first proved by Karol Borsuk\footnote{Stanislaw Ulam (1909-1984) was a Polish mathematician and nuclear scientist. He was one of the fathers of the hydrogen bomb.} in 1933.\footnote{Karol Borsuk (1905-1982) was a Polish mathematician. He lost his job at the university of Warsaw after the German invasion in 1939. To survive financially he developed a board game and produced and sold it during the war. Almost all copies of the game were lost during the Warsaw uprising in 1944, but in the 1990s one surviving copy was found and the game was republished. We refer to \[https://en.wikipedia.org/wiki/Animal_Husbandry_(game)\] for more details.}
(2) In Sections 65.6 and 90.3 we will provide two other proofs of the Borsuk-Ulam Theorem 59.3.

(3) The Borsuk-Ulam Theorem has an almost endless string of consequences, many of which lie in combinatorics and graph theory, we refer to [Mato08, Stein85, Stein93] for an extensive discussion of the Borsuk-Ulam theorem and its corollaries. We will give three applications in Sections 65.6 and 90.3.

The key ingredient in the proof of Theorem 59.3 is the following proposition.

**Proposition 59.4.** Let \( f : S^n \to S^n \) be a map. If \( f(-x) = -f(x) \) for all \( x \in S^n \), then \( \deg(f) \) is odd.

**Proof of Proposition 59.4.** Let \( f : S^n \to S^n \) be a map such that \( f(-x) = -f(x) \) for all \( x \in S^n \). By Lemma 57.22 it suffices to show that \( f_* : H_n(S^n; \mathbb{Z}_2) \to H_n(S^n; \mathbb{Z}_2) \) is an isomorphism.

We start out with the observation that the map \( f : S^n \to S^n \) evidently descends to a well-defined map

\[
\overline{f} : \mathbb{R}P^n \to \mathbb{R}P^n, \quad [x] \mapsto [f(x)].
\]

**Claim.** The diagram

\[
\begin{array}{ccc}
H_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{p^*} & H_k(S^n; \mathbb{Z}_2) \\
\downarrow f_* & & \downarrow f_* \\
H_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{p^*} & H_k(S^n; \mathbb{Z}_2)
\end{array}
\]

commutes.

By Proposition 43.11 it suffices to show that the following diagram commutes for any \( k \in \mathbb{N}_0 \):

\[
\begin{array}{cccc}
0 & \xrightarrow{\partial} & C_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{p^*} C_k(S^n; \mathbb{Z}_2) & \xrightarrow{p^*} C_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{\partial} 0 \\
\downarrow f_* & & \downarrow f_* & & \downarrow f_* \\
0 & \xrightarrow{\partial} & C_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{p^*} C_k(S^n; \mathbb{Z}_2) & \xrightarrow{p^*} C_k(\mathbb{R}P^n; \mathbb{Z}_2) & \xrightarrow{\partial} 0.
\end{array}
\]

Here the right-hand square commutes since by definition we have \( p \circ f = \overline{f} \circ p \). Now we argue that the left-hand square commutes. So let \( \sigma : \Delta^k \to \mathbb{R}P^n \) be a singular \( k \)-simplex. We pick a point \( P \in \Delta^k \). Furthermore we pick \( Q \in S^n \) with \([Q] = \sigma(1,0,\ldots,0) \in \mathbb{R}P^n \). We denote by \( \tilde{\sigma}_1 \) and \( \tilde{\sigma}_2 \) the two lifts of \( \sigma \) to \( S^n \). Now we consider the singular simplex \( \overline{f} \circ \sigma \). It remains to show that \( p^*(\overline{f} \circ \sigma) = f \circ \tilde{\sigma}_1 + f \circ \tilde{\sigma}_2 \). But this is indeed the case for the following reason:

1. By construction we have \( p \circ f = \overline{f} \circ p \) which implies that \( f \circ \tilde{\sigma}_1 \) and \( f \circ \tilde{\sigma}_2 \) are both lifts of \( \overline{f} \circ \sigma \).
2. It follows from \( f(Q) = -f(Q) \) that \( f \circ \tilde{\sigma}_1 \) and \( f \circ \tilde{\sigma}_2 \) are two different lifts. \( \square \)
Now we consider the following diagram:

\[
\begin{array}{ccccccc}
H_n(S^n; \mathbb{Z}_2) & \xleftarrow{\imath^*} & H_n(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & H_{n-1}(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & \cdots & \xrightarrow{\partial} & H_1(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & H_0(\mathbb{RP}^n; \mathbb{Z}_2) \\
\downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* \\
H_n(S^n; \mathbb{Z}_2) & \xleftarrow{\imath^*} & H_n(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & H_{n-1}(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & \cdots & \xrightarrow{\partial} & H_1(\mathbb{RP}^n; \mathbb{Z}_2) & \xrightarrow{\partial} & H_0(\mathbb{RP}^n; \mathbb{Z}_2).
\end{array}
\]

We make the following observations:

1. the diagram commutes by the previous claim,
2. all the horizontal maps are isomorphisms by the discussion on page 1448,
3. by the discussion on page 1088 the right vertical map is an isomorphism.

It follows that the left vertical map is an isomorphism. But that is exactly what we had wanted to prove.

Now we turn to the proof of the Borsuk-Ulam Theorem 59.3.

**Proof of Theorem 59.3** Let \( g : S^n \to \mathbb{R}^n \) be a map. Suppose there exists no pair of antipodal points \( x \) and \(-x\) in \( S^n \) with \( g(x) = g(-x) \). Put differently, suppose that for any \( x \in S^n \) we have \( g(x) \neq g(-x) \). We consider the composition of the following two maps

\[
\Phi : S^{n-1} \times [0, 1] \to \mathbb{R}^n, \quad \Phi(x, t) = x + (1-t^2)^{1/2} \cdot g(x) - t g(-x)
\]

Now we see that

by definition we have \( \Phi(-x, 0) = -\Phi(x, 0) \), thus it follows from Proposition 59.4 that \( \Lambda(\Phi_0) \) is even

\[
\text{odd number} = \deg(\Phi_0) = \deg(\Phi_1) = \deg(\text{constant map}) = 0.
\]

by Lemma 45.11 (3) since \( \Phi_0 \) and \( \Phi_1 \) are homotopic by definition of \( \Phi_1 \) Lemma 45.11 (2)

We have thus obtained a contradiction.

**59.4. Applications of the Borsuk-Ulam Theorem I.** In this and in the subsequent section we will state and prove four particularly interesting consequences of the Borsuk-Ulam Theorem 59.3. The first of our applications was first proved by the Soviet mathematicians Lazar Lusternik and Lev Schnirelmann in 1930.

**Theorem 59.5. (Lusternik-Schnirelmann Theorem)** Let \( A_1, \ldots, A_{n+1} \) be closed subsets of \( S^n \) with \( A_1 \cup \cdots \cup A_{n+1} = S^n \). Then there exists an \( i \in \{1, \ldots, n+1\} \) such that \( A_i \) contains antipodal points, i.e. there exists a point \( x \) on \( S^n \) such that both \( x \) and \(-x\) lie in \( A_i \).

**Examples.**

1. For \( n = 1 \) we obtain that if we have a decomposition \( S^1 = A \cup B \) with \( A \) and \( B \) two closed subsets (which do not need to be connected), then the subset \( A \) or the subset \( B \) contains antipodal points. How can one prove this statement “naively”?
(2) We consider the surface of our earth, we take $A_1$ to be the closure of the land mass, we take $A_2$ to be the closure of the Pacific ocean and we take $A_3$ to be the closure of all seas except for the Pacific. Then at least one of $A_1, A_2$ or $A_3$ contains a pair of antipodal points. Which of $A_1, A_2$ and $A_3$ is it?

(3) The proposition is optimal in the following sense: it is easy to find three closed subsets $A_1, A_2, A_3$ that cover all of $S^1$, but such that none of the $A_i$ contain antipodal points.

**Proof.** Let $A_1, \ldots, A_{n+1}$ be closed subsets of $S^n$ with $A_1 \cup \cdots \cup A_{n+1} = S^n$. Without loss of generality we can assume that all $A_i$ are non-empty. (Indeed, at least one of the $A_i$ is evidently non-empty; if one of them is empty we just replace it with the non-empty $A_i$.)

Given a non-empty subset $A$ of $S^n$ and $x \in S^n$ we write

$$d(x, A) := \inf \{d(x, a) \mid a \in A\},$$

where $d(x, a)$ denotes the distance function on the Riemannian manifold $S^n$ that we introduced on page 880.913 We make the following two observations:

(1) If $A$ is closed, then $d(x, A) = 0$ if and only if $x \in A$.

(2) It follows easily from Proposition 32.9 that $d(x, A)$ is continuous in $x$.

Now we consider the function

$$f : S^n \rightarrow \mathbb{R}^n \quad x \mapsto (d(x, A_1), \ldots, d(x, A_n)).$$

By the Borsuk-Ulam Theorem 59.3 there exists an $x \in S^n$ with $f(x) = f(-x)$. We first suppose that there exists an $i \in \{1, \ldots, n\}$ with $d(x, A_i) = 0$. From $f(x) = f(-x)$ it follows that $d(-x, A_i) = 0$ as well. Since $A_i$ is closed it follows that both $x$ and $-x$ lie in $A_i$.

Now suppose that $d(-x, A_i) = d(x, A_i) \neq 0$ for $i = 1, \ldots, n$. Since $A_1 \cup \cdots \cup A_{n+1} = S^n$ it follows that both $x$ and $-x$ lie in $A_{n+1}$. $\blacksquare$

Before we can state the next consequence of the Borsuk-Ulam Theorem 59.3, we need to introduce one more definition.

**Definition.** Let $A \subset \mathbb{R}^n$ be a measurable subset of finite volume. We say a hyperplane $H \subset \mathbb{R}^n$ bisects $A$ if for the two half-spaces $V, V'$ determined by $H$ we have the equality $(\nu)(A \cap V) = (\nu)(A \cap V')}$. 

We continue with the following pretty theorem.

**Theorem 59.6. (Ham-Sandwich Theorem)** Let $A_1, \ldots, A_n$ be measurable finite-volume subsets of $\mathbb{R}^n$. Then there exists an $(n-1)$-dimensional hyperplane in $\mathbb{R}^n$ that bisects $A_1, \ldots, A_n$.

**Remark.**

(1) The Ham-Sandwich Theorem gets its name from the following “application”. Suppose we are given a sandwich with an upper piece of bread $A_1$, some ham $A_2$ and a lower piece of bread $A_3$. Then using a knife one can cut the sandwich, along a hyperplane,

\footnote{Put differently, $d(x, a)$ is the infimum of all lengths of piecewise smooth paths on $S^n$ from $x$ to $a$.}

\footnote{Here “measurable” means Lebesgue-measurable in the sense of say [Frie16b], [Caro00] or [RudiW87] Chapter 2].
into two pieces such that each piece of bread and the ham are bisected. This situation is, more or less convincingly, illustrated in Figure 879.

Figure 879. Illustration of the “Ham-Sandwich Theorem”.

(2) The 2-dimensional version of the Ham-Sandwich Theorem is sometimes referred to as the “Pancake Theorem”; since one can bisect the two pancakes along a line into two equal sized halves.

Figure 880. Illustration of the “Pancake Theorem”.

(3) The Ham-Sandwich Theorem is sometimes also called, more prosaically, the Stone-Tukey theorem after the mathematicians Arthur Stone and John Tukey [StT42].

In the proof of the Ham-Sandwich Theorem we will need the following result from measure theory.

**Proposition 59.7.** Suppose that for each \( t \in \mathbb{R} \) we have a measurable subset \( X_t \) of \( \mathbb{R}^n \) such that for each \( s \leq t \in \mathbb{R} \) we have \( X_s \subset X_t \). Then \( \bigcup_{t \in \mathbb{R}} X_t \) is also measurable and

\[
\lim_{t \to \infty} (\nu)(X_t) = (\nu)\left( \bigcup_{t \in \mathbb{R}} X_t \right).
\]

**Proof of Proposition 59.7.** The proposition can be deduced easily from basic facts of the Lebesgue measure, see [Caro00, Chapter 16] or [Frie16b, Proposition 6.2 (6)].

Now we can provide the proof of the Ham-Sandwich Theorem.

**Proof of the Ham-Sandwich Theorem.** Let \( A_1, \ldots, A_n \) be measurable finite-volume subsets of \( \mathbb{R}^n \). Without loss of generality we can assume that the volume of \( A_n \) is positive.
Given a point \( P \in S^{n-1} \) and \( t \in \mathbb{R} \) we write
\[
H_{P,t} := \{ t \cdot P + w \mid P \cdot w = 0 \}
\]
and
\[
V^+_{P,t} := \{ t \cdot P + w \mid P \cdot w \geq 0 \}
\]
\[
V^-_{P,t} := \{ t \cdot P + w \mid P \cdot w \leq 0 \}.
\]
(We refer to Figure 881 on the left for an illustration.) Put differently, \( H_{P,t} \) is the hyperplane through \( t \cdot P \) orthogonal to \( P \), and \( V^\pm_{P,t} \) are the two half-spaces determined by \( H_{P,t} \). We make the following two observations:

(i) by definition we have \( V^\pm_{P,-t} = V^\mp_{P,t} \),

(ii) for a subset \( A \subset \mathbb{R}^n \) of finite volume we have the equality
\[
(\nu)(A \cap V^+_{P,t}) = (\nu)(A \cap (\mathbb{R}^n \setminus V^-_{P,t})) = (\nu)(A) - (\nu)(A \cap V^-_{P,t}).
\]
since \( H_{P,t} = V^+_{P,t} \cap V^-_{P,t} \) is a set of measure zero.

We continue with the following claim.

Claim. There exists a function \( t : S^{n-1} \to \mathbb{R} \) with the following two properties:

1. for any \( P \in S^{n-1} \) we have \( (\nu)(A \cap V^+_{P,t}) = \frac{1}{2}(\nu)(A) \), i.e. the hyperplane \( H_{P,t}(P) \) bisects \( A \),
2. for any \( P \in S^{n-1} \) we have \( t(-P) = -t(P) \),
3. the function \( t \) is continuous.

To prove the claim we first fix \( P \in S^{n-1} \). We consider the function
\[
\mathbb{R} \to \mathbb{R}_{\geq 0} \quad t \mapsto (\nu)(A \cap V^+_{P,t}).
\]
This function is continuous\(^{915}\) and we have
\[
\lim_{t \to -\infty} (\nu)(A \cap V^+_{P,t}) = (\nu)(\bigcup_{t \in \mathbb{R}} (A \cap V^+_{P,t})) = (\nu)(A).
\]
Proposition \(^{59.7}\)

and
\[
\lim_{t \to \infty} (\nu)(A \cap V^+_{P,t}) = (\nu)(A) - \lim_{t \to -\infty} (\nu)(A \cap V^-_{P,t}) = 0.
\]
by (ii) \(^{915}\) by Proposition \(^{59.7}\)

We deduce from the Intermediate Value Theorem that
\[
T := \{ t \in \mathbb{R} \mid (\nu)(A \cap V^+_{P,t}) = \frac{1}{2}(\nu)(A) \}\]

\(^{915}\) This requires at least a little bit of thought since we do not assume that \( A \) is bounded, we only assume it has finite volume. We leave it as a not entirely trivial exercise to prove this statement using basics facts of Lebesgue measures.
is a non-empty set. It is straightforward to see that it is a connected subset of \( \mathbb{R} \), i.e. it is an interval. Since \((\nu)(A_n) > 0\) we know that \( T \) is a finite interval. We define

\[
t(P) := \frac{1}{2}(\inf(T) + \sup(T)).
\]

Note that it follows immediately from the definitions that \( t(-P) = -t(P) \). Furthermore with some elementary measure theory one can show that the function \( S^{n-1} \to \mathbb{R} \) given by \( P \mapsto t(P) \) is continuous. We leave the verification of the details to the reader.

![Diagram](https://via.placeholder.com/150)

**Figure 881.** Illustration for the proof of the Ham-Sandwich Theorem

Now we consider the map

\[
f : S^{n-1} \to \mathbb{R}^{n-1}
\]

\[
P \mapsto ( (\nu)(A_1 \cap V_{P,t}^{+}(P)), \ldots, (\nu)(A_{n-1} \cap V_{P,t}^{+}(P)) ).
\]

From the continuity of \( t : S^{n-1} \to \mathbb{R} \) it follows that \( f \) itself is continuous. By the Borsuk-Ulam Theorem \[59.3\], there exists a point \( P \in S^{n-1} \) with \( f(P) = f(-P) \). We claim that the hyperplane \( H_{P,t}(P) \) has the desired property.

By definition of \( t(P) \) the hyperplane \( H_{P,t}(P) \) bisects \( A_n \). Furthermore, for \( i = 1, \ldots, n-1 \) we have

\[
(\nu)(A_i \cap V_{P,t}^{+}(P)) = (\nu)(A_i \cap V_{P,t}^{+}(-P)) \quad \text{since } f(P) = f(-P)
\]

\[
(\nu)(A_i \cap V_{P,t}^{-}(P)) = (\nu)(A_i \cap V_{P,t}^{-}(-P)) \quad \text{since } t(-P) = -t(P)
\]

\[
V_{P,t}^{+} = V_{P,-t}^{-}
\]

This shows that the hyperplane \( H_{P,t}(P) \) also bisects \( A_1, \ldots, A_{n-1} \).

**Remark.** The proof for the existence of the hyperplane that bisects the given sets \( A_1, \ldots, A_n \) is non-constructive, in the sense that even with some flexibility in mathematical rigor one cannot turn it into an algorithm that given \( A_1, \ldots, A_n \) finds the hyperplane that bisects all of the subsets.

We conclude this section with an application of the Borsuk-Ulam Theorem \[59.3\] to algebra. First we have the following definition.

**Definition.** Let \( R \) be a commutative ring. The level \( s(R) \) of \( R \) is defined as the smallest number \( n \in \mathbb{N}_0 \) such that \(-1\) can be written as the sum of \( n \) squares in \( R \). If \(-1\) is not the sum of squares in \( R \), then we define \( s(R) = \infty \).

\[^{916}\text{One might think that } T \text{ consists of just a point, but for example if } A_n \text{ is disconnected, then it can happen that } T \text{ is in fact an interval that is not just a point.}\]
In 1966 Albrecht Pfister [Pf65] showed that the level of a field is either $\infty$ or a power of 2. Furthermore he showed that any power of 2 appears as the level of a field. In 1977 Manfred Knebusch [Kneb77] asked whether every $n \in \mathbb{N}_0$ is the level of some commutative ring. The following theorem, proved by Dai–Lang–Peng [DLP80] gives an affirmative answer.

**Theorem 59.8.** Given any $n \in \mathbb{N}_0$ there exists a commutative ring $R$ with $s(R) = n$.

**Proof.** We consider the ring $R = \mathbb{R}[x_1^2, \ldots, x_n^2]/(1 + x_1^2 + \cdots + x_n^2)$. Evidently $s(R) \leq n$. We need to show that $s(R) \geq n$. So suppose that $s(R) < n$. This implies that there exist $f_0(x), f_1(x), \ldots, f_{n-1}(x) \in \mathbb{R}[x] = \mathbb{R}[x_1, \ldots, x_n]$ such that

$$-1 = f_1(x)^2 + \cdots + f_{n-1}(x)^2 + f_0(x)(1 + x_1^2 + \cdots + x_n^2) \in \mathbb{R}[x_1, \ldots, x_n].$$

Let $j \in \{0, \ldots, n-1\}$. Since $f_j(x)$ is a real polynomial we can write $f_j(ix) = p_j(x) + iq_j(x)$ where $p_j(x)$ is an even real polynomial and $q_j(x)$ is an odd real polynomial. Thus if we plug $ix$ into the above equality and if we compare the real parts we obtain the following equality:

$$-1 = \sum_{j=1}^{n-1} (p_j(x)^2 - q_j(x)^2) + p_0(x)(1 - x_1^2 - \cdots - x_n^2).$$

Next we consider the map $Q := (q_1, \ldots, q_{n-1}) : \mathbb{R}^n \to \mathbb{R}^{n-1}$. Since the polynomials $q_1, \ldots, q_{n-1}$ are odd we see that for every $a \in S^{n-1}$ we have $Q(-a) = -Q(a)$. Furthermore, by the Borsuk-Ulam Theorem 59.3 there exists an $a = (a_1, \ldots, a_n) \in S^{n-1}$ with $Q(-a) = Q(a)$. Note that it follows from the above symmetry of $Q$ that we have $Q(a) = 0$. Now we see that

$$-1 = \sum_{j=1}^{n-1} (p_j(a)^2 - q_j(a)^2) + p_0(a)(1 - a_1^2 - \cdots - a_n^2) = \sum_{j=1}^{n-1} p_j(a)^2.$$

Since the right-hand side is non-negative we have thus obtained a contradiction. \hfill $\blacksquare$

### 59.5. Applications of the Borsuk-Ulam Theorem II: The Necklace Theorem 🎁

We conclude this chapter with another, fun consequence of the Borsuk-Ulam Theorem. As we will see, this application is particularly far-removed from what one would usually consider to be the realm of topology.

The setting is the following: Two thieves steal an open necklace with precious stones of $k$ different types. Conveniently enough, of each type of stone there is an even number. The thieves want to cut the string of the open necklace such that they can distribute the resulting pieces in such a way that both thieves obtain the same number of stones of each type. The question is, what is the minimal number of cuts necessary? In Figure 882 we show two necklaces, one with two types of stones and one with three types of stones. Furthermore we show possible cuts to evenly distribute the stones.

Another open necklace is shown in Figure 883. In this particular example the $k$ different types of stones are grouped together. It is pretty clear that one will need at least $k$ cuts to distribute the stones. It turns out that this is the worst case, more precisely, it turns out that any string of $k$ different types of stones can be distributed evenly using at most $k$ cuts. The following theorem is a formalization of that statement.
nechlace with two types of stones

\[ \text{cuts} \]

\[ \text{thief 1} \quad \text{thief 2} \]

necklace with three types of stones

\[ \text{cuts} \]

\[ \text{thief 1} \quad \text{thief 2} \]

Figure 882

necklace with four types of stones

\[ \text{cuts} \]

\[ \text{thief 1} \quad \text{thief 2} \]

this is the unique solution with a minimal number of cuts

Figure 883

**Theorem 59.9. (Necklace Theorem)** Let \( S_1, \ldots, S_k \) be disjoint finite subsets of the interval \([0, 1]\) such that each subset \( S_i \) has an even number of elements. There exists a \( d \in \{0, \ldots, k\} \) and \( 0 = z_0 \leq z_1 \leq \cdots \leq z_d \leq z_{d+1} = 1 \) such that for each “color” \( c \in \{1, \ldots, k\} \) we have

\[
\sum_{i \text{ even}} \#(\lfloor z_i, z_{i+1} \rfloor \cap S_c) = \sum_{i \text{ odd}} \#(\lfloor z_i, z_{i+1} \rfloor \cap S_c).
\]

**Remark.**

1. The Necklace Theorem 59.9 was first formulated and proved by Charles Goldberg and Douglas West [GW85] in 1985 using topological methods. The proof we give was found shortly afterwards by Noga Alon and Douglas West [AW86].
2. A topology-free proof of the Necklace Theorem 59.9 was found in 2008 by Frédéric Meunier [Meu08].
3. The Necklace Theorem 59.9 has been generalized by Noga Alon [Nog87], again using topological methods, to the case of more than two thieves. It seems like there is no known proof for that more general statement, that does not rely on topology.
4. The proofs of the Necklace Theorem 59.9 and of the Continuous Necklace Theorem 59.10 are both nicely animated in the following video:

https://www.youtube.com/watch?v=yuVqxCSsE7c&t=868s

The Necklace Theorem 59.9 is a priori a discrete problem, far removed from the world of topological spaces. In fact the proof consists of two steps, first we will use the Borsuk-Ulam Theorem 59.3 to prove a “continuous analogue” of the Necklace Theorem 59.9. Afterwards we will show how we can reduce the “discrete Necklace Theorem” from the “continuous Necklace Theorem”. Since we will not make use of any of the results of this section we will feel free to use slightly more informal language than usual.
Without further ado, here is the promised continuous analogue of the Necklace Theorem

**Theorem 59.10. (Continuous Necklace Theorem)** Let \( f : [0, 1] \to \{1, \ldots, k\} \) be a function \(^{917}\) such that each preimage \( f^{-1}(\{c\}) \) is a measurable set (e.g. a union of finitely many intervals). There exists a \( d \in \{0, \ldots, k\} \) and \( 0 = y_0 \leq y_1 \leq \cdots < y_d \leq y_{d+1} = 1 \) such that for each “color” \( c \in \{1, \ldots, k\} \) we have

\[
\sum_{i \text{ even}} \operatorname{vol}(\left[ y_i, y_{i+1}\right) \cap f^{-1}(\{c\})) = \sum_{i \text{ odd}} \operatorname{vol}(\left[ y_i, y_{i+1}\right) \cap f^{-1}(\{c\})).
\]

The same statement also holds for functions \( f \) which are defined on \([0, 1)\).

**Proof.** We adopt the following notation: given \((w_0, \ldots, w_k) \in S^k\) we set \( x_0 = 0 \) and for \( i = 1, \ldots, k \) we write \( x_i := w_0^2 + \cdots + w_i^2 \). We make the following observation which is the key to the subsequent proof:

Let \((w_0, \ldots, w_k) \in S^k\). We note that \( x_0 = 0 \leq x_1 \leq \cdots \leq x_k \leq x_{k+1} = 1 \). Thus any point in \( S^k \) corresponds to a splitting of the interval \([0, 1)\) into \( k + 1 \) (possibly empty) intervals. In fact, if we remember the signs of the \( w_i \), then we obtain a way to assign each interval to one of the two thieves, say we award \([x_i, x_{i+1})\) to thief 1 if \( w_i < 0 \) and to thief 2 if \( w_i > 0 \). Thus the set of splittings of the interval corresponds to the topological space \( S^k \).

For \( c = 1, \ldots, k \) we consider the following map:

\[
ge_c : S^k \to \mathbb{R}
\]

\[
(w_0, \ldots, w_k) \mapsto \sum_{i \text{ with } w_i > 0} \operatorname{vol}(\left[ x_i, x_{i+1}\right) \cap f^{-1}(\{c\}))
\]

\[
\uparrow
\]

here we use the above definition of \( x_0, \ldots, x_{k+1} \) as determined by \( w_0, \ldots, w_k \)

We leave it to the meticulous reader to show, using standard properties of the Lebesgue-measure, that the map \( g_c \) is actually continuous.\(^{918}\)

Next we combine all these maps and we obtain a map \( g = (g_1, \ldots, g_k) : S^k \to \mathbb{R}^k \). By the Borsuk-Ulam Theorem \(^{59.3}\) there exists a point \((w_0, \ldots, w_k) \in S^k\) such that

---

\(^{917}\)Evidently for once the convention that all maps are continuous does not apply.

\(^{918}\)The fact that we take the sum over all \( i \) with \( w_i > 0 \) might make the reader slightly nervous. But note that for \( w_i = 0 \) we have \( x_{i+1} = x_i \), thus \( \operatorname{vol}(\left[ x_i, x_{i+1}\right) \cap f^{-1}(\{c\})) = 0 \).
\( g(-w_0, \ldots, -w_k) = g(w_0, \ldots, w_k) \). This just means that for each \( c \in \{1, \ldots, k\} \) we have

\[
\sum_{i \text{ with } w_i < 0} \text{vol} \left( (x_i, x_{i+1}) \cap f^{-1}(\{c\}) \right) = \sum_{i \text{ with } w_i > 0} \text{vol} \left( (x_i, x_{i+1}) \cap f^{-1}(\{c\}) \right).
\]

Finally, we consider the numbers \( x_0 \leq x_1 \leq \cdots \leq x_{k+1} = 1 \). Now we just need to combine adjacent intervals for which the \( w_i \)'s have the same sign. More precisely, iteratively we remove each \( x_i \) for which \( w_i \geq 0 \) and \( w_{i+1} \geq 0 \) and we remove each \( x_i \) for which \( w_i \leq 0 \) and \( w_{i+1} \leq 0 \). It is now fairly elementary to verify that the remaining numbers, let us call them \( 0 = y_0 < y_1 < \cdots < y_d < y_{d+1} = 1 \), have the desired properties. \( \blacksquare \)

Now we can provide the proof of the original Necklace Theorem 59.9.

**Proof of the Necklace Theorem 59.9** Let \( S_1, \ldots, S_k \) be disjoint finite subsets of the interval \([0, 1]\) such that each \( S_i \) has an even number of elements. Evidently we can assume that \( S_1 \cup \cdots \cup S_k \neq \emptyset \). We set \( s := \#(S_1 \cup \cdots \cup S_k) \). It is straightforward to see that without loss of equality we can assume that the points break \([0, 1]\) into intervals of the same lengths \( \frac{1}{s} \). More precisely, we can assume that \( \bigcup_{i=1}^{k} S_i = \{ \frac{i}{s} \mid i = 0, \ldots, s-1 \} \). Now let \( f: [0, 1) \rightarrow \{1, \ldots, k\} \) be the function which is uniquely determined by the property that for each \( c \in S_i \) we have \( f(x) = i \) for \( x \in [c, c + \frac{1}{s}) \). By the Continuous Necklace Theorem 59.10 there exists a \( d \in \{0, \ldots, k\} \) and \( 0 = y_0 \leq y_1 \leq \cdots \leq y_d \leq y_{d+1} = 1 \) such that for each \( c \in \{1, \ldots, k\} \) we have

\[
\sum_{i \text{ even}} \text{vol} \left( [y_i, y_{i+1}) \cap f^{-1}(\{c\}) \right) = \sum_{i \text{ odd}} \text{vol} \left( [y_i, y_{i+1}) \cap f^{-1}(\{c\}) \right).
\]

If each of the \( y_i \) lies in the “lattice” \( L := \{ \frac{i}{s} \mid i = 0, \ldots, s \} \), then we can set \( z_i := y_i - \frac{1}{2s} \), \( i = 1, \ldots, d \) and we are done. (This setting is shown in Figure 885.) Thus it remains to prove the following claim.

- **Claim.** We can find \( 0 = y_0 \leq y_1 \leq \cdots \leq y_d \leq y_{d+1} = 1 \) which satisfy (*) and such that each \( y_i \) lies in \( L = \{ \frac{i}{s} \mid i = 0, \ldots, s \} \).

We prove the claim by induction on the number of \( y_i \) that do not lie in the subset \( L = \{ \frac{i}{s} \mid i = 0, \ldots, s \} \). Throughout the proof of the claim we use the following slightly non-standard notation: given \( y \in [0, 1] \) we define \([y] \) and \( \overline{y} \) as the result of rounding \( y \).
down and up to the closest point in $L$. More precisely, we set $\lfloor y \rfloor := \max\{l \in L \mid l \leq y\}$ and we set $\lceil y \rceil := \min\{l \in L \mid y \leq l\}$. So suppose there does exist some $y_i$ that does not lie in $L$. In this case we perform the following three steps:

1. Among all $y_i$ which do not lie in $L$ we pick a $y_i$ which is closest to a point in $L$. Without loss of generality we can assume that $i$ is odd.
2. We define $d$ to be the distance of $y_i$ to some point in $L$. In other words, if the point on $L$ that is closest to $y_i$ is to the left, then we set $d := y_i - \lfloor y_i \rfloor$. Otherwise we set $d := \lceil y_i \rceil - y_i$.
3. It follows fairly easily from ($\ast$) and the hypothesis that $S_c$ has an even number of elements that there exists a $j \neq i$ such that $f(y_j) = c$ and such that $y_j \notin L$. We distinguish two cases:
   (a) If $j$ is even, then among those we pick the one with a lowest value for $y_j - \lfloor y_j \rfloor$.
   We replace $y_i$ by $y_i - d \in L$ and we replace $y_j$ by $y_j - d$.
   (b) If $j$ is odd, then among those we pick the one with a lowest value for $\lceil y_j \rceil - y_j$.
   We replace $y_i$ by $y_i - d \in L$ and we replace $y_j$ by $y_j + d$.

One can easily verify that these new numbers still have all the required properties, except that now $y_i$ also lies in $L$. By induction we are now done. \[\square\]

---

**Exercises for Chapter 59**

**Exercise 59.1.** Let $k \in \mathbb{N}$ and let $l \in \{1, \ldots, k - 1\}$. Furthermore let $f : S^k \to \mathbb{R}^l$ be a map with $f(x) = -f(x)$ for all $x \in S^k$. Show that there exists an $x \in S^k$ with $f(x) = 0$.

**Exercise 59.2.** We consider the string of jewels shown in Figure 887. Use four cuts to distribute the jewels evenly.

---

**Exercise 59.3.** We consider the setting of the Continuous Necklace Theorem 59.10. More precisely we are given a map $f : [0, 1] \to \{1, \ldots, k\}$ be a function such that each preimage $f^{-1}\{x\}$ is a measurable set. For each “color” $c \in \{1, \ldots, k\}$ let $y_c \in [0, 1]$ be such that $(\nu)(f^{-1}\{c\} \cap [0, y_c]) = (\nu)(f^{-1}\{c\} \cap [y_c, 1])$. Do these points $y_1, \ldots, y_k$, after ordering them, necessarily satisfy the conclusion of the Continuous Necklace Theorem 59.10?
60. Division algebras and generalized projective spaces

60.1. Division algebras. We start out with the following purely algebraic definition.

Definition. An algebra over a field $\mathbb{F}$ is an $\mathbb{F}$-vector space $A$ together with an $\mathbb{F}$-bilinear map

$$A \times A \to A \quad (v, w) \mapsto v \cdot w.$$ 

(1) We say that the algebra is **commutative** if for all $a, b \in A$ we have $a \cdot b = b \cdot a$.
(2) We say that the algebra is **associative** if for all $a, b, c \in A$ we have $a \cdot (b \cdot c) = (a \cdot b) \cdot c$.
(3) We say that the algebra **has an identity** if there exists an element $1 \in A$ with $1 \neq 0$ such that $1 \cdot a = a \cdot 1 = a$ for all $a \in A$.
(4) If $A$ is an algebra with identity $1$, then given $a \in A$ we say that $b \in A$ is an **inverse** of $a$ if $a \cdot b = b \cdot a = 1$.
(5) A **division algebra** is an algebra such that for all $a \neq 0$ and $b \in A$ there exists an $x \in A$ with $a \cdot x = b$ and a $y \in A$ with $y \cdot a = b$.

Examples.

(1) The complex numbers $\mathbb{C} = \mathbb{R} \oplus \mathbb{R} \cdot i$ with the usual multiplication are an algebra over $\mathbb{R}$ that is commutative and associative, it has an identity, and it is a division algebra.
(2) The set of $(n \times n)$-matrices $M(n \times n, \mathbb{F})$ over a field $\mathbb{F}$, where the multiplication is given by the usual matrix multiplication, is an associative algebra over $\mathbb{F}$ with an identity. If $n \geq 2$ this algebra is clearly neither commutative nor is it a division algebra.
(3) The real vector space $\mathbb{R}^3$ together with the cross product

$$\mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}^3 \quad \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix}, \begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} \mapsto \begin{pmatrix} v_2w_3 - w_2v_3 \\ -(v_1w_3 - w_1v_3) \\ v_1w_2 - w_1v_2 \end{pmatrix}$$

is an algebra over $\mathbb{R}$. We recall that the geometric interpretation of the cross product is given as follows: for $v, w \in \mathbb{R}^3$ the cross product $v \times w$ is the unique vector in $\mathbb{R}^3$ that satisfies the following three properties:

(a) the vector is orthogonal to $v$ and $w$,  
(b) the length equals the area of the parallelogram spanned by $v$ and $w$,  
(c) we have $\det((v \ w \ v \times w)) \geq 0$.\footnote{If $v$ and $w$ are non-zero this just means that $v, w$ and $v \times w$ form a positive basis for $\mathbb{R}^3$.}

We make the following observations:

(a) Clearly we have $v \times w = -w \times v$, hence the algebra is non-commutative.
(b) We have

$$(e_1 \times e_1) \times e_2 = 0 \times e_2 = 0 \neq -e_2 = e_1 \times e_3 = e_1 \times (e_1 \times e_2),$$

which shows that this algebra is non-associative.
(c) It follows easily from the definition or the geometric interpretation that for \( v \neq 0 \) there is no vector \( w \) with \( v \times w = v \), hence the algebra does not have an identity element.

(d) Finally it is straightforward to see that \((\mathbb{R}^3, \times)\) is not a division algebra. More precisely, one can easily show, using the geometric interpretation of the cross product, that given \( a, b \in \mathbb{R}^3 \) there exists a vector \( x \in \mathbb{R}^3 \) with \( a \times x = b \) if and only if \( b \) is orthogonal to \( a \).

We consider the next example in greater detail.

**Definition.** The *quaternions* \( \mathbb{H} \) are defined as the 4-dimensional real vector space \( \mathbb{R}^4 \) spanned by \( 1, i, j, k \) and the multiplication which is determined by

1. \( i^2 = j^2 = k^2 = -1 \),
2. \( 1 \cdot i = i \cdot 1 = i \), \( 1 \cdot j = j \cdot 1 = j \), \( 1 \cdot k = k \cdot 1 = k \), and
3. \( i \cdot j = k \), \( j \cdot k = i \), \( k \cdot i = j \) and \( j \cdot i = -k \), \( k \cdot j = -i \), \( i \cdot k = -j \).

For a quaternion

\[
  z := a \cdot 1 + b \cdot i + c \cdot j + d \cdot k \in \mathbb{H}
\]

we define the *conjugate*

\[
  \overline{z} := a \cdot 1 - b \cdot i - c \cdot j - d \cdot k
\]

and the *norm*

\[
  |z| := \sqrt{a^2 + b^2 + c^2 + d^2}
\]

the same way as we did for complex numbers.

The following lemma summarizes a few key properties of the quaternions. In particular we see that the conjugate and the norm of the quaternions behave in a quite similar fashion as the conjugate and norm of complex numbers.

**Lemma 60.1.**

1. The quaternions are a non-commutative algebra over \( \mathbb{R} \) with identity.
2. For any \( z \in \mathbb{H} \) we have \( \overline{z} + z \in \mathbb{R} \).
3. For all \( z, w \in \mathbb{H} \) we have

\[
  \overline{z} = z, \quad \overline{z + w} = \overline{z + w} \quad \text{and} \quad \overline{z \cdot w} = w \cdot \overline{z}.
\]
4. If we make the obvious identification \( \mathbb{H} = \mathbb{R}^4 \), then the norm \( | - | \) on \( \mathbb{H} \) agrees with the Euclidean norm \( \| - \| \) on \( \mathbb{R}^4 \).
5. For every \( z \in \mathbb{H} \) we have \( z \cdot \overline{z} = |z|^2 \in \mathbb{R} = \mathbb{R} \cdot 1 \).
6. For every \( z \neq 0 \) a multiplicative inverse is given by \( z^{-1} = \frac{\overline{z}}{|z|^2} \).
7. For all \( z, w \in \mathbb{H} \) we have \( |z \cdot w| = |z| \cdot |w| \).
8. The quaternions are associative.
9. The quaternions are a division algebra.

\[ \text{Put differently, we have } i \cdot j = k \text{ and } j \cdot i = -k, \text{ and both of the equalities hold for cyclic permutations of } \{i, j, k\}. \]
Proof. Statements (1) to (3) follow from elementary calculations. We provide the details for the remaining statements:

(4) This statement follows immediately from the definition of $|z|$.
(5) This statement follows from a straightforward calculation.
(6) This statement follows immediately from (5).
(7) Let $z_1 = a_1 \cdot 1 + b_1 \cdot i + c_1 \cdot j + d_1 \cdot k$ and $z_2 = a_2 \cdot 1 + b_2 \cdot i + c_2 \cdot j + d_2 \cdot k$ be two quaternions. We see that

$$|z_1 \cdot z_2|^2 = |(a_1 \cdot 1 + b_1 \cdot i + c_1 \cdot j + d_1 \cdot k) \cdot (a_2 \cdot 1 + b_2 \cdot i + c_2 \cdot j + d_2 \cdot k)|^2$$

$$= (a_1 a_2 - b_1 b_2 - c_1 c_2 - d_1 d_2)^2 + (a_1 b_2 + b_1 a_2 + c_1 d_2 - d_1 c_2)^2 +$$

$$+ (a_1 c_2 - b_1 d_2 + c_1 a_2 + d_1 b_2)^2 + (a_1 d_2 + b_1 c_2 - c_1 b_2 + d_1 a_2)^2$$

$$= (a_1^2 + b_1^2 + c_1^2 + d_1^2) \cdot (a_2^2 + b_2^2 + c_2^2 + d_2^2) = |z_1|^2 \cdot |z_2|^2.$$  

(8) Since the quaternions are an algebra we only have to check associativity for products of three of the generators $\{1, i, j, k\}$ and that can be done easily by hand.

(9) It remains to prove that $H$ is in fact a division algebra. Thus let $a \neq 0$ and $b$ be two elements in $H$. We set $y := b \cdot a^{-1}$. Then

$$y \cdot a = (b \cdot a^{-1}) \cdot a = b \cdot (a^{-1} \cdot a) = b \cdot 1 = b.$$  

\[\uparrow\]

since by (8) we know that $H$ is associative

The same way we show that there exists an $x \in H$ with $a \cdot x = b$.  

In Theorem 51.2 we saw that $SU(2)$ is diffeomorphic to $S^3$. We give a refined version of this statement.

**Proposition 60.2.**

1. The set $S^3 = \{z \in H = \mathbb{R}^4 \mid |z| = 1\}$ forms a group under multiplication of quaternions.
2. (a) The map $\mathbb{H} \times \mathbb{C} \to \mathbb{H}$ given by $(z, w) \mapsto z \cdot w$ defines a complex vector space structure on $\mathbb{H}$.
   (b) A basis for $\mathbb{H}$ viewed as a complex vector space is given by $\{1, j\}$.
   (c) Let $z + j \cdot w \in \mathbb{H}$ with $z, w \in \mathbb{C}$. Left-multiplication by $z + j \cdot w$ defines a complex linear map $\mathbb{H} \to \mathbb{H}$. With respect to the basis $\{1, j\}$ this linear map is represented by the matrix $\begin{pmatrix} z & \overline{w} \\ -\overline{w} & \overline{z} \end{pmatrix}$.
   (d) Left-multiplication by some $h \in \mathbb{H}$ defines a homomorphism of real vector spaces. If $h \neq 0$, then this homomorphism is represented, with respect to the standard basis of $\mathbb{H}$ as a real vector space, by a matrix in $GL_+(4, \mathbb{R})$.
The map 

\[ f: S^3 \rightarrow SU(2) \]

\[ (z, w) = z + j \cdot w \mapsto \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \]

matrix that represents left-multiplication by \( z + j \cdot w \) with respect to the complex basis \( \{1, j\} \) of \( \mathbb{H} \)

is a diffeomorphism and it defines an isomorphism of groups.

Remark. Note that the map \( f: S^3 \rightarrow SU(2) \) from Proposition 60.2 satisfies in particular

\[ f(1) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad f(i) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad f(j) = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \text{and} \quad f(k) = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}. \]

Recall that in Lemma 51.1 we defined a homomorphism \( q: SU(2) \rightarrow SO(3) \). In Exercise 51.1 we calculated \( q(f(i)), q(f(j)) \) and \( q(f(k)) \).

Proof.

(1) This statement follows immediately from Lemma 60.1 (5), (6) and (7).

(2) (a) This statement follows immediately from the observation that the obvious map \( \mathbb{C} \rightarrow \mathbb{H} \) is a ring homomorphism.

(b) It follows from \( k = -j \cdot i \) that any quaternion \( a \cdot 1 + b \cdot i + c \cdot j + d \cdot k \) can be uniquely written as \( (a \cdot 1 + b \cdot i) + j \cdot (c \cdot 1 - d \cdot i) \) where \( a \cdot 1 + b \cdot i \) and \( c \cdot 1 - d \cdot i \) are complex numbers. This shows that \( \{1, j\} \) is a basis for \( \mathbb{H} \), viewed as a complex vector space.

(c) First note that it follows from the associativity of quaternions that left-multiplication by a quaternion commutes with right-multiplication by a quaternion, in particular with right-multiplication by a complex number. This shows that left-multiplication by a quaternion is indeed a complex linear map. Now let us turn to the statement regarding the representative matrix. This statement is elementary, but we think it is nonetheless worth doing. So we consider the basis \( \{1, j\} \). Evidently we have \((z + j \cdot w) \cdot 1 = 1 \cdot z + j \cdot w\). Thus the first column of the matrix is given by \( \begin{pmatrix} z \\ w \end{pmatrix} \). More interestingly, we have

\[
(z + j \cdot w) \cdot j = z \cdot j + j \cdot w \cdot j = j \cdot \overline{z} + \overline{w} \cdot j \cdot j = j \cdot \overline{z} + 1 \cdot (−\overline{w}).
\]

↑

both equalities follow from the fact that \( i \cdot j = −j \cdot i \)

Thus the second column of the matrix is given by \( \begin{pmatrix} \overline{z} \\ −\overline{w} \end{pmatrix} \).

(d) This statement follows easily from (c).

\[ 92 \]

Here we view \( \mathbb{C} \) as a subset of \( \mathbb{H} \) in the obvious way. Note that the order in the definition is important since \( \mathbb{H} \) is not commutative.
(3) We already saw in Theorem 1.2 that the map \( f: S^3 \to SU(2) \) is a diffeomorphism. It follows from the associativity of quaternion multiplication and (2c), or alternatively from a tedious calculation, that the map
\[
f: \mathbb{H} \to M(2 \times 2, \mathbb{C})
\]
\[ (z, w) = z + j \cdot w \mapsto \begin{pmatrix} z & -w \\ w & z \end{pmatrix} \]
is a ring homomorphism, in particular it preserves the ring structure. This implies that the given map \( f: S^3 \to SU(2) \) is a group homomorphism.

Before we move on to the octonions it is helpful to give an alternative description of the quaternions. Namely we can view the Hamiltonians as elements in \( \mathbb{C} \oplus \mathbb{C} \) with the multiplication given by
\[
(z_1, z_2) \cdot (w_1, w_2) := (z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)
\]
the conjugate given by
\[
\overline{(w, z)} := (\overline{w}, -z)
\]
and the norm given by
\[
|w, z| := \sqrt{(w, z) \cdot (w, z)}.
\]
One easily verifies that this norm is multiplicative, i.e. given \( a, b \in \mathbb{H} = \mathbb{C} \oplus \mathbb{C} \) one has \( |a \cdot b| = |a| \cdot |b| \). An elementary calculation shows that the map \( (w, z) \mapsto w + z \cdot j \) defines an isomorphism between the two descriptions of \( \mathbb{H} \), furthermore one can verify easily that this isomorphism preserves the conjugate and the norm.

Considering the above description of the quaternions one might hope to be lucky and just try to recycle the definitions:

**Definition.** The Cayley octonions \( \mathbb{O} \) (or usually just octonions) are defined as \( \mathbb{O} = \mathbb{H} \oplus \mathbb{H} \) with the multiplication given by
\[
(z_1, z_2) \cdot (w_1, w_2) := (z_1 w_1 - \overline{w}_2 z_2, z_2 \overline{w}_1 + w_2 z_1)
\]
the conjugate given by
\[
\overline{(w, z)} := (\overline{w}, -z)\]
and the norm given by

\[ |(w, z)| := \sqrt{(w, z) \cdot (w, z)}. \]

The following lemma is the analogue of Lemma 60.1.

**Lemma 60.3.** The statements of Lemma 60.1 (1) to (7) also hold for octonions. For completeness’ sake we spell out the precise statements:

1. The octonions are a non-commutative algebra over \( \mathbb{R} \) with identity.
2. For any \( z \in \mathbb{O} \) we have \( z + z \in \mathbb{R} \).
3. For all \( z, w \in \mathbb{O} \) we have \( z = z, z + w = z + w \) and \( z \cdot w = w \cdot z \).
4. If we make the obvious identification \( \mathbb{O} = \mathbb{H} \oplus \mathbb{H} = \mathbb{R}^4 \oplus \mathbb{R}^4 = \mathbb{R}^8 \), then the norm \( |−| \) on \( \mathbb{O} \) agrees with the Euclidean norm \( \|−\| \) on \( \mathbb{R}^8 \).
5. For every \( z \in \mathbb{O} \) we have \( z \cdot z = |z|^2 \in \mathbb{R} = \mathbb{R} \cdot 1 \).
6. For every \( z \neq 0 \) a multiplicative inverse is given by \( z^{-1} = \frac{\overline{z}}{|z|^2} \).
7. For all \( z, w \in \mathbb{O} \) we have \( |z \cdot w| = |z| \cdot |w| \).

Furthermore, we have the following three statements:

8. The octonions are alternative, this means that given any \( x, y \in \mathbb{O} \) we have the equalities \( (x \cdot y) \cdot y = x \cdot (y \cdot y) \) and \( (x \cdot x) \cdot y = x \cdot (x \cdot y) \).
9. Given any \( x, y \in \mathbb{O} \) the algebra generated by \( 1, x \) and \( y \) is associative.
10. The octonions are a division algebra.

**Remark.**

1. By the remark on page 82 we know that in an associative ring we can ignore parentheses when it comes to multiplication. Now that we are dealing with the octonions, which are not associative, we have to carefully keep track of parentheses.
2. Our proof of Lemma 60.3 (9) gets outsourced to a theorem of Artin. An alternative proof for Lemma 60.3 (9), which does not rely on Artin’s Theorem, is given in [CSm03, p. 76].

**Proof.** As in the case of Lemma 60.1 the verification of (1) to (3) is totally elementary. The task of filling in the details is once again left to the reader. For later on it is helpful to consider the elementary proof of (4) in the notes:

4. Given \((z, w) \in \mathbb{O}\) we calculate that

\[ |(w, z)|^2 = (w, z) \cdot (w, z) = (w, z) \cdot (w, \overline{z}) = (w\overline{w} + zz, zw - zw) = \|w\|^2 + \|z\|^2. \]

5. This statement holds by definition of \( |−| \).
6. This statement follows immediately from (5).

Now we turn to the arguably more interesting proofs of the remaining four statements:

7. It turns out that the proof of this statement is not totally straightforward. Thus let \( z = (z_1, z_2) \) and \( w = (w_1, w_2) \) in \( \mathbb{O} \). We need the following super-technical claim.

\[^{922}\text{In fact these formulas also work for defining } \mathbb{C} \text{ as } \mathbb{R} \oplus \mathbb{R} \text{ where we equip } \mathbb{R} \text{ with the trivial involution.}\]
Claim. We have
\[ z_2 \overline{w}_1 z_1 \overline{w}_2 + w_2 z_1 w_1 \overline{z}_2 - z_1 w_1 \overline{z}_2 w_2 - \overline{w}_2 z_2 \overline{w}_1 \overline{z}_1 = 0. \]
\[ = S(w_2) \]
Evidently, if \( w_2 \) is a real number, then we have \( S(w_2) = 0 \). Now suppose that \( w_2 \) is a purely imaginary quaternion, i.e. \( w_2 = a \cdot i + b \cdot j + c \cdot j \) for some \( a, b, c \in \mathbb{R} \). In this case we calculate that
\[ S(w_2) = w_2 (\overline{z}_2 \overline{w}_1 \overline{z}_1 + z_1 w_1 \overline{z}_2) - (\overline{z}_2 \overline{w}_1 \overline{z}_1 + z_1 w_1 \overline{z}_2) w_2 = w_2 \cdot c - c \cdot w_2 = 0. \]
Finally note that for any \( a, b \in \mathbb{H} \) we have \( S(a+b) = S(a) + S(b) \). Since any quaternion is the sum of a real number and a purely imaginary we see that \( S(w_2) = 0 \) for any quaternion \( w_2 \).

Now we can provide the actual proof that the norm is multiplicative. Indeed, we calculate that
\[ |z \cdot w|^2 = |(z_1, z_2) \cdot (w_1, w_2)|^2 = |(z_1 w_1 - \overline{w}_2 z_2, z_2 w_1 + w_2 z_1)|^2 \]
\[ = (z_1 w_1 - \overline{w}_2 z_2) \cdot (z_1 w_1 - \overline{w}_2 z_2) + (z_2 w_1 + w_2 z_1) \cdot (z_2 w_1 + w_2 z_1) \]
\[ \uparrow \]
\[ = (z_1 w_1 - \overline{w}_2 z_2) \cdot (z_1 w_1 - \overline{w}_2 z_2) + (z_2 w_1 + w_2 z_1) \cdot (z_2 w_1 + w_2 z_1) \]
\[ = (z_1 w_1)(w_1 z_1) + (\overline{w}_1 z_1)(\overline{w}_2 z_2) + (z_2 w_1)(w_1 z_1) + (\overline{w}_2 z_2)(w_2 z_1) \]
\[ \uparrow \]
by the claim and the fact that the quaternions are associative
\[ = (z_1 z_1 + z_2 z_2)(w_1 w_1 + w_2 w_2) = |(z_1, z_2)|^2 \cdot |(w_1, w_2)|^2 = |z|^2 \cdot |w|^2. \]

(8) Let \( x, y \in \mathbb{O} \). We start out with the following claim.

Claim. We have the equalities \((x \cdot y) \cdot \overline{y} = x \cdot (y \cdot \overline{y}) \) and \((x \cdot \overline{x}) \cdot y = x \cdot (\overline{x} \cdot y) \).
Let us first prove the first equality. We write \( x = (x_1, x_2) \), \( y = (y_1, y_2) \) with \( x_1, x_2, y_1, y_2 \in \mathbb{H} \). Hereditarily we calculate that
\[ (xy) \cdot \overline{y} = ((x_1, x_2)(y_1, y_2)) \cdot (\overline{y}_1, -\overline{y}_2) = (x_1 y_1 - \overline{y}_2 x_2, y_2 x_1 + x_2 \overline{y}_1 \cdot (\overline{y}_1, -\overline{y}_2) \]
\[ = (\overline{y}_1 y_1 + \overline{y}_2 x_2)(y_2 x_1 + x_2 \overline{y}_1) + (\overline{y}_2 x_1 + x_2 \overline{y}_1)(-\overline{y}_2)(x_1 y_1 - \overline{y}_2 x_2) + (y_2 x_1 + x_2 \overline{y}_1) y_1 \]
\[ = ((|y_1|^2 + |y_2|^2) x_1, (|y_1|^2 + |y_2|^2) x_2) \cdot (x_1, x_2) \]
\[ \uparrow \]
since \( \mathbb{H} \) is associative we have \((\overline{y}_2 x_2)\overline{y}_1 = \overline{y}_2(y_2 x_1) \) and \( y_2(x_1 y_1) = (y_2 x_1) y_1 \)
we also use that \( \overline{y}_1 y_1 = |y_1|^2 \in \mathbb{R} \), hence it commutes with any \( z \in \mathbb{H} \)
\[ = |y|^2 \cdot x = x \cdot |y|^2 = x \cdot (y \overline{y}). \]

The proof of the second equality is basically the same. \( \square \)

Now, we use (2) to write \( \overline{x} = -x + 2a \) and \( \overline{y} = -y + 2b \) with \( a, b \in \mathbb{R} \). We plug these equalities into the equalities of the claim and, since we are dealing with an
algebra over the real numbers, we obtain the desired equalities 

\[(x \cdot y) \cdot y = x \cdot (y \cdot y)\]

and 

\[(x \cdot x) \cdot y = x \cdot (x \cdot y)\].

(9) It is a non-trivial theorem of Emil Artin that any alternative algebra \(A\) has the property that given any two \(x, y \in A\) the algebra generated by 1, \(x\) and \(y\) is associative. A proof is for example provided in \[\text{SchaR66} \] Theorem 3.1. Alternatively see \[\text{Bae01}, \text{p. 155}\].

(10) It remains to prove that \(\mathbb{O}\) is in fact a division algebra. Since the octonions are not associative we can not copy-paste the proof of Lemma \[60.1\] (9), since the latter proof used the associativity of the quaternions. Fortunately the spartan associativity result given in (8) is enough to give us the desired result.

Let \(a, b \in \mathbb{O}\) with \(a \neq 0\). We need to show that there exists an \(x \in \mathbb{O}\) with \(a \cdot x = b\) and a \(y \in \mathbb{O}\) with \(y \cdot a = b\). We set \(x = a^{-1} \cdot b\). We calculate that

\[a \cdot x = a \cdot (a^{-1} \cdot b) = a \cdot \left(\frac{1}{|a|^2} \cdot a \cdot b\right) = \frac{1}{|a|^2} \cdot a \cdot (a \cdot b) = \frac{1}{|a|^2} \cdot (a \cdot a) \cdot b = b.\]

by the claim in the proof of (8)

Basically the same calculation shows that we have \(y \cdot a = b\). \[\square\]

Remark.

(1) The octonions were discovered\[^{923}\] by Arthur Cayley in 1845, shortly after Hamilton found the quaternions.

(2) The discussion in the previous pages shows that starting from \(\mathbb{R}\) one can construct the complex numbers, which give rise to the quaternions and finally we obtain the octonions. When we move from the complex numbers to the quaternions we lose commutativity and when we go from the quaternions to the octonions we also lose associativity. Evidently the octonions are not commutative, but even worse, one can easily verify that the octonions are not even associative\[^{924}\]. The octonions are discussed in much greater detail in \[\text{Bae01}, \text{CSm03}, \text{Chapter 6}\] and \[\text{KaS89}, \text{Chapter 6}\].

(3) The definition of quaternions \(\mathbb{H} = \mathbb{C} \oplus \mathbb{C}\) out of the complex numbers and the definition of the octonions \(\mathbb{O} = \mathbb{H} \oplus \mathbb{H}\) out of the quaternions is a general procedure known as the Cayley-Dickson construction. This construction is discussed in greater detail in \[\text{Bae01} \] Section 2.2. In particular one can easily see that this process can be extended to define, basically by the same recipe, a 16-dimensional algebra \(\mathbb{S} = \mathbb{O} \oplus \mathbb{O}\) with an identity, called the sedenions, this algebra is evidently neither commutative nor associative. On the other hand the properties stated in Lemma \[60.1\] (1)–(6) and Lemma \[60.3\] (1)–(6) hold the same way, in particular \(\mathbb{S}\) has multiplicative inverses, i.e. for each \(a \in \mathbb{S} \setminus \{0\}\) there exists a \(b \in \mathbb{S}\) with \(a \cdot b = b \cdot a = 1\). But the proof of Lemma \[60.3\] (7) and (8) do not carry over, since in the proof we made use of the fact that the quaternions are actually associative. In fact it turns out that the analogue of

\[^{923}\]Or were they invented by Arthur Cayley? This question whether mathematics is “discovered” or “invented” is a source for endless philosophical discussions.

\[^{924}\]To quote from \[\text{Fri12}, \text{p. 5}\], “here, associativity is obviously a concern".
(7) does not hold for sedenions and that the sedenions are not a division algebra. We refer to [More97] for more information on the failure of the sedenions to be a division algebra.

60.2. Commutative division algebras. After the discovery of quaternions and the octonions the question arose whether one can also find division algebras on \( \mathbb{R}^n \) for some \( n \neq 1, 2, 4, 8 \). The following theorem, which was first proved by Heinz Hopf [Hopf40a, Hopf40b, Hopf64] in 1940, is the best theorem that we can prove in this direction with our present knowledge.

**Theorem 60.4. (Hopf Theorem on commutative division algebras)** Any finite-dimensional division algebra over \( \mathbb{R} \) which is commutative and which has an identity is isomorphic either to \( \mathbb{R} \) or to \( \mathbb{C} \).

**Remark.**

1. Note that in Theorem 60.4 we do not assume that the division algebra is associative. It is a nice exercise in algebra and real analysis to show, using the Fundamental Theorem of Algebra, the weaker statement that if \( V \) is a finite-dimensional commutative and associative division algebra over \( \mathbb{R} \), then \( V \) is isomorphic either to \( \mathbb{R} \) or to \( \mathbb{C} \).

2. The statement of Theorem 60.4 does not hold if we drop the “finite dimension” condition. For example the field \( \mathbb{R}(t) \) of rational functions over \( \mathbb{R} \) is a commutative division algebra, but it is an infinite-dimensional real vector space.

3. In Theorem 90.23 we will obtain further results on division algebras.

In the proof of Theorem 60.4 we will need the following basic lemma which might already be familiar from earlier algebra courses.

**Lemma 60.5.** Let \( A \) be a finite-dimensional algebra over a field \( \mathbb{F} \). The following two statements are equivalent:

1. \( A \) is a division algebra,
2. \( A \) has no zero-divisors, i.e. for any \( a, b \in A \) with \( a \cdot b = 0 \) we have \( a = 0 \) or \( b = 0 \).

**Remark.** Let \( A \) be a division algebra over a field \( \mathbb{F} \). If \( A \) is associative, then it is clear that \( A \) has no zero-divisors. Indeed, if \( a \cdot b = 0 \) with \( a \neq 0 \), then we pick \( x \) with \( x \cdot a = 1 \) and we see that \( 0 = x \cdot 0 = x \cdot (a \cdot b) = (x \cdot a) \cdot b = 1 \cdot b = b \). The point about Lemma 60.5 is that it applies to non-associative algebras, as long as they are finite-dimensional.

---

By [More97] In fact this construction can be iterated and one obtains algebras which are creatively called pathions (32-dimensional), chingons (64-dimensional), routons (128-dimensional), voudons (256-dimensional). We challenge the reader to come up with the explanations for these names. Alternatively the reader can look at [dMar02] p. 7.

By [More97] Perhaps more fruitfully, the Cayley-Dickson construction can be applied to the real numbers to give the complex numbers and it can also be applied to the complex numbers to give the quaternions.
Proof. Let $A$ be a finite-dimensional algebra over a field $\mathbb{F}$. Let $a \in A$ be non-zero. Then the following holds:

for any $y \in A$ there exists $x \in A$ with $ax = y$ ⇔ the map $A \to A$, $x \mapsto ax$ is surjective ⇔ the map $A \to A$, $x \mapsto ax$ is injective

since $x \mapsto ax$ is a homomorphism of finite-dimensional $\mathbb{F}$-vector spaces ⇔ for any $b \neq 0$ we have $ab \neq 0$.

The same statement holds for left-multiplication. The equivalence of (1) and (2) now follows easily from this observation and the definitions. ■

Now we turn to the proof of Theorem 60.4.

Proof of Theorem 60.4 Let $(A, *)$ be a finite-dimensional division algebra over $\mathbb{R}$ which is commutative and which has an identity. Since $A$ is a finite-dimensional vector space we can, after applying an isomorphism, assume that $A = \mathbb{R}^n$ for some $n \in \mathbb{N}$.

We first consider the case $n = 1$. We define $a := 1 \cdot 1$. Since “$*$” is bilinear we have for all $x, y \in \mathbb{R}$ that $x \cdot y = (x \cdot 1) \cdot (y \cdot 1) = x \cdot (1 \cdot 1) \cdot y = xay$. Since the algebra is a division algebra we obtain from Lemma 60.5 that $a \neq 0$. Then the map $\varphi(x) = ax$ defines an isomorphism from the algebra $(\mathbb{R}, *)$ to the algebra $(\mathbb{R}, \cdot)$.

Now suppose that $n \geq 2$. We first want to show that $n = 2$. To do this we consider the map

$$f : S^{n-1} \to S^{n-1}$$

$$x \mapsto f(x) := \frac{x \cdot x}{\|x \cdot x\|}.$$

This map is indeed well-defined, since for $x \neq 0$ it follows from our hypothesis on $(\mathbb{R}^n, *)$ and from Lemma 60.5 that $x \cdot x \neq 0$. The map $f$ is continuous since the multiplication map $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is bilinear, hence continuous.

Since “$*$” is bilinear we have $f(-x) = f(x)$ for all $x \in \mathbb{R}^n$. It follows from Lemma 3.22 that the map $f$ descends to a continuous map

$$\overline{f} : \mathbb{RP}^{n-1} \to S^{n-1}$$

$$[x] \mapsto \overline{f}([x]) := f(x).$$

Claim. The map $\overline{f} : \mathbb{RP}^{n-1} \to S^{n-1}$ is injective.

So let $[x], [y] \in \mathbb{RP}^{n-1} = S^{n-1}/\sim$. We have

$$\overline{f}([x]) = \overline{f}([y]) \implies f(x) = f(y) \implies x \cdot x = \alpha^2 \cdot (y \cdot y) \text{ for } \alpha := \sqrt{\|x \cdot x\| \cdot \|y \cdot y\|}$$

$$\implies 0 = x \cdot x - \alpha^2 \cdot (y \cdot y) = (x + \alpha y) \cdot (x - \alpha y)$$

$$\implies \text{ since “$*$” is commutative and bilinear}$$

$$\implies x = \pm \alpha y \implies x = \pm y \implies [x] = [y].$$

Lemma 60.5 since $x, y \in S^{n-1}$.

\[927\] Indeed, for $x, y \in \mathbb{R}$ we have $\varphi(x \cdot y) = \varphi(x \cdot a \cdot y) = a \cdot x \cdot a \cdot y = (a \cdot x) \cdot (a \cdot y) = \varphi(x) \cdot \varphi(y)$.

\[928\] Indeed, the fact that the map is bilinear implies that there exists a real $n \times n$-matrix $P$ such that for any $v, w \in \mathbb{R}^n$ we have $v \cdot w = v^T P w$, hence the map is continuous.
Since $S^{n-1}$ is closed and connected (here we use that $n \geq 2$) and since $\mathbb{R}P^{n-1}$ is a closed smooth manifold it follows from Corollary 50.8 that $\overline{f}: \mathbb{R}P^{n-1} \to S^{n-1}$ is in fact a homeomorphism. In particular the fundamental groups of $\mathbb{R}P^{n-1}$ and $S^{n-1}$ are isomorphic. But it follows from Proposition 14.14 and Corollary 16.18 that this is only possible if $n = 2$.

It remains to show that the algebra $(A, \ast) = (\mathbb{R}^2, \ast)$ is isomorphic to the algebra $(\mathbb{C}, \cdot)$. We start out with the following claim.

**Claim.** There exists a $k \in A \setminus \mathbb{R} \cdot 1$ with $k \ast k = c \cdot 1$ for some $c \in \mathbb{R}_{<0}$.

We first pick a random element $j \in A \setminus \mathbb{R} \cdot 1$. Then 1 and $j$ are a basis for $A = \mathbb{R}^2$ and therefore we can write $j \ast j = a \cdot 1 + b \cdot j$ for some $a, b \in \mathbb{R}$. Then multiplying out and using this equality we see that

$$
\left( j - \frac{b}{2} \cdot 1 \right) \ast \left( j - \frac{b}{2} \cdot 1 \right) = \left( a + \frac{1}{4} b^2 \right) \cdot 1.
$$

We set $k := j - \frac{b}{2} \cdot 1$ and $c := a + \frac{1}{4} b^2$. We still need to show that $c < 0$. Suppose that $c \geq 0$. Then $k \ast k = c \cdot 1$ implies that $(k + \sqrt{c} \cdot 1) \ast (k - \sqrt{c} \cdot 1) = k \ast k - c \cdot 1 = 0$. From Lemma 60.3 we conclude that $k = \pm \sqrt{c} \cdot 1$. But this is not possible since $k = j - \frac{b}{2} \cdot 1$ is linearly independent from $1$.

One can now easily verify that

$$
A \to \mathbb{C}
$$

$$
x \cdot 1 + y \cdot k \mapsto x + y \cdot \frac{i}{\sqrt{-c}} \quad \text{with } x, y \in \mathbb{R}
$$

is an isomorphism from the algebra $(A, \ast)$ to the algebra $(\mathbb{C}, \cdot)$.

It is natural to ask what other division algebras exist. The following, purely algebraic, theorem classifies associative division algebras.

**Theorem 60.6.** Any finite-dimensional division algebra over $\mathbb{R}$ which is associative and which has an identity is isomorphic to $\mathbb{R}, \mathbb{C}$ or to $\mathbb{H}$.

**Proof.** The statement was first proved by Frobenius in 1878. A short self-contained proof is for example given in [Pal68].

Finally let us record the following question.

**Question 60.7.** For which $n \in \mathbb{N}$, besides $n = 1, 2, 4, 8$ does $\mathbb{R}^n$ admit the structure of a division algebra?

We will answer this question in Theorem 90.25.

60.3. **Quaternionic and octonionic projective spaces ($\ast$).** In this section we introduce the quaternionic projective spaces $\mathbb{H}P^n$ and we introduce the significantly more subtle octonionic projective space $\mathbb{O}P^2$. These smooth manifolds get added to our ever expanding list of amusing topological spaces. At a later stage they will play an essential role.

On page 935, given $n \in \mathbb{N}_0$, we introduced the real projective space $\mathbb{R}P^n$ and the complex projective spaces $\mathbb{C}P^n$. In the following we will introduce the quaternionic projective spaces $\mathbb{H}P^n$. Since the quaternions $\mathbb{H}$ are non-commutative we do the constructions carefully.
Lemma 60.8. Given \( v, w \in \mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\} \) we write \( v \sim w \) if there exists a non-zero \( h \in \mathbb{H} \) with \( h \cdot v = w \). This defines an equivalence relation on \( \mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\} \). The analogous statement also holds for \( \mathbb{H}^\infty \setminus \{0\} \).

Proof.

(1) It is clear that \( \sim \) is reflexive.
(2) Since \( \mathbb{H} \) is a skew field we see that \( \sim \) is symmetric.
(3) Finally suppose that \( u \sim v \) and \( v \sim w \). Thus there exist \( g, h \in \mathbb{H} \setminus \{0\} \) with \( gu = v \) and \( hv = w \). Then
\[
(hg)u = h(gu) = hv = w.
\]
since the quaternions are associative! ■

Now we can define the quaternionic projective spaces.

Definition. Let \( n \in \mathbb{N}_0 \).

(1) For \( (h_0, \ldots, h_n) \in \mathbb{H}^{n+1} \setminus \{0\} \) we denote by \([h_0 : \ldots : h_n]\) the corresponding equivalence class.
(2) Given \( n \in \mathbb{N} \) we define the quaternionic projective space
\[
\mathbb{H}P^n := (\mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\})/\sim.
\]
Similarly, we define the infinite-dimensional quaternionic projective space
\[
\mathbb{H}P^\infty := (\mathbb{H}^\infty \setminus \{0\})/\sim.
\]

The following lemma summarizes some key properties of quaternionic projective spaces \( \mathbb{H}P^n \). We will make use of some of them later on.

Lemma 60.9. Let \( n \in \mathbb{N}_0 \).

(1) \( \mathbb{H}P^n \) is a closed orientable \( 4n \)-dimensional smooth manifold.
(2) The map
\[
\mathbb{H}P^1 \to \mathbb{H} \cup \{\infty\} = \mathbb{R}^4 \cup \{\infty\} = S^4
\]
\[
[z_0 : z_1] \mapsto \left\{ \begin{array}{ll}
z_0 \cdot z_1^{-1}, & \text{if } z_1 \neq 0, \\
\infty, & \text{if } [z_0 : z_1] = [1 : 0]
\end{array} \right.
\]
by Lemma 2.44
is a homeomorphism.
(3) \( \mathbb{H}P^n \) admits a CW-structure that has exactly one cell in the dimensions \( 0, 4, 8, \ldots, 4n \).
(4) We have \( \chi(\mathbb{H}P^n) = n + 1 \).
(5) \( \mathbb{H}P^n \) is 3-connected, i.e. we have \( \pi_i(\mathbb{H}P^3) = 0 \) for \( i = 1, 2, 3 \).
(6) We have a homeomorphism \( \limn \mathbb{H}P^n = \mathbb{H}P^\infty \).
(7) We can equip \( \mathbb{H}P^\infty \) with a CW-structure that has exactly one cell in the dimensions \( 0, 4, 8, \ldots \).

Proof.

(1) This statement is proved in a very similar way as Lemma 12.5.
(2) The proof of this statement is basically the same as the proof of Lemma 3.42 (2).
(3) The proof of this statement is an easy modification of the proof of Lemma 36.1.
(4) This statement follows immediately from (3).
(5) This follows from (3) and Proposition 40.9.
(6) This statement is proved basically the same way as Lemma 36.5 (1).
(7) This statement is proved basically the same way as Lemma 36.5 (3).

Since the octonions are not associative the definition on page 935 cannot be applied to the octonions. But there is some hope in low dimensions. More precisely, as we will see shortly, one can use the octonions to construct smooth manifolds that have all the properties that one would naively expect $\mathbb{O}P^1$ and $\mathbb{O}P^2$ to have.

**Definition.**

1. We equip $T_2 := \mathbb{O}^2 \setminus \{(0,0)\}$ with the equivalence relation where

\[(x_1, y_1) \sim (x_2, y_2) \iff \text{there exists a } \lambda \in \mathbb{R}_{>0} \text{ such that } x_1 \bar{x}_1 = \lambda \cdot x_2 \bar{x}_2 \text{ and } x_1 \bar{y}_1 = \lambda \cdot x_2 \bar{y}_2.\]

We set $\mathbb{O}P^1 := T_2/\sim$ and we refer to $\mathbb{O}P^1$ as the octonionic projective line.

2. We equip $T_3 := \{ (x, y, z) \in \mathbb{O}^3 \setminus \{(0,0,0)\} \mid 1, x, y, z \text{ generate an associative algebra} \}$ with the equivalence relation where

\[(x_1, y_1, z_1) \sim (x_2, y_2, z_2) \iff \text{there exists a } \lambda \in \mathbb{R}_{>0} \text{ such that } x_1 \bar{x}_1 = \lambda \cdot x_2 \bar{x}_2, \quad y_1 \bar{y}_1 = \lambda \cdot y_2 \bar{y}_2, \quad z_1 \bar{z}_1 = \lambda \cdot z_2 \bar{z}_2.\]

We set $\mathbb{O}P^2 := T_3/\sim$ and we refer to $\mathbb{O}P^2$ as the octonionic projective plane. In the literature the octonionic projective plane is often also called the Cayley projective plane.

3. We denote the equivalence class of a point $(x, y) \in T_2$ by $[x : y]$ and we denote the equivalence class of a point $(x, y, z) \in T_3$ by $[x : y : z]$.

The following proposition hopefully convinces the reader that the octonion line $\mathbb{O}P^1$ and the octonion plane $\mathbb{O}P^2$ deserve their names.

---

929 What happens if we use these definitions of $\mathbb{O}P^1$ and $\mathbb{O}P^2$, but if we replace the octonions by our more familiar friends $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{H}$?

930 Note that this is obviously an equivalence relation.

931 The definition of the equivalence relation is a priori asymmetric in the first and the second variable. As we will see in Exercise 60.6 this sense of asymmetry is an illusion.

932 As for $\sim$ on $T_2$, this is basically by definition an equivalence relation.
Proposition 60.10.

1. The octonionic projective line $\mathbb{OP}^1$ and the octonionic projective plane $\mathbb{OP}^2$ are both compact.
2. The map

\[
\mathbb{OP}^1 \to \mathbb{O} \cup \{\infty\} = \mathbb{R}^8 \cup \{\infty\} = S^8
\]

\[
[x : y] \mapsto \begin{cases} 
  x \cdot y^{-1}, & \text{if } y \neq 0, \\
  \infty, & \text{if } [x : y] = [1 : 0]
\end{cases}
\]

is well-defined and it is a homeomorphism.
3. The octonionic projective plane $\mathbb{OP}^2$ is a closed orientable 16-dimensional smooth manifold.
4. The map

\[
\mathbb{OP}^1 \to \mathbb{OP}^2
\]

\[
[x : y] \mapsto [x : y : 0]
\]

is an embedding. We use it to view $\mathbb{OP}^1$ as a subspace of $\mathbb{OP}^2$.
5. The octonionic projective plane $\mathbb{OP}^2$ admits a $CW$-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Furthermore this $CW$-structure can be chosen such that the 8-skeleton is precisely $\mathbb{OP}^1$.
6. We have $\chi(\mathbb{OP}^2) = 3$.
7. $\mathbb{OP}^2$ is 7-connected, i.e. we have $\pi_i(\mathbb{OP}^2) = 0$ for $i = 1, 2, \ldots, 7$.

Proof.

1. It is straightforward to define equivalence relations on $S^{15}$ and on $S^{23}$ such that the octonionic projective line $\mathbb{OP}^1$ is homeomorphic to $S^{15}/\sim$ and such that the octonionic projective plane $\mathbb{OP}^2$ is homeomorphic to $S^{23}/\sim$. It follows from Lemma 2.40 that $\mathbb{OP}^1$ and $\mathbb{OP}^2$ are both compact.
2. First we need to show that the given map $\Theta: \mathbb{OP}^1 \to \mathbb{O} \cup \{\infty\}$ is well-defined. Thus suppose that we are given two points $(x_1, y_1)$ and $(x_2, y_2)$ in $\mathbb{O}^2 \setminus \{(0, 0)\}$ that are equivalent. One can verify easily that $y_1 \neq 0$ if and only if $y_2 \neq 0$. By definition of $\Theta$ we only need to worry about the case that $y_1, y_2 \neq 0$. In this case we do indeed have

\[
\frac{x_1y_1^{-1}}{y_1} = x_1, \quad \frac{1}{|y_1|^2}, \quad \frac{1}{y_1} \cdot \frac{1}{y_1} = \frac{1}{y_1^2} \cdot \frac{1}{y_2^2}, \quad \frac{1}{y_2^2} = \cdots = \frac{x_2y_2^{-1}}{y_2}.
\]

Lemma 60.3 (7) Lemma 60.3 (6) by definition of “$\sim$” we have same steps backwards $y_1y_1 = \lambda \cdot y_2y_2$ and $y_1y_1 = \lambda \cdot y_2y_2$

We have thus shown that $\Theta$ is well-defined. It is clear that the map $\Theta$ is a surjection. In Exercise 60.5 we will verify that $\Theta$ is also an injection. Next note that the argument in the proof of Lemma 3.42 (2) shows that $\Theta$ is continuous. We just saw in (1) that $\mathbb{OP}^1$ is compact. Evidently $\mathbb{O} \cup \{\infty\} = S^8$ is Hausdorff. In summary we obtain from Proposition 2.43 (3) that $\Theta: \mathbb{OP}^1 \to \mathbb{O} \cup \{\infty\}$ is a homeomorphism.

---

\footnote{It follows from Lemma 60.3 (9) that this map is well-defined, i.e. given any point $(x_1, y_1, 0) \in T_2$ we have indeed $(x_1, y_1, 0) \in T_3$.}
We start out with the following claim:

**Claim.** The map

\[
\Phi_z : \{[x : y : z] \in \mathbb{O}P^2 \mid z \neq 0\} \rightarrow \mathbb{O}^2 \\
[x : y : z] \mapsto (xz^{-1}, yz^{-1})
\]

is a homeomorphism between an open subset of \(\mathbb{O}P^2\) and \(\mathbb{O}^2 = \mathbb{R}^{16}\).

We prove the claim in three mostly elementary steps.

(a) Basically the same argument as in (2) shows that the map \(\Phi_z\) is well-defined.

(b) It follows easily from the definition of the quotient topology that the domain of the map \(\Phi_z\) is indeed an open subset of \(\mathbb{O}P^2\).

(c) Finally we consider the map

\[
\Psi_z : \mathbb{O}^2 \rightarrow \{[x : y : z] \in \mathbb{O}P^2 \mid z \neq 0\} \\
(x, y) \mapsto [x : y : 1].
\]

Note that here we use the non-trivial Lemma 60.3 (9) to conclude that \(\Psi_z\) is actually well-defined, i.e. to conclude that \((x, y, 1)\) is actually an element in \(T_3\). Furthermore note that it follows from Lemma 3.22 that \(\Psi_z\) is continuous. It is clear that \(\Phi_z \circ \Psi_z = \text{id}\). Finally note that given \([x : y : z] \in \mathbb{O}P^2\) with \(z \neq 0\) we have

\[
\Psi_z(\Phi_z([x : y : z])) = [xz^{-1} : yz^{-1} : 1] = [x : y : z]
\]

follows with \(\lambda = |z|^2\) and from the observation that the hypothesis \((x, y, z) \in T_3\) together with Lemma 60.3 (2) implies that the elements \(x, y, z, \overline{x}, \overline{y}, \overline{z}\) generate an associative algebra.

We have thus shown that \(\Psi_z\) is an inverse to \(\Phi_z\). This implies that \(\Phi_z\) is indeed a homeomorphism. \(\Box\)

Similarly we define charts \(\Phi_x\) and \(\Phi_y\). It is straightforward to verify that the transition maps between the three charts are smooth and orientation-preserving. In particular these three charts define a smooth atlas for \(\mathbb{O}P^2\). We obtain from Lemma 6.4 that \(\mathbb{O}P^2\) is second-countable. In (1) we showed that \(\mathbb{O}P^2\) is compact. Finally in Exercise 60.7 we will show that \(\mathbb{O}P^2\) is Hausdorff. The combination of all of the above shows that \(\mathbb{O}P^2\) is indeed a closed 16-dimensional smooth manifold. Finally, since the transition maps between the three charts are orientation-preserving we obtain from Lemma 6.45 that \(\mathbb{O}P^2\) is actually orientable.

(4) It follows basically immediately from Exercise 60.6 that the given map \(\mathbb{O}P^1 \rightarrow \mathbb{O}P^2\) is an injection. By (1) we know that \(\mathbb{O}P^1\) is compact and by (3) we know that \(\mathbb{O}P^2\) is Hausdorff. Thus it follows from Proposition 2.43 (2) that the given map \(\mathbb{O}P^1 \rightarrow \mathbb{O}P^2\) is an embedding.

(5) We view \(\mathbb{O}P^1 = S^8\) as a CW-complex with one 0-cell and one 8-cell in the obvious way. Next, similar to the proof of Lemma 36.1 we consider the attaching map

\[
\varphi : S^{15} = \{(x_1, x_2) \in \mathbb{O}^2 \mid |x_1|^2 + |x_2|^2 = 1\} \rightarrow \mathbb{O}P^1 \\
(x_1, x_2) \mapsto [x_1 : x_2].
\]

An arguably more elegant proof that \(\mathbb{O}P^2\) is Hausdorff is given in [Lackm12].
Furthermore we consider the map

$$\Theta : \mathbb{O}P^1 \cup \mathbb{B}^{16} \rightarrow \mathbb{O}P^2$$

$$[P] \mapsto \begin{cases} [x_1 : x_2 : 0], & \text{if } P = [x_1 : x_2] \in \mathbb{O}P^1, \\ [P : 1 - ||P||], & \text{if } P \in \mathbb{B}^{16}. \end{cases}$$

It follows from Lemma 60.3 (8) that the map actually does take values in $\mathbb{O}P^2$. We leave the slightly tedious task of verifying that the map is well-defined and a bijection to the reader. The left-hand side is compact and the right-hand side is Hausdorff by (2). Thus it follows from Proposition 2.43 (3) that the map is a homeomorphism. But this implies that $\mathbb{O}P^2$ admits a CW-structure with precisely three cells, one in dimensions 0, 8 and 16.

(6) Statement (6) is an immediate consequence of (5).

(7) Finally Statement (7) follows from (5) and Proposition 40.9. ■

It is natural to ask whether there exists a smooth manifold that deserves the name $\mathbb{O}P^n$ for $n \geq 3$. In the proof of Proposition 60.10 we used that $n = 2$ has the property, provided by Lemma 60.3 (9), that for any $x_1, \ldots, x_n \in \mathbb{O}$ the elements $1, x_1, \ldots, x_n$ generate an associative algebra. It is straightforward to see that this statement is not true for $n \geq 3$. Nonetheless, one can wonder whether there exists an alternative way to define a meaningful higher dimensional octonionic projective space. This slightly vague question can be formulated in many different ways. Here is one possible interpretation of this question.

**Question 60.11.** Let $n \geq 3$. Does there exist a closed orientable $8n$-dimensional smooth manifold that admits a CW-structure with precisely one cell in dimensions 0, 8, 16, \ldots, 8n?

We will answer this question in Exercise 110.2.

Proposition 60.10 says in particular that the octonion plane $\mathbb{O}P^2$ is a closed orientable 16-dimensional smooth manifold that is 7-connected and that has odd Euler characteristic. The following question is, to the best of my knowledge, open:

**Question 60.12.** Does there exist an 8-connected closed orientable smooth manifold with odd Euler characteristic?

In [Hoe17 Theorem 1.2 together with Proposition 4.2] it is shown that the dimension of an 8-connected closed orientable smooth manifold with odd Euler characteristic, if it exists, has to be divisible by 16.

-------------------

**Exercises for Chapter 60**

**Exercise 60.1.** Let $q_1, q_2 \in S^3 = \{h \in \mathbb{H} \mid ||h|| = 1\}$. We consider the map

$$\mathbb{R}^4 = \mathbb{H} \rightarrow \mathbb{R}^4 = \mathbb{H}$$

$$z \mapsto q_1 z q_2^{-1}.$$  

Show that the map is linear and that it is represented by a matrix in $\text{SO}(4)$.
Exercise 60.2. Let \( n \in \mathbb{Z} \). Show that the degree of the map
\[
S^3 = \{ v \in \mathbb{H} | \|v\| = 1 \} \to S^3, \quad z \mapsto z^n
\]
equals \( n \).
Hint. You could use Proposition 45.23.

Exercise 60.3. Let \( A = \mathbb{R} \oplus \mathbb{R} \cdot i \oplus \mathbb{R} \cdot j \oplus \mathbb{R} \cdot k \). We define the multiplication on \( A \) the same way as we did for the quaternions, see page 1462 except that we set \( i^2 = -1 + \epsilon \cdot j \).

(a) Show that \( A \) is a division algebra.
(b) Show that \( i \) has a left-inverse and a right-inverse.
(c) Show that the left-inverse and the right-inverse of \( i \) differ for sufficiently small \( \epsilon > 0 \).

Exercise 60.4. Show that the octonions \( \mathbb{O} \) are not associative.

Exercise 60.5. Show that the map
\[
\mathbb{O}P^1 \to \mathbb{O} \cup \{ \infty \}, \quad [x : y] \mapsto \begin{cases} x \cdot y^{-1}, & \text{if } y \neq 0, \\ \infty, & \text{if } [x : y] = [1 : 0] \end{cases}
\]
is an injection.

Exercise 60.6. Let \((x_1, y_1) \in \mathbb{O}^2 \setminus \{(0, 0)\} \). Suppose there exists a \( \lambda \in \mathbb{R}_{>0} \) such that \( x_1 \overline{x_1} = \lambda \cdot x_2 \overline{x_2} \) and \( x_1 \overline{y_1} = \lambda \cdot x_2 \overline{y_2} \). Show that there exists a \( \mu \in \mathbb{R}_{>0} \) such that
\[
x_1 \overline{x_1} = \mu \cdot x_2 \overline{x_2}, \quad x_1 \overline{y_1} = \mu \cdot x_2 \overline{y_2} \text{ and } y_1 \overline{y_1} = \mu \cdot y_2 \overline{y_2}.
\]
Hint. Consider norms.

Exercise 60.7. Show that \( \mathbb{O}P^2 \) is Hausdorff.
Hint. First show that \( \mathbb{O}P^2 \) is in fact homeomorphic to a suitable quotient of the sphere \( S^{23} = \{(x, y, z) \in \mathbb{O}^3 | |x|^2 + |y|^2 + |z|^2 = 1 \} \) and then apply Lemma 3.26.
Part VII

Simplicial Complexes
61. Simplicial complexes: Definition, examples and basic properties

In this section we introduce the notion of an abstract simplicial complex. Similar to the notion of an abstract graph these are purely combinatorial objects. The connection to topology comes from the fact that simplicial complexes admit topological realizations which can be used to combinatorially describe many interesting topological spaces. These topological realizations also lead to the notion of a simplicial complex which can be viewed as a special class of CW-complexes with particularly nice properties.

61.1. Abstract simplicial complexes. Before we do anything else we recall the following notation that we introduced on page 73.

Notation. Given a set \( X \) we denote by \( \mathcal{P}(X) \) its power set, i.e. \( \mathcal{P}(X) \) is the set of all subsets of \( X \).

We continue with the following initially rather abstract definition.

Definition. An abstract simplicial complex is a pair \( (V,S) \) where \( V \) is a set and \( S \) is a subset of the power set \( \mathcal{P}(V) \) of \( V \) such that the following conditions are satisfied:

1. each \( s \in S \) is finite and non-empty,
2. if \( s \in S \), then any non-empty subset of \( s \) also lies in \( S \),
3. given any \( v \in V \) the set \( \{v\} \) lies in \( S \).

We refer to the elements of \( V \) as the vertices of the abstract simplicial complex and we refer to the elements of \( S \) as the simplices of the abstract simplicial complex.

Examples.

0. The pair \( (\emptyset, \emptyset) \) is an abstract simplicial complex, it is called the empty abstract simplicial complex. Every other abstract simplicial complex is called non-empty.

1. We consider the set \( U = \{A,B,C\} \). It is straightforward to verify that the pair \( X := (U,S) \) with \( S = \{\{A\}, \{B\}, \{C\}, \{A,B\}, \{A,C\}, \{B,C\}\} \) and that the pair \( Y := (U,T) \) with \( T = \mathcal{P}(U) \setminus \{\emptyset\} \) are abstract simplicial complexes. We illustrate these two abstract simplicial complexes in Figure 890.

2. Let \( n \in \mathbb{N} \). The pairs
   (a) \( D_n := (V,S) \) with \( V = \{0, \ldots, n\} \) and \( S = \mathcal{P}(V) \setminus \{\emptyset\} \), and
   (b) \( S_{n-1} := (V,T) \) with \( V = \{0, \ldots, n\} \) and \( T = \mathcal{P}(V) \setminus \{\emptyset, V\} \),

are abstract simplicial complexes.

3. (a) Given \( n \in \mathbb{N}_{\geq 3} \) the pair \( R_n = (V,S) \) with
   \[ V := \mathbb{Z}_n \quad \text{and} \quad S := \{\{k\} \mid k \in \mathbb{Z}_n\} \cup \{\{k, k + 1\} \mid k \in \mathbb{Z}_n\} \]

is an abstract simplicial complex.

\[935\] To simplify the figures we will not draw the “trivial” simplices that are given by the vertices.
(b) The pair $R_\infty := (V, S)$ with
\[ V := \mathbb{Z} \quad \text{and} \quad S := \{\{n\} \mid n \in \mathbb{Z}\} \cup \{\{n, n + 1\} \mid n \in \mathbb{Z}\} \]
is an abstract simplicial complex.

We illustrate these two abstract simplicial complexes in Figure 891.

```
R_5 =
```

```
R_\infty = \cdots
```

**Figure 891**

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex.

1. We say $K = (V, S)$ is finite if $V$ is finite. Similarly we say $K = (V, S)$ is countable if $V$ is countable.
2. If $s \in S$ has $k + 1$ elements, then $s$ is called a $k$-dimensional simplex, or shorter, a $k$-simplex of $(V, S)$.
3. If $K = (V, S)$ is the empty abstract simplicial complex, then we define its dimension as $-1$. Now suppose that $K = (V, S)$ is non-empty. We define

\[ \dim(K) := \max\{\#s - 1 \mid s \in S\} \in \mathbb{N}_0 \cup \{\infty\}. \]

In other words, the dimension of $K = (V, S)$ is the maximal dimension of a simplex of $K = (V, S)$.

**Examples.**

1. The above abstract simplicial complex $(U, S)$ is 1-dimensional and the above abstract simplicial complex $(U, T)$ is 2-dimensional.
2. Let $n \in \mathbb{N}$. The abstract simplicial complex $D_n$ is $n$-dimensional and the abstract simplicial complex $S_{n-1}$ is $(n - 1)$-dimensional.
3. The abstract simplicial complexes $R_n$ and $R_\infty$ are one-dimensional.

We continue with a few more harmless definitions and statements.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex. Let $t$ be a simplex. A face of $t$ is a simplex $s$ with $s \subset t$.

**Lemma 61.1.** Let $K = (V, S)$ be an abstract simplicial complex. Furthermore let $s$ and $t$ be two simplices. Then either the intersection $s \cap t$ is empty, or the intersection $s \cap t$ is again a simplex and it is a face of $s$ and $t$.

**Proof.** Let $s$ and $t$ be two simplices of an abstract simplicial complex $K = (V, S)$. If $s \cap t = \emptyset$ then there is nothing to show. Now suppose that $s \cap t \neq \emptyset$. Evidently $s \cap t$ is a non-empty subset of $s$ and $t$. By definition of an abstract simplicial complex this means that $s \cap t$ is also a simplex. Furthermore, since $s \cap t \subset s$ and $s \cap t \subset t$ the intersection is a face of $s$ and $t$. $\blacksquare$

\footnote{Note that this implies that $S$ is also finite. In fact since every $v \in V$ defines a simplex we see that an abstract simplicial complex is finite if and only if $S$ is finite.}
Definition. Let \(L = (W, T)\) be an abstract simplicial complex. An abstract subcomplex of \(L = (W, T)\) is a pair \(K = (V, S)\) with \(V \subseteq W\), with \(S \subseteq T\) and such that \(K = (V, S)\) is an abstract simplicial complex in its own right. On most occasions we just say “subcomplex” instead of “abstract subcomplex”.

Examples.

1. Basically by definition \(X = (U, S)\) is a subcomplex of \(Y = (U, T)\).
2. Let \(n \in \mathbb{N}\). Again, basically by definition \(S_{n-1}\) is a subcomplex of \(D_n\).
3. Let \(K = (V, S)\) be an abstract simplicial complex and let \(n \in \mathbb{N}_0\). We refer to \(V\) together with all simplices of dimension \(\leq n\) as the \(n\)-skeleton of the abstract simplicial complex. It is basically clear from the definitions that the \(n\)-skeleton is a subcomplex. For convenience we also write \(K^n := K\).
4. Let \(K = (V, S)\) be an abstract simplicial complex and let \(s \in S\).
   a. The pair \((s, \mathcal{P}(s) \setminus \{\emptyset\})\) is a subcomplex of \(K\). Often we abbreviate this subcomplex to \(s\).
   b. The pair \((s, \mathcal{P}(s) \setminus \{\emptyset, s\})\) is a subcomplex of \(K\). Usually we refer to this subcomplex as \(\partial s\).

The following lemma gives us elementary ways to construct subcomplexes.

**Lemma 61.2.** Let \(\{L_i = (W_i, T_i)\}_{i \in I}\) be a family of abstract simplicial complexes. The following statements hold:

1. \(\bigcap_{i \in I} L_i := \left( \bigcap_{i \in I} W_i, \bigcap_{i \in I} V_i \right)\) and \(\bigcup_{i \in I} L_i := \left( \bigcup_{i \in I} W_i, \bigcup_{i \in I} V_i \right)\) are abstract simplicial complexes.
2. \(\bigcap_{i \in I} L_i\) is a subcomplex of each \(L_i\) and each \(L_i\) in turn is a subcomplex of \(\bigcup_{i \in I} L_i\).
3. If each \(L_i\) is a subcomplex of some abstract simplicial complex \(K\), then \(\bigcap_{i \in I} L_i\) and \(\bigcup_{i \in I} L_i\) are also subcomplexes of \(K\).

**Proof.** The lemma is close to being a tautology. ■

As the reader will know by now, not only do we want to study objects, we also want to study maps or morphisms between them. The following gives us the type of maps we are now interested in.
Definition. Let $K = (V, S)$ and $L = (W, T)$ be abstract simplicial complexes.

1. A simplicial map $f: K \to L$ is defined as a map $f: V \to W$ such that for every $s \in S$ we have $f(s) \in T$. In particular a simplicial map induces a map $S \to T$.

2. A simplicial isomorphism between $K = (V, S)$ and $L = (W, T)$ is a simplicial map that is a bijection on the set of vertices and on the set of simplices.

Examples.

1. The identity map of $U = \{A, B, C\}$ defines a simplicial map from $X = (U, S)$ to $Y = (U, T)$.

2. The map $f: \{0, 1, 2\} \to \{A, B, C\}$ given by $f(0) = A$, $f(1) = B$ and $f(2) = C$ defines a simplicial isomorphism between $D_2$ and $(U, T)$ and it defines a simplicial isomorphism between $S_1$ and $(U, S)$. Similarly one sees that the abstract simplicial complex $R_3$ is simplicially isomorphic to $S_1$ and $(U, S)$.

3. The inclusion of a subcomplex into an abstract simplicial complex is, basically by definition, a simplicial map.

It is clear that the composition of simplicial maps is again a simplicial map. Thus it makes sense to introduce the following definition.

Definition. We call the category $\text{AbsSimpCplx}$ with

$$\text{Ob}(\text{AbsSimpCplx}) := \text{all abstract simplicial complexes},$$

$$\text{Mor}(K, L) := \text{all simplicial maps from } K \text{ to } L,$$

together with the usual composition of maps the category of abstract simplicial complexes.

For future reference let us record the following lemma.

Lemma 61.3. Let $K$ and $L$ be two abstract simplicial complexes.

1. If $K$ and $L$ are finite, then there exist only finitely many simplicial maps from $K$ to $L$.

2. If $K$ is finite and if $L$ is countable, then there exist only countably many simplicial maps from $K$ to $L$.

Proof.

1. This statement is obvious.

2. Let $K = (V, S)$ and $L = (W, T)$ be two abstract simplicial complexes. We assume that $K$ is finite and that $L$ is countable. It follows from Lemma 1.7 (6) that there exist only countably many maps $V \to W$. Furthermore, since $V$ is finite we see that given any map $V \to W$ there are only finitely many maps $S \to T$ such that the resulting map is a simplicial map. It follows from Lemma 1.7 (3) that there are indeed only countably many simplicial maps. □

Remark. The reader might have a certain sense of déjà vu: the definition of a 1-dimensional abstract simplicial complex sounds very similar to the definition of an undirected abstract graph which we gave on page 226. In fact some thought shows that the concepts are different since undirected graphs are more flexible. But once we rule out loops and multi-edges (see Figure 893 for a pictorial reminder of the definitions), then the concepts are basically
the same. More precisely it follows easily from the definitions that the maps
\[ (V, E, \varphi: E \to \mathcal{P}(V)) \quad \mapsto \quad (V, \varphi(E)) \quad \text{and} \quad (V, S \subseteq \mathcal{P}(V)) \quad \mapsto \quad (V, S, \text{id}: S \to \mathcal{P}(V)) \]
define an isomorphism between the “category of undirected abstract graphs without loops and multi-edges” and the “category of 1-dimensional simplicial complexes”.

![Figure 893](image)

61.2. **Ordered abstract simplicial complexes.** We recall the following definition from page 77.

**Definition.**

1. A relation that is reflexive, transitive and antisymmetric is called a *partial order*.
2. A *partially ordered set* is a set together with a partial order.
3. A partial order that is connex is called a *total order*.
4. A *totally ordered set* is a set together with a total order.
5. In a totally ordered set \((P, \leq)\) we write \(a < b\) if \(a \leq b\) and \(a \neq b\).

**Examples.**

1. Let \(X\) be a set. We consider the power set \(\mathcal{P}(X)\). The relation “\(\subseteq\)” is a partial order on \(\mathcal{P}(X)\).
2. The usual relation “\(\leq\)” on \(\mathbb{Z}\) turns \(\mathbb{Z}\) into a totally ordered set.
3. Any subset of \(\{A, B, \ldots, Z\}\) with the usual alphabetical ordering is a totally ordered set.

We continue with the following definition.

**Definition.**

1. A *total order* on an abstract simplicial complex \((V, S)\) is a total order on the vertex set \(S\).
2. An *order* on an abstract simplicial complex \((V, S)\) is a partial order on \(V\) which has the property that the restriction to each simplex is actually a total order.
3. An *ordered abstract simplicial complex* is an abstract simplicial complex together with an order.

**Remark.**

1. Every totally ordered abstract simplicial complex is automatically also an ordered simplicial complex.
2. By the Well-ordering Theorem we know that every set admits a total ordering. Thus every abstract simplicial complex can be turned into a totally ordered abstract simplicial complex.
The following definition is the obvious variation on the definition provided on page 1483.

**Definition.** We call the category $C$ with

$\text{Ob}(C) :=$ all ordered abstract simplicial complexes,

$\text{Mor}(K, L) :=$ all order-preserving simplicial maps from $K$ to $L$,

together with the usual composition of maps the category $\text{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes.

61.3. **The topological realization of an abstract simplicial complex.** Since we are topologists we want to study abstract simplicial complexes with topological methods. The idea is to associate to an abstract simplicial complex a corresponding topological space. Before we can do so we need to introduce the following notation which is inspired by the definition of the free abelian group $\mathbb{Z}^{(S)}$ that we gave on page 580.

**Notation.**

1. Given any set $V$ we write

$\mathbb{R}^V :=$ all maps from $V$ to $\mathbb{R}$

$\mathbb{R}^{(V)} :=$ all maps from $V$ to $\mathbb{R}$ which are non-zero for only finitely many $v \in V$.

We have the following conventions and observations:

(a) Given $v \in V$ we sometimes denote by $v$ also the map $v \mapsto 1$ and $w \mapsto 0$ for $w \neq v$.

(b) One can easily verify that with this interpretation the set $V$ forms a basis for the real vector space $\mathbb{R}^{(V)}$.

(c) If $V = \{v_1, \ldots, v_n\}$ is a finite set, then the map $v_i \mapsto e_i$ defines an isomorphism from $\mathbb{R}^V = \mathbb{R}^{(V)}$ to $\mathbb{R}^n$. In particular, if $V$ is a finite set with a total order, then it follows from Exercise 1.1 that we have a natural isomorphism $\mathbb{R}^V \xrightarrow{\cong} \mathbb{R}^{|V|}$.

2. If $V$ is a subset of some set $W$, then we view $\mathbb{R}^{(V)}$ as a subset of $\mathbb{R}^{(W)}$ in the obvious way.

The following definition is the first step in our shift back to topology.

**Definition.** Let $K = (V, S)$ be some abstract simplicial complex. For a given $n$-simplex $s = \{v_0, \ldots, v_n\}$ we define

$|s| := \left\{ \alpha \in \mathbb{R}^{(V)} \mid \begin{align*}
(1) & \alpha(v) \geq 0 \text{ for all } v \in s \\
(2) & \alpha(v) = 0 \text{ for all } v \notin s \\
(3) & \text{ we have } \sum_{v \in V} \alpha(v) = 1 \end{align*} \right\} = \left\{ \sum_{i=0}^{n} t_i \cdot v_i \mid \begin{align*}
(1) & \text{ for each } i \text{ we have } t_i \geq 0 \\
(2) & t_0 + \cdots + t_n = 1 \end{align*} \right\}$

Furthermore we set

$|K| := \bigcup_{s \in S} |s| \subset \mathbb{R}^{(V)}$.

Sometimes, by a serious abuse of language, we refer to $|s|$ as a $n$-simplex in $|K|$.

**Examples.**
(1) We consider the abstract simplicial complexes \( X = (U, S) \) and \( Y = (U, T) \) as above. The corresponding sets \( |X| \) and \( |Y| \) are the subsets of \( \mathbb{R}^U = \mathbb{R}^{(A, B, C)} = \mathbb{R}^3 \) that are shown in Figure 894.

(2) Let \( n \in \mathbb{N} \). Given the abstract simplicial complex \( R_n \) the corresponding set \( |R_n| \) is a subset of \( \mathbb{R}^{Z^n} = \mathbb{R}^{n-1} \). This means that for \( n \geq 5 \) we have serious problems with visualizing the set \( |R_n| \). The problem is even bigger for the infinite abstract simplicial complex \( R_\infty \).

![Figure 894](image)

**Lemma 61.4.** Given any abstract simplicial complex \( K = (V, S) \) we have

\[
|K| = \left\{ \alpha \in \mathbb{R}^{(V)} \mid \begin{array}{l}
(1) \text{ the set } \{ v \in V \mid \alpha(v) \neq 0 \} \text{ is a simplex of } K \\
(2) \text{ for every } v \in V \text{ we have } \alpha(v) \geq 0 \\
(3) \text{ we have } \sum_{v \in V} \alpha(v) = 1
\end{array} \right\}.
\]

**Proof.** We leave the elementary task of proving the equality to the reader. Note though that one actually needs to use that \( K = (V, S) \) is an abstract simplicial complex. \( \blacksquare \)

Note that as of right now \( |K| \) is just a set. But rest assured, we will equip \( |K| \) with a suitable topology shortly. But first let us introduce a convention.

**Convention.** Let \( K = (V, S) \) be an abstract simplicial complex. As discussed above, we can view \( V \) as a subset of \( \mathbb{R}^{(V)} \). In fact it follows easily from the definitions that \( V \subset |K| \). Throughout these notes we use this observation to view \( V \) as a subset of \( |K| \).

We continue with the following definition.

**Definition.** Let \( K = (V, S) \) be an abstract simplicial complex. Let \( k \in \mathbb{N}_0 \) and let \( s \) be a \( k \)-simplex.

(1) If \( v_0 \leq \cdots \leq v_k \) is a total order on the set of vertices of \( s \), then we refer to the map

\[
\Phi_s : \Delta^k = \left\{ (t_0, \ldots, t_k) \in \mathbb{R}_{\geq 0}^{k+1} \mid \sum_{i=0}^k t_i = 1 \right\} \to |K|
\]

\[(t_0, \ldots, t_k) \mapsto \sum_{i=0}^k t_i \cdot v_i\]

as a **characteristic map of the simplex** \( s \).
(2) If $K$ is actually an ordered abstract simplicial complex, then we use the corresponding order on $s$ and we write $\Phi_s^\leq: \Delta^k \to |K|$. In this case we can refer to $\Phi_s^\leq$ unambiguously as the characteristic map of the simplex $s$.

**Remark.**

(1) Note that if in the above definition of a characteristic map we use two different orderings of the vertices of $s$, then we get two maps $\Phi, \Psi: \Delta^k \to |K|$ with the same image and such that $\Psi^{-1} \circ \Phi: \Delta^k \to \Delta^k$ is a homeomorphism. In other words, any two characteristic maps differ by precomposing by a homeomorphism. In practice this means that any two characteristic maps exhibit the same properties and we do not need to distinguish between different characteristic maps.

(2) Given a $k$-simplex $s$ we have, by definition, $\Phi_s(s) = |s|$.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex.

(1) We say that a subset $U \subset |K|$ is open if for every simplex $s$ of $K$ the preimage $\Phi_s^{-1}(U)$ under a characteristic map $\Phi_s$ is open. An argument as in Exercise 2.35 shows that this defines a topology on $|K|$.

(2) We refer to the set $|K|$, together with this topology, as the topological realization of $K$.

The following lemma summarizes a few basic properties of the topological realization of an abstract simplicial complex.

**Lemma 61.5.** Let $K$ be an abstract simplicial complex.

(1) A subset $A \subset |K|$ is closed if and only if for every simplex $s$ of $K$ the preimage $\Phi_s^{-1}(A)$ under a characteristic map $\Phi_s$ is closed.

(2) The topological realization $|K|$ is Hausdorff.

(3) For every $k$-simplex $s = \{v_0, \ldots, v_k\}$ of $K$ any characteristic map $\Phi_s: \Delta^k \to |K|$ is a closed embedding. In particular the map $\Phi_s: \Delta^k \to |s|$ is a homeomorphism.

**Proof.** Let $K = (V, S)$ be an abstract simplicial complex.

(1) This statement follows almost immediately from the definition of the topology on $|K|$ together with the elementary Lemma 1.3(7).

(2) Let $P$ and $Q$ be two disjoint points on $|K|$. Given $f, g \in \mathbb{R}^{|V|}$ we write

$$d(f, g) := \sqrt{\sum_{v \in V} (f(v) - g(v))^2}.$$  

One can easily verify that this is a metric on $\mathbb{R}^{|V|}$. By Proposition 2.11 we know that there exists an $\epsilon > 0$ such that the open $\epsilon$-balls $B_\epsilon(P)$ and $B_\epsilon(Q)$ are disjoint in $\mathbb{R}^{|V|}$. It remains to show that $B_\epsilon(P) \cap |K|$ and $B_\epsilon(Q) \cap |K|$ are open in $|K|$. By definition of the topology on $|K|$ we need to prove the following claim.

**Claim.** Let $U := B_\epsilon(R)$ be an $\epsilon$-ball in $\mathbb{R}^{|V|}$. For every simplex $s$ the preimage $\Phi_s^{-1}(U \cap |K|)$ under a characteristic map $\Phi_s$ is open.

---

---
Let \( s = \{v_0, \ldots, v_k\} \) be a \( k \)-simplex. We make the following observations:

(a) We have \( \Phi^{-1}_s(U \cap |K|) = \Phi^{-1}_s(U) \).

(b) It follows from (a) and the observation that \( U \) is an open subset of the topological space \((\mathbb{R}(V), d)\) that it suffices to show that the map \( \Phi_s: \Delta^k \to (\mathbb{R}(V), d) \) is continuous.

(c) We view \( \Phi_s: \Delta^k \to \mathbb{R}(V) \) as the composition of the maps

\[
\Delta^k \xrightarrow{\Phi_s} \mathbb{R}^{k+1} = \mathbb{R}^{(s)} \hookrightarrow \mathbb{R}(V).
\]

We consider the two maps separately.

(i) Note that \( \mathbb{R}^{k+1} = \mathbb{R}^{(s)} \) is a finite-dimensional vector space and that the map \( \Phi_s: \Delta^k \to \mathbb{R}^{(s)} \) is an affine linear map. It follows almost immediately from Lemma 41.1 that this map is continuous.

(ii) It follows easily from the definition of topology on \( \mathbb{R}^{k+1} \), via the usual Euclidean metric, and the definition of the metric \( d \) on \( \mathbb{R}(V) \), together with the simple-minded Exercise 2.14 (a), that the map \( \mathbb{R}^{k+1} = \mathbb{R}^{(s)} \to \mathbb{R}(V) \) is continuous.

Thus we see that the map \( \Phi_s: \Delta^k \to (\mathbb{R}(S), d) \) itself is continuous.

(3) Let \( s \) be a \( k \)-simplex of \( K \). It follows almost immediately from the definitions that the map \( \Phi_s: \Delta^k \to |K| \) defines a bijection \( \Phi_s: \Delta^k \to |s| \). It follows immediately from the definition of the topology on \( |K| \) that \( \Phi_s \) is continuous. Evidently \( \Delta^k \) is compact. By (1) we know that \( |K| \) is Hausdorff. So once again Proposition 2.43 (2) rides to our rescue and tells us that \( \Phi_s \) is indeed an embedding and that the image is a closed subset.

The following is the simplicial analogue of the corresponding Lemma 36.7 for CW-complexes.

**Lemma 61.6.** Let \( K = (V, S) \) be an abstract simplicial complex and let \( f: |K| \to X \) be a map to some topological space \( X \).

1. If for each \( k \)-simplex \( s \in S \) with characteristic map \( \Phi_s: \Delta^k \to |K| \) the composition \( f \circ \Phi_s: \Delta^k \to X \) is continuous, then the map \( f \) is continuous.

More generally we have the following continuity criterion:

2. If for each simplex \( s \in S \) there exists a \( k \)-simplex \( t \) with \( s \subset t \) such that for some characteristic map \( \Phi_t: \Delta^k \to |K| \) the composition \( f \circ \Phi_t: \Delta^k \to X \) is continuous, then the map \( f \) is continuous.

**Proof.**

1. This statement follows immediately from the definition of the topology on \( |K| \).

2. This statement follows immediately from (1) and the observation that characteristic maps are continuous.

The following proposition shows that not only do abstract simplicial complexes give rise to topological spaces, but simplicial maps also give rise to continuous maps between the topological realizations.
**Proposition 61.7.**

(1) If \( f: K = (V,S) \to L = (W,T) \) is a simplicial map, then the map
\[
|f|: |K| \to |L|
\]
\[
\left( \alpha: V \to \mathbb{R} \right) \mapsto \left( \begin{array}{c} W \to \mathbb{R} \\ w \mapsto \sum_{v \in f^{-1}(w)} \alpha(v) \end{array} \right)
\]
is well-defined and continuous. We refer to Figure 895 for an illustration.

(2) Let \( \text{AbsSimpCplx} \) be the category of abstract simplicial complexes. The maps
\[
K \mapsto |K|
\]
\[
(f: K \to L) \mapsto (|f|: |K| \to |L|)
\]
define a covariant functor from the category \( \text{AbsSimpCplx} \) of abstract simplicial complexes to the category \( \text{Top} \) of topological spaces.

**Remark.**

(1) Let \( f: K = (V,S) \to L = (W,T) \) be a simplicial map. It is elementary to see that, given a simplex \( s = \{v_0, \ldots, v_k\} \) of \( K \), the restriction of \( |f| \) to \( |s| \subset |K| \) is the map
\[
|f|: |s| \to |f(s)|
\]
\[
\sum_{i=0}^{k} t_i \cdot v_i \mapsto \sum_{i=0}^{k} t_i \cdot f(v_i).
\]

(2) As we will see, the proof of Proposition 61.7 (1) is slightly delicate since the topology of the topological realization of a simplicial complex is designed, see Lemma 61.6, in such a way that it is straightforward to verify that a map \textit{out} of the topological realization is continuous. It is much less clear how one can show that a map \textit{to} a topological realization is continuous. The same health-warning applies also to CW-complexes.

**Proof.**

(1) Let \( f: K = (V,S) \to L = (W,T) \) be a simplicial map. A priori we have written down a map \( |f|: |K| \to \mathbb{R}^{|W|} \). But it is straightforward to verify, e.g. using Lemma 61.4, that the map \( |f| \) does indeed take values in the subset \( |L| \). It remains to show that \( |f|: |K| \to |L| \) is continuous. By Lemma 61.6 (1) it suffices to show that for each \( m \)-simplex \( s \in S \) with some characteristic map \( \Phi_s: \Delta^m \to |K| \) the composition \( f \circ \Phi_s: \Delta^m \to |L| \) is continuous.
Thus suppose we are given such \( s \) and \( \Phi_s \). We write \( t := f(s) \). By definition of a simplicial map we know that \( t \) is some \( n \)-simplex of \( T \). For clarity we consider the following commutative diagram:

\[
\begin{array}{ccc}
\Phi_s & \rightarrow & |K| \\
\Phi_s \downarrow & & \downarrow |f| \\
\Delta^n & \Rightarrow & |L| \\
\end{array}
\]

\[
\begin{array}{ccc}
\Delta^n & \Rightarrow & |s| \\
\Phi_t \downarrow & & \downarrow |t| \\
\Phi_t^{-1} \circ |f| \circ \Phi_s & \rightarrow & \Delta^n.
\end{array}
\]

We make the following clarifications and observations:

(a) We define \( |s| \subset |K| \) and \( |t| \subset |L| \) as in Lemma 61.5 (3). We equip both with the subspace topology coming from \( |K| \) and \( |L| \). By the super elementary Lemma 2.30 (2) we know that the inclusion maps \( i: |s| \rightarrow |K| \) and \( j: |t| \rightarrow |L| \) are continuous.

(b) It follows immediately from the definition of \( |f| \) that the restriction of \( |f| \) to \( |s| \) takes values in \( |t| \).

(c) We picked a characteristic map \( \Phi_t: \Delta^n \rightarrow |t| \) for \( t \).

(d) By Lemma 61.5 (3) we know that the characteristic map \( \Phi_t: \Delta^n \rightarrow |t| \) is a homeomorphism. In particular the inverse \( \Phi_t^{-1}: |t| \rightarrow \Delta^n \) exists and it is continuous.

(e) It follows almost immediately from the definitions of the maps \( \Phi_s, \Phi_t \) and \( |f| \) that the map \( \Phi_t^{-1} \circ |f| \circ \Phi_s: \Delta^n \rightarrow \Delta^n \) is an affine linear map. Hence it follows, say from Lemma 41.1, that the map is continuous.

(f) It follows immediately from the above that the map

\[
|f| \circ \Phi_s = j \circ \Phi_t \circ (\Phi_t^{-1} \circ |f| \circ \Phi_s): \Delta^n \rightarrow Y
\]

is indeed continuous.

(2) Let \( f: K \rightarrow L \) and \( g: L \rightarrow M \) be simplicial maps. For any vertex \( v \) of \( M \) we have \( f^{-1}(g^{-1}(v)) = (g \circ f)^{-1}(v) \). It follows immediately from this observation that \( |g| \circ |f| = |g \circ f| \). It is now straightforward to see that the given maps define a covariant functor. \( \blacksquare \)

The following lemma can be viewed as an analogue of Lemma 36.18.

**Lemma 61.8.** Let \( K = (V, S) \) be a subcomplex of some given abstract simplicial complex \( L = (W, T) \).

1. The inclusion \( \mathbb{R}^{|V|} \rightarrow \mathbb{R}^{|W|} \) restricts to an inclusion \( |K| \rightarrow |L| \).
2. The inclusion \( |K| \rightarrow |L| \) is a closed embedding.
3. Let \( \{K_i\}_{i \in I} \) be a family of subcomplexes of an abstract simplicial complex \( K \). Then

\[
|\bigcap_{i \in I} K_i| := \bigcap_{i \in I} |K_i| \quad \text{and} \quad |\bigcup_{i \in I} K_i| := \bigcup_{i \in I} |K_i|.
\]

are subcomplexes of \( K \).
**Remark.** The statement and the proof of Lemma 61.8 is closely related to the content of Lemma 36.18.

**Convention.** Let $K = (V, S)$ be a subcomplex of some given abstract simplicial complex $L = (W, T)$. We will use Lemma 61.8 to view $|K|$ as a subset of $|L|$. By Lemma 61.8 (2) we know that $|K|$ is in fact a closed subset of $|L|$.

**Proof.** Let $L = (W, T)$ be a simplicial complex and let $K = (V, S)$ be a subcomplex. We denote by $i: K \to L$ the inclusion map.

1. It follows immediately from the definitions that the inclusion $\mathbb{R}^{|V|} \to \mathbb{R}^{|W|}$ restricts to an inclusion $|K| \to |L|$.
2. This statement also follows immediately from the definitions. For readers who want to fill in the details, perhaps it is clearest to look at the description given in Lemma 61.4.
3. Since $i: K \to L$ is a simplicial map we obtain from Proposition 61.7 (1) that the induced map $|i|: |K| \to |L|$ is continuous. Furthermore it follows easily from the definitions that the map $|i|: |K| \to |L|$ is in fact just the inclusion. In the remainder of the proof we will view $|K|$ as a subset of $|L|$.

By Lemma 2.42 (1) it remains to show that the inclusion $|K| \to |L|$ is a closed map. Thus let $A \subset |K|$ be a closed subset. We need to show that $A$ is also a closed subset of $|L|$. By Lemma 61.5 (1) and (3) it suffices to show that for each $t \in T$ the set $A \cap |t|$ is closed. Note that every simplex, in particular $t$ itself, has only finitely many faces. Let $f_1, \ldots, f_m$ be the faces of $t$ that are contained in $K$. We consider the subsets $|f_1|, \ldots, |f_m|$ of $|K|$ and the subset $|t|$ of $|L|$ as defined on page 1485. We make the following observation:

(*) It follows from Lemma 61.5 that the subspace topologies on $|f_i|$ coming from $|f_i| \subset |K|$ and $|f_i| \subset |t|$ of $|L|$ agree and that $|f_i|$ is a closed subset of $|K|$ and a closed subset of $|t|$.

We have

1. $A \cap |t| = A \cap (|K| \cap |t|)$
2. $\uparrow$ since $A \subset |K|$
3. $= A \cap \bigcup_{i=1}^m |f_i|$ (by Lemma 2.38 (2) since by Lemma 61.5 (3) we know that the $|f_i|$ are closed subsets of $|t|$)
4. $= \bigcup_{i=1}^m (A \cap |f_i|)$ (this follows from (3) since $K$ is a subcomplex)
5. $= \bigcup_{i=1}^m$ closed subset of $|f_i|$ (since $A$ is closed in $|K|$ and since $f_1, \ldots, f_m \in S$ are simplices of $K$)
6. $= \bigcup_{i=1}^m$ closed subset of $|t|$ = closed subset of $|t|$.

\[ \square \]

**Figure 896.** Illustration for the proof of Lemma 61.8.
Example. Let $n \in \mathbb{N}$. We consider again the simplicial complex $D_n$ and its subcomplex $S_{n-1}$. It follows almost immediately from Lemma 61.5 (3) that the map
\[ \Psi : |D_n| \to \Delta^n \]
\[ \sum_{i=0}^{n} t_i \cdot \{i\} \mapsto (t_0, \ldots, t_n) \]
is a homeomorphism. By Proposition 61.7 (2) the map $|S_{n-1}| \to |D_n|$ is an embedding. Thus $\Psi$ restricts to a homeomorphism $\Psi|_{S_{n-1}} : |S_{n-1}| \to \Psi(|S_{n-1}|)$ but basically by definition we have $\Psi(|S_{n-1}|) = \partial \Delta^n$. This shows that $|S_{n-1}|$ is homeomorphic to $\partial \Delta^n$.

Before we consider some examples we want to consider the topology for finite abstract simplicial complexes in greater detail. We recall that given any finite set $X$ the vector space $\mathbb{R}^{|X|}$ is a finite-dimensional vector space. Furthermore recall that by the discussion on page 116 we know that any finite-dimensional real vector space has a natural topology.

**Lemma 61.9.** Let $K = (V, S)$ be an abstract simplicial complex. If $K$ is finite, then the following two conclusions hold:

1. The topological realization $|K|$ is compact.
2. The topology of the topological realization $|K|$, defined on page 1487, agrees with the subspace topology which we obtain from viewing $|K|$ as a subset of the finite-dimensional real vector space $\mathbb{R}^V$.

**Proof.** Let $K = (V, S)$ be a finite abstract simplicial complex.

1. By Lemma 61.5 we know in particular that for each $k$-simplex $s$ the characteristic map $\Phi_s : \Delta^k \to |K|$ is continuous. Since $\Delta^k$ is compact we obtain from Lemma 2.40 that $|s| = \Phi_s(\Delta^k)$ is compact. By definition $|K|$ is the union of all the subsets $|s|$. Thus, since $K$ is finite we see that $|K|$ is the union of finitely many compact subsets. By Lemma 2.16 (1) this implies that $|K|$ itself is compact.

2. We write $V = \{v_1, \ldots, v_n\}$ and we identify the vector spaces $\mathbb{R}^V$ and $\mathbb{R}^n$ in the obvious way. We denote by $\mathcal{T}$ the topology on $|K|$ defined above and we denote by $\mathcal{R}$ the subspace topology which comes from $\mathbb{R}^V$. We need to show that the identity map defines a homeomorphism $(|K|, \mathcal{T}) \to (|K|, \mathcal{R})$. We make the following observations:

   a. For any $k$-simplex $s \in S$ and any characteristic map $\Phi_s : \Delta^k \to |s|$ the corresponding map $\Delta^k \xrightarrow{\Phi_s} |s| \to |K| \to \mathbb{R}^V = \mathbb{R}^n$ is an affine linear map. It follows from Lemma 41.1 that this map is continuous. It follows from this observation together with Lemma 61.6 (1) that the map $(|K|, \mathcal{T}) \to (|K|, \mathcal{R})$ is continuous.

   b. In (1) we just argued that $(|K|, \mathcal{T})$ is compact.

   c. The topological space $(|K|, \mathcal{R})$ is evidently Hausdorff.

   It follows from Proposition 2.43 (3) that the identity map is indeed a homeomorphism.

As we already noted above, the topological realizations of abstract simplicial complexes have a voracious appetite for dimensions. Fortunately, as well see shortly, in many cases we can reduce the dimensions drastically.
Lemma 61.10. Let $K = (V, S)$ be a finite abstract simplicial complex and let $\varphi : \mathbb{R}^V \to \mathbb{R}^n$ be a linear map such that the restriction of $\varphi$ to $|K|$ is an injection. Then $\varphi : |K| \to \mathbb{R}^n$ is an embedding.

Proof. By Lemma 61.9 (1) we know that $|K|$ is compact. Furthermore, note that it follows from Lemma 61.9 (2) that the linear map $\varphi : \mathbb{R}^V \to \mathbb{R}^n$ restricts to a continuous map $\varphi : |K| \to \mathbb{R}^n$. Since $\mathbb{R}^n$ is Hausdorff it follows from Proposition 2.43 (2) that $\varphi : |K| \to \mathbb{R}^n$ is indeed an embedding.

Example.

1. Let $n \in \mathbb{N}_{\geq 3}$. As above we consider the abstract simplicial complex $R_n$. We consider the linear map $\varphi : \mathbb{R}^{Z_n} \to \mathbb{R}^2$ that is given by $[k] \mapsto e^{2\pi i k/n}$. One can easily verify that the restriction of $\varphi$ to $|R_n|$ is an injection. Thus we see that $|R_n|$ is homeomorphic to the regular $n$-gon that is shown in Figure 897.

![Figure 897](regular_5-gon_in_R2)

2. Using Proposition 2.43 one can formulate a suitable generalization of Lemma 61.10 to infinite abstract simplicial complexes. We will not work this out in detail, but using this approach one can fairly easily show that the topological realization of the abstract simplicial complex $R_\infty$ is homeomorphic to $\mathbb{R}$. We refer to Figure 898 for a very convincing illustration of this fact.

![Figure 898](regular_infinite_5-gon_in_R2)

Given an $n$-simplex $s$ of an abstract simplicial complex $K = (V, S)$ we defined on page 1487 the corresponding subset $|s| \subset |K|$, which, somewhat dangerously, we referred to as an $n$-simplex of $|K|$. The following definition gives us a convenient variation on that definition.

Definition. Let $K = (V, S)$ be an abstract simplicial complex. If we are given an $n$-simplex $s = \{v_0, \ldots, v_n\} \in S$, then we refer to\textsuperscript{939} $\langle s \rangle := \{ \alpha \in \mathbb{R}^V | (1) \alpha(v) > 0 \text{ for all } v \in s, \quad (2) \alpha(v) = 0 \text{ for all } v \notin s, \quad (3) \text{ we have } \sum_{v \in V} \alpha(v) = 1 \}$ as the corresponding open $n$-simplex of $|K|$.

\textsuperscript{939}Here we use the convention of page 1486 which allows us to view $V$ as a subset of $\mathbb{R}^V$. 

The following lemma summarizes a few properties of open simplices.
Lemma 61.11. Let $K = (V, S)$ be an abstract simplicial complex.

1. Let $s \in S$ be a $k$-simplex.
   - (a) The closure of the open simplex $\langle s \rangle$ is given by $|s|$.
   - (b) Every characteristic map $\Phi_s : \Delta^k \to |s|$ restricts to a homeomorphism $\Delta^k \to \langle s \rangle$.
2. The topological realization $|K|$ is the disjoint union of the open simplices, i.e.
   $$|K| = \bigcup_{s \in S} \langle s \rangle.$$

Put differently, given any $\alpha \in |K|$ there exists a unique simplex $s$ with $\alpha \in \langle s \rangle$.

3. For two distinct simplices $s \neq t$ we have $\langle s \rangle \cap \langle t \rangle = \emptyset$.
4. The union of the open simplices is precisely $|K|$.
5. If $J = (U, R)$ is a subcomplex of $K$, then
   $$|J| = \bigcup_{r \in R} \langle r \rangle = \bigcup_{r \in R} |r|$$
   and for any $s \in S \setminus R$ we have $|J| \cap \langle s \rangle = \emptyset$.

In particular, if $s$ is a simplex of $K$ with $\langle s \rangle \cap |J| \neq \emptyset$, then $s$ is a simplex of $J$ which implies that $|s| \subset |J|$.

6. Let $s$ and $t$ be simplices. If $|s| \subset |t|$, then $s \subset t$. In particular, either $\dim(s) < \dim(t)$ or $s = t$.
7. Let $s \in S$ be a simplex. If $U \subset |K|$ is an open subset with $U \cap |s| \neq \emptyset$, then $U \cap \langle s \rangle \neq \emptyset$.

Proof (*).

1. Let $s \in S$ be a $k$-simplex and let $\Phi_s : \Delta^k \to |s|$ be a characteristic map. By Lemma 61.5 (3) we know that the map $\Phi_s : \Delta^k \to |s|$ is a homeomorphism and that $|s|$ is a closed subset of $|K|$. By definition we have $\langle s \rangle \subset |s|$.

   (b) It is clear that $\Phi_s$ restricts to a bijection $\Delta^k \to \langle s \rangle$. Thus it follows immediately that $\Phi_s$ restricts to a homeomorphism $\Delta^k \to \langle s \rangle$.

   (a) Since $|s|$ is a closed subset of $|K|$ we see that the closure of $\langle s \rangle$ in $|K|$ is contained in $|s|$. It is elementary to see that $\Delta^k$ is the closure of $\Delta^k$. Since $\Phi_s : \Delta^k \to |s|$ is a homeomorphism it follows almost immediately that $|s| = \Phi_s(\Delta^k)$ is indeed the closure of $\langle s \rangle = \Phi_s(\Delta^k)$.

2. Let $\alpha \in |K|$. We set $s := \{ v \in V \mid \alpha(v) \neq 0 \}$. By definition of $|K|$ we know that $s$ is a simplex. Evidently $\alpha \in \langle s \rangle$ and evidently $s$ is unique.

3. This statement follows immediately from (1).

4. Conveniently enough this statement also follows immediately from (1).
(5) Let $J$ be a subcomplex of $K$. If $r \in R$, then evidently we have $\langle r \rangle \subset |r| \subset |J|$. Keeping (1) in mind we see that it remains to show that if we have $s \in S$ with $|J| \cap \langle s \rangle \neq \emptyset$, then $s \in R$. Thus let $s$ be a simplex of $K$ with $|J| \cap \langle s \rangle \neq \emptyset$. It follows from (1), applied to the abstract simplicial complex $J = (U, \mathcal{R})$, that there exists a simplex $r$ of $J$ with $\langle s \rangle \cap \langle r \rangle \neq \emptyset$. But since $r$ is also a simplex of $K$ we obtain from (1), applied to $K$, that $s = r \in R$.

(6) Let $s$ and $t$ be simplices with $|s| \subset |t|$. We apply (4) to the subcomplex that is defined by $s$. We immediately obtain that $s \subset t$. If $s \subsetneq t$, then by definition we have $\dim(s) = \#S - 1 < \#T - 1 = \dim(t)$.

(7) Let $s \in S$ be a $k$-simplex and let $U \subset |K|$ be an open subset with $U \cap |s| \neq \emptyset$. Let $\Phi_s: \Delta^k \rightarrow |s|$ be a characteristic map. By definition of the topology on $|K|$ and by our hypothesis we know that $\Phi_s^{-1}(U)$ is a non-empty open subset of $\Delta^k$. It is elementary to see that $\Phi_s^{-1}(U) \cap \Delta^k \neq \emptyset$. It now follows from (1b) that $U \cap \langle s \rangle \neq \emptyset$. \hfill \blacksquare

The following proposition reminds us of Theorem 36.14 which gives an analogous statement for CW-complexes. The proposition can also be viewed as a converse to Lemma 61.9 (1).

**Proposition 61.12.** Let $L$ be an abstract simplicial complex.

1. If $X \subset |L|$ is a compact subset, then there exists a finite subcomplex $K$ of $L$ such that $X \subset |K|$.
2. If $|L|$ is compact, then $L$ is a finite abstract simplicial complex.

**Remark.** Let $K$ be an abstract simplicial complex. Lemma 61.9 (1) together with Proposition 61.12 shows that $|K|$ is compact if and only if $K$ is finite. Later on in Proposition 62.6 we will prove the related result that $|K|$ is regionally compact if and only if $K$ is “locally finite”.

**Proof.** Let $L = (W, \mathcal{T})$ be an abstract simplicial complex. Clearly (2) is just a special case of (1). Thus it suffices to prove (1). Now let $X \subset |L|$ be a compact subset. For each simplex $t$ of $L$ with $\langle t \rangle \cap X \neq \emptyset$ we pick a point $y_t \in \langle t \rangle \cap X$. We denote by $Y$ the set given by all the $y_t$. We equip $Y$ with the subspace topology coming from $|L|$.

**Claim.**

1. Every subset of $Y$, in particular $Y$ itself, is a closed subset of $|L|$.
2. $Y$ is a discrete subset of $|L|$.

We turn to the proof of the two statements.

1. Let $A \subset Y$ be a subset. We need to show that $A$ is a closed subset of $|L|$. By Lemma 61.5 (1) and (3) it suffices to show that for every simplex $t$ of $|L|$ the intersection $A \cap |t|$ is closed. By Lemma 61.11 (5) we know that $|t|$ intersects only the interiors of the simplices $s$ with $s \subset t$. Since there are only finitely many simplices contained in $t$ we see that $A \cap |t|$ is finite, in particular it is compact. By Lemma 61.5 \footnote{This finiteness statement makes the proof of this proposition significantly simpler than the technically slightly tricky proof of Theorem 36.14}
We claim that $\mathcal{A}$ is Hausdorff. Hence we obtain from Lemma 2.17(2) that $A \cap |t|$ is indeed closed.

(2) We need to show that the subspace topology of $Y$ is the discrete topology. It follows from (1) and Lemma 2.4 that every subset of $Y$ is in fact a closed subset of $Y$. But this implies that every subset of $Y$ is in fact an open subset of $Y$. In other words, the subspace topology is indeed the discrete topology. □

It follows from (1) and the definition of the subspace topology that $Y$ is a closed subset of the compact set $X$. Furthermore by (2) we know that $Y$ is a discrete subset of $|L|$. Since $Y \subset X \subset |L|$ we see that $Y$ is also a discrete subset of $X$. Since $X$ is compact we obtain from Lemma 2.18 that $Y$ is finite.

We define $S := \{ t \in T | X \cap \langle t \rangle \neq \emptyset \}$. Note that $|S| = |Y|$. Thus, by the above discussion we know that $S$ is finite. Now we set $K$ to be the subcomplex that is given the union of all the simplices $t \in S$.

Since $t$ is finite we see that $K$ is a finite subcomplex. Now we have

\[
\begin{align*}
\text{Lemma 61.11 (4)} & \quad \text{by definition of } t \\
X & = X \cap \bigcup_{t \in S} \langle t \rangle = \bigcup_{t \in S} X \cap \langle t \rangle \subset \bigcup_{t \in S} \langle t \rangle \subset \bigcup_{t \in S} |s| = |K|.
\end{align*}
\]

\[\text{Figure 900. Illustration for the proof of Proposition 61.12}\]

We conclude this section with the following lemma which gives a criterion for a subset of a simplicial complex to be a subcomplex.

**Lemma 61.13.** (*) Let $L = (W, T)$ be an abstract simplicial complex and let $X \subset |L|$ be a closed subset. If for every simplex $t \in T$ we have either $\langle t \rangle \cap X = \emptyset$ or $\langle t \rangle \subset X$, then there exists a subcomplex $K$ of $L$ with $|K| = X$.

**Proof.** (*) We consider

\[V := W \cap X \quad \text{and} \quad S := \{ t \in T | \langle t \rangle \subset X \} .\]

**Claim.** We claim that $(V, S)$ is a subcomplex of $L = (W, T)$.

Let $s \in S$ be a simplex and let $r$ be a face of $s$. We need to show that $r \in S$, i.e. we need to show that $\langle r \rangle \subset X$. Basically by definition we have $\langle r \rangle \subset |s|$. Thus it suffices to show that $|s| \subset X$.

Now note note that by Lemma 61.11 we know that $|s|$ is the closure of the subset $\langle s \rangle$. Since $X$ is by hypothesis a closed subset of $|L|$ we obtain from elementary point-set topology, see e.g. Exercise 2.18(a), that $|s| \subset X$. □

---

941 Strictly speaking we view the simplices as subcomplexes, and then take the union as defined in Lemma 61.2.
Now we see that
\[
|K| = \bigcup_{t \in S} \langle t \rangle = \bigcup_{t \in T \text{ with } \langle t \rangle \subseteq X} \langle t \rangle = \bigcup_{t \in T} (\langle t \rangle \cap X) = X.
\]

Lemma 61.11 (5) definition by the hypothesis that Lemma 61.11 (2)

\[
|K| = \bigcup_{t \in S} \langle t \rangle = \bigcup_{t \in T \text{ with } \langle t \rangle \subseteq X} \langle t \rangle = \bigcup_{t \in T} (\langle t \rangle \cap X) = X.
\]

\[
|K| = \bigcup_{t \in S} \langle t \rangle = \bigcup_{t \in T \text{ with } \langle t \rangle \subseteq X} \langle t \rangle = \bigcup_{t \in T} (\langle t \rangle \cap X) = X.
\]

Lemma 61.11 (2)

61.4. **Simplicial complexes.** As on so many other occasions we start out this new section with a definition.

**Definition.**

(1) Let \( X \) be a topological space. A **simplicial structure** for \( X \) is a pair \((K, \Theta: |K| \to X)\) where the following holds:

(a) \( K \) is an abstract simplicial complex,

(b) \( \Theta \) is a homeomorphism between the topological realization \(|K|\) of \( K \) and the topological space \( X \).

(2) A **simplicial complex** is a pair \((X, (K = (V, S), \Theta: |K| \to X))\) given by a topological space \( X \) together with a simplicial structure \((K = (V, S), \Theta: |K| \to X)\). We refer to \( X \) as the underlying topological space of the simplicial complex. To keep the notation at a manageable level we will often not distinguish in the notation between a simplicial complex and its underlying topological space.

(3) We say a simplicial complex is **finite** (respectively **countable**) if the corresponding abstract simplicial complex is **finite** (respectively **countable**).

(4) We say a simplicial complex is (**totally** ordered) if the corresponding abstract simplicial complex is (**totally** ordered).

(5) Let \((X, (K = (V, S), \Theta: |K| \to X))\) be a simplicial complex. We introduce the following notions which are basically self-explanatory:

(a) Given \( v \in V \) we refer to \( \Theta(v) \) as a **vertex** of the simplicial complex.

(b) Let \( s \in S \) be a \( k \)-simplex.

(i) We refer to \( \Theta(|s|) \subseteq X \) as a **\( k \)-simplex of the simplicial complex**. Furthermore we refer to \( \Theta(|(s)|) \subseteq X \) as an **open \( k \)-simplex of the simplicial complex**.

(ii) If \( \Phi_s: \Delta^k \to |s| \) is a characteristic map as defined on page 1487 then we refer to \( \Theta \circ \Phi_s: \Delta^k \to X \) as a **characteristic map of \( X \)**.

(iii) If \( t \) is a face of \( s \), then we refer to \( \Theta(|t|) \) as a **face of the simplex** \( \Theta(|s|) \).

(c) We define the **dimension of the simplicial complex** to be the dimension of the corresponding abstract simplicial complex.

(d) Given \( n \in \mathbb{N}_0 \) we denote by \( |K^n| \subseteq |K| \) the topological realization of the \( n \)-skeleton of \( K \). We refer to \( X^n := \Theta(|K^n|) \) as the **\( n \)-skeleton of the simplicial complex** \( X \).

(6) Let \((Y, (L, \Theta: |L| \to Y))\) be a simplicial complex. A **subcomplex** is a simplicial complex \((X, (K, \Omega: |K| \to X))\) where \( X \) is a subspace of \( Y \), \( K \) is a subcomplex of \( L \) and where the inclusion \( X \to Y \) is precisely the map \( \Theta \circ |i| \circ \Omega^{-1} \), where \( i: K \to L \) is the inclusion map.

**Remark.**

(1) In many cases the choice of a simplicial structure gets suppressed from the notation.
(2) In the literature a *simplicial structure* is often called a *triangulation*.

**Examples.**

1. Given any abstract simplicial complex $K$ its topological realization $|K|$ is a simplicial complex in an obvious way.
2. On page 1492 we wrote down an explicit homeomorphism $|D_n| \xrightarrow{\cong} \Delta^n$ which restricts to a homeomorphism $|S_{n-1}| \xrightarrow{\cong} \partial \Delta^n$. These two homeomorphisms endow $\Delta^n$ and $\partial \Delta^n$ with a simplicial structure, called the *standard simplicial structure*.
3. We consider the topological space $X$ to the left of Figure 901. To the right we show an abstract simplicial complex $K$ with seven vertices such that $X$ is homeomorphic to $|K|$.

![Figure 901](image)

*Figure 901*

Before we continue with more examples of simplicial complexes we want to formulate the following lemma which summarizes a few basic properties of simplices in a simplicial complex.

**Lemma 61.14.** Let $Y$ be a simplicial complex.

1. Any $k$-simplex of $Y$ is homeomorphic to $\Delta^k$.
2. The intersection of two simplices of $Y$ is either empty or it is given by a single face of the two simplices.
3. Let $X$ be a subcomplex of $Y$ and let $s$ be a simplex of $Y$. If the corresponding open simplex intersects $X$, then $s \subset X$.
4. If $X \subset Y$ is the union of simplices of $X$, then $Y$ admits a natural structure of a subcomplex.

**Proof.**

1. This statement is a reformulation of Lemma 61.5.
2. This statement is an immediate consequence of Lemma 61.1.
3. This follows from Lemma 61.11 (5).
4. This statement follows almost immediately from the definitions.  

**Remark.**

1. In the following a simplicial structure for a topological space is often indicated by a suitable decomposition into simplices, i.e. into subsets which (look like they) are homeomorphic to some $\Delta^k$. Some care though needs to be taken to make sure that one actually does define a simplicial structure. In particular one needs to ensure that

---

Footnote 942: What is the role of the vertices $A$, $F$ and $G$? Are they really needed?
the statements of Lemma 61.14 (1) and (2) are satisfied. We refer to Figure 902 for an illustration of examples and non-examples of simplicial complexes.

(2) In the following we often draw a simplicial complex and rely on the good will of the reader to read off the corresponding abstract simplicial complex.

two “simplices” that do not intersect in a face

two “simplices” intersect in more than one face

“simplex” is not injective

We continue with more examples of simplicial complexes.

Examples.

(1) In Figure 903 to the left we show several simplicial structures for the disk $\overline{B}^2$. Furthermore, in Figure 903 to the right we show a simplicial structure for the sphere $S^2$.

(2) In Figure 904 we show the torus $T = ([0, 1] \times [0, 1]) / \sim$ together with three attempts at endowing it with a simplicial structure. Using Lemma 61.14 we see that the two attempts to the left do not define a simplicial structure. Only the fairly complicated attempt to the right actually provides us with a simplicial structure for the torus.
(3) Let \( n \in \mathbb{N} \). We will now equip the closed ball \( \overline{B}^n \) and the sphere \( S^n \) with a canonical simplicial structure. To do so we consider the simplicial complex \( D_n \) and its subcomplex \( S_{n-1} \) that we introduced on page 1480. On page 1492 we saw that there exists a canonical homeomorphism \( f: |D_n| \to \Delta^n \) which restricts to a homeomorphism \( |S_{n-1}| \to \partial \Delta^n \). Furthermore, in Lemma 41.1 we gave an explicit homeomorphism \( \Phi: \overline{B}^n \to \Delta^n \) that restricts to a homeomorphism \( S^{n-1} \to \partial \Delta^n \). We see that \((D_n, \Phi^{-1} \circ f: |D_n| \to \overline{B}^n)\) is a simplicial structure for \( \overline{B}^n \) and that \((S_{n-1}, \Phi^{-1} \circ f|_{S_{n-1}}: |S_{n-1}| \to S^{n-1})\) is a simplicial structure for \( S^{n-1} \). We refer to these as the canonical simplicial structures of \( \overline{B}^n \) and \( S^{n-1} \).

![Diagram](image)

**Figure 905.** Canonical simplicial structures for spheres and balls.

It is now abundantly clear that most simplicial complexes admit many different simplicial structures. Finally we consider maps between simplicial complexes. What comes next is basically self-explanatory and only written down out of a sense of duty.

**Definition.** Let \((X, (K, \Theta: |K| \to X))\) and \((Y, (L, \Omega: |L| \to Y))\) be two simplicial complexes.

1. A map \( f: X \to Y \) is called simplicial if there exists a simplicial map \( g: K \to L \) such that \( f = \Omega \circ |g| \circ \Theta^{-1} \).
2. We say the two simplicial complexes are simplicially isomorphic if there exist simplicial maps between the two simplicial complexes that are inverses of one another.

**Example.** If \( Y \) is a simplicial complex and \( X \) is a subcomplex, then it follows immediately from the definitions that the inclusion \( X \to Y \) is a simplicial map.

It follows immediately from the definitions that the composition of two simplicial maps is again simplicial. This leads us to the following definition.

**Definition.** We call the category \( \text{SimpCplx} \) with

\[
\text{Ob}(\text{SimpCplx}) := \text{all simplicial complexes},
\]
\[
\text{Mor}(K,L) := \text{all simplicial maps from } K \text{ to } L,
\]

together with the usual composition of maps the category of simplicial complexes. Similarly we define the category of (totally) ordered simplicial complexes.

We conclude this section with the following basic lemma.

**Lemma 61.15.** Let \((X, (K = (V,S), \Theta: |K| \to X))\) and \((Y, (L = (W,T), \Omega: |L| \to Y))\) be two simplicial complexes. Given a simplicial map \( \varphi: K \to L \) there exists a unique
simplicial map $\Phi: X \to Y$ such that the following diagram commutes:
\[
\begin{array}{ccc}
V & \xrightarrow{\varphi} & W \\
\Theta \downarrow & & \downarrow \Omega \\
X & \xrightarrow{\Phi} & Y.
\end{array}
\]

**Proof.** The map $\Phi$ is given by $\Omega \circ |\varphi| \circ \Theta^{-1}$. Since $\Omega$ and $\Theta$ are homeomorphisms we see that $\Phi$ is also unique. ■

61.5. The product of (abstract) simplicial complexes. In this section we want to consider the product of (abstract) simplicial complexes. Let us first consider the simplicial complexes $X = Y = [0, 1]$ with the “obvious” simplicial structure. As we see in Figure 906 there are two very reasonable looking simplicial structures on the product $[0, 1] \times [0, 1]$.

![Figure 906](image_url)

It is not clear which of the two simplicial structures shown in Figure 906 is preferable or “more canonical”. In fact to break the tie and to end up with a clear winner we need to work with ordered abstract simplicial complexes, as introduced on page 1480.

First we recall the following definition from page 76.

**Definition.** Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. Given $(a, b)$ and $(a', b')$ in $A \times B$ we define

$$(a, b) < (a', b') \iff \text{either } a < a' \text{ or } a = a' \text{ and } b < b'$$

and we define $(a, b) \leq (a', b')$ if either $(a, b) = (a', b')$ or $(a, b) < (a', b')$. We refer to “$\leq$” on $A \times B$ as the **lexicographic order** on $A \times B$.

**Remark.** Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. One can show easily that the lexicographic order is a partial order on $A \times B$ and similarly one can show easily that if $(A, \leq)$ and $(B, \leq)$ totally ordered sets, then the lexicographic order is also a total order.

**Definition.** Let $K = (V, S)$ and $L = (W, T)$ be two (totally) ordered abstract simplicial complexes. We define the product $K \times L$ of the abstract simplicial complexes to be the abstract simplicial complex that is given by the vertex set $V \times W$ and the simplex set

$$\left\{ (v_0, w_0), \ldots, (v_k, w_k) \right\} \mid \left\{ v_0, \ldots, v_k \right\} \in S \text{ and } \left\{ w_0, \ldots, w_k \right\} \in T \text{ and we have } v_0 \leq \cdots \leq v_k \text{ and } w_0 \leq \cdots \leq w_k$$

We equip $K \times L$ with the lexicographic order and we view $K \times L$ again as a (totally) ordered abstract simplicial complex.
Before we discuss examples we first state the following lemma which basically reassures us that we are doing something reasonable.

**Lemma 61.16.** Let $K = (V, S)$ and $L = (W, T)$ be two ordered abstract simplicial complexes.

1. The two obvious “projection maps” $p: K \times L \to K$ and $q: K \times L \to L$ are simplicial maps.

2. The map $|p| \times |q|: |K \times L| \to |K| \times |L|$ is a continuous bijection. If $K$ and $L$ are finite, then the map is in fact a homeomorphism.

Thus given two finite simplicial complexes $K$ and $L$ we can view the product also as a simplicial complex.

**Remark.**

1. Lemma 36.24 teaches us that it is safer to stick to finite abstract simplicial complexes. In fact that is also all we ever need. For products of arbitrary abstract simplicial complexes we refer to [FrP90a, Proposition 4.3.5] and [LW69, Corollary III.5.2]. Note though that one needs to tread carefully to make sure that the definitions and statements are indeed as desired.

2. As mentioned earlier, the topology of the topological realization of an abstract simplicial complex is designed to make it easy to show that a map out of the topological realization is continuous. Furthermore, as we mentioned in Remark 3.7 the topology of a product of topological spaces makes it easy to find continuous maps to the product. This explains why in Lemma 61.16 we have a continuous map from left to right, but why we struggle to find a continuous map from right to left.

**Proof.**

1. It follows immediately from the definitions that the projection maps are indeed simplicial.

2. It follows from (1) together with Proposition 61.7 and the elementary Lemma 3.6 (1) that the map $|p| \times |q|: |K \times L| \to |K| \times |L|$ is continuous. We leave it to the reader to verify that the map is a bijection.

Finally suppose that $K$ and $L$ are finite. It follows from Proposition 2.43 (3), together with Lemmas 61.5 (1) and 61.9 (1) and Proposition 3.12 that the map is indeed a homeomorphism.

**Examples.**

---

943 One can indeed easily verify that this defines an abstract simplicial complex.

944 To rule out any potential confusion, the $v_0, \ldots, v_k$ and also the $w_0, \ldots, w_k$ do not need to be distinct vertices.

945 It follows almost immediately from the above remark that with this definition $K \times L$ is in fact a (totally) ordered abstract simplicial complex.
(1) We consider the two totally ordered abstract simplicial complexes $K$ and $L$ that are shown in Figure 907. Here we use the obvious total orders given by $0 < 1 < 2$ and $A < B < C$. We also show the corresponding product $K \times L$.

![Diagram of simplicial complexes](image)

Figure 907

(2) We equip $S^1$ with the canonical simplicial structure defined on page 1500. The product simplicial structure on the torus $S^1 \times S^1$ is simplicially isomorphic to the simplicial structure shown in Figure 904 to the right.

(3) Let $I$ be the abstract simplicial complex given by $(V = \{0, 1\}, S = \{\emptyset, \{1\}, \{0, 1\})$. As in (1) we use the obvious total order given by $0 < 1$. We consider the product $I \times I$. Given any $n \in \mathbb{N}$ we can now view the cube $[0, 1]^n$ as a simplicial complex. For $n = 2$ we obtain the simplicial complex drawn in Figure 906 on the left. We refer to this simplicial structure as the canonical simplicial structure of $[0, 1]^n$.

In plain English, the following lemma says that the $\mathbb{Z}^n$-translates of the canonical simplicial structure of $[0, 1]^n$ give a linear simplicial structure for $\mathbb{R}^n$.

**Lemma 61.17.** Let $n \in \mathbb{N}$. We denote by $(K = (V, S), \Theta: |K| \to [0, 1]^n)$ the canonical simplicial structure of $[0, 1]^n$. We define a new simplicial complex $\tilde{K} = (\tilde{V}, \tilde{S})$ where

$$\tilde{V} := \mathbb{Z}^n \quad \text{and} \quad \tilde{S} := \{v_0 + w, \ldots, v_k + w\} | \{v_0, \ldots, v_k\} \in S \text{ and } w \in \mathbb{Z}^n\}.$$ 

The (hopefully) obvious map $\tilde{\Theta}: |\tilde{K}| \to \mathbb{R}^n$ is a homeomorphism, in particular it equips $\mathbb{R}^n$ with the structure of a linear simplicial complex.

![Illustration of Lemma 61.17](image)

**Figure 908. Illustration of Lemma 61.17**

**Proof.** It is elementary to see that the map $\tilde{\Theta}: |\tilde{K}| \to \mathbb{R}^n$, once it is written down properly, is continuous and a bijection. It follows from Proposition 2.45 that the map is in fact a homeomorphism. \[\square\]
Arguably the most important ways to construct new topological spaces out of given ones are by taking products and by taking quotients. Within reasonable limits we saw in Proposition \[36.23\] and Lemma \[36.32\] (3) that both operations can be done with CW-complexes. Furthermore, we just saw in Lemma \[61.16\] that we can take products of finite simplicial complexes. Quotients on the other hand are a problem. In general, as is illustrated in Figure \[909\], given a simplicial complex \(Y\) and a subcomplex \(X\) the simplicial structure of \(Y\) does not descend to a simplicial structure on the quotient \(Y/X\).

![Figure 909](image)

Let us jot down the following question.

**Question 61.18.** Let \(Y\) be a simplicial complex and let \(X\) be a subcomplex. Does the quotient \(Y/X\) admit a simplicial structure?

In Corollary \[61.26\] we will give a partial answer to Question 61.18.

### 61.6. The simplicial join of (abstract) simplicial complexes.

In this section we will continue with our task of finding useful constructions of (abstract) simplicial complexes that correspond to constructions that we already know from the world of topological spaces. More precisely, we want to consider the join construction from page 207 that so far we had not seriously used.

**Definition.** Let \(X\) and \(Y\) be two non-empty topological spaces. We define the *join* \(X \ast Y\) to be the topological space obtained from \(X \times [0, 1] \times Y\), equipped with the product topology, by performing the following two types of identifications:

1. For every \(x \in X\) we identify all points in \(\{x\} \times \{0\} \times Y\) to a single point and
2. For every \(y \in Y\) we identify all points in \(X \times \{1\} \times \{y\}\) to a single point.

Furthermore, if one of \(X\) or \(Y\) is the empty topological space, then we define \(X \ast Y\) to be the other topological space.

To get into the mood of thinking about joins let us first consider the following two examples.

**Examples.**

1. Let \(X\) be a non-empty topological space and let \(Y = \{1\}\) be the topological space given by a single point 1. We consider the maps

\[
X \ast \{1\} = (X \times [0, 1] \times \{1\}) / \sim \rightarrow \text{Cone}(X) = (X \times [0, 1]) / (X \times \{1\})
\]

\[
[(x, t, 1)] \mapsto [(x, t)]
\]

One can easily verify that the map is a bijection. Furthermore, using Lemma \[3.22\] and Lemma \[3.21\] (3) it is straightforward to see that this map and its inverse are continuous. Thus the map is a homeomorphism.

2. Let \(X\) be a non-empty topological space and let \(Y = \{-1, 1\}\) be the topological space given by the set with two elements ±1 and the discrete topology. We also consider
the suspension
\[ \Sigma(X) := (X \times [-1, 1]) / \sim \]
which is defined by squashing all points in \( X \times \{ -1 \} \) to a single point and by squashing all points in \( X \times \{ 1 \} \) to a single point. We consider the map
\[
X \ast \{-1, 1\} = (X \times [0, 1] \times \{-1, 1\}) / \sim \rightarrow \Sigma(X) = (X \times [-1, 1]) / \sim
\]
\[ [(x, t, \epsilon)] \mapsto [(x, \epsilon \cdot t)] \]
With some minor effort one can show that this map is a bijection. Using Lemma 3.22 and Lemma 3.21 (3) it is straightforward to see that this map is continuous. The fact that the inverse is also continuous needs slightly more effort, in fact this argument also requires Lemmas 3.28 and Lemma 3.45. We leave it to the reader to fill in the details. We refer to Figure 910 for \( X = S^1 \) for an illustration of the homeomorphism.

\[ \Sigma(X) \]

For completeness we note that for the empty topological space we have, basically by definition, that \( \emptyset \ast \{ 1 \} = \text{Cone}(\emptyset) \) and \( \emptyset \ast \{ \pm 1 \} = \Sigma(\emptyset) \)

The following lemma gives us a few examples of joins which will play a role later on.

**Lemma 61.19.**

1. Given any \( m, n \in \mathbb{N}_0 \) the map
   \[
   S^m \ast S^n \rightarrow \Delta^{m+n+1}
   \]
   \[ [(x, t), y)] \mapsto (x \cdot \cos \left( \frac{\pi t}{2} \right), y \cdot \sin \left( \frac{\pi t}{2} \right)) \]
   \[ \epsilon \in \mathbb{R}^{m+1} \times \mathbb{R}^{n+1} = \mathbb{R}^{m+n+2} \]
   is a homeomorphism.

2. Given any \( m, n \in \mathbb{N}_0 \) the map
   \[
   \Delta^m \ast \Delta^n \rightarrow \Delta^{m+n+1}
   \]
   \[ [(x_0, \ldots, x_m, t, y_0, \ldots, y_n)] \mapsto (t \cdot x_0, \ldots, t \cdot x_m, (1 - t) \cdot y_0, \ldots, (1 - t) \cdot y_n) \]
   is a homeomorphism.
Given any \( n \in \mathbb{N}_0 \) the map

\[
\partial \Delta^n \ast \{\ast\} \to \Delta^n
\]

\[
[(x, t, \ast)] \mapsto x \cdot (1 - t) + \left( \frac{1}{n+1}, \ldots, \frac{1}{n+1} \right) \cdot t
\]

**Proof.** The proof of (1), (2) and (3) is basically identical. In each case it is straightforward to verify that the map is well-defined and a bijection. It follows from Lemma 3.22 that the given map is continuous. Finally it follows from Lemma 3.48 together with Proposition 2.43 (3) that the given map is in fact a homeomorphism. \( \blacksquare \)

It turns out that in the simplicial setting we have an analogous construction.

**Definition.** Let \( K_i = (V_i, S_i) \), \( i = 1, \ldots, m \) be abstract simplicial complexes. We define the *simplicial join* of \( K_1, \ldots, K_m \) to be the abstract simplicial complex

\[
K_1 \ast \cdots \ast K_m := \left( \bigcup V_i, \bigcup \left\{ s_1 \cup \cdots \cup s_m \mid \text{for } i = 1, \ldots, m \text{ we have } s_i \in S_i \cup \{\emptyset\} \text{ and there exists at least one } s_i \neq \emptyset \right\} \right).
\]

This definition is illustrated, with limited success, in Figure 911.

**Remark.** It follows immediately from the definitions that the join construction is associative, i.e. given abstract simplicial complexes \( K, L \) and \( M \) we have a natural isomorphism \((K \ast L) \ast M = K \ast (L \ast M)\) of abstract simplicial complexes.

The examples on page 1504 motivate the following definitions.

**Definition.** Let \( K \) be an abstract simplicial complex. Furthermore let \( \{1\} \) be the abstract simplicial complex consisting of a single vertex \( 1 \) and finally let \( S_0 \) be the abstract simplicial complex \( S_0 = \{\{0, 1\}, \{\emptyset\}, \{\{0\}\}\} \) that we introduced on page 1480. We refer to

\[
\text{Cone}(K) := K \ast \{1\} \quad \text{respectively} \quad \Sigma(K) := K \ast S_0
\]

as the *simplicial cone* on the abstract simplicial complex \( K \) respectively the *simplicial suspension* of the abstract simplicial complex \( K \).

**Example.** Let \( n \in \mathbb{N}_0 \). We see that

\[
\text{Cone} \left( \{0, \ldots, n\}, \mathcal{P}(\{0, \ldots, n\}) \setminus \{\emptyset\} \right) \cong \left( \{0, \ldots, n\}, \mathcal{P}(\{0, \ldots, n\}) \setminus \{\emptyset\} \right) \cong D_{n+1}
\]

follows from the definition of the simplicial cone induced by \( * \mapsto n + 1 \).

\[946\] In fact this statement is just the content of Lemma 3.50.

\[947\] To avoid confusion it is perhaps worth recalling that the empty set is not a simplex.

\[948\] One can easily verify that this is indeed an abstract simplicial complex.
Lemma 61.20. Let \( K \) and \( L \) be two abstract simplicial complexes. If one of \( K \) or \( L \) is empty, then by definition we have a natural homeomorphism \(|K| \ast |L| \cong |K \ast L|\). If \( K \) and \( L \) are non-empty, then the map

\[
\Theta: \frac{|K| \times [0, 1] \times |L|}{[(x, r, y)]} \to |K \ast L| \subset \mathbb{R}^{(V \cup W)} = \mathbb{R}^V \times \mathbb{R}^W
\]

is a bijection and its inverse \( \Theta^{-1} \) is continuous. Furthermore, if \( K \) and \( L \) are finite, then \( \Theta \) is in fact a homeomorphism.

**Proof.** Let \( K = (V, S) \) and \( L = (W, T) \) be two abstract simplicial complexes. If one of \( K \) or \( L \) is empty, then the statement is true basically by definition. Thus let us now assume that \( K \) and \( L \) are both non-empty. We consider the map

\[
\Theta: \frac{|K| \times [0, 1] \times |L|}{[(x, r, y)]} \to |K \ast L| \subset \mathbb{R}^{(V \cup W)} = \mathbb{R}^V \times \mathbb{R}^W
\]

is a bijection and its inverse \( \Theta^{-1} \) is continuous. Furthermore, if \( K \) and \( L \) are finite, then \( \Theta \) is in fact a homeomorphism.

We leave it to the reader to verify that the map does indeed take values in \(|K \ast L|\) and that it is a bijection. Next we show that the inverse \( \Theta^{-1}: |K \ast L| \to |K| \ast |L| \) is continuous.

**Claim.** The map \( \Theta^{-1}: |K \ast L| \to |K| \ast |L| \) is continuous.

We use the continuity criterion from Lemma 61.6 (2) to show that \( \Theta^{-1} \) is continuous. Since \( K \) and \( L \) are non-empty we see that every simplex of \( K \ast L \) is contained in a simplex of the form \( s \sqcup t \) where \( s \in S \) and \( t \in T \) are simplices. Thus let \( s \in S \) be a \( k \)-simplex and let \( t \in T \) be an \( l \)-simplex. Note that by Lemma 61.19 (2) we know that the map

\[
\Xi: \Delta^k \ast \Delta^l \to \Delta^{k+l+1}
\]

\[
[(x_0, \ldots, x_k, r, y_0, \ldots, y_l)] \mapsto (r \cdot x_0, \ldots, r \cdot x_k, (1-r) \cdot y_0, \ldots, (1-r) \cdot y_l)
\]

This might be viewed as an odd formulation, but it is easier to write down the map \( \Theta \) than to write down its inverse \( \Theta^{-1} \).
is a homeomorphism. Next we pick corresponding characteristic maps \( \Phi_s : \Delta^k \to |K| \) and \( \Phi_t : \Delta^l \to |L| \). It follows easily from the definitions that the map

\[
\Phi_{s\cup t} : \Delta^{k+l+1} \xrightarrow{\Xi^{-1}} \frac{\Delta^k \times [0,1] \times \Delta^l}{(x, r, y)} \xrightarrow{\Omega} \frac{|K \ast L| \subset \mathbb{R}^{(V \lor W)} = \mathbb{R}^V \times \mathbb{R}^W}{(r \cdot \Phi_s(x), (1-r) \cdot \Phi_t(y))}
\]

is a characteristic map for the simplex \( s \sqcup t \). We obtain the following diagram

\[
\begin{array}{ccc}
\Delta^{k+l+1} & \xrightarrow{\Phi_{s\cup t}} & |K \ast L| \\
\parallel & \searrow \Xi^{-1} & \swarrow \Theta^{-1} \\downarrow \parallel
\end{array}
\]

\[
\begin{array}{ccc}
\Delta^k \times \Delta^l & \searrow \Omega & |K| \ast |L| \\
\parallel & \swarrow \Phi_s \ast \Phi_t & \parallel
\end{array}
\]

We make the following observations:

1. It follows immediately from the definitions that the triangle to the left diagram commutes. Furthermore it is equally trivial to see that \( \Theta \circ (\Phi_s \ast \Phi_t) = \Omega \), thus the triangle to the right also commutes.
2. By Lemma 61.19 (2) we know that the left diagonal map is continuous.
3. By Lemma 3.47 we know that the right diagonal map is continuous.
4. It follows from the above that \( \Theta^{-1} \circ \Phi_{s\cup t} \) is continuous.

It now follows from Lemma 61.6 (2) that \( \Theta^{-1} : |K \ast L| \to |K| \ast |L| \) is continuous. □

In the remainder of the proof we now assume that \( K \) and \( L \) are finite. We need to show that \( \Theta \) is a homeomorphism. We already know that \( \Theta \) is a bijection and that the inverse \( \Theta^{-1} : |K \ast L| \to |K| \ast |L| \) is continuous. Furthermore, by Lemma 61.3 (2) together with Lemma 3.51 we know that \( |K| \ast |L| \) is Hausdorff. Thus it follows, as so often, from Proposition 2.43 (3) that \( \Theta^{-1} \) is a homeomorphism. Thus \( \Theta \) is also a homeomorphism. ■

**Example.** Let \( n \in \mathbb{N}_0 \). Recall that on page 1500 we gave an explicit simplicial structure \((S_n, \Theta : |S_n| \to S^n)\) for \( S^n \). Now let \( m, n \in \mathbb{N} \). By Lemma 61.19 (1) we know that \( S^{m+n+1} \) is homeomorphic to \( S^m \ast S^n \). This observation, together with Lemma 61.20, gives us lots of different simplicial structures on spheres. We sketch the resulting three simplicial structures for \( S^2 \) in Figure 913.

\[ |S_2| \quad |S_1| \quad |S_0| \]

\[ |\Sigma(S_1)| = |S_1 \ast S_0| \quad |\Sigma(S_0)| = |S_0 \ast S_0 \ast S_0| \]

**Figure 913**

**Corollary 61.21.** If \( X = (K, \Theta : |K| \to X) \) is a finite simplicial complex, then the suspen- sion \( \Sigma(X) \) and the cone \( \text{Cone}(X) \) admit natural simplicial structures where the corresponding abstract simplicial complexes are given by \( \Sigma(K) \) and \( \text{Cone}(K) \).
Proof. The corollary follows immediately from Lemma 61.20 together with the two examples on page 1505. ■

Remark. In Section 62.4 we will introduce the simplicial analogue of the mapping cylinder and mapping cone.

61.7. Linear simplicial complexes. In this short section we discuss an important special case of a simplicial complex.

Definition. A simplicial complex \((X, (K, \Theta: |K| \to X))\) is called linear if \(X\) is a subspace of some \(\mathbb{R}^n\) and for each simplex \(s \in K\) the map \(\Theta: |s| \to X\) is an affine linear map.

Example. Let \(n \in \mathbb{N}\). The topological space \(\mathbb{R}^n\) together with the canonical simplicial structure defined in Lemma 61.17 is clearly a linear simplicial complex.

Remark. (1) Different books have different definitions for “simplicial complexes”. Our approach mostly follows the approach taken in [Spa95, Chapter 3]. In many books what we call a “linear simplicial complex” is basically used as the definition of a simplicial complex, see e.g. [Matv06, p. 6] or [Bre93, Chapter 21].

(2) Linear simplicial complexes play an important role in computer visualizations. More precisely, in computer visualizations surfaces in \(\mathbb{R}^3\) are usually approximated by linear simplicial complexes. These have the nice feature that they can be described by a fairly small amount of data. We refer to Figure 914 for an illustration.

![linear simplicial structure for the torus](image1)

![linear simplicial structure for a bunny](image2)

Figure 914

Lemma 61.22. Every finite simplicial complex is simplicially isomorphic to a finite linear simplicial complex.

Remark. An (abstract) simplicial complex is called locally finite if each simplex is the face of only finitely many simplices. With this definition one can formulate a much stronger version of Lemma 61.22. By [FrPi90a, Theorem 3.3.15] a simplicial complex is homeomorphic to a linear simplicial complex if and only if it is finite-dimensional, countable and locally finite. We will discuss this statement in Exercise 61.8.

Proof. By definition a finite simplicial complex is homeomorphic to the topological realization \(|K|\) of a finite abstract simplicial complex \(K = (V, S)\). In Lemma 61.7 we showed that we can view \(|K|\) as a linear simplicial complex in \(\mathbb{R}^V = \mathbb{R}^m\). ■

We adopt the following notation.

950 In particular we assume that \(X\) is endowed with the subspace topology coming from \(\mathbb{R}^n\).
Notation. Given \( v_0, \ldots, v_k \in \mathbb{R}^n \) we write 
\[
|\{v_0, \ldots, v_k\}| := \left\{ \begin{array}{ll}
\sum_{i=0}^{k} t_i \cdot v_i & (1) \text{ for each } i \text{ we have } t_i \geq 0 \\
t_0 + \cdots + t_k = 1
\end{array} \right\}
\]

Remark. Let \( v_0, \ldots, v_k \in \mathbb{R}^n \). Furthermore let \( w_0, \ldots, w_m \in |\{v_0, \ldots, v_k\}| \). An elementary calculation shows that \( |\{w_0, \ldots, w_m\}| \subset |\{v_0, \ldots, v_k\}| \). This inclusion can also be obtained from Exercise \textbf{2.36 (a)}.

Lemma 61.23.

1. Let \( K \) be a linear simplicial complex in \( \mathbb{R}^n \).
   
   a. Every \( k \)-simplex of \( K \) is of the form \( |\{v_0, \ldots, v_k\}| \) for some distinct vertices \( v_0, \ldots, v_k \).
   
   b. Every simplex of \( K \) is a convex subset of \( \mathbb{R}^n \).
   
   c. Let \( v_0, \ldots, v_k \) be distinct vertices of \( K \). The following three statements are equivalent:
   
   i. \( |\{v_0, \ldots, v_k\}| \) is a simplex of \( K \),
   
   ii. \( \{v_0, \ldots, v_k\} \) is the vertex set of a simplex of \( K \),
   
   iii. \( |\{v_0, \ldots, v_k\}| \subset K \).

2. Let \( f: K \to L \) be a simplicial map between two linear simplicial complexes. The restriction of \( f \) to any \( k \)-simplex \( |\{v_0, \ldots, v_k\}| \) of \( K \) is given by 
\[
|\{v_0, \ldots, v_k\}| \to |\{\varphi(v_0), \ldots, \varphi(v_k)\}|
\]
\[
\sum_{i=0}^{k} t_i \cdot v_i \mapsto \sum_{i=0}^{k} t_i \cdot \varphi(v_i).
\]

Proof.

1. Almost all of these statements follow easily from the definitions. The only statement which needs a little bit of thought is the fact that (iii) implies (i). Since we will not make use of this statement we feel comfortable with the thought of leaving the details to the reader.

2. This statement follows immediately from the definition of a simplicial map, see page \textbf{1483} and the definition of the topological realization of a simplicial map between abstract simplicial complexes, see Proposition \textbf{61.7}. \[\blacksquare\]

61.8. Simplicial structures and CW-structures I. It is pretty clear that simplicial complexes and CW-complexes have structural similarities. In particular few readers will be surprised by the following lemma.

Lemma 61.24. Every (ordered) simplicial complex admits a (natural) CW-complex structure where given any \( n \in \mathbb{N} \) the \( n \)-simplices of the simplicial structure are precisely the \( n \)-cells of the CW-structure. In particular the following statements hold:

1. The simplicial subcomplexes are precisely the cellular subcomplexes,

\footnote{We do not assume that \( v_0, \ldots, v_k \) are distinct.}
For each \( n \in \mathbb{N}_0 \) the \( n \)-skeleton of the simplicial complex equals the \( n \)-skeleton of the CW-complex.

Any simplicial map \( f : X \to Y \) between simplicial complexes is a cellular map between the corresponding CW-complexes.

Remark. Lemma 61.24 says in particular that there exists a functor

\[
F : \text{category } OrdAbsSimpCplx \to \text{category } CW
\]

which has the property that the functor keeps the underlying topological space fixed. The functor is faithful but not fully faithful. The latter is just a fancy way of saying that there exist cellular maps that are not simplicial. For example, consider the simplicial complex \( X = [0, \infty) \) with the vertex set given by \( \mathbb{N}_0 \). We view \( X \) also as a CW-complex with the cellular structure that is induced from the simplicial structure. The map \( f : X \to X \) given by \( x \mapsto 2x \) is cellular but it is not simplicial. We refer to Figure 915 for an illustration.

![Figure 915](image)

Sketch of proof. Basically by definition of a simplicial complex it suffices to prove the statement for (ordered) abstract simplicial complexes and their topological realizations. The lemma now follows from fleshing out the following steps for a given (ordered) abstract simplicial complex \( K = (V, S) \).

(a) Let \( n \in \mathbb{N}_0 \). Recall that in Lemma 41.1 we had written down a specific homeomorphism \( \Psi_n : (B^n, S^{n-1}) \to (\Delta^n, \partial \Delta^n) \).

(b) Given \( n \in \mathbb{N}_0 \) we denote by \( K^n \) the \( n \)-skeleton of \( K \). Recall that \( K^n \) is a subcomplex of \( K \).

(c) Given \( n \in \mathbb{N}_0 \) let \( I_n \) be the set of \( n \)-simplices of \( K \). For each \( i \in I_n \) let \( \Theta_i : \Delta^n \to |K| \) be a characteristic map as defined on page 1487. Recall that if \( K \) is ordered, then we saw on page 1487 that there is a natural choice of a characteristic map.

(d) Given \( i \in I_n \) we write \( \Phi_i := \Theta_i \circ \Psi_n : B^n \to |K| \) and \( \varphi_i := \Phi_i|_{S^{n-1}} : S^{n-1} \to |K^{n-1}| \). Note that \( \varphi_i \) takes values in \( |K^{n-1}| \).

(e) Starting from \( X^0 := V \) we can build up a CW-complex such that for each \( n \in \mathbb{N}_0 \) the attaching maps are precisely the maps \( \varphi_i : S^{n-1} \to |K^{n-1}| \). The maps \( \Psi_i \) give rise to a map \( \Xi_n : |X^n| \to |K^n| \) which is, basically by definition, a bijection.

(f) Eventually we get a CW-complex \( X = \lim_{\to} X_n \) and the bijections \( \Xi_n \) can be combined to obtain a bijection \( \Xi : |X| \to |K| \).

(g) It remains to show that \( \Xi \) is continuous. First note that it follows easily from Lemma 61.6 (1) together with Lemma 36.7 (1) that \( \Xi \) is continuous. Furthermore, it follows from Lemma 36.7 (4) together with Lemma 61.5 (3) that \( \Xi^{-1} \) is also continuous.

\(^{952}\)Recall that cells and simplices are subsets, so it makes sense to talk of equality.
(h) In summary we have shown that $\Xi: |X| \to |K|$ is a homeomorphism. It follows basically immediately from the construction of the CW-structure on $|K|$ that the properties (1), (2) and (3) are satisfied.

\[ \begin{array}{c}
\text{Figure 916. Illustration for the proof of Lemma 61.24.} \\
\text{Lemma 61.24 allows us to import many previous results about CW-complexes to the context of simplicial complexes. For example, Proposition 36.10 (2) gives us a new proof that simplicial complexes are Hausdorff. More interesting of course are new results. The following corollary summarizes some of the nicest and most important ones.}
\end{array} \]

**Corollary 61.25.**

1. Simplicial complexes are normal.
2. Simplicial complexes are locally contractible\(^{963}\)
3. A simplicial complex is connected if and only if it is path-connected.
4. Let $X$ be a simplicial complex and let $A$ be a subcomplex. The following statements hold:
   a. The inclusion $A \to X$ is a cofibration.
   b. The map $\varphi: \text{Cone}(i: A \to X) \to X/A$
      \[ P \mapsto \begin{cases} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a, t)] \text{ with } a \in A \text{ and } t \in [0, 1] \end{cases} \]
      is a homotopy equivalence.
   c. If $A$ is contractible, then the projection $X \to X/A$ is a homotopy equivalence.
5. If $X$ is a finite simplicial complex, then
   \[ \chi(X) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{number of } n\text{-simplices of } X. \]

**Proof.**

(1),(2) These two statements follow from Lemma 61.24 together with Proposition 36.10 (2) and (6).

(3) This statement follows from (1) combined with Lemma 2.72.

(4) a. This statement follows from (1) together with Theorem 39.1
b. This statement follows from (a) together with Lemma 39.9 (2).
c. This statement follows from (a) together with Lemma 39.9 (3).

\(^{963}\)In the rather unlikely event that the reader forgot what these properties are good for, recall that by Corollary 29.9 this means in particular that any path-connected simplicial complex admits a universal covering. In Exercise 61.9 we will see that any covering of a simplicial complex is again a simplicial complex.
(5) This statement follows from Lemma \ref{61.24} together with Proposition \ref{55.1}. 

Now we can give a partial answer to Question \ref{61.18}.

**Corollary 61.26.** Let \( Y \) be a simplicial complex and let \( X \) be a subcomplex. If \( Y \) is finite, then there exists a finite simplicial complex, namely \( Y \cup \text{Cone}(X) \), that is homotopy equivalent to \( Y/X \).

**Remark.** We leave it as an entertainment for long winter nights to figure out whether Lemma \ref{36.8} can be used to generalize Corollary \ref{61.26} to infinite simplicial complexes.

**Proof.** Basically by definition we only need to deal with abstract simplicial complexes and their topological realizations. Thus let \( L = (W, T) \) be a finite abstract simplicial complex and let \( K = (V, S) \) be a subcomplex. We denote by \( i: K \to L \) the inclusion map. Recall that \( i \) is, basically by definition, simplicial. Since \( K \) and \( L \) are finite we can consider the abstract simplicial complex \( \text{Cone}(i: K \to L) \) that we will introduce on page \ref{1533}. Now we see that

\[
|L|/|K| \underset{\text{Corollary 61.25}}{\xleftarrow{\cong}} \text{Cone}(i: |K| \to |L|) = \left| |L| \cup_{|K|} \text{Cone}(|K|) \right| \underset{\text{Corollary 61.24}}{\xleftarrow{\cong}} \left| |L| \cup_{|K|} \text{Cone}(|K|) \right|
\]

It is pretty clear that there is no naive converse to Lemma \ref{61.24}. For example, the CW-complex constructed in the proof of Lemma \ref{61.24} has some special properties:

1. It follows from Lemma \ref{61.3} that each characteristic map is an embedding.
2. The CW-structure on the image of a characteristic map of an \( n \)-cell is equivalent to the one corresponding to the standard simplicial structure on \( \partial \Delta^n \) that we defined on page \ref{1498}.

Both types of examples are illustrated in Figure \ref{918}. Thus we see that many, arguably most, CW-structures do not come directly from simplicial structures.

A characteristic map is not a homeomorphism onto its image

\[
\begin{array}{c}
\includegraphics[width=0.3\textwidth]{figure918a.png}
\end{array}
\]

the image of the attaching map is not a triangle

**Figure 918**
It is perhaps more reasonable to ask, when does a CW-complex admit a simplicial structure? For example it is fairly obvious that the two cellular complexes shown in Figure 918 admit a simplicial structure. To formulate the relevant proposition we need the following definition.

**Definition.** A CW-complex is called regular if every characteristic map is an embedding.

**Examples.**

1. The CW-complex shown in Figure 918 to the left is non-regular, whereas the CW-complex shown to the right is regular.
2. Let $X$ be a simplicial complex. We use Lemma 61.24 to view $X$ as CW-complex. It follows from Lemma 61.3 (3) that this CW-complex is regular.

Now we can formulate the promised proposition.

**Proposition 61.27.** Every (countable) regular CW-complex admits the structure of a (countable) simplicial complex.

**Sketch of proof.** We will not make use of this theorem, thus we refer to [Geo08, Corollary 5.3.9] or alternatively to [FrP90a, Theorem 3.4.1] for a proof.

Here we only provide a sketch of a sketch of the proof. Thus let $X$ be a regular CW-complex. We turn inductively the skeleton $X^n$ into a simplicial complex. Suppose we already equipped $X^{n-1}$ with a simplicial structure. For each $n$-cell of $X^n$ we pick a point in the corresponding open cell and we use it to divide said $n$-cell into a suitable number of $n$-simplices. If the CW-complex $X$ was countable, then it follows from the construction together with Lemma 61.3 that the simplicial complex is also countable. The reader should have no troubles with turning the above sketch of an argument into a formal proof.

![Sketch of proof](attachment:sketch.png)

**Figure 919.** Illustration for the proof of Proposition 61.27

The relatively strong hypothesis of Proposition 61.27 indicates that it is perhaps too much to hope that every CW-complex admits a simplicial structure. Indeed, this fear turns out to be fully justified:

**Proposition 61.28.** There exists a finite CW-complex that does not admit a simplicial structure.

**Remark.** Proposition 61.28 is rather disappointing. Later on in Proposition 62.12 and Theorem 85.20 we will see that every (finite) CW-complexes is homotopy equivalent to a (finite) simplicial complexes.
Remark. In Exercise 62.5 we will construct an explicit simplicial structure for all exercises for Chapter 61.

We consider the function
\[ f : [0, 1] \to \mathbb{R} \]
and we consider the map \( g : [0, 1]^2 \to \mathbb{R}^3 \)
\[ (s, t) \mapsto (s, s \cdot t, f(t)) \]
Note that \( f \) assumes its maximum at \( t = 1 \) and that it assumes its minimum at a unique \( t_0 \in (0, 1) \). We set \( X := g([0, 1]^2) \). It is not particularly difficult to see that \( X \) admits a CW-structure with five 0-cells, five 1-cells and one 2-cell. We refer to Figure 920 for an illustration.

In [FrP90a] p. 128-130 a careful argument is given why \( X \) does not admit a simplicial structure. Other examples of finite CW-complexes that do not admit a simplicial structure are given in [LW69] p. 81] (with a very sketchy proof) and [Met67].

\[ \begin{array}{c}
\text{absolute minimum at } t_0 \\
\text{graph of } f \\
\text{these get sent to the same point via } g
\end{array} \]

\[ \begin{array}{c}
\text{the five dots are the 0-cells}
\end{array} \]

Figure 920. Illustration for the proof of Proposition 61.28

---

**Exercises for Chapter 61**

**Exercise 61.1.** For each \( g \geq 2 \) give an explicit simplicial structure for the surface of genus \( g \).

**Exercise 61.2.** Give an explicit simplicial structure for \( \mathbb{R}P^2 \).

*Remark.* In Exercise 62.5 we will construct an explicit simplicial structure for all \( \mathbb{R}P^n \).

**Exercise 61.3.** In Figure 904 we gave a simplicial structure for the torus \( S^1 \times S^1 \) with 18 2-simplices. Does there exist a simplicial structure with less than 18 2-simplices?

**Exercise 61.4.**

(a) Show that the set of isomorphism classes of finite abstract simplicial complexes is countable.

(b) Show that the set of isomorphism classes of countable abstract simplicial complexes is uncountable.

**Exercise 61.5.** We consider the abstract simplicial complex \( K = (V, S) \) which is given by \( V = \mathbb{Z} \cup \{\ast\} \) and \( S = \{\{v\} \mid v \in V\} \cup \{\{\ast, n\} \mid n \in \mathbb{Z}\} \). Show that \( |K| \) is not homeomorphic to a linear simplicial complex.

The five 0-cells and the five 1-cells are clearly indicated in Figure 920.
Remark. \((V,S)\) is just the simplicial cone on the abstract simplicial complex with vertex set \(\mathbb{Z}\) and which has no simplices of dimension \(\geq 1\).

**Exercise 61.6.** Let \(m,n \in \mathbb{N}_0\). Show that the simplicial join \(D_m \ast D_n\) of the abstract simplicial complexes \(D_m\) and \(D_n\) is simplicially isomorphic to \(D_{m+n+1}\).

**Exercise 61.7.** Let \(K\) be a finite \(n\)-dimensional simplicial complex. Show that \(K\) is homeomorphic to a finite linear simplicial complex that is contained in \(\mathbb{R}^{2n+1}\).

Remark. In Proposition 56.7 we already showed that there exist finite 1-dimensional simplicial complexes that cannot be embedded into \(\mathbb{R}^{2n}\). In fact the van Kampen-Flores Theorem, which can be proved using the Borsuk-Ulam Theorem 59.3, says that given any \(n \in \mathbb{N}\) there exists a finite \(n\)-dimensional simplicial complex \(K\) that does not admit a map \(K \to \mathbb{R}^{2n}\) which is a homeomorphism onto its image. We refer to [Mato08 Theorem 5.1.1] for details.

**Exercise 61.8.** Let \(K = (V,S)\) be an abstract simplicial complex that is finite-dimensional and countable. Furthermore we assume that it is locally finite, which means that each simplex is the face of only finitely many simplices. Show that \(|K|\) is homeomorphic to a linear simplicial complex.

*Hint.* Use Proposition 2.45.

**Exercise 61.9.** Let \(K = (V,S)\) be an abstract simplicial complex and let \(p: \tilde{K} \to K\) be a covering in the sense of the definition on page 493. Show that \(\tilde{K}\) admits a structure of a simplicial complex such that \(p\) is simplicial.

**Exercise 61.10.** Let \(K = (V,S)\) be an abstract simplicial complex and let \(J = (U,R)\) be a subcomplex such that for any choice of simplices \(r \in R\) and \(s \in S \setminus R\) we have \(r \cap s = \emptyset\). Show that \(|J|\) is an open subset of \(|K|\).

Remark. Note that by Lemma 61.8 (2) we know that \(|J|\) is always a closed subset of \(|K|\).

**Exercise 61.11.** Let \(K = (V,S)\) be an abstract simplicial complex. We say \(K = (V,S)\) is connected if given any \(v,v' \in V\) there exist 1-simplices \(s_0, \ldots, s_k \in S\) such that \(v \in s_0\), such that for every \(i \in \{0, \ldots, k-1\}\) we have \(s_i \cap s_{i+1} \neq \emptyset\) and such that \(v' \in s_k\).

Show that the following statements are equivalent:

(a) The abstract simplicial graph \(K\) is connected.

(b) Given any two simplices \(t,t' \in S\) there exist simplices \(s_0, \ldots, s_k \in S\) such that \(t \subset s_0\), such that for every \(i \in \{0, \ldots, k-1\}\) we have \(s_i \cap s_{i+1} \neq \emptyset\) and such that \(t' \in s_k\).

(c) The topological realization \(|K|\) is connected.

For completeness we mention that Corollary 61.25 (3) says that (c) is equivalent to the following statement:

(d) The topological realization \(|K|\) is path-connected.

Remark. The equivalence of (a) and (b) is straightforward.

Remark. For the equivalence of (b) and (c) use Lemma 2.62 Lemma 61.8 (2) and Exercise 61.10.

---

\(^{955}\)This definition is modelled on the definition of the connectedness of an abstract graph, see page 221.
Exercise 61.12. Let $K = (V, S)$ and $L = (W, T)$ be abstract simplicial complexes. We denote by $X$ and $Y$ the corresponding CW-complexes as defined in Lemma 61.24. Let $X \otimes Y$ be the topological space that is given by the product CW-structure, see page 963. Show that there exists a homeomorphism $|K \times L| \to X \otimes Y$.

Remark. Note that here we certainly do not assume that $K$ and $L$ are finite.

Exercise 61.13. Let $X$ be a topological space that admits the structure of a 1-dimensional CW-complex. Show that $X$ also admits the structure of a 1-dimensional simplicial complex.
In Chapter 61 we covered in great detail the basics of (abstract) simplicial complexes. In this chapter we will formulate and prove the first major result on simplicial complexes, namely the Simplicial Approximation Theorem.

62.1. The barycentric subdivision. In this section we introduce the barycentric subdivision of an abstract simplicial complex. This construction allows us to replace an abstract simplicial complex by a “finer” abstract simplicial complex. This will be a major tool in the proof of several theorems.

**Definition.** Let \( K = (V, S) \) be an abstract simplicial complex.

(1) For each \( k \)-simplex \( s = \{v_0, \ldots, v_k\} \in S \) we define the *barycenter* of \( s \) to be the point
\[
\bar{s} := \frac{1}{\text{dim}(s)+1} \cdot v_0 + \cdots + \frac{1}{k+1} \cdot v_k \in \langle s \rangle \subset \mathbb{R}^V.
\]
Note that if \( v \in V \) is a vertex, then the barycenter of the corresponding 0-simplex \( \{v\} \) is \( v \) itself.

(2) Given \( s, t \in S \) we write \( s \leq t \) if \( s \subset t \).

The following lemma summarizes a few properties of the barycenters.

**Lemma 62.1.** (*) Let \( K = (V, S) \) be an abstract simplicial complex.

(1) The map \( S \mapsto \mathbb{R}^V \) given by \( s \mapsto \bar{s} \) is natural.

(2) For simplices \( s, t \in S \) with \( s \neq t \) we have \( \bar{s} \neq \bar{t} \).

(3) For each 0-simplex \( s \) we have \( s = \bar{s} \) and for each simplex \( s \) of dimension \( \geq 1 \) we have \( \bar{s} \notin V \).

**Proof (\(*\)).**

(1) The most difficult part is to figure out what “natural” means in this context. We leave it to the reader to figure this out. Afterwards the statement is basically obvious.

(2) This statement follows from Lemma 61.11 (2).

(3) This statement is trivial. (But it is nonetheless useful.)

The following lemma is much more interesting.

**Lemma 62.2.** Let \( K = (V, S) \) be an abstract simplicial complex.

(1) The pair
\[
\text{sd}(K) = (\{s\}_{s \in S}, \{\{s_0, \ldots, s_k\} \mid s_0 \subset \cdots \subset s_k\})
\]
is an abstract simplicial complex, called the barycentric subdivision of \( K \).

(2) The relation “\( \leq \)” on the vertex set \( \{s\}_{s \in S} \) turns the barycentric subdivision \( \text{sd}(K) \) into an ordered abstract simplicial complex.

The definition of \( \text{sd}(K) \) is illustrated in Figure 921.

\(^{956}\)Here we view, as usual, \( V \) as a subset of \( \mathbb{R}^V \).
induces a natural isomorphism between the abstract simplicial complex \( K \) and the abstract simplicial complex. Given a simplicial complex \( K \), its topological realization, and a linear simplicial complex that is simplicially isomorphic to the topological realization. In particular, the illustrations shown in Figure 921 are dramatically dimensionally reduced.

**Remark.**

(1) Perhaps it is helpful to restate the definition of the barycentric subdivision \( \text{sd}(K) \) in other words: The vertices of \( \text{sd}(K) \) are precisely the barycenters of the original simplices and the simplices of the barycentric subdivision are given by the barycenters of an ascending sequence of simplices in \( K \).

(2) The statement of Lemma 62.2 (2) is quite amazing: ex nihilo we created order where there was chaos.

(3) There is an alternative more formal, but basically equivalent definition of the barycentric subdivision. Namely, given an abstract simplicial complex \( K = (V, S) \) one can consider the following abstract simplicial complex:

\[
\tilde{\text{sd}}(K) = \{ S, \{ \{ s_0, \ldots, s_k \} \mid s_0 \subseteq \cdots \subseteq \} \}.
\]

The map \( s \mapsto \tilde{s} \) induces a natural isomorphism between the abstract simplicial complex \( \text{sd}(K) \) and the abstract simplicial complex \( \tilde{\text{sd}}(K) \). Our first definition is arguably mnemonically superior, the second definition, which is for example used in [dLon13] p. 179], is arguably purer.

**Proof.** The statements follow immediately from the definitions. 

**Notation.** Let \( K = (V, S) \) be an abstract simplicial complex. Given \( i \in \mathbb{N} \) we refer to

\[
\text{sd}^i(K) := \text{sd}(\ldots \text{sd}(\text{sd}(K)) \ldots)_{\text{sd applied } i \text{ times}}
\]

as the \( i \)-th iterated barycentric subdivision of \( K \).

The following lemma summarizes the most important properties of the barycentric subdivision of an abstract simplicial complex.

**Lemma 62.3.** Let \( K = (V, S) \) be an abstract simplicial complex.

(1) If \( K \) is finite, then \( \text{sd}(K) \) is also finite.

(2) The dimension of \( \text{sd}(K) \) equals the dimension of \( K \).
(3) The map
\[
\bar{\Omega}: |\text{sd}(K)| \rightarrow |K|
\]
\[
\alpha \mapsto \left( V \rightarrow \mathbb{R}_{\geq 0} \sum_{\mathbf{s} \in S \text{ with } \mathbf{v} \in \mathbf{s}} \frac{1}{\dim(s)+1} \cdot \mathbf{s} \right)
\]
\[
\mathbf{s} \text{ is a vertex of } \text{sd}(K), \text{ hence } \alpha(\mathbf{s}) \text{ is defined}
\]
has the following properties:

(a) Let \( \sigma \) be a \( k \)-simplex of \( \text{sd}(K) \). By definition this means that \( \sigma = \{s_0, \ldots, s_k\} \) where \( s_0 \subseteq \cdots \subseteq s_k \) is an ascending sequence of simplices of \( K \). The restriction of the map \( \bar{\Omega}: |\text{sd}(K)| \rightarrow |K| \) to \( |\sigma| \) is given by
\[
|\sigma| \rightarrow |K|
\]
\[
\sum_{i=0}^{k} \lambda_i \cdot s_i \mapsto \sum_{i=0}^{k} \lambda_i \cdot s_i
\]
viewed as basis element of \( \mathbb{R}^{(\text{sd}(K))} \) viewed as vector in \( \mathbb{R}^{(V)} \).

In particular we have \( \bar{\Omega}(|\sigma|) \subseteq |s_k| \) and \( \bar{\Omega}(|\langle \sigma \rangle|) \subseteq \langle s_k \rangle \).

(b) The map \( \bar{\Omega} \) sends each vertex \( s \in \text{sd}(K) \) to the corresponding point \( s \in |K| \).

(c) Given any \( k \)-simplex \( t \) of \( K \) the map \( \bar{\Omega} \) restricts to a homeomorphism
\[
\bigcup_{s=\{a_0, \ldots, a_{k-1}, t\}} |s| \xrightarrow{\alpha} |t|.
\]

(d) The map \( \bar{\Omega} \) is a natural homeomorphism.

(4) If \( f: K = (V, S) \rightarrow L = (W, T) \) is a simplicial map between two abstract simplicial complexes, then the map
\[
\{s\} \mapsto \{f(s)\}
\]
defines a simplicial map \( f_*: \text{sd}(K) \rightarrow \text{sd}(L) \). This map has the property that the following diagram commutes:
\[
\begin{array}{ccc}
|\text{sd}(K)| & \xrightarrow{\bar{\Omega}_K} & |K| \\
|f_*| & \downarrow & |f| \\
|\text{sd}(L)| & \xrightarrow{\bar{\Omega}_L} & |L|.
\end{array}
\]

(5) The maps from (4) turn \( K \mapsto \text{sd}(K) \) into a covariant functor from the category of abstract simplicial complexes to the category of (ordered) abstract simplicial complexes.

---

Note that this shows that \( \bar{\Omega} \) does take values in \( |K| \).

Here we use the convention from page 1486 that says that we view the vertex of an abstract simplicial complex as a subset of the topological realization.
the 2-simplices of \( sd(K) \) of the form \( \{a_0, a_1, t\} \)

\[ \text{simplex } t \text{ of } K \]

\[ \text{the barycenters} \]

\[ \text{the open simplex corresponding to } \sigma = \{s_0, t\} \]

**Figure 9.22. Illustration of Lemma 62.3 (3).**

Given any abstract simplicial complex \( K \) and given any \( i \in \mathbb{N} \) we will use the homeomorphism from Lemma 62.3 (3) to make the identification \( |sd(K)| = |K| \).

**Proof.**

1. This statement is basically clear.
2. We will prove this statement in Exercise 62.3.
3. Now we need to show that \( \mathcal{U} \) has all the promised properties:
   
   a. Let \( \sigma = \{s_0, \ldots, s_k\} \) be a \( k \)-simplex of \( sd(K) \). Given a point \( P = \sum_{i=0}^{k} \alpha_i \cdot s_i \) we calculate that
   
   \[ \mathcal{U}(P) = \mathcal{U}\left( \sum_{i=0}^{k} \alpha_i \cdot s_i \right) = \sum_{i=0}^{k} \alpha_i \cdot \mathcal{U}(s_i) = \sum_{i=0}^{k} \alpha_i \cdot \mathcal{U}\left( \sum_{v \in s_i} \frac{1}{\dim(s_i)+1} \cdot v \right) = \sum_{i=0}^{k} \alpha_i \cdot s_i. \]

   Note that \( s_0, \ldots, s_k \) lie in \( |s_k| \). Thus it follows from the calculation, together with the remark on page 1510, that \( \mathcal{U}(|\sigma|) \subset |s_k| \). Furthermore, if \( P \in \langle \sigma \rangle \), then \( \alpha_k > 0 \), which in turn implies almost immediately that \( \mathcal{U}(P) \in \langle s_k \rangle \).

b. This statement follows immediately from (a).

c. Let \( t \) be a \( k \)-simplex \( t \) of \( K \). We leave it to the reader to verify that \( \mathcal{U} \) restricts to a bijection

\[ X := \bigcup_{s = \{a_0, \ldots, a_{k-1}, t\}} |s| \xrightarrow{\mathcal{U}} |t|. \]

Note that the left-hand side \( X \) is actually a finite subcomplex of \( \{sd(K)\} \). Given a simplex \( s = \{a_0, \ldots, a_{k-1}, t\} \) we pick a characteristic map \( \Phi_s: \Delta^k \to |s| \). Furthermore we pick a characteristic map \( \Phi_t: \Delta^k \to |t| \). It follows almost immediately from the definitions that the map \( \Phi_t^{-1} \circ \mathcal{U} \circ \Phi_s: \Delta^k \to \Delta^k \) is an affine linear map, in particular it is continuous. It follows from Lemma 61.6 (1) and Lemma 61.5 that the above map \( \mathcal{U}: X \to |t| \) is continuous. It now follows, as always, from Proposition 2.43 (3) together with Proposition 61.12 and Lemma 61.5 that the map \( \mathcal{U}: X \to |t| \) is a homeomorphism.

\[ ^{960}\text{For the proof that } \mathcal{U}(\langle \sigma \rangle) \subset \langle s_k \rangle \text{ it is arguably more efficient to work with the initial description of } \mathcal{U}. \]
(d) Using (c) one can easily verify that $\mathcal{D}$ is a bijection. Furthermore, it follows from Lemma 61.6 (1) together with (c) that $\mathcal{D}$ is continuous. Finally, it follows from (c) that for each simplex $t$ of $K$ the map $\mathcal{D}^{-1}: |t| \to |sd(K)|$ is continuous. By Lemma 61.6 (1) this shows that $\mathcal{D}^{-1}: |K| \to |sd(K)|$ is continuous. We have thus shown that $\mathcal{D}$ is indeed a homeomorphism. It follows easily from the definitions and Lemma 62.1 (1) that the homeomorphism is in fact natural.

(4) We leave the elementary task of verifying this statement to the reader.

(5) This statement follows almost immediately from the definitions. The only step which requires a short moment of reflection is to show that if $f: K \to L$ is a simplicial map, then the induced map $f_*: sd(K) \to sd(L)$ is actually order-preserving, i.e. it is a morphism in the category $\text{OrdAbsSimpCplx}$ of ordered abstract simplicial complexes.

The following definition is almost self-explanatory.

**Definition.** Let $(X, (K, \Theta: |K| \to X))$ be a simplicial complex and let $i \in \mathbb{N}_0$. We define the $i$-th barycentric subdivision of $(X, \Theta)$ to be $(X, (sd^i(K), \Theta: |sd^i(K)| = |K| \to X))$.

For completeness we state the following elementary lemma.

**Lemma 62.4.** For every $k \in \mathbb{N}_0$ the barycentric subdivision of a linear simplicial complex in $\mathbb{R}^n$ is again a linear simplicial complex in $\mathbb{R}^n$.

**Proof.** This statement follows almost immediately from the definition of the barycentric subdivision.

62.2. Stars and links in simplicial complexes. Given an (abstract) simplicial complex $K$ and a simplex $s$ we introduce and study the corresponding star $\text{St}(K, s)$ and $\text{Lk}(K, s)$. Both concepts are elementary, but both also play a major role in the study of (abstract) simplicial complexes.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex.

(1) Let $s \in S$ be a simplex. We introduce the following subsets of $|K|$:

\[
\text{star } \text{St}(K, s) := \bigcup_{t \in S \text{ with } s \subseteq t} |t| \quad \text{and the open star } \hat{\text{St}}(K, s) := \bigcup_{t \in S \text{ with } s \subseteq t} \langle t \rangle.
\]

Furthermore we define the link of $s$ to be

\[
\text{Lk}(K, s) := \bigcup_{t \in S \text{ with } s \cup t \subseteq S \text{ but with } s \cap t = \emptyset} |t|.
\]

(2) Given a vertex $v$ we use the obvious shorthand notations

\[
\text{St}(K, v) := \text{St}(K, \{v\}), \quad \hat{\text{St}}(K, v) := \hat{\text{St}}(K, \{v\}) \quad \text{and } \text{Lk}(K, v) := \text{Lk}(K, \{v\}).
\]

If $K$ is understood, then we drop it from the notation. Furthermore we extend the definition in the obvious way to simplicial complexes. (We refer to Figures 923 and 924 for illustrations of the definitions.)
Example. Let $K$ be an abstract simplicial complex. We consider the simplicial cone $\text{Cone}(K) = K \star \{\ast\}$ and the simplicial suspension $\Sigma(K) = K \star \{\pm 1\}$ as defined on page 1506. Let $\epsilon \in \{-1, 1\}$. It follows easily from the definitions that $\text{St}(\Sigma(K), \epsilon)$ is simplicially isomorphic to $\text{Cone}(K)$ and that $\text{Lk}(\Sigma(K), \epsilon) = K$.

Lemma 62.5. Let $(X, (K = (V, S), \Theta: |K| \to X))$ be a simplicial complex.

1. For every simplex $s \in S$ the following statements hold:
   a. We have the equality
      $$\text{Lk}(s) = \text{St}(s) \setminus \bigcup_{r \in S \text{ with } r \subset s} \hat{\text{St}}(r).$$
   b. The star $\text{St}(s)$ and the link $\text{Lk}(s)$ are subcomplexes of $X$. The corresponding abstract simplicial complexes are given by
      $$\left( \bigcup_{t \in S \text{ with } s \subset t} t, \{t \in S \mid s \cup t \in S\} \right) \quad \text{and} \quad \left( \bigcup_{t \in S \text{ with } s \subset t} t \setminus s, \{t \in S \mid s \cup t \in S \text{ and } s \cap t = \emptyset\} \right).$$

   Furthermore $X \setminus \hat{\text{St}}(s)$ is a subcomplex, the corresponding abstract simplicial complex is given by
      $$\left( V \setminus s, \{t \in S \mid t \cap s = \emptyset\} \right).$$

   c. The star $\text{St}(s)$ is naturally simplicially isomorphic to the simplicial join of the link $\text{Lk}(s)$ with the simplex $s$.

   d. (a) The open star $\hat{\text{St}}(s)$ is an open neighborhood of every point $P \in \Theta(|s|)$, in particular $\hat{\text{St}}(s)$ is an open subset of $X$.
   
      (b) The star $\text{St}(K, s)$ is a closed neighborhood of every point $P \in \Theta(|s|)$, in particular $\text{St}(K, s)$ is a closed subset of $X$.

   e. (a) The star $\text{St}(s)$ admits a deformation retraction to the simplex $\Theta(|s|)$. 

(β) The open star \(\hat{\text{St}}(s)\) admits a deformation retraction to the open simplex \(\Theta((s))\).

(f) Both \(\text{St}(s)\) and \(\hat{\text{St}}(s)\) are contractible.

(g) (α) The link \(\text{Lk}(s)\) is a deformation retract of \(\text{St}(s) \setminus \Theta(|s|)\).

(β) Given any \(P \in \Theta((s))\) the subcomplex \(\partial s \ast \text{Lk}(s)\) is a deformation retract of \(\text{St}(s) \setminus \{P\}\).

(h) If \(t\) is a simplex with \(s \subset t\), then \(\text{St}(t) \subset \text{St}(s)\).

(2) (a) Let \(s \in S\) be a simplex. For \(P \in \Theta((s))\) and \(v \in V\) we have \(P \in \hat{\text{St}}(v)\) if and only if \(v \in S\).

(b) The open stars \(\{\hat{\text{St}}(v)\}_{v \in V}\) defined by the vertices are an open cover of \(X\).

(3) Given simplices \(s_0, \ldots, s_n \in S\) the following equality holds:\footnote{Here we view \(\text{St}(s)\), \(\text{Lk}(s)\) and \(s\) as simplicial complexes.}

\[
\hat{\text{St}}(s_0) \cap \cdots \cap \hat{\text{St}}(s_n) = \begin{cases} 
\hat{\text{St}}(s_0 \cup \cdots \cup s_n), & \text{if } s_0 \cup \cdots \cup s_n \text{ is a simplex}, \\
\emptyset, & \text{otherwise}.
\end{cases}
\]

(Note that in Exercise 62.4 we will see that the analogous statement for the stars does not hold.)

(4) Given vertices \(v_0, \ldots, v_n \in V\) the following statement holds:

\[
\hat{\text{St}}(v_0) \cap \cdots \cap \hat{\text{St}}(v_n) \neq \emptyset \iff \{v_0, \ldots, v_n\} \text{ is a simplex of } K = (V, S).
\]

\footnote{In Exercise 62.2 we will prove the related statement that there exists a natural simplicial isomorphism \(\text{Lk}(K, s) \ast \partial s \cong \text{Lk}(\text{sd}(K), s)\).}

\footnote{To avoid confusion we point out that here, and in (4), we do not demand that the \(s_0, \ldots, s_n\) are distinct.}

\[\text{Figure 925. Illustration for Lemma 62.5 (3).}\]
Proof. Basic ally by definition we can assume that we are dealing with the topological realization $X = |K|$ of an abstract simplicial complex $K = (V, S)$.

(1) Let $s \in S$ be a $k$-simplex.

(a) We have the following equalities:

$$\operatorname{St}(s) \setminus \bigcup_{r \subset s} \overset{\cdot}{\operatorname{St}}(r) = \bigcup_{s \subset t} \{t\} \setminus \bigcup_{r \subset s \subset t} \{t\} = \bigcup_{s \subset t} \{t\} \setminus \bigcup_{r \subset s \subset t} \{t\}$$

(b) It follows easily from the definitions, (a) and Lemma 61.14 (4) that the star $\operatorname{St}(s)$, that the link $\operatorname{Lk}(s)$ and that $|K| \setminus \overset{\cdot}{\operatorname{St}}(s)$ are subcomplexes of $X$ and that the corresponding abstract simplicial complexes are the ones we wrote down.

(c) This statement follows immediately from the description of the abstract simplicial complexes given in (b) and the definition of the simplicial join that we gave on page 1506.

(d) First we show that $\overset{\cdot}{\operatorname{St}}(s)$ is an open subset of $|K|$. By the definition of the topology on $|K|$, see page 1487, we need to show that for every $k$-simplex $u$, with some characteristic map $\Phi_u : \Delta^k \to |u|$, the preimage $\Phi_u^{-1}(\overset{\cdot}{\operatorname{St}}(s))$ is an open subset of $\Delta^k$. In fact

$$\Phi_u^{-1}(\overset{\cdot}{\operatorname{St}}(s)) = \Phi_u^{-1}\left(\bigcup_{s \subset t} \{t\}\right) = \bigcup_{s \subset t} \Phi_u^{-1}(\{t\}) = \begin{cases} \Phi_u^{-1}(\{t\}) = \Delta^k \setminus \partial \Delta^k, & \text{if } s \subset u \\ \emptyset, & \text{else.} \end{cases}$$

Since $\Delta^k \setminus \partial \Delta^k$ and $\emptyset$ are open subsets of $\Delta^k$ we are done. A very similar argument also shows that $\overset{\cdot}{\operatorname{St}}(s)$ is a closed subset of $|K|$. Now let $P \in \Theta(\langle s \rangle)$. By definition $P \in \overset{\cdot}{\operatorname{St}}(s) \subset \operatorname{St}(s)$. Since $\overset{\cdot}{\operatorname{St}}(s)$ is an open subset of $|K|$ we see that $\overset{\cdot}{\operatorname{St}}(s)$ and $\operatorname{St}(s)$ are both neighborhoods of $P$.

(e) (a) We write $s = \{v_0, \ldots, v_k\}$. Note that by (1) and Lemma 61.8 we can view $\operatorname{St}(s)$ as a simplicial complex in its own right. Now let $t$ be a simplex $t$ with $s \subset t$. We write $t = \{v_0, \ldots, v_k, v_{k+1}, \ldots, v_l\}$. We consider the map

$$F_t : [t] \times [0, 1] \to [t]$$

$$\left( \sum_{i=0}^{k} \lambda_i \cdot v_i, r \right) \mapsto \sum_{i=0}^{k} \lambda_i \cdot v_i + (1-r) \cdot \sum_{i=k+1}^{l} \lambda_i \cdot v_i + r \cdot \left( \sum_{i=k+1}^{l} \lambda_i \right) \cdot v_k.$$

It follows immediately from the definitions that that these maps $F_t$ combine to give a well-defined map $F : \operatorname{St}(s) \times [0, 1] \to \operatorname{St}(s)$. Furthermore it is fairly straightforward to deduce from the fact that $\operatorname{St}(s)$ is a simplicial complex, Lemma 61.24 and Lemma 36.8 (3) that $F$ is actually continuous. Now that continuity is out of the way it is clear that $F$ is a deformation retraction from $\operatorname{St}(s)$ to $|s|$. 

62. THE SIMPLICIAL APPROXIMATION THEOREM 1525
(β) In (α) we just gave an explicit deformation retraction from \( \text{St}(s) \) to \(|s|\). It follows basically from the definitions that this map restricts to a deformation retraction from \( \tilde{\text{St}}(s) \) to the open simplex \( \langle s \rangle \).

(f) This statement follows immediately from (e), together with Lemma \ref{lem:abstract-simplicial-complex} (3) and the observation that \( \Delta^k \) and \( \tilde{\Delta}^k \) are contractible.

![Illustration for the proof of Lemma \ref{lem:abstract-simplicial-complex}(1).](image)

FIGURE 926. Illustration for the proof of Lemma \ref{lem:abstract-simplicial-complex}(1).

(g) Let \( P \in \Theta(\langle s \rangle) \). The proofs that the link \( Lk(s) \) is a deformation retract of \( \text{St}(s) \setminus |s| \) and that the subcomplex \( \partial s \ast Lk(s) \) is a deformation retract of \( \text{St}(s) \setminus \{P\} \) is quite similar to the proof of (e). We will fill in the details in Exercise \ref{ex:abstract-simplicial-complex}.

(h) If \( t \) is a simplex with \( s \subset t \), then it follows immediately from the definitions that \( \text{St}(t) \subset \text{St}(s) \).

(2) (a) Let \( s \in S \) be a simplex, let \( P \in \langle s \rangle \) and let \( v \in V \). We have

\[
P \in \tilde{\text{St}}(v) = \bigcup_{t \in S \text{ with } v \in t} \langle t \rangle \quad \iff \quad \langle s \rangle \subset \bigcup_{t \in S \text{ with } v \in t} \langle t \rangle \quad \iff \quad v \in s.
\]

Both statements follow from Lemma \ref{lem:open-cover} (2).

(b) Recall that Lemma \ref{lem:open-cover} (2) says that given any point \( P \in K \) there exists an \( s \in S \) with \( P \in \langle s \rangle \). By (a) we know that for any vertex \( v \) of \( s \) we have \( P \in \langle s \rangle \subset \tilde{\text{St}}(v) \). This shows that the open stars corresponding to the vertices cover all of \( K \). By (1d) we know that this cover is in fact an open cover.

(3) Let \( s_0, \ldots, s_n \in S \). We have the following equality:

\[
\bigcap_{i=0}^n \tilde{\text{St}}(s_i) = \bigcap_{i=0}^n \bigcup_{t \in S \text{ with } s_i \subset t} \langle t \rangle = \bigcup_{t \in S \text{ with } s_0, \ldots, s_n \subset t} \langle t \rangle = \begin{cases} 
\tilde{\text{St}}(s_0 \cup \cdots \cup s_n), & \text{if } s_0 \cup \cdots \cup s_n \in S, \\
\emptyset, & \text{otherwise.}
\end{cases}
\]

(4) Given \( v_0, \ldots, v_n \in V \) the following holds:

\[
\tilde{\text{St}}(v_0) \cap \cdots \cap \tilde{\text{St}}(v_n) \neq \emptyset \quad \iff \quad \text{there exists a } t \in S \text{ with } v_0, \ldots, v_n \in t \quad \iff \quad \{v_0, \ldots, v_n\} \text{ is a simplex.}
\]

\[\text{by (3)}\]

\[\text{by definition of an abstract simplicial complex} \]

**Definition.** An abstract simplicial complex \( K = (V, S) \) is called *locally finite* if given any vertex \( v \in V \) there exist only finitely many simplices that contain \( v \).

The following proposition can be viewed as an analogue of Proposition \ref{prop:abstract-simplicial-complex}.
**Proposition 62.6.** Let \( K = (V, S) \) be an abstract simplicial complex. The following three statements are equivalent:

1. The abstract simplicial complex \( K \) is locally finite.
2. For every vertex \( v \in V \) the star \( \text{St}(K, \{v\}) \) is a finite simplicial complex.
3. For every vertex \( v \in V \) the link \( \text{Lk}(K, \{v\}) \) is a finite simplicial complex.
4. The topological realization \( |K| \) is regionally compact.

**Proof (\(*\)).** Let \( K = (V, S) \) be an abstract simplicial complex.

We start out with (1) \(\Leftrightarrow\) (2) \(\Leftrightarrow\) (3). This equivalence of statements follows almost immediately from the definitions and the observation that an abstract simplicial complex is finite if and only if it has finitely many vertices.

We continue with (3) \(\Rightarrow\) (4). We need to show that \( |K| \) is regionally compact. By Lemma 62.5 (2) together with Lemma 61.3 (2) it suffices to show that every point \( P \in |K| \) admits a compact neighborhood. By Lemma 61.11 there exists a simplex \( s \in S \) such that \( P \) is contained in the open simplex \( \langle s \rangle \). By Lemma 62.5 (1d) we know that \( \text{St}(K, s) \) is a neighborhood of \( P \). Since \( \text{St}(K, s) \) is a finite simplicial complex we obtain from Lemma 61.9 that \( \text{St}(K, s) \) is compact.

Finally we prove (4) \(\Rightarrow\) (3). Now we assume that \( |K| \) is regionally compact. Let \( v \in V \) be a vertex. By Lemma 62.5 (1d) we know that the open star \( \overset{\circ}{\text{St}}(K, \{v\}) \) is an open neighborhood of \( v \). Since \( |K| \) is regionally compact there exists a compact neighborhood \( X \) of \( v \) with \( X \subset \overset{\circ}{\text{St}}(K, \{v\}) \). Since \( X \) is compact we know by Proposition 61.12 that there exists a finite subcomplex \( L \) of \( K \) such that \( X \) is contained in \( |L| \).

Since \( X \) is a neighborhood of \( v \) we know that there exists an open neighborhood \( U \) of \( v \) with \( v \in U \subset X \). It follows from Lemma 61.11 (7) that for any simplex \( s \) with \( v \in s \) we have \( U \cap \langle s \rangle \neq \emptyset \). But by Lemma 61.11 (5) that implies \( |s| \subset |L| \). In other words, we see that \( \text{St}(K, \{v\}) \subset |L| \). Since \( L \) is finite we see that \( \text{St}(K, \{v\}) \) is a finite simplicial complex.

![Illustration](image-url)

*Figure 9.27.* Illustration for the proof of Proposition 62.6 (4) \(\Rightarrow\) (3).

We recall the following definition from page 141.

**Definition.** The **diameter** of a non-empty subset \( A \) of some \( \mathbb{R}^n \) is defined as

\[
\text{diam}(A) := \sup \{ \|a - b\| \mid a, b \in A \} \in \mathbb{R}_{\geq 0} \cup \{\infty\}.
\]

It is pretty clear that the barycentric subdivision of a linear simplicial complex results in more but smaller simplices. The following lemma is one way of formulating precisely that the simplices shrink.
Lemma 62.7. If $X$ is a finite linear non-empty simplicial complex in $\mathbb{R}^n$, then
\[
\lim_{k \to \infty} \max_{v \text{ is a vertex of } sd^k(X)} \{\text{diam}(St(sd^k(X), v))\} = 0.
\]

the underlying topological space of $X$ and $sd^k(X)$ is the same

![Diagram](image)

the maximal diameter of a star shrinks

Figure 928. Illustration of Lemma 62.7

Proof ($*$). Let $Y$ be a finite linear non-empty $d$-dimensional simplicial complex in $\mathbb{R}^n$. We define the mesh of $Y$ as
\[
\text{mesh}(Y) := \max\{\text{diam}(s) \mid s \text{ is a simplex of } Y\}.
\]

The lemma follows from Lemma 62.3 (1) and (2), Lemma 62.4 and the following claim. Claim.

(1) For every vertex $v$ of $Y$ we have $\text{diam}(St(v)) \leq 2 \cdot \text{mesh}(Y)$.
(2) For every $k \in \mathbb{N}_0$ we have
\[
\text{mesh}(sd^k(Y)) \leq \left(\frac{d}{d+1}\right)^k \cdot \text{mesh}(Y).
\]

We turn to the proofs of the two statements:

(1) Let $v$ be a vertex of $Y$. We need to show that $\text{diam}(St(v)) \leq 2 \cdot \text{mesh}(Y)$. Thus let $P, Q \in St(v)$. By definition of the star $\text{St}(v)$ there exist simplices $s$ and $t$ with $v, P \in s$ and with $v, Q \in t$. We see that
\[
\|P - Q\| \leq \|P - v\| + \|Q - v\| \leq \text{diam}(s) + \text{diam}(t) \leq 2 \text{mesh}(Y).
\]

triangle inequality since $v, P \in s$ and $v, Q \in t$ definition of mesh

(2) Once the reader has untangled the definitions it will have become clear that this statement is nothing but a reformulation of Lemma 43.29.

\[
\]

Figure 929. Illustration of the proof of Lemma 62.7
62.3. **The Simplicial Approximation Theorem.** In this section we will state and prove the Simplicial Approximation Theorem which is one of the main tools in the study of simplicial complexes. Before we can state the theorem we need to introduce one last basically self-explanatory notion.

**Definition.** Let $X$ be an (abstract) simplicial complex and let $A$ be a subcomplex. We refer to $(X, A)$ as a pair of (abstract) simplicial complexes.

Now we are ready to formulate the main theorem of this section.

**Theorem 62.8. (Simplicial Approximation Theorem)** Let $(X, A)$ and $(Y, B)$ be pairs of simplicial complexes. Let $f: (X, A) \to (Y, B)$ be a map of pairs of topological spaces. If $X$ is finite, then there exists an iterated barycentric subdivision $(\tilde{X}, \tilde{A})$ of $(X, A)$ and a simplicial map $\tilde{f}: (\tilde{X}, \tilde{A}) \to (Y, B)$ with the following properties:

1. The map $\tilde{f}$ is homotopic to $f$ as a map $(X, A) \to (Y, B)$ of pairs of topological spaces.
2. For every vertex $v$ of $\tilde{X}$ we have $f(\text{St}(\tilde{X}, v)) \subset \text{St}(Y, \tilde{f}(v))$.

**Example.** We consider the simplicial complexes $X$ and $Y$ and the map $f: X \to Y$ that are illustrated in Figure 930. This map is actually not homotopic to a simplicial map $\tilde{f}: \text{sd}(X) \to Y$. But after a single barycentric subdivision we see that $f$ is homotopic to a simplicial map $\tilde{f}$: $\text{sd}(X) \to Y$.

**Remark.**

1. The first statement of the Simplicial Approximation Theorem 62.8 is of course somewhat similar to the statement of the Cellular Approximation Theorem 38.13. But since simplicial complexes and simplicial maps are more rigid than their cellular siblings there are some important differences:

   (a) On the negative side the Simplicial Approximation Theorem 62.8 only applies to finite domains and we need to allow for several barycentric subdivisions.

   (b) On the plus side the output is much stronger since simplicial maps are much more restrictive than cellular maps. We will make use of this shortly.

2. The second statement of the Simplicial Approximation Theorem 62.8 essentially says that the new map $\tilde{f}$ does not stray too far away from the original map $f$.

Before we give a proof of the Simplicial Approximation Theorem 62.8 let us point out an important consequence. On page 1326 we saw that homotopy groups of fairly simple topological spaces, e.g. $S^1 \vee S^2$, can be uncomfortably large, for example we saw that $\pi_2(S^1 \vee S^2)$ is not necessarily finitely generated. In Question 10.16 we asked whether
the homotopy groups of a countable CW-complex are actually countable. The following proposition gives us some evidence for a positive answer.

**Proposition 62.9.** If $X$ is a simplicial complex with countably many simplices, then for every $n \in \mathbb{N}$ and every $x_0 \in X$ the group $\pi_n(X, x_0)$ is countable.

**Proof.** Let $X$ be a simplicial complex and let $n \in \mathbb{N}$. By the discussion on page 1500 we can pick a finite simplicial structure for $S^n$. Let $\ast$ be a vertex of $S^n$. By Proposition 40.5 it suffices to show that for a single vertex $x_0$ of $X$ the group $\pi_n(X, x_0)$ is countable.

Next note that by the Simplicial Approximation Theorem 62.8, applied to the maps $(S^n, \{\ast\}) \to (X, x_0)$ we have a surjection

$$\bigcup_{i \in \mathbb{N}_0} \text{set of simplicial maps } (sd^i(S^n), \{\ast\}) \to (X, x_0) \to [(S^n, \ast), (X, x_0)] = \pi_n(X, x_0).$$

By Lemma 61.3 (2) together with Lemma 1.7 (3) the set on the left-hand side is countable. It follows from Lemma 1.7 (3) that the set on the right-hand side, i.e. $\pi_n(X, x_0)$, is also countable.

It is not immediately clear how one could possibly generalize the proof of Proposition 62.9 from simplicial complexes to CW-complexes. In particular at the moment we still lack the tools to tackle Question 40.16 completely. We will return to Question 40.16 with Proposition 85.19.

Before we turn to the proof of the Simplicial Approximation Theorem 62.8 let us record the following immediate corollary to Proposition 62.9.

**Corollary 62.10.** For every $n, k \in \mathbb{N}$ the group $\pi_n(S^k)$ is countable.

Now we turn to the proof of the Simplicial Approximation Theorem 62.8. In an attempt to keep the notation at a manageable level we will assume for simplicity that $A = B = \emptyset$. We leave it to the reader to modify the subsequent proof to provide a proof for the general case.

Thus let $(X, (K = (V, S), \Theta: |K| \to X))$ and $(Y, (L = (W, T), \Omega: |L| \to Y))$ be two simplicial complexes. For convenience we identify $V$ with its image $\Theta(V) \subset X$ and we identify $W$ with its image $\Omega(W) \subset Y$. Furthermore let $f: X \to Y$ be a continuous map. We make the following preparations.

1. Recall that we assume that $X$ is finite. Evidently we can assume that $X$ is non-empty.
2. It follows from the hypothesis that $X$ is finite and the combination of Lemma 61.9, Lemma 2.40 and Proposition 61.12 that $f(X)$ is contained in a finite subcomplex of $Y$. Thus we can assume that $Y$ is also a finite simplicial complex.
3. Since $X$ and $Y$ are finite it follows from Lemma 61.22 that we can and will assume that $X$ and $Y$ are linear simplicial complexes contained in some $\mathbb{R}^m$ respectively some $\mathbb{R}^n$. Recall that this means, by definition, that $X$ and $Y$ are equipped with the subspace topology coming from $\mathbb{R}^m$ and $\mathbb{R}^n$. In particular we can use the usual Euclidean metric on $\mathbb{R}^m$ to view $X$ as a metric space.
We start out with the following claim.

**Claim 1.** There exists a \( k \in \mathbb{N}_0 \) such that for every vertex \( v \) of \( \text{sd}^k(X) \) there exists a \( w \in W \) with \( f(\text{St}(\text{sd}^k(X), v)) \subseteq \overset{\circ}{\text{St}}(Y, w) \).

Recall that by Lemma 62.5(2) we know that the open stars \( \{\overset{\circ}{\text{St}}(w)\}_{w \in W} \) form an open cover of \( Y \). It follows that the sets \( U_w := f^{-1}(\overset{\circ}{\text{St}}(w)) \subseteq X \) form an open cover of \( X \). Since \( X \) is compact we obtain from the Lebesgue Lemma 2.75 that there exists an \( \epsilon > 0 \) such that for every subset \( A \) of \( X \) with \( \text{diam}(A) < \epsilon \) there exists a \( w \in W \) with \( A \subseteq U_w \).

By Lemma 62.7 there exists a \( k \in \mathbb{N}_0 \) such that for every vertex \( v \) of \( \text{sd}^k(X) \) we have \( \text{diam}(\text{St}(\text{sd}^k(X), v)) < \epsilon \). In other words, this \( k \) has the desired property. □

**Figure 931.** Illustration for the proof of the Simplicial Approximation Theorem 62.8

By Lemma 62.3(1) and Lemma 62.4 we know that \( \text{sd}^k(X) \) is again a finite linear simplicial complex in \( \mathbb{R}^m \). Thus we can safely replace \( X \) by \( \text{sd}^k(X) \). We are now in the following setting:

\( (*) \) For every \( v \in V \) there exists a \( w \in W \) with \( f(\text{St}(X, v)) \subseteq \overset{\circ}{\text{St}}(Y, w) \). In other words, there exists a map \( \varphi : V \to W \) with the property that for every vertex \( v \in V \) we have \( f(\text{St}(X, v)) \subseteq \text{St}(Y, \varphi(v)) \).

We continue the proof with the following claim.

**Claim 2.** For every simplex \( s \in S \) the image \( \varphi(s) \) is a simplex in \( T \).

Let \( s = \{v_0, \ldots, v_k\} \) be a simplex of \( K = (V, S) \). Note that

- \( v_0, \ldots, v_k \) form a simplex in \( X \)
- \( \overset{\circ}{\text{St}}(v_0) \cap \ldots \cap \overset{\circ}{\text{St}}(v_k) \neq \emptyset \) \( \Rightarrow f(\overset{\circ}{\text{St}}(v_0) \cap \ldots \cap \overset{\circ}{\text{St}}(v_k)) \neq \emptyset \)
- \( f(\overset{\circ}{\text{St}}(v_0)) \cap \ldots \cap f(\overset{\circ}{\text{St}}(v_k)) \neq \emptyset \) \( \Rightarrow \overset{\circ}{\text{St}}(\varphi(v_0)) \cap \ldots \cap \overset{\circ}{\text{St}}(\varphi(v_k)) \neq \emptyset \)
- By choice of \( \varphi \) we have \( f(\text{St}(v_i)) \subseteq \overset{\circ}{\text{St}}(\varphi(v_i)) \)
- \( \{\varphi(v_0), \ldots, \varphi(v_k)\} \) is a simplex in \( T \). □

Claim 2 says that \( \varphi : V \to W \) defines a simplicial map \( K = (V, S) \to L = (W, T) \). It follows from Lemma 61.15 that there exists a simplicial map \( g : X \to Y \) with \( g|_V = \varphi \). We claim that \( g \) is the desired map.

First note that it follows immediately from the construction of \( \varphi \) and \( g \) that for any vertex \( v \) of \( \text{sd}(X) \) we have \( f(\text{St}(X, v)) \subseteq \text{St}(Y, g(v)) \). Thus it remains to show that \( g \) is in
fact homotopic to our original map $f$. To do so we consider the usual interpolation between the maps $f$ and $g$:

$$F: X \times [0, 1] \to \mathbb{R}^n$$

$$(x, t) \mapsto f(x) \cdot (1 - t) + g(x) \cdot t.$$  

It remains to show the map $F$ actually takes values in the subset $Y \subset \mathbb{R}^n$. For each $x \in X$ we know that $f(x) \in Y$ and $g(x) \in Y$. We need to show that for each $t \in [0, 1]$ the point $f(x) \cdot (1 - t) + g(x) \cdot t$ also lies in $Y$. In our setting this follows from the observation that simplices are convex, see Lemma 61.23 (1b), together with the following claim.

**Claim 3.** For every $x \in X$ there exists a $t \in T$ such that both $f(x)$ and $g(x)$ are contained in $\Omega(|t|)$.

Now let $x \in X$. By Lemma 61.11 (2) there exists a unique simplex $s = \{v_0, \ldots, v_k\}$ such that $x \in \Theta(\langle s \rangle)$. We see that

by Lemma 62.3 (3), since $s = \{v_0, \ldots, v_k\}$

$x \in \Theta(\langle s \rangle) \Rightarrow x \in \hat{S}(v_0) \cap \cdots \cap \hat{S}(v_k) \Rightarrow f(x) \in f(\hat{S}(v_0) \cap \cdots \cap \hat{S}(v_k))$

$\Rightarrow f(x) \in f(\hat{S}(v_0)) \cap \cdots \cap f(\hat{S}(v_k)) \Rightarrow f(x) \in \hat{S}(\varphi(v_0)) \cap \cdots \cap \hat{S}(\varphi(v_k))$

by choice of $\varphi$ we have $f(\hat{S}(v_i)) \subset \hat{S}(\varphi(v_i))$

$\Rightarrow$ there exists a $t \in T$ which contains $\varphi(s) = \{\varphi(v_0), \ldots, \varphi(v_k)\}$ and with $f(x) \in \Omega(|t|)$.

It remains to show that $g(x) \in \Omega(|t|)$. In fact we see that

$x \in \Theta(\langle s \rangle) \Rightarrow x \in \Theta(|s|) \Rightarrow g(x) \in \Omega(|\varphi(s)|) \Rightarrow g(x) \in \Omega(|t|)$.

by definition of $\langle s \rangle$ and $|s|$ follows from the discussion since $\varphi(s) \subset t$

We have thus found the desired simplex $t$.

the image of every closed star is contained in an open star

the simplicial map $g$

\[\text{Figure 9.32. Illustration for the proof of Theorem 62.8}\]

62.4. **Mapping cylinders and mapping cones of simplicial maps.** In this section we will see that there exist simplicial analogues of the mapping cylinder and the mapping cone that we introduced on page 697 and 701. The definitions of these simplicial analogues that we give are taken from [Kas14].

\[\text{Note that we showed in Lemma 18.1 that this map is actually continuous.}\]
Definition. Let $f: K \to L$ be a simplicial map between two abstract simplicial complexes. The simplicial mapping cylinder $\text{Cyl}(f: K \to L)$ is the abstract simplicial complex that is given by the following data:

1. The vertex set is the disjoint union of the vertex set of the barycentric subdivision $\text{sd}(K)$ of $K$ and the vertex set of $L$.
2. The set of simplices is given by

$$\left\{ \sigma \sqcup \tau \mid \sigma = \emptyset \text{ or } \sigma \text{ a simplex of } \text{sd}(K) \& \tau = \emptyset \text{ or } \tau \text{ a simplex of } L \text{ or such that } \right\}$$

$$\uparrow$$

for every vertex $v = s \in \sigma$ and every vertex $w \in \tau$ we have $w \in f(s)$

Remark. It is not clear to me whether the statement of Lemma 62.11 (2) also holds if $K$ is infinite. For example one might be able to get stronger results using Lemma 38.11. But for our purposes it is good enough to know that the statement holds if $K$ is finite.

**Figure 933**

Let $f: K \to L$ be a simplicial map between two finite abstract simplicial complexes. One might expect that the next lemma states, say under the hypothesis that $K$ is finite, that the topological realization $|\text{Cyl}(f: K \to L)|$ of the simplicial mapping cylinder is homeomorphic to the mapping cylinder $|\text{Cyl}(|f|: |K| \to |L|)|$ of the map between the topological realizations. We will prove a weaker statement, but which nonetheless says that the simplicial mapping cylinder has all the essential properties we really need.

**Lemma 62.11.** Let $f: K \to L$ be a simplicial map between two abstract simplicial complexes.

1. The simplicial mapping cylinder $\text{Cyl}(f: K \to L)$ contains $\text{sd}(K)$ and $L$ as subcomplexes.

We now assume that $K$ is actually a finite abstract simplicial complex. We denote by $\iota: \text{sd}(K) \to \text{Cyl}(f: K \to L)$ the natural inclusion and we denote by $\tilde{\iota}: |K| \to |\text{sd}(K)|$ the natural homeomorphism from Lemma 62.3.

2. There exists a deformation retraction $R: |\text{Cyl}(f)| \times [0, 1] \to |\text{Cyl}(f)|$ from $|\text{Cyl}(f)|$ to the subset $|L|$ such that $R_0 \circ \iota \circ \tilde{\iota} = f: |K| \to |\text{Cyl}(f)|$.

3. The map $|f|: |K| \to |\text{Cyl}(f)|$ is homotopic to the map $|\iota| \circ \tilde{\iota}: |K| \to |\text{Cyl}(f)|$.

**Remark.** It is not clear to me whether the statement of Lemma 62.11 (2) also holds if $K$ is infinite. For example one might be able to get stronger results using Lemma 38.11. But for our purposes it is good enough to know that the statement holds if $K$ is finite.
Sketch of proof. Let \( f : K \to L \) be a simplicial map between two abstract simplicial complexes.

1. By taking \( \tau = \emptyset \) respectively \( \sigma = \emptyset \) one sees immediately that \( \text{sd}(K) \) and \( L \) are subcomplexes of \( \text{Cyl}(f : K \to L) \).

We now assume that \( K \) is actually a finite abstract simplicial complex.

2. Given \( r \in \mathbb{N}_0 \) we denote by \( W_r \) the topological realization of the maximal subcomplex of \( \text{Cyl}(f : K \to L) \) that contains all vertices of \( L \) and that contains all vertices \( \text{sd}(K) \) of the form \( s \) where \( s \) is a \( \geq r \)-simplex of \( K \). We leave it to the reader to verify that for each \( r \in \mathbb{N}_0 \) there exists a unique homotopy

\[
F_r : W_r \times [0, 1] \to W_r
\]

with the following properties:

(a) The homotopy is stationary on \( W_{r-1} \).

(b) Given any vertex \( \tilde{g} \) that lies in \( W_r \) but that does not lie in \( W_{r-1} \) the homotopy is given by \( F_r(\tilde{g}, t) = \tilde{g} \cdot (1 - t) + f(s) \cdot t \).

(c) The restriction of \( F_r \) to each simplex takes values in a simplex and it is linear. Note that \( F_r \) is in particular a deformation retraction from \( W_r \) to \( W_{r-1} \). The composition of the homotopies \( F_{\text{dim}(K)}, \ldots, F_1 \) and \( F_0 \) has the desired properties.

3. This statement follows immediately from (2).

Definition. Let \( f : K \to L \) be a simplicial map between two abstract simplicial complexes. The simplicial mapping cone \( \text{Cone}(f : K \to L) \) is defined as the union of the simplicial mapping cylinder \( \text{Cyl}(f : K \to L) \) and the simplicial cone \( \text{Cone}(\text{sd}(K)) \) that we defined on page \([1506]\).
62. The Simplicial Approximation Theorem

62.5. Simplicial structures and CW-structures II. Recall that in Lemma 61.24 we saw that every (ordered) simplicial complex admits a (natural) CW-complex structure where given any \( n \in \mathbb{N} \) the \( n \)-simplices of the simplicial structure are precisely the \( n \)-cells of the CW-structure. The converse of this statement does not hold, in fact in Proposition 61.28 we showed that there exists a CW-complex that does not admit a simplicial structure.

Nonetheless, in this section we will prove a partial converse to Lemma 61.24, namely we will show that every CW-complex is homotopy equivalent to a simplicial complex. More precisely, we will prove the following proposition.

**Proposition 62.12.**

1. Every finite CW-complex is homotopy equivalent to a finite simplicial complex of the same dimension.
2. Every countable CW-complex is homotopy equivalent to a countable simplicial complex of the same dimension.
3. Every CW-complex is homotopy equivalent to a simplicial complex of the same dimension.

**Remark.** Alternative proofs for Proposition 62.12 are given in [Hat02, Theorem 2C.5], [LW69, Theorem 6.1], [Whd97b, Theorem 13] and [Gra75, Corollary 16.44].

Most of the work in the proof of Proposition 62.12 is done in the following lemma.

**Lemma 62.13.** Let \( X \) be a CW-complex that is homotopy equivalent to the topological realization of an abstract simplicial complex \( K \). Furthermore let \( \varphi : S^{k-1} \to X \) be a map. There exists an \( i \in \mathbb{N}_0 \) a simplicial map \( f : \text{sd}^i(S_{k-1}) \to K \) such that \( X \cup^\varphi B^k \) is homotopy equivalent to the topological realization of the simplicial mapping cone \( \text{Cone}(f : \text{sd}^i(S_{k-1}) \to K) \).

The key ingredient in the proof of Lemma 62.13 is the Homotopy Pushout Theorem which we recall for the reader’s convenience.
Theorem 39.18. (Homotopy Pushout Theorem) Suppose we are given the following commutative diagram of maps between topological spaces:

\[
\begin{array}{ccc}
Y & \xleftarrow{f} & X \\
\varphi_Y & & \varphi_X \\
Y' & \xleftarrow{f'} & X'.
\end{array}
\]

If the vertical maps are homotopy equivalences and if the maps \(i\) and \(i'\) to the right are closed cofibrations, then the induced map

\[Y \cup_A X \to Y' \cup_{A'} X'\]

between the pushouts is a homotopy equivalence.

Proof of Lemma 62.13. We start out with the following preparations:

1. By the discussion on page 1492 there exists a homeomorphism \(g: |D_k| \to B^k\) which restricts to a homeomorphism \(g: |S_{k-1}| \to S^{k-1}\).
2. Given any abstract simplicial complex \(L\) and given any \(i \in \mathbb{N}_0\) we always denote by \(\bar{c}: |L| \to \text{sd}^i(L)| \) the homeomorphism from Lemma 62.3 (3).
3. By the Simplicial Approximation Theorem 62.8 there exists an \(i \in \mathbb{N}_0\), a simplicial map \(f: \text{sd}^i(S_{k-1}) \to K\) and a homotopy \(F: |\text{sd}^i(S_{k-1})| \times [0,1] \to |K|\) such that \(F_0 = \theta \circ \varphi \circ g \circ \bar{c}^{-1}\) and such that \(F_1 = |f|\).
4. We denote by \(j: |K| \to |\text{Cyl}(f: \text{sd}^i(S_{k-1}) \to K)|\) the inclusion map. Note that by Lemma 62.11 (2) we know that \(j\) is a homotopy equivalence.
5. Finally note that it follows immediately from Lemma 62.11 (3) that there exists a homotopy \(G: |\text{sd}^i(S_{k-1})| \times [0,1] \to |\text{Cyl}(f: \text{sd}^i(S_{k-1}) \to K)|\) with \(G_0 = j \circ |f|\) and such that \(G_1 = |\iota| \circ \bar{c}\) where \(\iota: \text{sd}^{i+1}(S_{k-1}) \to \text{Cyl}(f: \text{sd}^i(S_{k-1}) \to K)\) is the natural inclusion.
We consider the following commutative diagram:

\[
\begin{array}{cccc}
X & \xleftarrow{\varphi} & S^{k-1} \cup & \xrightarrow{g^{-1}} B^k \\
\downarrow{\theta} & & \downarrow{g^{-1}} & \\
|K| & \xleftarrow{\theta \circ \varphi \circ g} & |S_{k-1}| & \xrightarrow{\iota} | \Cone(S_{k-1})| \\
\downarrow{id} & & \downarrow{\iota} & \\
|K| & \xleftarrow{\theta \circ \varphi \circ g \circ \iota^{-1}} & |\sd^i(S_{k-1})| & \xrightarrow{\iota} | \Cone(\sd^i(S_{k-1}))| \\
\downarrow{id} & & \downarrow{\iota} & \\
|K| & \xleftarrow{F} |\sd^i(S_{k-1})| \times [0,1] & \xrightarrow{\iota} | \Cone(\sd^i(S_{k-1}))| \times [0,1] \\
\downarrow{id} & & \downarrow{\iota} & \\
|K| & \xleftarrow{j} |\sd^i(S_{k-1})| & \xrightarrow{\iota} | \Cone(\sd^i(S_{k-1}))| \\
\downarrow{id} & & \downarrow{\iota} & \\
|\Cyl(f)| & \xleftarrow{j \circ f} |\sd^i(S_{k-1})| & \xrightarrow{\iota} | \Cone(\sd^i(S_{k-1}))| \\
\downarrow{id} & & \downarrow{\iota} & \\
|\Cyl(f)| & \xleftarrow{G} |\sd^i(S_{k-1})| & \xrightarrow{\iota} | \Cone(\sd^i(S_{k-1}))| \\
\downarrow{id} & & \downarrow{\iota} & \\
|\Cyl(f)| & \xleftarrow{|i|} |\sd^{i+1}(S_{k-1})| & \xrightarrow{\iota} | \Cone(\sd^{i+1}(S_{k-1}))|. \\
\end{array}
\]

It follows from (4) and elementary observations that all of the vertical maps are homotopy equivalences. Furthermore note that it follows immediately from Proposition 39.4 and 39.12 that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem 39.18 applied altogether eight times, that the induced maps between the various pushouts have homotopy inverses. Combining these eight homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence

\[
X \cup_{S_{k-1}} B^k \rightarrow |\Cyl(f)| \cup_{\sd^i(S_{k-1})} | \Cone(\sd^{i+1}(S_{k-1}))|.
\]

Proof of Proposition 62.12 (1). Let \(X\) be a finite CW-complex. An induction argument over the number of cells, using Lemma 62.13 shows that \(X\) is homotopy equivalent to a finite simplicial complex of the same dimension.

Sketch of a proof of Proposition 62.12 (2) and (3). Now let \(X\) be any (countable) CW-complex. Without loss of generality we can and will assume that \(X\) is connected and non-empty.

Claim. There exists an ascending sequence \(K_{-1} \subset K_0 \subset K_1 \subset K_2 \subset \ldots\) of abstract simplicial complexes and a sequence of homotopy equivalences \(\theta_n: X^n \rightarrow |K_n|, n \in \mathbb{Z}_{\geq -1}\)
such that for each $n \in \mathbb{N}_0$ there exists a homotopy $F_n: X^n \times [0, 1] \to |K_{n+1}|$ between the maps $X^n \theta_n |K_n| \to |K_{n+1}|$ and $X^n \to X^{n+1} \theta_{n+1} |K_{n+1}|$.

We take $K_{-1}$ to be the empty simplicial complex. Assume that we have already constructed $K_{-1}, \ldots, K_{n}$ and $\theta_{-1}, \ldots, \theta_n$. We denote by $\{\varphi_i: S^n \to X^n\}_{i \in I}$ the attaching maps of the $(n+1)$-cells of $X$. By basically the same argument as in the proof of Lemma [62.13] we obtain $d_i \in \mathbb{N}_0$, simplicial maps $f_i: \text{sd}^{d_i}(S_n) \to K_n$ and a homotopy equivalence

$$\theta_{n+1}: X^n \cup \bigcup_{i \in I} B^{n+1} \ni \longmapsto \text{Cyl} \left( \bigcup_{i \in I} f_i \cup \text{sd}^{d_i}(S_n) \to K \big) \cup \bigcup_{i \in I} \text{Cone}(\text{sd}^{d_i+1}(S_n)) \right]$$

such that the maps $X^n \theta_n |K_n| \to |K_{n+1}|$ and $X^n \to X^{n+1} \theta_{n+1} |K_{n+1}|$ are homotopic. $\square$

We set $K := \bigcup_{n \in \mathbb{N}_0} K_n$. If $X$ is countable, then $K$ is also countable. Thus it remains to show that $X$ is homotopy equivalent to $|K|$.  

(1) As on page 101 we equip $[0, \infty)$ with the CW-structure where the 0-skeleton is given by $\mathbb{N}$ and we refer to the CW-complex

$$T(X) := \bigcup_{n \in \mathbb{N}_0} X^n \times [n, n+1] \subset X \times [0, \infty)$$

as the telescope of $X$.

(2) The homotopies $F_i$ define a map $F: T(X) \to |K|$ which is continuous by Lemma [36.7].

(3) Furthermore the projection maps $X^n \times [0, 1] \to X^n$ define a map $p: T(X) \to X$ which is also continuous by Lemma [36.7].

We pick $P \in X^0$. It follows fairly easily from Proposition [40.11] and the claim that for every $n \in \mathbb{N}$ the maps $F_n: \pi_n(T(X), P) \to \pi_n(|K|, P)$ and $p_n: \pi_n(T(X), P) \to \pi_n(X, P)$ are isomorphisms. It follows from the Whitehead Theorem [119.9] that $F: T(X) \to |K|$ and $p: T(X) \to X$ are homotopy equivalences. We have thus shown that $X$ is homotopy equivalent to $|K|$. $\blacksquare$

---

\[\text{\cite{1996}}\] We leave it to the industrious reader to figure out whether one can avoid the cheap exit via the Whitehead Theorem [119.9] by using say Lemma [38.12] in a clever fashion.

---

\[\text{\cite{1996}}\] Illustration for the proof of Proposition [62.12] (2) and (3).
Exercises for Chapter 62

Exercise 62.1. Let $K = (V, S)$ be an abstract simplicial complex. By Lemma 62.5 (3) we know that for any choice of simplices $s_0, \ldots, s_n \in S$ the following equality regarding open stars holds:

$$\text{St}(s_0) \cap \cdots \cap \text{St}(s_n) = \begin{cases} \text{St}(s_0 \cup \cdots \cup s_n), & \text{if } s_0 \cup \cdots \cup s_n \text{ is a simplex}, \\ \emptyset, & \text{otherwise}. \end{cases}$$

Show that in general the analogous statement for stars does not hold.

Exercise 62.2. Let $K$ be an abstract simplicial complex and let $s$ be a $k$-simplex. Show that there exists a natural simplicial isomorphism $\text{Lk}(K, s) \ast \partial s \cong \text{Lk}(\text{sd}(K), s)$.

Exercise 62.3. Let $K = (V, S)$ be an abstract simplicial complex. Show that the dimension of the barycentric subdivision $\text{sd}(K)$ equals the dimension of $K$.

Exercise 62.4. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$.

(a) Show that the link $\text{Lk}(s)$ is a deformation retract of $\text{St}(s) \setminus \{s\}$.

Hint. Consider the proof of Lemma 62.5 (e).

(b) Let $P \in \langle s \rangle$. Show that $\partial s \ast \text{Lk}(s)$ is a deformation retract of $\text{St}(s) \setminus \{P\}$.

Hint. Turn the idea of “pushing away from $P^n$ into a rigorous argument.

Exercises for Chapter 62

Exercise 62.5. Let $n \in \mathbb{N}$. As on page 1480 we consider the abstract simplicial complex $S_n := (V, T)$ with $V = \{0, \ldots, n+1\}$ and $T = \mathcal{P}(V) \setminus \{\varnothing, V\}$. Note that given a $k$-simplex $s$ of $S_n$ the set $V \setminus s$ is an $(n-k)$-simplex. Next we consider the barycentric subdivision $\text{sd}(S_n)$ together with the map

$$f: \text{sd}(S_n) \rightarrow \text{sd}(S_n)$$

$$s \mapsto V \setminus s.$$

(a) Show that $f$ is a simplicial map.

(b) Show that $S_n / s \sim f(s)$, interpreted in the obvious way, is an abstract simplicial complex with $2^{n+1} - 1$ vertices.

(c) Sketch the abstract simplicial complex $S_n / s \sim f(s)$ for $n = 1$ and $n = 2$.

(d) Show that the topological realization of $S_n / s \sim f(s)$ is homeomorphic to the real projective space $\mathbb{R}P^n = S^n / x \sim -x$.

Remark. It is not known what is the “smallest” simplicial structure for the real projective spaces $\mathbb{R}P^n$. It is shown in [ArM91] that any simplicial structure for $\mathbb{R}P^n$ needs to have at least $\frac{1}{2}(n+1)(n+2)$ vertices. But all known simplicial structures seem to have about $2^n$ vertices.
Exercise 62.6. Let $n \in \mathbb{N}$ and let $k \in \{1, \ldots, n-1\}$. Use the Simplicial Approximation Theorem 62.8 to show that $\pi_k(S^n) = 0$.

Remark. This statement is of course the content of Proposition 40.10 which we proved using the Cellular Approximation Theorem 38.13.

Exercise 62.7. We say an abstract simplicial complex $K = (V, S)$ is a flag complex if the following condition is satisfied:

(*) If $v_0, \ldots, v_n \in V$ have the property that $\{v_i, v_j\} \in S$ for all $i, j \in \{0, \ldots, n\}$, then $\{v_0, \ldots, v_n\} \in S$.

More loosely speaking, $K$ is a flag complex, if a simplex exists whenever its 1-skeleton exists. We refer to Figure 939 for an illustration of the definition.

(a) Show that every flag complex is determined by its 1-skeleton. More precisely, let $K = (V, S)$ and $L = (W, T)$ be two abstract simplicial complexes. Suppose that $\varphi: K^1 \cong L^1$ is a simplicial isomorphism between the 1-skeleta. We suppose that $K$ and $L$ are flag complexes. Show that $\varphi$ can be extended to a simplicial isomorphism $K \cong L$.

(b) Let $K$ be an abstract simplicial complex. Show that the barycentric subdivision $\text{sd}(K)$ is a flag complex.

![Diagram showing flag complex and not a flag complex with a 2-simplex missing](image-url)
In this chapter we introduce the simplicial homology groups of an (ordered) abstract simplicial complex. As we will see, the definition is refreshingly straightforward. Later in the chapter we discuss the relationship between simplicial and singular homology.

Before we get into details it is convenient to recall the following definition from basic group theory which we will need on numerous occasions throughout this chapter.

**Definition.** Let \( n \in \mathbb{N} \). Given a permutation \( \sigma \in S_n \) we refer to

\[
\text{sign}(\sigma) := \text{determinant of the} \ (n \times n)\text{-matrix for which the}
\]

\((i, \sigma(i))\text{-entries are one and all the other entries are zero}

as the *sign of the permutation*.

The following lemma summarizes the two key properties of the sign of a permutation.

**Lemma 63.1.** Let \( n \in \mathbb{N} \).

1. The map \( \text{sign}: S_n \to \{-1, 1\} \) is a homomorphism.
2. If \( \sigma \) is a transposition, then \( \text{sign}(\sigma) = -1 \).

**Proof.** The proof follows immediately from standard properties of the determinant. \( \square \)

**Definition.** Let \( X \) be a finite set and let \( \sigma \in \text{Bij}(X) \). We set \( n := \#X \). We pick a bijection \( \varphi: \{1, \ldots, n\} \to X \). We define \( \text{sign}(\sigma) = \text{sign}(\varphi^{-1} \circ \sigma \circ \varphi) \). It follows easily from Lemma 63.1 that this definition is independent of the choice of the bijection \( \varphi \).

Throughout this chapter we adopt the following convention.

**Convention.** Given \( n \in \mathbb{N} \) we identify the permutation group \( S_n = \text{Bij}\{1, \ldots, n\} \) with the group \( \text{Bij}\{0, \ldots, n-1\} \) in the obvious way.

**63.1. Simplicial homology of an ordered abstract simplicial complex.** In this section we will define the simplicial chain complex and the simplicial homology groups of an *ordered* abstract simplicial complex. This is going to be surprisingly easy. In the subsequent section we will then deal with abstract simplicial complex that are not equipped with an order.

We start out with the following elementary observation which we will use frequently throughout this chapter.

**Observation.** Let \((T, \leq)\) be a totally ordered set and let \( v_0, \ldots, v_n \in T \). By Exercise 1.1 there exists a unique permutation \( \sigma \in S_{n+1} \) such that \( v_{\sigma(0)} < \cdots < v_{\sigma(n)} \).

After this preliminary remark we can now turn to an interesting definition.

**Definition.** Let \( K = (V, S) \) be an ordered abstract simplicial complex. Given \( n \in \mathbb{N}_0 \) we define

\[
C_n^{\text{simp}, \leq}(K) := \text{free abelian group generated by the set of} \ n\text{-simplices of} \ K.
\]

Surely the reader will have seen the definition of the sign of a permutation. We leave it to the reader to show that the previous definition agrees with our definition.
Furthermore we consider the boundary map
\[ \partial_n : C_{n}^{\text{simp}, \leq}(K) \to C_{n-1}^{\text{simp}, \leq}(K) \]
\[ \{v_0 < \cdots < v_n\} \mapsto \sum_{i=0}^{n} (-1)^i \cdot \{v_0, \ldots, v_{i-1}, \hat{v}_i, v_{i+1}, \ldots, v_n\}. \]

any \( n \)-simplex \( s \) is uniquely
of the form \( s = \{v_0, \ldots, v_n\} \)
with \( v_0 < \cdots < v_n \).

\[ \left( C_{*}^{\text{simp}, \leq}(K), \partial_\ast \right) \]

\[ \text{is a chain complex}. \]

\textbf{Lemma 63.2.} Let \( K = (V, S) \) be an ordered abstract simplicial complex. Given any \( n \in \mathbb{N}_0 \) we have \( \partial_{n-1} \circ \partial_n = 0 \). In other words, \( (C_{*}^{\text{simp}, \leq}(K), \partial_\ast) \) is a chain complex.

\textbf{Proof.} The proof of the lemma is almost verbatim the same as the proof of Proposition 41.2. We leave it to the reader to make the necessary minute modifications. \( \blacksquare \)

The reader is by now well aware of the fact that such a lemma leads straight to the following definition.

\textbf{Definition.} Let \( K \) be an ordered abstract simplicial complex. We refer to the chain complex \( (C_{*}^{\text{simp}, \leq}(K), \partial_\ast) \) as the simplicial chain complex. Given \( n \in \mathbb{N}_0 \) we define the \( n \)-th simplicial homology group of \( K \) as the \( n \)-th homology group of the simplicial chain complex, i.e. we define
\[ H_n^{\text{simp}, \leq}(K) := \frac{\ker \left( \partial_n : C_n^{\text{simp}, \leq}(K) \to C_{n-1}^{\text{simp}, \leq}(K) \right)}{\text{im} \left( \partial_{n+1} : C_{n+1}^{\text{simp}, \leq}(K) \to C_n^{\text{simp}, \leq}(K) \right)}. \]

\textbf{Example.} We consider the 1-dimensional abstract simplicial complex \( K = (V, S) \) shown in Figure 940. It has five vertices \( \{A, B, C, D, E\} \), it has the corresponding five 0-simplices and it has five 1-simplices. We view \( K = (V, S) \) as an ordered abstract simplicial complex in the obvious way, i.e. we have \( A < B < C < D < E \). The corresponding simplicial chain complex is given as follows:

\[
\begin{align*}
0 & \to \begin{array}{c}
\mathbb{Z} \cdot \{A, B\} \\
\mathbb{Z} \cdot \{B, C\} \\
\mathbb{Z} \cdot \{C, D\} \\
\mathbb{Z} \cdot \{D, E\} \\
\end{array} \\
& \begin{array}{c}
\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\
-1 & 1 & 0 & 0 & 0 \\
0 & -1 & 1 & 0 & 1 \\
0 & 0 & -1 & 1 & 0 \\
0 & 0 & 0 & -1 & -1 \\
\end{pmatrix} \\
\end{array} \\
& \begin{array}{c}
\mathbb{Z} \cdot \{A\} \\
\mathbb{Z} \cdot \{B\} \\
\mathbb{Z} \cdot \{C\} \\
\mathbb{Z} \cdot \{D\} \\
\end{array} \\
& \to 0.
\end{align*}
\]

We leave it as an elementary exercise in linear algebra to show that
\[ H_n^{\text{simp}, \leq}(K) \cong \begin{cases} 0, & \text{if } n > 1, \\
\mathbb{Z}, & \text{if } n = 0, 1. \end{cases} \]

Furthermore one can easily show that
\[ H_1^{\text{simp}, \leq}(K) = \ker \left( \partial_1 : C_1^{\text{simp}, \leq}(K) \to C_0^{\text{simp}, \leq}(K) \right) = \mathbb{Z} \cdot \left( \{C, D\} + \{D, E\} - \{C, E\} \right). \]

\textbf{Recall that according to the definition on page 1484 “ordered” means that the vertex set \( V \) is equipped with a partial order such that the restriction to each simplex is a total order.}
As always, not only do we want to associate groups to our given objects, but we really want to construct a functor. This is done in the following lemma.

**Lemma 63.3.**

1. Given an order-preserving simplicial map \( f : K = (V, S) \to L = (W, T) \) between ordered abstract simplicial complexes we define
   \[
   f_* : C^\text{simp} \leq_n (K) \to C^\text{simp} \leq_n (L)
   \]
   \[
   \{v_0, \ldots, v_n\} \mapsto \begin{cases} 
   \{f(v_0), \ldots, f(v_n)\}, & \text{if } f(v_0), \ldots, f(v_n) \text{ are pairwise different,} \\
   0, & \text{otherwise.}
   \end{cases}
   \]
   These maps form a chain map, thus they induce maps \( f_* : H^\text{simp} \leq_n (K) \to H^\text{simp} \leq_n (L). \)

2. The maps
   \[
   (K, \leq) \mapsto C^\text{simp} \leq_n (K)
   \]
   \[
   (f : (K, \leq) \to (L, \leq)) \mapsto (f_* : C^\text{simp} \leq_n (K) \to C^\text{simp} \leq_n (L))
   \]
   define a covariant functor from the category \( \text{OrdAbsSimpCplx} \) of ordered abstract simplicial complexes to the category \( \text{ChCplx} \) of chain complexes. In particular, for each \( n \in \mathbb{N}_0 \) the maps
   \[
   (K, \leq) \mapsto H^\text{simp} \leq_n (K)
   \]
   \[
   (f : (K, \leq) \to (L, \leq)) \mapsto (f_* : H^\text{simp} \leq_n (K) \to H^\text{simp} \leq_n (L))
   \]
   define a covariant functor from the category \( \text{OrdAbsSimpCplx} \) of ordered abstract simplicial complexes to the category \( \text{AbGr} \) of abelian groups.

**Proof.** The statements follow easily from the definitions. We leave it to the reader to fill in the details.

Naturally the question arises, to what degree do the simplicial homology groups of an ordered abstract simplicial complex depend on the choice of the order. As the following lemma shows, the answer is, not very much.

**Lemma 63.4.** Let \( K = (V, S) \) be an abstract simplicial complex and let \( \leq \) and \( \leq \) be two orders on \( K \). The maps
   \[
   C^\text{simp} \leq_n (K) \to C^\text{simp} \leq_n (K)
   \]
   \[
   \{v_0 < \cdots < v_n\} \mapsto \text{sign}(\sigma) \cdot \{v_{\sigma(0)} < \cdots < v_{\sigma(n)}\}
   \]
   where \( \sigma \in S_n \) is the unique permutation such that \( v_{\sigma(0)} < \cdots < v_{\sigma(n)} \)
   define an isomorphism of chain complexes.
Proof. The proof of the lemma is an appealing little calculation that will be done in Exercise 63.1.

63.2. Simplicial homology. In the last section we introduced simplicial homology for ordered abstract simplicial complexes. In this section we will introduce simplicial homology for “unordered” abstract simplicial complexes. Evidently the definition is going to be very similar, but as we will see, the definition is ever so more subtle.

Definition. Let \( K = (V, S) \) be an abstract simplicial complex and let \( n \in \mathbb{N}_0 \).

1. An ordered \( n \)-simplex of \( K \) is an \( (n+1) \)-tuple \((v_0, \ldots, v_n) \in V^{n+1} \) such that \( \{v_0, \ldots, v_n\} \) is an \( n \)-simplex of \( K = (V, S) \).

2. Given an ordered \( n \)-simplex \((v_0, \ldots, v_n)\) we denote by \([v_0, \ldots, v_n]\) := \( \{v_0, \ldots, v_n\} \).

3. Let \( n \in \mathbb{N}_0 \). We define \( \hat{C}_n^{\text{simp}}(K) := \text{free abelian group generated by the set of ordered } n \)-simplices of \( K \).

Furthermore we define the \( n \)-th simplicial chain group to be

\[
C_n^{\text{simp}}(K) := \hat{C}_n^{\text{simp}}(K)/I_n
\]

where \( I_n \) is the subgroup of \( \hat{C}_n^{\text{simp}}(K) \) generated by all elements of the form

\[
(v_0, \ldots, v_n) - \text{sign}(\sigma) \cdot (v_{\sigma(0)}, \ldots, v_{\sigma(n)}) \quad \text{where } \sigma \in S_{n+1} = \text{Bij}\{0, \ldots, n\}
\]

Given an ordered simplex \((v_0, \ldots, v_n)\) we denote its image in \( C_n^{\text{simp}}(K) \) by \([v_0, \ldots, v_n]\).

Remark. Let \( K = (V, S) \) be an abstract simplicial complex. Since the set of vertices is in a natural bijection with the set of 0-simplices and since the permutation group \( S_1 \) is trivial we see that we have a natural identification \( C_0^{\text{simp}}(K) = \mathbb{Z}^{(V)} \).

Lemma 63.5. Let \( K = (V, S) \) be an abstract simplicial complex. If “\( \leq \)" is an order on \( K = (V, S) \), then for each \( n \in \mathbb{N}_0 \) the map

\[
C_n^{\text{simp}}(\leq)(K) \rightarrow C_n^{\text{simp}}(K)
\]

\[
\{v_0 < \cdots < v_n\} \mapsto [v_0, \ldots, v_n]
\]

is a natural isomorphism.

Proof (*). Let \( n \in \mathbb{N}_0 \). First note that it follows immediately from the definitions that the map is natural.

It remains to show that the given map is an isomorphism. We denote by \( P_n \) the set of ordered \( n \)-simplices, as defined above. Note that by definition we have \( \hat{C}_n^{\text{simp}}(K) = \mathbb{Z}^{(P_n)} \).

In the following we denote by \( Q_n \) the set of all ordered \( n \)-simplices \((v_0, \ldots, v_n)\) such that \( v_0 < \cdots < v_n \). By Lemma 19.1 there exist unique homomorphisms as follows:

\[
\Phi : \mathbb{Z}^{(P_n)} \rightarrow \mathbb{Z}^{(Q_n)}
\]

\[
(v_0, \ldots, v_n) \mapsto \text{sign}(\sigma) \cdot (v_{\sigma(0)}, \ldots, v_{\sigma(n)})
\]

and

\[
\Psi : \mathbb{Z}^{(Q_n)} \rightarrow \mathbb{Z}^{(P_n)}
\]

\[
(v_0, \ldots, v_n) \mapsto (v_0, \ldots, v_n).
\]

Here \( \sigma \in S_{n+1} \) is the unique permutation with \( v_{\sigma(0)} < \cdots < v_{\sigma(n)} \).
Furthermore we denote by \( \pi : \mathbb{Z}^{(P_n)} \to \mathbb{Z}^{(P_n)}/I_n = C_n^{\text{simp}}(K) \) the obvious projection. It follows easily from Lemma 63.1 that \( \Phi : \mathbb{Z}^{(P_n)} \to \mathbb{Z}^{(Q_n)} \) descends to a homomorphism \( \Phi : \mathbb{Z}^{(P_n)}/I_n \to \mathbb{Z}^{(Q_n)} \). Note that it is an immediate consequence of the definitions that \( \Phi \circ \pi \circ \Psi \) is the identity on the basis \( Q_n \) of \( \mathbb{Z}^{(Q_n)} \) and that \( \pi \circ \Psi \circ \Phi \) is the identity on the generating set \( \pi(P_n) \) of \( \mathbb{Z}^{(P_n)}/I_n \). This shows that \( \pi \circ \Psi \) and \( \Phi \) are isomorphisms. The promised statements follow readily from this observation. \( \blacksquare \)

**Lemma 63.6.** Let \( K \) be an abstract simplicial complex.

1. Given any \( n \in \mathbb{N}_0 \) the group \( C_n^{\text{simp}}(K) \) is a free abelian group where the rank is given by the cardinality of the set \( S_n \) of \( n \)-simplices of \( K \). In fact, if we choose for each \( n \)-simplex \( s \in S_n \) an ordered \( n \)-simplex \( \tilde{s} \) with \( |\tilde{s}| = s \), then \( \{ |\tilde{s}| \}_{s \in S_n} \) is a basis for \( C_n^{\text{simp}}(K) \).

2. Let \( n \in \mathbb{N} \). There exists a unique homomorphism

\[
\partial_n : C_n^{\text{simp}}(K) \to C_{n-1}^{\text{simp}}(K)
\]

with the property that given any ordered \( n \)-simplex \( (v_0, \ldots, v_n) \) of \( K \) we have

\[
\partial_n([v_0, \ldots, v_n]) = \sum_{i=0}^{n} (-1)^i \cdot [v_0, \ldots, \hat{v}_i, v_{i+1}, \ldots, v_n].
\]

3. For every \( n \in \mathbb{N}_0 \) we have \( \partial_{n-1} \circ \partial_n = 0 \).

**Remark.** Let \( K = (V,S) \) be an abstract simplicial complex and let \( n \in \mathbb{N}_0 \). Lemma 63.5 and Lemma 63.6 (1) say in particular that \( C_n^{\text{simp}}(K) \) is a free abelian group. If \( K = (V,S) \) is an ordered abstract simplicial complex, then this free abelian group has a natural basis. In the absence of an order there is only a natural basis where each element of the basis is well-defined “up to sign”.

**Example.** For an ordered simplex \( (v_0, v_1, v_2) \) in an abstract simplicial complex \( K \) we see that

\[
\partial([v_0, v_1, v_2]) = [v_1, v_2] - [v_0, v_2] + [v_0, v_1] = [v_0, v_1] + [v_1, v_2] + [v_2, v_0].
\]

In other words, if we consider Figure 941 then we see that the boundary is exactly what we would naively had thought.

\[
\partial \left( \begin{bmatrix} v_0 \\ v_1 \\ v_2 \end{bmatrix} \right) = \begin{bmatrix} v_0 \\ v_1 \\ v_2 \end{bmatrix} + \begin{bmatrix} v_0 \\ v_1 \\ v_2 \end{bmatrix} + \begin{bmatrix} v_0 \\ v_1 \\ v_2 \end{bmatrix}
\]

**Figure 941**

**Proof.**

1. It follows from the Well-Ordering Theorem 1.6 that we can equip \( K = (V,S) \) with an order. Thus the desired statement is now an almost immediate consequence of Lemma 63.5.
(2) Let \( n \in \mathbb{N} \). By Lemma [19.1] there exists a unique homomorphism
\[
\partial_n : \tilde{C}^{\text{simp}}_n(K) \rightarrow C^{\text{simp}}_{n-1}(K)
\]
with the property that given any ordered \( n \)-simplex \((v_0, \ldots, v_n)\) of \( K \) we have
\[
\partial_n((v_0, \ldots, v_n)) = \sum_{i=0}^{n} (-1)^i [v_0, \ldots, v_{i-1}, \widehat{v}_i, v_{i+1}, \ldots, v_n].
\]
It remains to show that \( \partial_n \) factors through \( C^{\text{simp}}_n(K) = \tilde{C}^{\text{simp}}_n(K)/I_n \). In other words, we need to show that \( \partial_n \) vanishes on \( I_n \). Since the permutation group \( S_n \) is generated by transpositions and since transpositions have the sign \(-1\) it remains to prove the following claim.

**Claim.** For any \( 0 \leq k < l \leq n \) and any ordered \( n \)-simplex \((v_0, \ldots, v_n)\) of \( K \) we have
\[
\partial_n(v_0, \ldots, v_k, \ldots, v_l, \ldots, v_n) = -\partial_n(v_0, \ldots, v_k, \ldots, v_l, \ldots, v_n).
\]
Let \((v_0, \ldots, v_n)\) be an ordered \( n \)-simplex and let \( 0 \leq k < l \leq n \). We calculate that
\[
\partial_n(\ldots, v_l, \ldots, v_k, \ldots) =
\sum_{i \neq k, l} (-1)^i [\ldots, v_l, \ldots, \widehat{v}_i, \ldots, v_k, \ldots] + (-1)^k [\ldots, \widehat{v}_l, \ldots, v_k, \ldots] + (-1)^l [\ldots, v_l, \ldots, \widehat{v}_k, \ldots],
\]
where the summands are equal up to a sign that is \( (-1)^{l-k-1} \) if \( k < l \), \( (-1)^{k-1} \) if \( k > l \), and \( 0 \) otherwise. Hence,
\[
\partial_n(\ldots, v_l, \ldots, v_k, \ldots) = -\partial_n(\ldots, v_l, \ldots, v_k, \ldots).
\]

(3) The proof of this lemma is almost verbatim the same as the proof of Proposition [41.2].

We leave the pleasant task of copy-pasting the proof to the reader. \( \blacksquare \)

**Lemma [63.6]** leads us right away to the following definition.

**Definition.** Let \( K \) be an abstract simplicial complex. We refer to the chain complex
\((C^*_{\text{simp}}(K), \partial_*)\) as the *simplicial chain complex*. Given \( n \in \mathbb{N}_0 \) we define the *\( n \)-th simplicial homology group* of \( K \) as the \( n \)-th homology group of the simplicial chain complex, i.e. we define
\[
H^{\text{simp}}_n(K) := \frac{\ker(\partial_n : C^{\text{simp}}_n(K) \rightarrow C^{\text{simp}}_{n-1}(K))}{\text{im}(\partial_{n+1} : C^{\text{simp}}_{n+1}(K) \rightarrow C^{\text{simp}}_n(K))}.
\]

**Examples.**

(1) We consider the 2-dimensional abstract simplicial complex \( K = (V, S) \) shown in Figure [942]. It has four vertices \( \{A, B, C, D\} \), it has the corresponding four 0-simplices, it has four 1-simplices and it has one 2-simplex. The corresponding simplicial chain complex is given as follows:

\[
0 \rightarrow \mathbb{Z} \cdot [B, C, D] \rightarrow \begin{pmatrix} 0 & 1 & 1 \\ 1 & -1 & 0 \\ 1 & 0 & -1 \end{pmatrix} \rightarrow \mathbb{Z} \cdot [A, B] \rightarrow \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & -1 & 0 & 1 \\ 0 & 0 & -1 & -1 \end{pmatrix} \rightarrow \mathbb{Z} \cdot [A] \rightarrow \mathbb{Z} \cdot [B] \rightarrow \mathbb{Z} \cdot [C] \rightarrow \mathbb{Z} \cdot [D] \rightarrow 0.
\]
Elementary linear algebra shows that

\[ H_n^{\text{simp}}(K) \cong \begin{cases} 
0, & \text{if } n > 0, \\
\mathbb{Z}, & \text{if } n = 0.
\end{cases} \]

(2) If \( K = (V,S) \) is an abstract simplicial complex with no simplices of dimension \( \geq 1 \), then it follows immediately from the definitions that for \( n \in \mathbb{N}_0 \) we have

\[ H_n^{\text{simp}}(K) \cong \begin{cases} 
C_n^{\text{simp}}(K) = \mathbb{Z}(V), & \text{if } n = 0, \\
0, & \text{otherwise.}
\end{cases} \]

The following is the obvious analogue of Lemma 63.3.

Lemma 63.7.

(1) Given a simplicial map \( f: K = (V,S) \rightarrow L = (W,T) \) we define

\[ f_*: C_n^{\text{simp}}(K) \rightarrow C_n^{\text{simp}}(L) \]

\[[v_0, \ldots, v_n]] \mapsto \begin{cases} 
[f(v_0), \ldots, f(v_n)], & \text{if } f(v_0), \ldots, f(v_n) \text{ are pairwise different,} \\
0, & \text{otherwise.}
\end{cases} \]

These maps form a chain map, thus they induce maps \( f_*: H_n^{\text{simp}}(K) \rightarrow H_n^{\text{simp}}(L) \).

(2) The maps

\[ K \mapsto C_*(K) \quad (f: K \rightarrow L) \mapsto (f_*: C_*(K) \rightarrow C_*(L)) \]

define a covariant functor from the category \( \text{AbsSimpCplx} \) of abstract simplicial complexes to the category \( \text{ChCplx} \) of chain complexes. For each \( n \in \mathbb{N}_0 \) the maps

\[ K \mapsto H_n^{\text{simp}}(K) \quad (f: K \rightarrow L) \mapsto (f_*: H_n^{\text{simp}}(K) \rightarrow H_n^{\text{simp}}(L)) \]

define a covariant functor from the category \( \text{AbsSimpCplx} \) of abstract simplicial complexes to the category \( \text{AbGr} \) of abelian groups.

Proof. As in the case of the proof of Lemma 63.3 we leave it to the reader to provide the proof. \( \square \)

For completeness we state the following elementary lemma.

Lemma 63.8. Let \( K = (V,S) \) be an ordered abstract simplicial complex. The maps

\[ \Omega_n: C_n^{\text{simp}, \leq}(K) \rightarrow C_n^{\text{simp}}(K) \]

\[ \{v_0 < \cdots < v_n\} \mapsto [v_0, \ldots, v_n] \]
define a natural isomorphism of chain complexes. In particular they induce natural isomorphisms
\[ \Omega_n : H_n^\text{simp,} \leq(K) \to H_n^\text{simp}(K). \]

**Remark.** In the following we will discuss the simplicial homology groups \( H_n^\text{simp}(K) \) in greater detail. By Lemma 63.8 the subsequent statements have obvious analogues for the simplicial homology groups \( H_n^\text{simp,} \leq(K) \).

**Proof.** A very short moment of reflection shows that the given map is a natural chain map. We deduce from Lemma 63.6 (1) that the chain map is in fact an isomorphism of chain complexes. ■

The next lemma can be viewed as an analogue of Lemma 48.1 (2) and (3).

**Lemma 63.9.** Let \( K \) be an abstract simplicial complex and let \( m \in \mathbb{N}_0 \cup \{\infty\} \). As usual we denote by \( K^m \) the \( m \)-skeleton of \( K \). Furthermore let \( n \in \mathbb{N}_0 \).

1. If \( K \) has only finitely many \( n \)-simplices, then \( H_n^\text{simp}(K) \) is finitely generated.
2. If \( n > m \), then \( H_n^\text{simp}(K^m) = 0 \).
3. If \( n < m \), then the inclusion induced map \( H_n^\text{simp}(K^m) \to H_n^\text{simp}(K) \) is an isomorphism.

Analogous statements also hold for ordered abstract simplicial complexes and the homology groups \( H_n^\text{simp,} \leq(K^m) \) and \( H_n^\text{simp,} \leq(K) \).

**Proof.**

1. This statement follows easily from the definitions together with Lemma 19.8 (2b).
2. This statement follows from the observation that \( C_n^\text{simp}(K^m) = 0 \) for \( n > m \).
3. This statement follows almost immediately from the observation that by definition we have \( C_i^\text{simp}(K^m) = C_i^\text{simp}(K) \) for \( i = 0, \ldots, m \). ■

It is clear that given any finite abstract simplicial complex one can compute the corresponding homology groups by a brute force calculation. But for large examples this can be very inefficient. Furthermore, it is rather unsatisfactory to outsource calculations to a computer. It is much more entertaining to try to do calculations cleverly on one’s own. In the following we will get to know a few approaches to calculating simplicial homology groups. We will develop more techniques in Exercises 63.3 and 63.7.

As for singular homology, some calculations, statements and proofs become easier if we consider reduced simplicial homology.

**Definition.** Let \( K \) be an abstract simplicial complex.

1. We refer to the map \( \epsilon : C_0^\text{simp}(K) \to \mathbb{Z} \)
   \[ \sum_{i=1}^m a_i \cdot [v_i] \mapsto \sum_{i=1}^m a_i \]
as the augmentation.
We consider the following generalized\(^{970}\) chain complex

\[
\begin{array}{cccc}
\cdots & \delta_2 & C_2^{\text{simp}}(K) & \partial_2 \\
& & \downarrow & \\
& & C_1^{\text{simp}}(K) & \partial_1 \\
& & \downarrow & \\
& & C_0^{\text{simp}}(K) & \epsilon \\
& & \downarrow & \\
\& & \mathbb{Z} & \rightarrow & 0.
\end{array}
\]

We introduce the following two definitions.

(a) We refer to this chain complex as the \textit{augmented simplicial chain complex} \(\tilde{C}^{\text{simp}}_*(K)\) of \(K\).

(b) Let \(k \in \mathbb{N}_0\). We define the \(k\)-th \textit{reduced simplicial homology group} \(\tilde{H}^{\text{simp}}_k(K)\) of \(K\) to be the \(k\)-th homology group of the augmented chain complex.

\textbf{Remark.} The above definition also makes sense for the empty abstract simplicial complex \(\emptyset\). Furthermore, similar to Lemma \[43.1\](0) we see that \(H^{\text{simp}}_{-1}(\emptyset) = \mathbb{Z}\) and \(H^{\text{simp}}_i(\emptyset) = 0\) for \(i \neq -1\).

The following lemma is the analogue of Lemma \[43.1\](4). It basically says that in the following it suffices to calculate reduced simplicial homology groups.

\textbf{Lemma 63.10.} Let \(K = (V,S)\) be an abstract simplicial complex.

(1) Given any vertex \(v \in V\) the map

\[
\tilde{H}^{\text{simp}}_0(K) \oplus \mathbb{Z} \rightarrow H^{\text{simp}}_0(K)
\]

\[\left[\sigma\right] \oplus n \mapsto \left[\sigma\right] + \left[n \cdot P\right]\]

is an isomorphism.

(2) For every \(n \geq 1\) we have the equality \(H^{\text{simp}}_n(K) = \tilde{H}^{\text{simp}}_n(K)\).

\textbf{Proof.} The proof is basically identical to the already rather straightforward proof of Lemma \[43.1\](4). \(\blacksquare\)

By Lemma \[24.1\] we know that the cone on a topological space is contractible, in particular we know by Corollary \[42.8\](3) that its reduced homology groups vanish. The following lemma can be viewed as a simplicial analogue of this observation.

\textbf{Lemma 63.11.} Let \(K\) be an abstract simplicial complex. Let \(\text{Cone}(K)\) be the simplicial cone as defined on page \[1506\]. Given any \(k \in \mathbb{N}_0\) we have

\[
\tilde{H}^{\text{simp}}_k(\text{Cone}(K)) = 0.
\]

\textbf{Proof.} Let \(K = (V,S)\) be an abstract simplicial complex. We set \(L := \text{Cone}(K)\). Note that it follows from Lemma \[42.4\] that it remains to prove that the identity map \(\text{id} : C_*^{\text{simp}}(L) \rightarrow C_*^{\text{simp}}(L)\) is homotopic to the zero map. In other words, it suffices to prove the following claim.

\textsuperscript{969}\textsuperscript{970}Morally the group \(\mathbb{Z}\) is the free abelian group on the “empty” simplex.

\textsuperscript{970}It requires about one second to verify that this is indeed a generalized chain complex.
Claim. We can find “diagonal” maps $P_n$, $n \in \mathbb{Z}_{\geq -1}$, to obtain a diagram

$$
\cdots \longrightarrow C^\text{simp}_3(L) \xrightarrow{\partial_3} C^\text{simp}_2(L) \xrightarrow{\partial_2} C^\text{simp}_1(L) \xrightarrow{\partial_1} C^\text{simp}_0(L) \xrightarrow{\partial_0=\epsilon} \mathbb{Z} \longrightarrow 0
$$

such that for every $n \in \mathbb{Z}_{\geq -1}$ we have the equality

$$
(*) \quad \partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n = \text{id}.
$$

In the following we denote the cone point of $\text{Cone}(L)$ by “$\ast$”. To prove the claim we consider the map

$$
P_{n-1}: \mathbb{Z} \rightarrow C^\text{simp}_0(L) \quad \text{and for } n \geq 0 \quad P_n: C^\text{simp}_n(L) \rightarrow C^\text{simp}_{n+1}(L)
$$

we consider the map$^{97}$

$$
[n] \mapsto n \cdot [\ast]
$$

We claim that $(*)$ holds for all $n \in \mathbb{Z}_{\geq -1}$. The case $n = -1$ can be verified easily. Thus it remains to show that $(*)$ holds if $n \in \mathbb{N}_0$. In fact, given $[v_0, \ldots, v_n] \in C^\text{simp}_n(L)$ with $v_0, \ldots, v_n \in V$ we immediately see that

$$
[v_0, \ldots, v_n] + \sum_{i=1}^{n+1} (-1)^i \cdot [\ast, v_0, \ldots, \hat{v}_{i-1}, \ldots, v_n] + \sum_{i=0}^{n} (-1)^i \cdot [\ast, v_0, \ldots, \hat{v}_i, \ldots, v_n] = [v_0, \ldots, v_n].
$$

Furthermore, given $[\ast, v_0, \ldots, v_{n-1}] \in C^\text{simp}_{n-1}(L)$ with $v_0, \ldots, v_{n-1} \in V$ it is equally straightforward to verify that the equality holds.$^\blacksquare$

Next we want to calculate the simplicial homology groups of the abstract simplicial complexes $D_n$ and $S_n$ that we introduced on page 1480. By Lemma 63.10 it suffices to compute the reduced simplicial homology groups.

**Lemma 63.12.** Given any $n \in \mathbb{N}$ and given any $k \in \mathbb{N}_0$ we have

$$
\tilde{H}^\text{simp}_k(D_n) = 0 \quad \text{and} \quad \tilde{H}^\text{simp}_k(S_n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise}. \end{cases}
$$

**Proof.**

(1) Given any $n \in \mathbb{N}$ and given any $k \in \mathbb{N}_0$ we calculate that

$$
\tilde{H}^\text{simp}_k(D_n) \cong \tilde{H}^\text{simp}_k(\text{Cone}(D_{n-1})) = 0.
$$

see page 1506 by Lemma 63.11

$^{97}$One can easily verify that the map $P_n$ is actually well-defined.
Let \( n \in \mathbb{N}_0 \). We consider the following diagram:

\[
\begin{array}{c}
0 \rightarrow 0 \rightarrow C_n^{simp}(S_n) \rightarrow C_{n-1}^{simp}(S_n) \rightarrow \ldots \rightarrow C_0^{simp}(S_n) \rightarrow \epsilon \rightarrow \mathbb{Z} \rightarrow 0 \\
\downarrow \quad \downarrow \quad \quad \downarrow \quad \quad \downarrow \quad \quad \downarrow \quad \quad \downarrow \\
0 \rightarrow C_n^{simp}(D_{n+1}) \rightarrow C_n^{simp}(D_{n+1}) \rightarrow \ldots \rightarrow C_0^{simp}(D_{n+1}) \rightarrow \epsilon \rightarrow \mathbb{Z} \rightarrow 0 \\
\downarrow \approx \quad \downarrow \quad \quad \downarrow \quad \quad \downarrow \\
0 \rightarrow \mathbb{Z} \rightarrow \partial \rightarrow 0 \rightarrow \partial \rightarrow \ldots \rightarrow \partial \rightarrow 0 \rightarrow \partial \rightarrow 0 \rightarrow 0.
\end{array}
\]

We make the following clarifications and comments:
(a) The top two horizontal sequences are the reduced chain complexes of the abstract simplicial complexes \( S_n \) and \( D_{n+1} \).
(b) Recall that by definition the simplices of \( S_n \) and \( D_{n+1} \) are the same except that \( D_{n+1} \) has a single \((n+1)\)-simplex whereas \( S_n \) has no \((n+1)\)-simplices. This observation explains the vertical maps.
(c) The diagram clearly commutes and it is clear that the vertical sequences are exact.
(d) It follows from the above that we can apply Proposition 43.11 and we obtain a long exact sequence of homology groups. Together with (1) we obtain the reduced simplicial homology groups of \( S_n \).

In Lemma 46.8 we studied the singular homology groups of a suspension. Statement 2 of the following lemma is the simplicial analogue of Lemma 46.8.

**Lemma 63.13.** Let \( K \) be a non-empty abstract simplicial complex.

1. Let \( n \in \mathbb{N}_0 \) and let \( S_n \) be the abstract simplicial complex that we introduced on page 1480. For every \( k \in \mathbb{N}_0 \) there exists a natural isomorphism
   \[
   \tilde{H}_k^{simp}(K \ast S_n) \cong \tilde{H}_k^{simp}((n+1))(K).
   \]

2. We denote by \( \Sigma(K) \) the simplicial suspension of \( K \) as defined on page 1506. For every \( k \in \mathbb{N}_0 \) there exists an isomorphism
   \[
   \tilde{H}_k^{simp}(\Sigma(K)) \cong \tilde{H}_k^{simp}(K).
   \]

**Example.** Let \( n \in \mathbb{N} \). Given any \( k \in \mathbb{N}_0 \) we see that

\[
\tilde{H}_k\left(\Sigma\left(\ldots \Sigma(S_0)\right)\right) \cong \tilde{H}_{k-n}(S_0) \cong \begin{cases} \mathbb{Z}, & \text{if } k - n = 0, \\ 0, & \text{otherwise.} \end{cases}
\]

**Proof.** Since the author has no intention of monopolizing all the fun we will leave the proof of Statement (1) as Exercise 63.2 to the reader. Note that Statement (2) is an immediate consequence of Statement (1) since \( \Sigma(K) \) is naturally isomorphic to \( K \ast S_0 \).

Next we extend the definition of simplicial homology groups in the obvious way to simplicial complexes:

---

**(true text content)**
Definition. Let \((X, (K = (V, S), \Theta : |K| \to X))\) be a simplicial complex. Given \(n \in \mathbb{N}_0\) we define
\[
H_n^\text{simp}(X) := H_n^\text{simp}(K).
\]
Similarly, given a simplicial map \(f: X = (X, \Theta) \to Y = (L, \Omega)\) between two simplicial complexes we define the induced map \(f_*: H_n^\text{simp}(X) \to H_n^\text{simp}(Y)\) as the induced map \(f_*: H_n^\text{simp}(K) \to H_n^\text{simp}(L)\).

Finally we introduce simplicial homology with coefficients in the obvious way. More precisely, we have the following definition which is the obvious variation on the definition given in Section 57.2.

Definition. Let \(G\) be an abelian group and let \(n \in \mathbb{N}_0\). Given an abstract simplicial complex \(K\) we set
\[
H_n^\text{simp}(K; G) := H_n(C_n^\text{simp}(K) \otimes G).
\]
If \(K\) is actually ordered we set \(H_n^\text{simp,\le}(K; G) := H_n(C_n^\text{simp,\le}(K) \otimes G)\). Finally given a simplicial complex \((X, (K = (V, S), \Theta : |K| \to X))\) we define, following the above convention, \(H_n^\text{simp}(X; G) := H_n^\text{simp}(K; G)\).

Surely there is no need to state all the self-evident properties of simplicial homology with coefficients. Let us just mention that it follows from Lemma 57.3 (3) that given any abstract simplicial complex \(K\) and given any \(n \in \mathbb{N}_0\) the map
\[
H_n^\text{simp}(K; \mathbb{Z}) \to H_n^\text{simp}(K)
\]
\[
\left[ \sum_{i=0}^{k} s_i \otimes m_i \right] \mapsto \left[ \sum_{i=0}^{k} s_i \cdot m_i \right]
\]
is a natural isomorphism. Throughout these notes we will use this isomorphism to make the identification \(H_n^\text{simp}(K; \mathbb{Z}) = H_n^\text{simp}(K)\).

63.3. The Simplicial Künneth Theorem. Let \((K, \leq)\) and \((L, \leq)\) be two ordered abstract simplicial complexes. Recall that on page 1501 we introduced the corresponding product \(K \times L\). The following theorem, which can be viewed as the simplicial analogue of the Künneth Theorem 58.8 for Topological Spaces, computes the simplicial homology groups of \(K \times L\) in terms of the simplicial homology groups of \(K\) and \(L\).

**Theorem 63.14. (Simplicial Künneth Theorem)** Let \((K, \leq)\) and \((L, \leq)\) be two ordered abstract simplicial complexes. There exists a short exact sequence
\[
0 \to \bigoplus_{p+q=n} H_p^\text{simp,\le}(K) \otimes H_q^\text{simp,\le}(L) \xrightarrow{\Omega} H_n^\text{simp,\le}(K \times L) \to \bigoplus_{p+q=n-1} \text{Tor}(H_p^\text{simp,\le}(K), H_q^\text{simp,\le}(L)) \to 0
\]
with the following four properties:

1. Both maps are natural with respect to the ordered abstract simplicial complexes \(K\) and \(L\).
2. For \(p = 0\) the map \(\Omega: H_0^\text{simp,\le}(K) \otimes H_q^\text{simp,\le}(L) \to H_q^\text{simp,\le}(K \times L)\) is the “obvious” map, namely for any vertex \(v\) of \(K\) and any simplicial cycle \(\sigma \in C_q^\text{simp,\le}(L)\) the image of the class \([v] \otimes [\sigma] \in H_0^\text{simp,\le}(K) \otimes H_q^\text{simp,\le}(L)\) under \(\Omega\) equals the image of
[σ] under the map $H^\text{simp}_{q} \leq (L) \to H^\text{simp}_{q} \leq (\{v\} \times L) \to H^\text{simp}_{q} \leq (K \times L)$, where the first map is induced by the natural isomorphism and the second map is induced by the inclusion.

(3) The analogue of (2) also holds for $q = 0$.

(4) The above short exact sequence splits.

We will not really make use of the Simplicial Künneth Theorem 63.14, thus we will only provide a sketch of the proof. A full proof is given in [FePi11, Theorem III.6.4].

**Sketch of proof.** Using the Acyclic Model Theorem 80.16, together with Exercise 63.5, one can prove a simplicial analogue of the Eilenberg-Zilbter Theorem 58.4, i.e., one can prove that there exists a natural chain map

$$\Upsilon: C^\text{simp}_{*} \leq (K) \otimes C^\text{simp}_{*} \leq (L) \to C^\text{simp}_{*} \leq (K \times L)$$

with the following three properties:

1. The chain map is a chain homotopy equivalence.
2. Given any vertex $v$ of $K$ and given any ordered simplex $(w_0, \ldots, w_k)$ of $L$ we have $\Upsilon([v] \otimes [w_0, \ldots, w_k]) = [(v, w_0), \ldots, (v, w_k)]$.
3. The analogue of (2) with the roles of $K$ and $L$ swapped also holds.

The precise construction of such a map is given in [FePi11, Chapter III.6]. Next we consider the following maps:

$$0 \to \bigoplus_{p+q=n} H_p^\text{simp} \leq (K) \otimes H_q^\text{simp} \leq (L) \xrightarrow{\Omega} \bigoplus_{p+q=n-1} \text{Tor}(H_p^\text{simp} \leq (K), H_q^\text{simp} \leq (L)) \to 0.$$

Here the sequence on the top is the natural short exact sequence provided by the Künneth Theorem 58.7 for Chain Complexes. It follows from the above together with Corollary 42.3 that the vertical map is a natural isomorphism. It is now fairly straightforward to see that we obtain the desired short exact sequence from replacing the upper middle term by the lower middle term $H_n^\text{simp} \leq (C^\text{simp}_{*} \leq (K \times L))$. This completes the proof.

**Example.** We consider the ordered abstract simplicial spaces $K$ and $L$ that are shown in Figure 943. Both are simplicially isomorphic to the simplicial circle $S_1$. Furthermore, we consider the “simplicial torus” $K \times L$. It follows from the Simplicial Künneth Theorem 63.14 that

$$H_i^\text{simp}(K \times L) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, 2, \\ \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{if } i > 2. \end{cases}$$

Furthermore it follows easily from Statement (2) of the Simplicial Künneth Theorem 63.14 that the two singular cycles shown in Figure 943 form a basis for $H_1^\text{simp} \leq (K \times L)$. 

63.4. The topological invariance of simplicial homology I. The following question arises naturally.

**Question 63.15.** Let $(X, (K, \Theta : |K| \to X))$ be a simplicial complex and let $n \in \mathbb{N}_0$. Does the isomorphism type of the simplicial homology group $H_n^{\text{simp}}(X)$ only depend on the homeomorphism type of $X$?

For example, we know by the discussion on page 1500 and on page 1508 that the topological realizations of $S_n$ and of the $n$-fold simplicial suspension of $S_0$ are both homeomorphic to $S^n$ and conveniently enough we know by Lemma 63.12 and the last example of the previous section that the homology groups are indeed isomorphic.

The following “research program” summarizes the traditional approach to tackling Question 63.15

**Program 63.16.**

1. Show that any two (let us say finite) abstract simplicial complexes with homeomorphic topological realizations are related by a finite sequence of “moves”.
2. Show that the isomorphism type of simplicial homology groups is unchanged under these “moves”.

This idea leads straight to the definition of a subdivision of a simplicial complex.

**Definition.** We say that a simplicial complex $(X, (K = (V, S), \Omega: |K| \to X))$ is a subdivision of some simplicial complex $(X, (L = (W, T), \Theta: |L| \to X))$ if the following two conditions are satisfied:

1. Every simplex of $|K|$ is contained in some simplex of $|L|$. More precisely, given any simplex $s \in S$ of $K$ there exists a simplex $t \in T$ of $L$ such that $\Omega(|s|) \subset \Theta(|t|)$.
2. For every $k$-simplex $s$ of $K$ and every $l$-simplex $t$ of $L$ with $\Omega(|s|) \subset \Theta(|t|)$ the map $\Phi_t \circ \Theta \circ \Omega \circ \Phi_s : \Delta^k \to |s| \subset |t| \to \Delta^l$ is affine linear.

**Remark.**

1. Note that for linear simplicial complexes condition (3) is automatically satisfied.
2. The definition of a subdivision we give agrees with the definition in most sources, see e.g. [Hud69 p. 5], [Pon52 p. 36], [RS72 p. 15], [Gla70 p. 7], [Spa95 p. 121] and [Ze63b p. I.4].
(3) In [Mun84, p. 83] the definition of a subcomplex has the extra condition that every simplex of $X$ equals the union of finitely many simplices of $Y$. It follows from [Hud69] Lemma 1.2 together with Proposition 61.12 (2) that the above definition agrees with the definition provided in [Mun84, p. 83].

(4) The definition of a subdivision is somewhat unsatisfactory. In the spirit that abstract simplicial complexes should be purely combinatorial objects there should be a “topology free” definition of the subdivision of an abstract simplicial complexes, which then mirrors the topological definition given above. We will return to the question of how to work completely combinatorially in Section 64.6.

Examples.

(1) It follows from Lemma 62.3 (3a) and (3c) that the barycentric subdivision $sd(X)$ of a simplicial complex $X$ is indeed a subdivision in the sense of the above definition.

(2) In Figure 945 we see that a subdivision of the simplicial complex $|S_2|$ is simplicially isomorphic to $\Sigma(S_1)$.

(3) Let $n \in \mathbb{N}_0$. By Lemma 61.19 (3) we know that the map

$$f: \partial\Delta^n \ast \{\ast\} \to \Delta^n$$

$$[(x, t, \ast)] \mapsto x \cdot (1 - t) + \left(\frac{1}{n+1}, \ldots, \frac{1}{n+1}\right) \cdot t$$

is a homeomorphism. It follows easily from this observation that the simplicial complex $(S_{n-1} \ast \{\ast\}, |S_{n-1} \ast \{\ast\}| = \partial\Delta^n \ast \{\ast\} \xrightarrow{f} \Delta^n)$ is a subdivision of the simplicial complex $(D_n, \Omega: |D_n| \to \Delta^n)$. We refer to Figure 946 for an illustration.
For completeness’ sake we mention the following result.

**Proposition 63.17.**

1. Let \( X \) and \( Y \) be two finite linear simplicial complexes. If \( |X| = |Y| \), then there exist subdivisions \( X' \) of \( X \) and \( Y' \) of \( Y \) which are simplicially isomorphic.

2. If we are given two subdivisions \( X' \) and \( X'' \) of some finite linear simplicial complex \( X \), then there exists a subdivision \( Y \) of \( X \) which is a subdivision of \( X' \) and \( X'' \).

**Proof.**

1. This statement is proved in [Gla70, Corollary I.4] and [Ze63b, Corollary I.1].

2. This statement follows immediately from (1) together with Lemma 61.22.

The following theorem gives us part (2) of Program 63.16. We will not provide a proof, instead we refer to [Mun66a, Theorem 17.2] for a detailed proof.

**Theorem 63.18.** Let \( X \) be a simplicial complex and let \( X' \) be a subdivision of \( X \). If \( \varphi : X' \to X \) is a simplicial approximation of the identity map \( X' \to X \), then the induced map \( \varphi_* : H_n^{\text{simp}}(X') \to H_n^{\text{simp}}(X) \) is an isomorphism for every \( n \in \mathbb{N}_0 \).

So an obvious candidate for the “moves” of Program 63.16 is a combination of subdivisions and simplicial isomorphisms. Now that we have dealt with part (2) of Program 63.16, let us try to tackle part (1). In fact this part is the following conjecture, which came to be known as the “Hauptvermutung”. It was originally formulated by Heinrich Tietze [Tie1908, p. 13f] in 1908. The conjecture was also raised as a question by Ernst Steinitz [Steini1908, p. 32] in 1908.

**Conjecture 63.19. (Hauptvermutung)** Let \( X \) and \( Y \) be two finite simplicial complexes. If the underlying topological spaces are homeomorphic, then there exist subdivisions of \( X \) and \( Y \) which are simplicially isomorphic.

For better or worse it turned out that the Hauptvermutung was too optimistic. More precisely, the Hauptvermutung was eventually disproved by John Milnor [Miln61, Theorems 1 and 2] in 1961.

**Theorem 63.20.** There exist two finite linear simplicial complex \( X \) and \( Y \) for which the underlying topological spaces are homeomorphic, but such that there are no subdivisions of \( X \) and \( Y \) which are simplicially isomorphic.

**Remark.** In fact a few years later Rob Kirby and Larry Siebenmann [KSi77] (see also [Ran96, Chapter 4]) showed that given any \( n \geq 5 \) there exist such finite abstract simplicial complexes such that the underlying topological space is a compact \( n \)-dimensional topological manifold.

**Proof.** The theorem is proved in [Miln61, Theorems 1 and 2]. Alternative proofs are given in [Cohe73, p. 84], [Stal65b, p. 252] and [Ran96, Chapter 2].

Even though Part (1) of Program 63.16 did not work out, it turns out that Question 63.15 nonetheless has a positive answer. More precisely we have the following theorem.
Theorem 63.21. Let $X$ and $Y$ be two simplicial complexes. If the underlying topological spaces $X$ and $Y$ are homeomorphic, then for every $n \in \mathbb{N}_0$ the simplicial homology groups $H_n^{\text{simp}}(X)$ and $H_n^{\text{simp}}(Y)$ are isomorphic.

Using the Simplicial Approximation Theorem 62.8 and several other tools from the theory of simplicial complexes one can give a direct proof of Theorem 63.21. This approach is for example pursued in [Mun66a, Corollary 18.2], [Pra07, Chapter 2.2] and [Gib10, p. 136].

We will instead take an indirect approach to proving Theorem 63.21, namely we will show that given a simplicial complex the simplicial and singular homology groups are isomorphic. By the functoriality of singular homology the isomorphism type of singular homology groups only depends on the homeomorphism type of the topological space. With this observation in mind we see that Theorem 63.21 is a consequence of the following theorem.

Theorem 63.22. Let $X$ be a simplicial complex. For every $n \in \mathbb{N}_0$ there exists a natural\footnote{Here “natural” means that if $f : X \rightarrow Y$ is a simplicial map, then the following diagram commutes:}

isomorphism $\Phi_X : H_n^{\text{simp}}(X) \rightarrow H_n(X)$.

We postpone the proof of Theorem 63.22 to the next section. In fact, in the next section we will formulate and prove a more precise version of Theorem 63.22. But before we delve into the detailed arguments let us first discuss the respective advantages and disadvantages of simplicial homology.

In some textbooks, see e.g. [?, Mun84, SZ94, HY88], homology groups are initially introduced via simplicial homology. This approach has several advantages:

1. The definition of simplicial homology is much more elementary and intuitive than the definition of singular homology.

2. One can immediately compute the simplicial homology groups of interesting simplicial complexes, e.g. as we will see in Exercise 63.10 with enough patience and a little bit of cleverness one can compute the simplicial homology groups of abstract simplicial complexes that correspond to the surface of genus $g$.

Nonetheless there are serious disadvantages to this approach. A first problem, which is already apparent in the case of the torus, is that even for relatively simple examples the simplicial structures tend to have a large number of simplices, thus the corresponding chain complexes tend to be fairly large and brute force computations by hand become unpleasant. It turns out that there are some ways around this, for example one can extend the theory of simplicial homology from simplicial complexes to “$\Delta$-complexes”, which tend to have a significantly smaller number of simplices. Loosely speaking a $\Delta$-complex is a topological space that is decomposed into simplices but now we only demand that the interiors of
the simplices are embedded. To give a flavor of the theory we show three \( \Delta \)-complexes in Figure 947. The theory of \( \Delta \)-complexes is developed in detail in [Hat02 Chapter 2.1].

\[
\begin{align*}
\text{\( \Delta \)-complex structure} & \quad \text{for the torus} \\
\text{\( \Delta \)-complex structure} & \quad \text{for} \ \mathbb{RP}^2 \\
\text{\( \Delta \)-complex structure} & \quad \text{for the surface of genus 2}
\end{align*}
\]

\textbf{Figure 947}

Here are more serious reasons why we, and most modern authors, decided against starting out with simplicial homology and why we do not develop the theory of simplicial homology in greater detail:

1. For slightly more complicated topological spaces it is rather laborious to compute simplicial homology groups. For example we challenge the reader to compute the simplicial homology groups of the projective spaces \( \mathbb{RP}^n \) and \( \mathbb{CP}^n \) without reverting to cellular homology.
2. Most topological spaces one wants to study (e.g. the complement of a knot in \( S^3 \)), do not come with an obvious simplicial structure, it can be quite cumbersome to show that a simplicial structure exists, let alone to give an explicit simplicial structure.
3. For a given topological space \( X \) which admits a simplicial structure we know by Theorem 63.21 that we have a well-defined \textit{isomorphism type} of simplicial homology groups, but there is no single group that we can associate to \( X \).
4. Simplicial homology is functorial with respect to simplicial maps. Most maps are not simplicial. We do have the Simplicial Approximation Theorem 62.8 as a tool. But to use it in a sensible fashion one needs to show that the simplicial approximations of a given continuous map induce the same map on simplicial homology.

It should have become clear by now that simplicial homology comes with a Pandora’s box of issues and problems. Overall, the initial extra effort in developing the theory of singular homology groups eventually pays off handily. The theory of singular homology groups is much more natural and much more flexible than the rather pedestrian theory of simplicial homology groups.

We conclude this section with the following piece of wisdom which was handed down to the author from his advisor:

\textit{For actual calculations it is best to work with very small objects, for proving general statements it is best to work with very large objects.}

63.5. \textbf{The topological invariance of simplicial homology II.} In this section we will first show that given an abstract simplicial complex the simplicial homology groups are naturally isomorphic to singular homology groups. Afterwards we will try to find a natural chain homotopy equivalence.

We start out with the first key result of this section.
Theorem 63.23. Let \((K, \Theta : |K| \to X)\) be a simplicial complex. For each \(n_0 \in \mathbb{N}\) there exists a natural isomorphism \(H_{n_0}^{\text{simp}}(K) \to H_n(X)\).

The proof of Theorem 63.23 builds on a proposition which relates the simplicial chain complex to the cellular chain complex. Before we state the proposition we recall that given a CW-complex we consider \(C_n^{\text{CW}}(X) := H_n(X^n, X^{n-1})\) together with the boundary map \(d_n\) which is given by the composition

\[
H_n(X^n, X^{n-1}) \xrightarrow{\partial_n} H_{n-1}(X^{n-1}) \xrightarrow{j_{n-1}} H_{n-1}(X^{n-1}, X^{n-2}) =: d_n
\]

where \(\partial_n\) is the connecting map in the long exact sequence of the pair \((X^n, X^{n-1})\) and where \(j_{n-1}\) is the natural map from absolute to relative homology.

Now we can formulate the promised proposition.

Proposition 63.24. Let \(K\) be an abstract simplicial complex. Given an ordered \(n\)-simplex \(s = (v_0, \ldots, v_n)\) of \(K\) we denote by

\[
\Phi^\leq_s : \Delta^n = \left\{(t_0, \ldots, t_n) \in \mathbb{R}^{n+1}_{\geq 0} \, \middle| \sum_{i=0}^n t_i = 1 \right\} \to |X| = X
\]

\[
(t_0, \ldots, t_n) \mapsto \sum_{i=0}^n t_i \cdot v_i
\]

the corresponding characteristic map. The maps \(973\)

\[
\Upsilon_n : C_n^{\text{simp}}(K) \to C_n^{\text{CW}}(|K|)
\]

\[
[s] \mapsto (\Phi^\leq_s : \Delta^n \to |K|)
\]

form a natural isomorphism of chain complexes.

Proof of Proposition 63.24. Let \(K = (V, S)\) be an abstract simplicial complex. We write \(X := |K|\). Given \(n \in \mathbb{N}_0\) we denote by \(S_n\) the set of ordered \(n\)-simplices of \(K\). Next we consider the following diagram

\[
\begin{array}{ccc}
C_n^{\text{simp}}(K) := \left( \bigoplus_{s \in S_n} \mathbb{Z} \cdot s \right) / I_n & \xrightarrow{[s] \mapsto [\Phi^\leq_s]} & H_n(X^n, X^{n-1}) = C_n^{\text{CW}}(X) \\
\downarrow \partial_n & & \downarrow d_n \\
C_{n-1}^{\text{simp}}(K) := \left( \bigoplus_{s \in S_{n-1}} \mathbb{Z} \cdot s \right) / I_{n-1} & \xrightarrow{[s] \mapsto [\Phi^\leq_s]} & H_{n-1}(X^{n-1}, X^{n-2}) = C_{n-1}^{\text{CW}}(X).
\end{array}
\]

We make the following clarifications and observations:

1. If \(s\) is an ordered \(k\)-simplex, then it follows immediately from the definition of the CW-structure on \(X\) that \(\Phi^\leq_s(\Delta^k) \subset X^k\) and that \(\Phi^\leq_s(\partial \Delta^k) \subset X^{k-1}\). In particular this shows that \(\Phi^\leq_s\) represents an element in \(H_k(X^k, X^{k-1})\).

973 Recall that in Lemma 61.24 we showed that the simplicial complex \(|K|\) admits a natural CW-structure.
(2) It follows fairly easily from (1) together with Lemma 19.1 and Proposition 45.22 that the horizontal maps are well-defined.

(3) Basically the same argument as in Lemma 48.1 (1) shows that the horizontal maps are isomorphisms.

(4) As explained above, the top diagonal map $\partial: H_n(X^n, X^{n-1}) \to H_{n-1}(X^{n-1})$ is the connecting homomorphism of the pair $(X^n, X^{n-1})$ and the bottom diagonal map $j_{n-1}: H_{n-1}(X^{n-1}) \to H_{n-1}(X^{n-1}, X^{n-2})$ is the natural map from absolute homology to relative homology. The map $d_n$ is by definition the composition of these two maps. In other words, the triangle commutes by definition.

(5) It follows fairly immediately from the definition of the connecting homomorphism, see Proposition 43.15, and the definition of the maps $\Phi^s$ that the pentagon to the left commutes.

(6) It follows from (4) and (5) that the outer square of the diagram also commutes.

(7) The horizontal maps are basically by definition natural.

The above discussion shows that the horizontal maps define a natural isomorphism of chain complexes.

For the reader’s convenience we recall the following proposition.

**Proposition 48.4.** Given any CW-complex $X$ and given any $n \in \mathbb{N}_0$ there exists a uniquely determined isomorphism

$$\Phi_X: H_n(X) \xrightarrow{\cong} H_n^{CW}(X),$$

with the property that the following diagram commutes\(^6\).

$$
\begin{array}{ccc}
H_n(X) & \xrightarrow{\Phi_X} & H_n^{CW}(X) \\
\downarrow j_n & & \downarrow j_n \\
k_{n-1} & & k_{n-1}
\end{array}
$$

Furthermore this map $\Phi_X$ is natural.

\(^6\)Here we again denote by $j_n: H_n(X^n) \to H_n(X^n, X^{n-1})$ the obvious map. In the long exact sequence of the pair $(X^n, X^{n-1})$ we see that the image of $H_n(X^n)$ in $H_n(X^n, X^{n-1})$ lies in the kernel of the connecting homomorphism $\partial_n$. This implies that the map $j_n: H_n(X^n) \to H_n(X^n, X^{n-1})$ takes values in $\ker(d_n)$.

Now we can put everything together to obtain a proof of Theorem 63.23.

**Proof of Theorem 63.23** It follows immediately from the definitions that we only need to consider the case of the topological realization of an abstract simplicial complex $K$. We equip $|K|$ with the CW-structure provided by Lemma 61.24. Now given any $n \in \mathbb{N}_0$ we have the following two natural isomorphisms:

$$
\begin{array}{ccc}
H_n^{simp}(K) & \xrightarrow{\cong} & H_n^{CW}(|K|) \\
\uparrow \Phi_K & & \uparrow \Phi_{|K|} \\
H_n(|K|)
\end{array}
$$

The natural isomorphism $\Phi_X^{-1} \circ \Upsilon_K$ is the natural isomorphism of our desires.
One problem with Theorem 63.23 is that it does not give us an explicit isomorphism between the homology groups. This issue gets mostly resolved by the following more sophisticated theorem.

**Theorem 63.25.** Let \( K \) be an ordered abstract simplicial complex. The maps

\[
\Theta_n: \mathbb{C}^{\text{simp}, \leq}_n(K) \to \mathbb{C}_n(|K|)
\]

\[
s \mapsto (\Phi^\leq_s: \Delta^n \to |K|)
\]

are a natural chain homotopy equivalence. In particular for each \( n \in \mathbb{N}_0 \) the induced map

\[
\Theta_*: \mathbb{H}^{\text{simp}, \leq}_n(K) \to \mathbb{H}_n(|K|)
\]

is a natural isomorphism.

**Remark.** Theorem 63.25 can actually be quite useful in practice. Let us elaborate. In practice, given a topological space \( X \) one would like to perform the following three types of tasks:

1. Determine the isomorphism type of the homology groups \( H_k(X) \).
2. Determine explicit cycles in \( C_k(X) \) that represent a basis or a generating set for the homology groups \( H_k(X) \).
3. Calculate induced maps \( H_k(X) \to H_k(Y) \) with respect to, say, given bases or generating sets for the homology groups \( H_k(X) \) and \( H_k(Y) \).

In fact in many situations, for example in applications of the Mayer-Vietoris Theorem 46.5, these problems feed on one another. Even though by now we have a long list of tools, the fact that the singular chain groups \( C_*(X) \) are basically always of infinite, in fact mostly of uncountable, rank makes it hard to attack the above problems directly.

Fortunately, in many situations Theorem 63.25 allows us to translate the above problems into tasks in a simplicial chain complex. For reasonable abstract simplicial complexes, these problems in turn boil down to elementary problems in linear algebra that usually can be solved easily.

**Example.** We consider the 1-dimensional ordered abstract simplicial complex \( K \) shown in Figure 948, which we had already considered on page 1542. By the discussion on page 1542 we know that

\[
H^{\text{simp}, \leq}_1(K) = \ker (\partial_1: \mathbb{C}^{\text{simp}, \leq}_1(K) \to \mathbb{C}^{\text{simp}, \leq}_0(K)) = \mathbb{Z} \cdot [\{C, D\} + \{D, E\} - \{C, E\}].
\]

We write \( x = \Theta_1(\{C, D\}) \), \( y = \Theta_1(\{D, E\}) \) and \( z = \Theta_1(\{C, E\}) \). It follows from Theorem 63.25 and the above discussion that \( x + y - z \) represents a generator of \( H_1(|K|) \).

**Proof of Theorem 63.25.** Let \( K \) be an ordered abstract simplicial complex. It follows almost immediately from the definitions that the maps

\[
\Theta_n: \mathbb{C}^{\text{simp}, \leq}_n(K) \to \mathbb{C}_n(|K|)
\]

\[
s \mapsto (\Phi^\leq_s: \Delta^n \to |K|)
\]

974 Here “natural” means with respect to the category of ordered abstract simplicial complexes.

975 What other methods do you know for proving this statement?
define a natural chain map. We leave it to the skeptical reader to verify that this statement is indeed true and basically trivial. It remains to show that the maps \( \Theta_n \) define a chain homotopy equivalence. By Proposition 49.2 it now suffices to prove the following claim.

**Claim.** Let \( K \) be an ordered abstract simplicial complex. For every \( n \in \mathbb{N}_0 \) the induced map

\[
\Theta_* : H^{\text{simp}, \leq}_{n}(K) \to H_n(|K|)
\]

is an isomorphism.

We start out with two observations. Let \( K \) be an ordered abstract simplicial complex, let \( m \in \mathbb{N}_0 \cup \{ \infty \} \) and let \( n \in \mathbb{N}_0 \). We write \( X = |K| \). It follows from Lemma 63.9 and Lemma 48.1 that the following statements hold:

(i) The two inclusion induced maps

\[
\begin{align*}
H^{\text{simp}, \leq}_{n}(K^m) & \to H^{\text{simp}, \leq}_{n}(K) \\
H_n(|K^m|) & \to H_n(|K|)
\end{align*}
\]

are both isomorphisms whenever \( n < m \).

(ii) If \( n > m \), then

\[
\begin{align*}
H^{\text{simp}, \leq}_{n}(K^m) & = 0 \\
H_n(|K^m|) & = 0.
\end{align*}
\]

It follows immediately from (i) that it suffices to prove the claim for finite dimensional ordered abstract simplicial complexes. As usual, for finite dimensional ordered abstract simplicial complexes we proceed by induction on the dimension. The case of an empty and of a 0-dimensional ordered abstract simplicial complex is trivial. So suppose we have shown the statement for all ordered abstract simplicial complexes of dimension \( \leq m - 1 \). Now let \( K \) be an \( m \)-dimensional ordered abstract simplicial complex. We write \( X := |K| \) and we denote by \( i: K^{m-1} \to K \) and \( i: X^{m-1} \to X \) the inclusion maps. It follows from (i) and (ii), the naturality of \( \Theta \) and our induction hypothesis that we only need to worry about the two maps

\[
\Theta_* : H^{\text{simp}, \leq}_{m}(K) \to H_m(X) \quad \text{and} \quad \Theta_* : H^{\text{simp}, \leq}_{m-1}(K) \to H_{m-1}(X).
\]
To take care of this map we consider the following diagram:

\[
\begin{array}{c}
0 \to H^\text{simp}_{m-1}(K) \to \Omega_{m-1}^\text{simp}(K) \to H^\text{simp}_m(K) \to 0 \\
\downarrow \cong \quad \downarrow \cong \\
0 \to H_m(X) \to H_m(X, X^{m-1}) \to H_{m-1}(X^{m-1}) \to 0.
\end{array}
\]

We make the following observations and clarifications:

1. First we show that the horizontal maps on the top actually make sense. Since \( K = K^m \) we see that \( H^\text{simp}_{m-1}(K) \) is a subgroup of \( C^\text{simp}_{m-1}(K) \). In fact by definition it equals \( \ker(\partial): C^\text{simp}_{m-1}(K) \to C^\text{simp}_{m-1}(K) \). Furthermore note, that basically by definition, given \( s \in C^\text{simp}_{m-1}(K) \) we have \( \partial s \in C^\text{simp}_{m-1}(K^{m-1}) \). Since \( \partial \circ \partial = 0 \) we see that \( \partial s \) defines an element in \( H^\text{simp}_{m-1}(K^{m-1}) \).

2. Using (1) and using the explicit definitions of simplicial homology groups it is not hard to see that the top horizontal sequence is exact.

3. It follows from \( X = X^m \) and Lemma 48.1 that \( H_i(X, X^{m-1}) = 0 \) for \( i \neq m \). Thus we see that the bottom horizontal sequence is a segment of the long exact sequence of the pair \((X, X^{m-1})\).

4. It follows easily from the definition of the maps \( \Theta \) and \( \Psi \) and the explicit description of the connecting homomorphism \( \partial: H_m(X, X^{m-1}) \to H_{m-1}(X^{m-1}) \) that we gave in Proposition 43.15 that the two squares to the left commute. It follows from the naturality of \( \Theta_s \) that the square to the right commutes.

5. It follows from induction that the vertical map \( \Theta_s: H^\text{simp}_{m-1}(K^{m-1}) \to H^\text{simp}_{m-1}(X^{m-1}) \) to the right is an isomorphism.

6. By Proposition 63.24 we know that \( \Psi_s \) is an isomorphism.

7. It follows from all of the above together with the Five-Lemma 43.12 that the vertical maps \( \Theta_s: H^\text{simp}_{m-1}(K) \to H_m(X) \) and \( \Theta_s: H^\text{simp}_{m-1}(K) \to H_{m-1}(X) \) to the left and right are isomorphisms.

Given an abstract simplicial complex \( K \) together with an order \("\leq"\) on \( K \) we denote by \( \Omega_{\leq k}: C^\text{simp}_{k, \leq}(K) \to C^\text{simp}_k(K) \) the natural chain isomorphism given by Lemma 63.8. Together with Theorem 63.25 we obtain an isomorphism

\[
H^\text{simp}_k(K) \xrightarrow{\Omega_{\leq k}} H^\text{simp}_k(K) \xrightarrow{\Theta_{\leq k}} H_k(|K|).
\]

A priori this isomorphism depends on the choice of the order \("\leq"\). The next lemma shows that fortunately this is not the case.
**Lemma 63.26.** Let $K$ be an abstract simplicial complex and let “≤” and “⊆” be two orders on $K$. The two chain maps

\[
\begin{align*}
C_k^{\text{simp}}(K) & \xrightarrow{\Omega_{\leq,1}^{-1}} C_k^{\text{simp},\leq}(K) \xrightarrow{\Theta_{\leq,k}} C_k(|K|) \\
\text{and} \quad C_k^{\text{simp}}(K) & \xrightarrow{\Omega_{\leq,1}^{-1}} C_k^{\text{simp},\subseteq}(K) \xrightarrow{\Theta_{\leq,k}} C_k(|K|)
\end{align*}
\]

are chain homotopic. In particular they induce the same maps on homology.

**Proof.** Let $K = (V, S)$ be an abstract simplicial complex. We start with the following preparations:

1. For each $i \in \mathbb{N}_0$ we pick once and for all for each $i$-simplex $s \in S$ an ordered $i$-simplex $\tilde{s}$ with $|\tilde{s}| = s$. We denote by $\tilde{S}_i$ the set given by all these ordered $i$-simplices.

2. We introduce the following convention. If for some $i \in \mathbb{N}_0$ we are given for every $\tilde{s} \in \tilde{S}_i$ a singular chain $P_i(\tilde{s}) \in C_{i+1}(|\tilde{s}|)$ then we denote by $P_i$ the map

\[
C_i^{\text{simp}}(K) \to C_{i+1}(|K|)
\]

\[
\tilde{s} \mapsto P_i(\tilde{s}) \text{ viewed as an element in } C_{i+1}(|K|) \text{ via the inclusion } |\tilde{s}| \subseteq |K|
\]

Now let “≤” and “⊆” be two orders on $\Delta = (V, S)$.

**Claim.** Let $l \in \mathbb{N}$. Suppose that for every $i \in \{0, \ldots, l-1\}$ and for every $\tilde{s} \in \tilde{S}_i$ we are given a singular chain $P_i(\tilde{s}) \in C_{i+1}(|\tilde{s}|)$ such that for every $i \in \{0, \ldots, l-1\}$ we have the equality

\[
(\ast) \quad \partial_{i+1} \circ P_i + P_{i-1} \circ \partial_i = \Theta_{\leq,i} \circ \Omega_{\leq,i}^{-1} - \Theta_{\subseteq,i} \circ \Omega_{\subseteq,i}^{-1} : C_i^{\text{simp}}(K) \to C_i(|K|).
\]

Then for every $\tilde{s} \in \tilde{S}_l$ we can also find $P_l(s) \in C_{l+1}(|\tilde{s}|)$ such that the above equality holds for $i = 0, \ldots, l$.

Let $\tilde{s} \in \tilde{S}_l$. Note that we have

\[
\text{since } \Theta_{\leq,i} \circ \Omega_{\leq,i}^{-1} \text{ and } \Theta_{\subseteq,i} \circ \Omega_{\subseteq,i}^{-1} \text{ are chain maps}
\]

\[
\partial_i((P_{l-1} \circ \partial_l + \Theta_{\leq,l-1} \circ \Omega_{\leq,l-1}^{-1} - \Theta_{\subseteq,l-1} \circ \Omega_{\subseteq,l-1}^{-1})(\partial_l(\tilde{s}))) = (P_{l-2} \circ \partial_{l-1})(\partial_l(\tilde{s})) = P_{l-2}(\partial_{l-1} \circ \partial_l)(\tilde{s}) = 0.
\]

Then we can proceed similarly as before to prove the following diagram

\[
\begin{align*}
C_l^\text{simp}(\tilde{s}) & \xrightarrow{\partial_l} C_{l-1}^\text{simp}(\tilde{s}) \xrightarrow{\partial_{l-1}} C_{l-2}^\text{simp}(\tilde{s}) \\
C_{l+1}(\tilde{s}) & \xrightarrow{\partial_{l+1}} C_l(\tilde{s}) \xrightarrow{\partial_l} C_{l-1}(\tilde{s}) \xrightarrow{\partial_{l-1}} C_{l-2}(\tilde{s})
\end{align*}
\]

Note that we are dealing with $l \in \mathbb{N}_0$. This implies that $H_l(|\tilde{s}|) = 0$. But this means that every cycle is in fact a boundary. In particular the above cycle is the boundary of some
$P_{l+1}(\tilde{s}) \in C_{l+1}(|\tilde{s}|)$, i.e. we have

$$(\partial_{l+1}(P_{l+1}(\tilde{s}))) = (- P_{l-1} \circ \partial_l + \Theta_{\leq \ell} \circ \Omega_{\leq \ell}^{-1} - \Theta_{= \ell} \circ \Omega_{= \ell}^{-1})(\tilde{s}).$$

By construction all these $P_{l+1}(\tilde{s})$ have the desired property.

Now we can easily find the desired chain homotopy. Indeed, for every 0-simplex $s$ we set $P_0(s) = 0 \in C_1(|s|)$. Since $\Omega_{\leq 0} = \Omega_{\leq 0}: C_0^{\text{simp}}(K) \to C_0(|K|)$ we see that we can start the machine provided by the claim and iteratively we construct maps $P_l$ which are precisely the promised chain homotopy. 

The following is now an almost immediate corollary to Lemma 63.8, Theorem 63.25 and Lemma 63.26.

**Corollary 63.27.** Let $K$ be an abstract simplicial complex. We pick an order “$\leq$” on $K$. The maps

$$\Xi_k := \Theta_{\leq k} \circ \Omega_{\leq k}^{-1}: H_k^{\text{simp}}(K) \to H_k(|K|),$$

which by Lemma 63.26 do not depend on the choice of the order “$\leq$”, define a natural isomorphism between functors from the category $\text{AbsSimpCplx}$ of abstract simplicial complexes (the key here is that the word “ordered” is missing) to the category $\text{AbGr}$ of abelian groups.

It is worth repeating it:

1. Given any abstract simplicial complex $K$ and given any $k \in \mathbb{N}_0$ there exists a natural isomorphism $H_k^{\text{simp}}(K) \to H_k(|K|)$ of homology groups.
2. If $K$ is an ordered abstract simplicial, then there is in fact a natural chain homotopy equivalence $C_*^{\text{simp}, \leq}(K) \to C_*(|K|)$.

The alert reader will have noticed that given an abstract simplicial complex we gave two natural isomorphisms $H_n^{\text{simp}}(K) \to H_n(|K|)$. The following proposition shows that the two isomorphisms agree.

**Proposition 63.28.** Let $K$ be an abstract simplicial complex and let $n_0 \in \mathbb{N}$. We write $X = |K|$. We denote by

$$\Upsilon_*: C_*^{\text{simp}}(K) \to C_*^{\text{CW}}(X) \quad \text{and} \quad \Phi_n: H_n(X) \to H_n^{\text{CW}}(X)$$

the isomorphisms given by Propositions 63.24 and 48.4. Next we pick an order “$\leq$” on $K$. We consider the chain homotopy equivalences

$$\Omega: C_*^{\text{simp}, \leq}(K) \to C_*^{\text{simp}}(K) \quad \text{and} \quad \Theta: C_*^{\text{simp}, \leq}(K) \to C_*(|K|)$$

from Lemma 63.8 and Theorem 63.25. With this notation the following equality holds:

$$\Phi_n^{-1} \circ \Upsilon_* = \Theta \circ \Omega_*^{-1}: H_n^{\text{simp}}(K) \to H_n(X).$$

**Notation.** Let $K$ be an abstract simplicial complex and let $n_0 \in \mathbb{N}$. By a slight abuse of notation we denote by $\Theta_K: H_n^{\text{simp}}(K) \to H_n(|K|)$ the natural isomorphism given by Theorem 63.23 and Proposition 63.28.
Proof. We write $\Psi_X := \Upsilon_* \circ \Omega_* \circ \Theta_*^{-1}$. We need to show that $\Psi_X = \Phi_X$. To do so we consider the following diagram:

$$
\begin{align*}
H_{\text{simp}}^{\leq}(K^n) &\xrightarrow{i_*} H_{\text{simp}}^{\leq}(K) \\
H_n(X) &\xrightarrow{\Theta_*} H_n(X^n) \\
H_n^{\text{CW}}(X) &\xrightarrow{\Phi_X} \ker(d_n) \\
\end{align*}
$$

We make the following clarifications and observations:

1. The map $i: K^n \to K$ is the inclusion map.
2. The triangle shaped quadrangle to the upper left commutes by the naturality of $\Theta_*$. 
3. By the definition of $\Psi_X$ the quadrangle to the right commutes.
4. It follows easily from the definitions of the various maps that the “outer diagram” commutes, i.e. the two maps from $H_{\text{simp}}^{\leq}(K^n)$ to $H_n^{\text{CW}}(X)$ agree.
5. Since $\Upsilon_*$, $\Omega_*$ and $\Theta_*$ are isomorphisms we see that $\Psi_X$ is an isomorphism and we see, in combination with (2), (3) and (4), that $\Psi_X$ makes the parallelogram commute.

But by the characterization of $\Phi_X$ in Proposition 48.4 this means that $\Psi_X = \Phi_X$. □

63.6. Relative simplicial homology ($*$). In this section, given an (ordered) abstract simplicial complex $K$ together with a subcomplex $L$ we introduce the relative simplicial homology groups $H_k^{\text{simp}}(K, L)$ and $H_k^{\text{simp}, \leq}(K, L)$. This section contains no surprises and can be skipped easily. We will make little use of relative simplicial homology groups, except that they will come in handy in the proof of the Simplicial Poincaré Duality Theorem 41.4.

Definition. Let $K$ be an abstract simplicial complex and let $L$ be a (possibly empty) subcomplex of $K$.

1. Given $k \in \mathbb{N}_0$ we define

$$C_k^{\text{simp}}(K, L) := C_k^{\text{simp}}(K) / C_k^{\text{simp}}(L).$$

The usual boundary map $\partial_k: C_k^{\text{simp}}(K) \to C_{k-1}^{\text{simp}}(K)$ descends to a boundary map $\partial_k: C_k^{\text{simp}}(K, L) \to C_{k-1}^{\text{simp}}(K, L)$ and we can thus define the corresponding relative simplicial homology groups $H_k^{\text{simp}}(K, L)$.

2. If “$\leq$” is an order on $K$, then we endow $L$ with the corresponding order and we introduce $C_k^{\text{simp}, \leq}(K, L)$ and $H_k^{\text{simp}, \leq}(K, L)$ in the obvious way.

The following lemma is an immediate consequence of Proposition 43.11.
**Lemma 63.29.** Let $K$ be an abstract simplicial complex and let $L$ be a subcomplex of $K$. The sequence

$$\ldots \to H^\text{simp}_k(L) \to H^\text{simp}_k(K) \to H^\text{simp}_k(K, L) \xrightarrow{\partial_k} H^\text{simp}_{k-1}(L) \to \ldots$$

is exact and the connecting homomorphism is natural. The analogous statement also holds if $K$ is equipped with an order.

We conclude this short section with the following lemma.

**Lemma 63.30.** Let $K$ be an abstract simplicial complex and let $L$ be a subcomplex of $K$.

1. Let “$\leq$” be an order on $K$. The natural maps

$$C^\text{simp}_{\leq}(K, L) \to C^\text{simp}_k(K, L), \quad [\sigma] \mapsto [\Omega(\sigma)]$$

are chain homotopy equivalences. Furthermore the natural maps

$$H^\text{simp}_{\leq}(K, L) \to H^\text{simp}_k(K, L), \quad [\sigma] \mapsto [\Omega(\sigma)]$$

are isomorphisms.

2. The map $\Xi := \Omega \circ \Theta^{-1} : H^\text{simp}_k(K, L) \to H_k(|K|, |L|)$ does not depend on the choice of the order “$\leq$” on $K$, and it defines a natural isomorphism.

3. The following diagram commutes:

$$\begin{array}{ccccccccc}
\ldots & \to & H^\text{simp}_{\leq}(K) & \to & H^\text{simp}_{\leq}(K, L) & \xrightarrow{\partial_k} & H^\text{simp}_{\leq}(L) & \xrightarrow{\partial_k} & H^\text{simp}_{\leq}(K) & \to & \ldots \\
&& \downarrow{\varepsilon} && \downarrow{\varepsilon} && \downarrow{\varepsilon} && \downarrow{\varepsilon} \\
\ldots & \to & H_k(|K|) & \to & H_k(|K|, |L|) & \xrightarrow{\partial_k} & H_k(|L|) & \xrightarrow{\partial_k} & H_k(|K|) & \to & \ldots
\end{array}$$

**Proof.** We consider the following diagram:

$$\begin{array}{ccccccccc}
\ldots & \to & H^\text{simp}_k(L) & \to & H^\text{simp}_k(K) & \to & H^\text{simp}_k(K, L) & \xrightarrow{\partial_k} & H^\text{simp}_{k-1}(L) & \xrightarrow{\partial_k} & H^\text{simp}_{k-1}(K) & \to & \ldots \\
&& \uparrow{\Omega} && \uparrow{\Omega} && \uparrow{\Omega} && \uparrow{\Omega} && \uparrow{\Omega} \\
\ldots & \to & H^\text{simp}_{\leq}(L) & \to & H^\text{simp}_{\leq}(K) & \to & H^\text{simp}_{\leq}(K, L) & \xrightarrow{\partial_k} & H^\text{simp}_{\leq}(L) & \xrightarrow{\partial_k} & H^\text{simp}_{\leq}(K) & \to & \ldots \\
&& \uparrow{\Theta} && \uparrow{\Theta} && \uparrow{\Theta} && \uparrow{\Theta} && \uparrow{\Theta} \\
\ldots & \to & H_k(|L|) & \to & H_k(|K|) & \to & H_k(|K|, |L|) & \xrightarrow{\partial_k} & H_k(|L|) & \xrightarrow{\partial_k} & H_k(|K|) & \to & \ldots
\end{array}$$

It follows easily from the definitions and the naturality of the connecting homomorphisms, see Proposition 43.11, that the diagram commutes. By Lemma 63.29 and by Corollary 43.16 we know that the horizontal sequences are exact. Furthermore by Lemma 63.8 and Theorem 63.25 we know that the outer two vertical maps are isomorphisms. Now it follows from the Five-Lemma 43.12 that the middle vertical maps are also isomorphisms. It follows from Proposition 49.2 that the corresponding chain maps are chain homotopy equivalences. This concludes the proof Statement (1).
The same argument as in the proof of Corollary 63.27 shows that the composition of the middle vertical maps does not depend on the choice of the order “≤”.

Finally Statement (3) follows from the fact that the above diagram commutes. □

63.7. The Nerve Theorem. In this section we will state the “Nerve Theorem”. In many situations it gives an effective way for showing that a given topological space is homotopy equivalent to a simplicial complex.

**Definition.** Let $X$ be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be a cover of $X$.

1. We say the cover $\mathcal{U} = \{U_i\}_{i \in I}$ of $X$ is good if for every two choice of $i_1, \ldots, i_m \in I$ the intersection $U_{i_1} \cap \cdots \cap U_{i_m}$ is either empty or contractible.
2. We say the cover $\mathcal{U}$ of $X$ is point-finite if each point $x \in X$ is contained in only finitely many $U_i$.

**Example.** In Figure 949 we show the topological space $X = S^1$ with one cover which is not good and three covers which are actually good.

As we will see, the following lemma is a straightforward consequence of Lemma 62.5

**Lemma 63.31.** Let $K = (V, S)$ be an abstract simplicial complex. The open stars $\{\text{St}(v)\}_{v \in V}$ are an open good point-finite cover.

**Proof.** Let $K = (V, S)$ be an abstract simplicial complex. Let $P \in |K|$. By Lemma 61.11 (2) we know that there exists a unique $s \in S$ with $P \in \langle s \rangle$. Furthermore, by Lemma 62.5 (2) we know that $P \in \text{St}(v)$ if and only if $v$ is a vertex of $s$. This discussion, together with

---

Note that Exercise 43.3 shows that one cannot reduce this statement “Five Lemma”-style to the fact that we already know that the composition of the outer two vertical maps is independent of the choice of the order “≤”.

Note that this notion is weaker than the notion of a locally finite cover that we introduced on page 80.
Lemma 62.5 (2), shows that the open stars $\hat{\text{St}}(v)$ form an open point-finite cover of $|K|$. It remains to show that the cover is good. Thus let $v_0, \ldots, v_n \in V$. We have

$$\hat{\text{St}}(v_0) \cap \cdots \cap \hat{\text{St}}(v_n) = \begin{cases} \hat{\text{St}}(\{v_0, \ldots, v_n\}), & \text{if } \{v_0, \ldots, v_n\} \text{ is a simplex,} \\ \emptyset, & \text{otherwise}. \end{cases}$$

Lemma 62.5 (3)

We have thus shown that the open stars $\{\hat{\text{St}}(v)\}_{v \in V}$ are a good point-finite cover.  

As we will see shortly, Lemma 63.31 has a partial converse, namely the mysteriously named Nerve Theorem. To state this converse we need the following definition.

**Definition.** Let $X$ be a set and let $\mathcal{U} = \{U_i\}_{i \in I}$ be a family of subsets of $X$. We refer to the abstract simplicial complex that is given by the vertex set $I$ and the simplex set $\{\{i_1, \ldots, i_r\} | i_1, \ldots, i_r \in I \text{ with } U_{i_1} \cap \cdots \cap U_{i_m} \neq \emptyset\}$ as the nerve complex $N(\mathcal{U})$ of the covering.

**Example.** In Figure 951 we revisit the four covers of $S^1$ that we showed in Figure 949. This time we also show the topological realizations of the corresponding nerve complexes. As is clear from the figure, for the cover to the left, which is not good, the topological realization of the nerve complex does not look at all like $S^1$. On the other hand, for the three covers to the right, which are good, the topological realization of the nerve complex is homeomorphic or at least homotopy equivalent to $S^1$. As we will see in a minute, that is not a coincidence.

![Diagram of nerve complexes](image)

**Figure 951**

To formulate the Nerve Theorem of this section it is convenient to introduce the following definition.

**Definition.** We say that a map $f : X \to Y$ between path-connected topological spaces is a weak homotopy equivalence if there exists $x_0 \in X$ such that for every $k \in \mathbb{N}_0$ the induced map $f_* : \pi_k(X, x_0) \to \pi_k(Y, f(x_0))$ is an isomorphism.

---

It follows easily from the definitions that this is indeed an abstract simplicial complex.
By Proposition 40.7 (2) a homotopy equivalence between path-connected topological spaces is a weak homotopy equivalence. The following theorem says, rather amazingly, that for CW-complexes the converse holds.

**Theorem 119.9, (Whitehead Theorem)** Let $f: X \to Y$ be a map between two connected CW-complexes.\footnote{Note that we do not assume that the map $f$ is cellular.} If $f: X \to Y$ is a weak homotopy equivalence, then $f$ is a homotopy equivalence.

As is clear from the numbering, we will prove the Whitehead Theorem\footnote{We refer to page 1514 for the definition of a regular CW-complex, note that simplicial complexes are regular CW-complexes.} much later in these notes. But, as we will see, this theorem greatly facilitates the discussion of the Nerve Theorem.

Recall that in Lemma 63.31 we showed that every simplicial complex admits a good cover. We can now formulate and prove the Nerve Theorem which can in particular be viewed as a partial converse to Lemma 63.31.

**Theorem 63.32, (Nerve Theorem)** Let $X$ be a path-connected topological space and let $U = \{U_i\}_{i \in I}$ be an open good point-finite cover of $X$. The following two statements hold:

1. There exists a weak homotopy equivalence $|N(U)| \to X$ from the topological realization of the nerve complex $N(U)$ to $X$. In fact there exists a weak homotopy equivalence $f: |N(U)| \to X$ such that for any simplex $\{i_0, \ldots, i_k\}$ of $N(U)$ we have $f(|\{i_0, \ldots, i_k\}|) \subseteq U_{i_0} \cap \cdots \cap U_{i_k}$.
2. If $X$ is furthermore a CW-complex, then any map $f: |N(U)| \to X$ as in (1) is in fact a homotopy equivalence.

**Remark.**

1. The Nerve Theorem has its origins in the work of Karol Borsuk \[Bor48\] from 1948 and Jean Leray \[Ler50\] from 1950. As stated the theorem was basically proved by André Weil \[Weil52, p. 141\] in 1952.
2. Let $X$ be a CW-complex. It follows from Proposition 36.10 (8) that the conclusion of the Nerve Theorem 63.32 also holds if $U = \{U_i\}_{i \in I}$ is a family of subcomplexes which form a good point-finite cover of $X$.
3. There are many variations on the statement and on the proof of the Nerve Theorem 63.32:
   (a) In \[Bj95, Theorem 10.6\] and \[Bj03, Theorem 6\] a Nerve Theorem is formulated for the case that $X$ is a regular CW-complex\footnote{We refer to page 1514 for the definition of a regular CW-complex, note that simplicial complexes are regular CW-complexes.} and the $U_i$ are subcomplexes. In this case the cover does not need to be point-finite.
   (b) Other versions are formulated in \[Nag07, Theorem 3.3\] and \[BoS73, Theorem 8.2.1\].
   (c) An elegant proof of the Nerve Theorem 63.32 for the case of a finite cover is given in \[Koz08, Theorem 15.21\].

**Proof.** Statement (2) of the Nerve Theorem is an immediate consequence of Statement (1) together with the Whitehead Theorem 119.9. Thus it remains to prove Statement (1).
In the discussion below we will only sketch an argument. A full proof of Statement (1) is given in [McCor67, Theorem 1].

Thus let \( X \) be a topological space and let \( \mathcal{U} = \{ U_v \}_{v \in V} \) be an open good point-finite cover of \( X \). We adopt the following notation:

1. We set \( S := \{ (v_0, \ldots, v_n) | v_0, \ldots, v_n \in V \text{ with } U_{v_0} \cap \cdots \cap U_{v_n} \neq \emptyset \} \).

Recall that by definition the nerve complex is given by \( N(\mathcal{U}) := (V, S) \). For convenience we write \( N = N(\mathcal{U}) \).

2. Given \( s = \{ v_0, \ldots, v_n \} \in S \) we set \( U_s := U_{v_0} \cap \cdots \cap U_{v_n} \).

3. We consider the barycentric subdivision \( \text{sd}(N) = (\{ \emptyset \} \times S, \{ \{ s_0, \ldots, s_k \} | s_0 \subset \cdots \subset s_k \} ) \).

By Lemma 62.3 we have a natural homeomorphism \( |\text{sd}(N)| \rightarrow |N| \) which we use to identify these two topological spaces.

Next we define inductively a map \( F: |\text{sd}(N)| \rightarrow X \) which satisfies the following condition:

\[ (*) \text{ For every simplex } \{ s_0, s_1, \ldots, s_k \} \text{ of } |\text{sd}(N)| \text{ we have } F(|\{ s_0, s_1, \ldots, s_k \} |) \subset U_{s_0}. \]

We construct \( F \) inductively as follows:

1. For each \( \emptyset \) we pick a point \( F(\emptyset) \in U_s \).

2. Suppose that \( F \) is defined on the \((n-1)\)-skeleton of \( |\text{sd}(N)| \). We want to extend \( F \) to the \( n \)-skeleton of \( |\text{sd}(N)| \). Let \( t = \{ s_0, \ldots, s_n \} \) be an \( n \)-simplex of \( |\text{sd}(N)| \) and let \( \Phi_t^\leq: \Delta^n \rightarrow |\text{sd}(N)| \) be the corresponding characteristic map. Note that

\[ (F \circ \Phi_t^\leq)(\partial \Delta^n) = \bigcup_{i=0}^n F(|\{ s_0, \ldots, \hat{s_i}, \ldots, s_n \} |) \subset U_{s_0}. \]

By definition we have for \( s \subset t \) that \( U_t \subset U_s \), in particular we have \( U_{s_1} \subset U_{s_0} \).

3. By hypothesis we know that \( U_{s_0} \) is contractible. It follows from Proposition 40.7 and Lemma 40.4 together with the fact, shown in Lemma 41.1 (3), that the pair \((\Delta^n, \partial \Delta^n)\) is homeomorphic to \((B^n, S^{n-1})\), that \( F \circ \Phi_t^\leq: \partial \Delta^n \rightarrow U_{s_0} \) extends to a map \( G: \Delta^n \rightarrow U_{s_0} \). Now we define \( F \) on \(|t| = |\{ s_0, \ldots, s_n \} | \) to be the map \( G \circ \Phi_t^{-1} \). Note that this map still satisfies \((*)\).

It follows almost immediately from Lemma 62.3 and \((*)\) that \( F: |N| = |\text{sd}(N)| \rightarrow X \) has the desired property that for every simplex \( \{ v_0, \ldots, v_k \} \) of \( N = N(\mathcal{U}) \) we have the inclusion \( F(|\{ v_0, \ldots, v_k \} |) \subset U_{v_0} \cap \cdots \cap U_{v_k} \).

It remains to show that \( F \) is a weak homotopy equivalence. Unfortunately this is where our discussion of the proof peters out. We suggest to use Proposition 119.6 below to show...
that $F$ is a weak homotopy equivalence. One should be able to employ this proposition using the following two approaches:

1. One uses the Mayer–Vietoris and the HNN-Seifert–van Kampen Theorem and suitable analogues for simplicial complexes, to show that $F$ induces an isomorphism of homotopy groups.

2. One uses cleverly the naturality of the long exact sequence coming from the Mayer–Vietoris Theorem (or more elegantly, the naturality of the Mayer–Vietoris spectral sequence which we alluded to on page 1210) to show that the lift $\tilde{F}$ of $F$ to the universal covers of $\text{sd}(N)$ and $X$ induces an isomorphism of all homology groups.

We leave it as a rather challenging exercise to the reader to make the above approach work. Even the case of a finite cover is already rather delicate.

---

**Figure 952. Illustration of the proof of Nerve Theorem**

For completeness we also state the following variation on the Nerve Theorem.

**Theorem 63.33. (Nerve Theorem)** Let $X$ be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be an open good cover of $X$. If $X$ is paracompact, then there exists a homotopy equivalence $|N(\mathcal{U})| \to X$.

**Proof.** By definition of a paracompact topological space, see page 144 there exists a partition of unity $\{\varphi_i\}_{i \in I}$ subordinate to the covering. We define

$$G : X \to |N(\mathcal{U})|, \quad x \mapsto \left( \frac{I}{i} \mapsto \mathbb{R} \quad i \mapsto \varphi_i(x) \right).$$

In [Hat02] Proposition 4G.2 it is shown that the map $G$ is a homotopy inverse to the map $F : |N(\mathcal{U})| \to X$ that we constructed in the proof of the Nerve Theorem 63.32.

---

One of the many fun applications of the Nerve Theorem is the following theorem which was first proved by Eduard Helly in 1913 using much more elementary techniques. Our proof is arguably technological overkill, but it has the advantage that from our point of view it is very conceptual.

**Theorem 63.34. (Helly’s Theorem)** Let $n \in \mathbb{N}_0$ and let $U_1, \ldots, U_m$ be convex open subsets of $\mathbb{R}^n$. If any choice of $n + 1$ of those sets has non-empty intersection, then the intersection of all those sets is non-empty, i.e. we also have

$$U_1 \cap \cdots \cap U_m \neq \emptyset.$$
Examples.

(1) For $n = 1$ and $m = 3$ Helly’s Theorem 63.34 says that if we are given three open intervals such that any two of them have a non-empty intersection, then the intersection of the three open intervals is non-empty.

(2) For $n = 2$ and $m = 4$ Helly’s Theorem 63.34 says if we are given four convex open subsets of $\mathbb{R}^2$, such that any three of them have non-empty intersection, then the intersection of all four subsets is also non-empty. This situation is illustrated in Figure 953.

Remark.

(1) In our formulation of Helly’s Theorem 63.34 we require that the sets $U_i$ are open. This is in fact just an artifact of our proof. In fact the statement holds without this assumption. We refer to [Mato02, Theorem 1.3.2] for an elementary proof of this more general statement.

(2) As we mentioned above, our topological proof of Helly’s Theorem 63.34 is strictly speaking more difficult than necessary. But the advantage of the topological approach taken in these notes is that it is easier to generalize this approach to non-convex subsets.

(3) We refer to [Eckh93] for a long list of references for proofs of Helly’s Theorem and for a discussion of the relevance of Helly’s Theorem.

In our proof of Helly’s Theorem we will need the following proposition which is interesting in its own right.

**Proposition 63.35.** If $M$ is an open subset of $\mathbb{R}^n$, then $H_k(M) = 0$ for $k \geq n$.

**Proof.** The proposition follows from a fun argument using the Mayer–Vietoris Theorem 46.5. We invite the reader to fill in the details in Exercise 63.15. ■

**Proof of Helly’s Theorem 63.34** Let $n \in \mathbb{N}_0$. We prove the theorem by induction on $m$. For $m \leq n + 1$ there is nothing to show. Now suppose that the theorem holds for some $m \geq n + 1$. Let $\mathcal{U} := \{U_1, \ldots, U_{m+1}\}$ be a family of convex open subsets of $\mathbb{R}^n$ such that the intersection of any $n + 1$ of those subsets has non-empty intersection. By induction hypothesis we know that the following holds:

(i) The intersection of any $m$ of the sets in $\mathcal{U}$ is non-empty.

We need to show that $U_1 \cap \cdots \cap U_{m+1} \neq \emptyset$. We do a proof by contradiction. So we assume that the following holds:

(ii) $U_1 \cap \cdots \cap U_{m+1} = \emptyset$. 
Next we consider the corresponding nerve complex $N(\mathcal{U})$.

1. It follows immediately from (i) and (ii) that the nerve complex $N(\mathcal{U})$ is simplicially isomorphic to the simplicial complex $S_{m-1}$ that we introduced on page $1480$.

2. As we mentioned before, one of the key properties of convex subsets is that any intersection of convex subsets is again convex, in particular any intersection is contractible. Thus $\mathcal{U}$ is an open good finite cover of $U_1 \cup \cdots \cup U_{m+1}$.

Now we see that

by the Nerve Theorem $63.32$ which we can apply by (2), together with Corollary $42.8$

$$
\begin{align*}
Z & \cong H_{m-1}^{\text{simp}}(S_{m-1}) \cong H_{m-1}^{\text{simp}}(N(\mathcal{U})) \cong H_{m-1}(|N(\mathcal{U})|) \cong H_{m-1}(U_1 \cup \cdots \cup U_{m+1}) = 0.
\end{align*}
$$

Lemma $63.12$ by (1) Theorem $63.23$ by Proposition $63.35$ since $m - 1 \geq n$

We have thus obtained a contradiction to (ii).

The Nerve Theorem $63.32$ gives a practical tool for showing that a given topological space is homotopy equivalent to a simplicial complex. It is natural to go through familiar classes of topological spaces and to see whether it applies. Fortunately the next proposition shows that it applies to everybody’s favorite topological spaces, namely smooth manifolds.

**Proposition 63.36.**

1. Every compact smooth manifold admits an open good finite cover.
2. Every smooth manifold admits an open good point-finite cover.

**Remark.** To the best of my knowledge it is not known whether every topological manifold admits an open cover that is good, let alone good and point-finite.

**Sketch of proof.** The proposition is proved in detail in [Wei152 p. 120] and in less detail in [BoT82 Theorem 5.1], [KaL87 Chapter VI.3] and [Lee09 Theorem 10.17]. In the following we sketch the argument in the closed case.

Thus let $M$ be a closed $k$-dimensional smooth manifold. We point out that by Proposition $9.1$ we can view $M$ as a submanifold of some $\mathbb{R}^n$. Given $P \in M$ and $r > 0$ we write $C_r(P) := B_r^n(P) \cap M$. Furthermore, given $P \in M$ we denote by $\pi_P : \mathbb{R}^n \to V_P M$ the orthogonal projection onto the visual tangent space that we introduced on page $292$.

We leave it to the reader to show, using the compactness and the definition of a smooth map and using Proposition $6.20$ that there exists an $\epsilon > 0$ such that for any $P \in M$ the following statements hold:

1. the set $C_\epsilon(P)$ is an open subset of $M$,
2. for any $Q \in C_\epsilon(P)$ the projection $\pi_Q : C_\epsilon(P) \to V_Q M$ is an embedding such that the image is convex.

Since $M$ is compact it follows from (1) that there exist $P_1, \ldots, P_m \in M$ such that the open sets $C_\epsilon(P_1), \ldots, C_\epsilon(P_m)$ form an open cover of $M$. Since the intersection of convex subsets is again convex we obtain from (2) that this open cover is indeed good.

We obtain the following corollary from the combination of Proposition $63.36$ the Nerve Theorem $63.32$ and Lemma $61.24$. 

Corollary 63.37. Every (compact) smooth manifold is weakly homotopy equivalent to a (finite) simplicial complex, in particular it is weakly homotopy equivalent to a (finite) CW-complex.

Later, in Theorem 64.5 we will see that a much stronger version of Corollary 63.37 holds.

63.8. The simplicial subdivision map $(*)$. Let $(K, \leq)$ be an ordered abstract simplicial complex. By Theorem 63.23 and Lemma 62.3 we know that the simplicial homology groups of $K$ and of its barycentric subdivision $sd(K)$ are isomorphic.

In this section we will strengthen this result. More precisely, we will give a natural map $\sigma: sd(K) \to K$ and we will give a natural chain map

$$u_*: C^*_{\text{simp}, \leq}(K) \to C^*_{\text{simp}, \leq}(sd(K))$$

such that the chain maps $\sigma_*$ and $u_*$ are chain homotopy inverses of one another. These two constructions will prove their worth later on when we study continuous self-maps $f: |K| \to |K|$. More precisely, by the Simplicial Approximation Theorem 62.8 we know that a given continuous map $f: |K| \to |K|$ is homotopic to a simplicial map $g: |sd^i(K)| \to |K|$, thus we get an induced chain map $g_*: C^*_{\text{simp}, \leq}(sd^i(K)) \to C^*_{\text{simp}, \leq}(K)$. Unfortunately this is a chain map between different chain complexes. But if we combine $g_*$ with an $i$-fold iteration of $u_*$, then we obtain an endomorphism $C^*_{\text{simp}, \leq}(sd^i(K)) \to C^*_{\text{simp}, \leq}(sd^i(K))$ of a chain complex.

We start out with the following lemma

Lemma 63.38. Let $(K, \leq)$ be an ordered abstract simplicial complex.

1. There exists a unique simplicial map $\sigma: sd(K) \to K$ with the following property: given an $n$-simplex $s = \{v_0 < \cdots < v_n\}$ of $K$ the map $\sigma$ sends the corresponding vertex $\sigma(s)$ of $sd(K)$ to the vertex $v_n$ of $K$.

2. The stretching map $\sigma: sd(K) \to K$ is order-preserving. (Here we equip $sd(K)$ with the natural order introduced in Lemma 62.2(2).)

3. The stretch map $\sigma$ is natural. Here “natural” means that given any order-preserving simplicial map $f: (K, \leq) \to (L, \leq)$ between two ordered abstract simplicial complexes

Figure 954. Illustration of the proof of Proposition 63.36.
and given any \( n \in \mathbb{N}_0 \) the following diagram commutes:

\[
\begin{array}{ccc}
\text{sd}(K) & \xrightarrow{f_*} & \text{sd}(L) \\
\sigma \downarrow & & \downarrow \sigma \\
K & \xrightarrow{f_*} & L.
\end{array}
\]

We refer to this map \( \sigma \) as the stretching map.

**Figure 955.** Illustration of Lemma 63.38

**Proof.** It follows easily from the definitions that the given map on the set of vertices induces a simplicial map, that this map is order-preserving and that this map is natural. We leave it to the reader to fill in the details.

In basically all cases the stretching map \( \sigma : \text{sd}(K) \to K \) is not a simplicial isomorphism, in particular the induced map on the simplicial chain complexes is not an isomorphism. Our goal now is to show the “best possible result”, namely that the induced chain map \( \sigma_* : C^\text{simp}_{\leq}(\text{sd}(K)) \to C^\text{simp}_{\leq}(K) \) is a chain homotopy equivalence. We will do so by giving an explicit chain map in the other direction.

**Definition.** Let \((K, \leq)\) be an ordered abstract simplicial complex.

1. Given an \( n \)-simplex \( s = \{v_0 < \cdots < v_n\} \) of \( K \), given \( m \in \{0, \ldots, n\} \) and given \( \sigma \in \text{Bij}\{0, \ldots, n\} \) we write

\[
s_{\sigma, m} := \{v_{\sigma(0)}, \ldots, v_{\sigma(m)}\}.
\]

Note that \( s_{\sigma, n} = s \). Furthermore, we set

\[
s_\sigma := \{s_{\sigma, n}, s_{\sigma, n-1}, \ldots, s_{\sigma, 0}\}.
\]

Note that \( s_\sigma \) is an \( n \)-simplex of \( \text{sd}(K) \).

2. Given an \( n \)-simplex \( s \) of \( K \) we define

\[
u_n(s) := \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot s_\sigma \in C^\text{simp}_{\leq}(\text{sd}(K)).
\]

We refer to the resulting map as the simplicial subdivision map.

\[\text{sd}(K) \xrightarrow{f_*} \text{sd}(L)\]

\[\sigma \downarrow \quad \sigma \downarrow \]

\[K \xrightarrow{f_*} L.\]

\(^{\text{631}}\text{Recall that by Lemma 62.3 (5) we know that the maps } K \mapsto \text{sd}(K) \text{ define a covariant functor from the category } \text{OrdAbsSimpCplx} \text{ of ordered abstract simplicial complexes to itself.}\]
Let \((K, \leq)\) be an ordered abstract simplicial complex. The simplicial subdivision maps

\[ u_n : C^{\text{simp}, \leq}_n(K) \to C^{\text{simp}, \leq}_n(\text{sd}(K)), \quad n \in \mathbb{N}_0 \]

are a natural chain map. Here “natural” means that given any order-preserving simplicial map \(f : (K, \leq) \to (L, \leq)\) between two ordered abstract simplicial complexes and given any \(n \in \mathbb{N}_0\) the following diagram commutes:

\[
\begin{array}{ccc}
C^{\text{simp}, \leq}_n(K) & \xrightarrow{f_*} & C^{\text{simp}, \leq}_n(L) \\
\downarrow{u_n} & & \downarrow{u_n} \\
C^{\text{simp}, \leq}_n(\text{sd}(K)) & \xrightarrow{f_*} & C^{\text{simp}, \leq}_n(\text{sd}(L)).
\end{array}
\]

**Proof** \((*)\). Let \((K, \leq)\) be an ordered abstract simplicial complex. We need to show that the maps

\[ u_n : C^{\text{simp}, \leq}_n(K) \to C^{\text{simp}, \leq}_n(\text{sd}(K)), \quad n \in \mathbb{N}_0 \]

are a natural chain map. In fact it follows immediately from the definitions and Lemma 62.1 (1) that the maps \(u_n\) are natural. Thus it remains to prove that the maps \(u_n\) are a chain map. We will do so in the following claim.

**Claim.** For any \(n \in \mathbb{N}_0\) and any \(n\)-simplex \(s\) of \(K\) we have the following equality:

\[ \partial u_n(s) = u_{n-1}(\partial s). \]

We introduce the following notation. Given an \(n\)-simplex \(t = \{w_0 < \cdots < w_n\}\) and given \(i \in \{0, \ldots, n\}\) we write \(t(i) = \{w_0 < \cdots < \widehat{w}_i < \cdots < w_n\}\), i.e. \(t(i)\) is the \((n-1)\)-simplex given by striking out the vertex \(w_i\). Now let \(s = \{v_0 < \cdots < v_n\}\) be an \(n\)-simplex.
of \(K\). We perform the following slightly messy calculation:

\[
\begin{align*}
\partial u_n(s) &= \partial \left( \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot s_{\sigma} \right) \\
&= \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot (s_{\sigma})(0) + \sum_{i=1}^{n} (-1)^i \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot (s_{\sigma})(i) \\
&= \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot (s_{\sigma})(0) + \sum_{i=0}^{n} (-1)^i \sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot (s_{\sigma})(i)
\end{align*}
\]

the second summand vanishes since for a fixed \(i \in \{1, \ldots, n\}\) and for \(\mu, \nu \in \text{Bij}(0, \ldots, n)\) we have \((s_{\mu})(i) = (s_{\nu})(i)\) if \(\mu(i-1) = \nu(i)\), if \(\mu(i) = \nu(i-1)\) and if all other values of \(\mu\) and \(\nu\) are the same, thus given the fixed \(i \in \{1, \ldots, n\}\) we can pair up the elements in \(\text{Bij}(0, \ldots, n)\) to give the same contribution \((s_{\sigma})(i)\) to the sum, but with opposite sign

\[
\sum_{\sigma \in \text{Bij}(0, \ldots, n)} \text{sign}(\sigma) \cdot (s_{\sigma})(0) = \sum_{\tau \in \text{Bij}(0, \ldots, n-1)} \sum_{i=0}^{n} (-1)^i \cdot \text{sign}(\tau) \cdot (s(i))_{\tau} = u_{n-1}(\partial s).
\]

The following lemma finally relates the stretching maps to the simplicial subdivision maps.

**Lemma 63.40.** Let \((K, \leq)\) be an ordered abstract simplicial complex. As before we denote by \(\sigma\): \(\text{sd}(K) \rightarrow K\) the stretching map introduced in Lemma 63.38

1. The induced chain map

\[
\sigma_*: C^\text{simp,\leq}_*(\text{sd}(K)) \rightarrow C^\text{simp,\leq}_*(K)
\]

and the simplicial subdivision maps

\[
u_n: C^\text{simp,\leq}_n(K) \rightarrow C^\text{simp,\leq}_n(\text{sd}(K)), \quad n \in \mathbb{N}_0
\]

are chain homotopy inverses of one another.

2. The maps \(\sigma_*\) and the maps \(\nu_*\) are chain homotopy equivalences.

3. The maps \(\sigma_*: H^\text{simp,\leq}_*(\text{sd}(K)) \rightarrow H^\text{simp,\leq}_*(K)\) and \(\nu_*: H^\text{simp,\leq}_*(K) \rightarrow H^\text{simp,\leq}_*(\text{sd}(K))\)

are natural isomorphisms and they are inverses of one another.

**Figure 957.** Illustration of Lemma 63.40

**Remark.** Lemma 63.40 (2) can be viewed as an analogue of Lemma 43.27 where we proved a similar statement for the singular subdivision map.
Proof (**). Statement (2) of the lemma is an immediate consequence of Statement (1). Furthermore Statement (3) follows from Statements (1) and (2) together with Corollary 42.3 and the naturality statements of Lemma 63.38 and Lemma 63.39. Thus it remains to prove Statement (1).

Let \((K, \leq)\) be an ordered abstract simplicial complex. It follows easily from the definitions that for each \(n \in \mathbb{N}_0\) the map \(\sigma_* \circ u_n : C^{\text{simp}, \leq}_n(K) \to C^{\text{simp}, \leq}_n(K)\) is the identity. Thus it remains to prove that \(u_* \circ \sigma_*\) is chain homotopic to the identity.

The definition of the chain homotopy requires some preparations and extra definitions. Let \(n \in \mathbb{N}_0\) and let \(t = \{s_0, \ldots, s_n\}\) be an \(n\)-simplex of \(\text{sd}(K)\) with \(#s_n = n + 2\). For convenience we set \(s_{-1} := \emptyset\). Since \(#s_n = n + 2\) and since for each \(i \in \{0, \ldots, n\}\) we have \(s_{i-1} \subset s_i\) we see that there exists a unique \(i \in \{0, \ldots, n\}\) with \(#s_i = #s_{i-1} + 2\). Thus there exist two vertices \(v < w\) of \(K\) such that \(s_i = s_{i-1} \cup \{v, w\}\). We say that \(t\) can be expanded upward if \(w\) is larger than every element in \(s_{i-1}\). In this case we set

\[
\Phi(t) := \left\{ s_0, \ldots, s_{i-1}, s_{i-1} \cup \{w\}, s_i, \ldots, s_n \right\}
\]

and

\[
\eta(t) := \text{sign}(\sigma) \text{ where } \sigma \in \text{Bij}\{0, \ldots, n\} \text{ with } \Phi(t) = (s_n)_\sigma.
\]

These definitions are illustrated in Figures 958 and 959. For each \(n \in \mathbb{N}_0\) we consider the following map

\[
P_n : C^{\text{simp}, \leq}_n(\text{sd}(K)) \to C^{\text{simp}, \leq}_{n+1}(\text{sd}(K))
\]

\[
t = \{s_0, \ldots, s_n\} \mapsto \begin{cases}
\eta(t) \cdot \Phi(t), & \text{if } #s_n = n + 2 \text{ and if } t \text{ can be expanded upward,} \\
0, & \text{otherwise.}
\end{cases}
\]

We leave it to the reader’s unredenting zest for verifying technical details to show that these maps \(P_n\) form a chain homotopy between the identity and the chain map \(\sigma_* \circ u_*\). ■

**Figure 958.** First illustration for the proof of Lemma 63.40

**Figure 959.** Second illustration for the proof of Lemma 63.40
We defined the simplicial subdivision map for *ordered* abstract simplicial complexes. As we will see shortly, the choice of an ordering is irrelevant.

**Definition.** Let \((K, \leq)\) be an abstract simplicial complex.

1. Let \(s = (v_0, \ldots, v_n)\) be an ordered \(n\)-simplex of \(K\). Given \(m \in \{0, \ldots, n\}\) we set
   \[ F_m(s) := \{v_0, \ldots, v_m\}. \]

   Furthermore we define
   \[ F(s) := (F_0(s), F_1(s), \ldots, F_n(s)). \]

   Note that \(F(s)\) is an ordered \(n\)-simplex of \(sd(K)\).

2. Note that any two ordered \(n\)-simplices \(s = (v_0, \ldots, v_n)\) and \(t = (w_0, \ldots, w_n)\) of \(K\) with \(\{v_0, \ldots, v_n\} = \{w_0, \ldots, w_n\}\) there exist a unique \(\sigma \in \text{Bij}\{0, \ldots, n\}\) such that \(v_i = w_{\sigma(i)}\) for all \(i = 0, \ldots, n\). We set \(\text{sign}(s, t) := \text{sign}(\sigma)\).

3. Given an ordered \(n\)-simplex \(s = (v_0, \ldots, v_n)\) we set
   \[ u_n(s) := \sum_{t = (w_0, \ldots, w_n) \text{ an ordered}} (-1)^{\text{sign}(s, t)} \cdot F(t). \]

More precisely, we have the following lemma.

**Lemma 63.41.** Let \(K\) be an abstract simplicial complex.

1. For every \(n \in \mathbb{N}_0\) the map
   \[ C_n^{\text{simp}}(K) \rightarrow C_n^{\text{simp}}(sd(K)) \]
   \[ [s] \mapsto [u_n(s)] \]
   is well-defined. We refer to this map again as the simplicial subdivision map.

2. The maps \(u_n\) are natural in the sense that given a simplicial map \(f: K \rightarrow L\) the following diagram commutes:
   \[ C_n^{\text{simp}}(K) \rightarrow C_n^{\text{simp}}(L) \]
   \[ u_n \downarrow \quad \downarrow u_n \]
   \[ C_n^{\text{simp}}(sd(K)) \rightarrow C_n^{\text{simp}}(sd(L)). \]

3. If \(K\) is equipped with an order “\(\leq\)”, then for every \(n \in \mathbb{N}_0\) the following diagram commutes:
   \[ C_n^{\text{simp}, \leq}(K) \rightarrow C_n^{\text{simp}, \leq}(sd(K)) \]
   \[ \cong \downarrow \quad \downarrow \cong \]
   \[ C_n^{\text{simp}}(K) \rightarrow C_n^{\text{simp}}(sd(K)). \]

   Here the vertical maps are the natural isomorphisms given by Lemma 63.5.

4. The maps \(u_n: C_n^{\text{simp}}(K) \rightarrow C_n^{\text{simp}}(sd(K))\) form a chain homotopy equivalence. In fact, if we pick an order on \(K\) and we consider the corresponding stretching map
σ: sd(K) → K, then the maps \( u_n \) and the maps \( \sigma_*: C^\text{simp}_*(sd(K)) \to C^\text{simp}_*(K) \) are chain homotopy inverses.

(5) The induced maps \( u_*: H^\text{simp}_n(K) \to H^\text{simp}_n(sd^\text{simp}(K)) \) are natural isomorphisms.

**Remark.** Note in contrast the stretching maps certainly do depend on the choice of an order.

**Proof.** The first three statements follow easily from the definitions. The only statement which perhaps needs a little bit of thought is the first statement. We leave it to the reader to fill in the details. Let us turn to the proof of Statement (4). As mentioned before, by the Well-ordering Theorem [1.6] we can pick an order "≤" on \( K \). Let \( n \in \mathbb{N}_0 \). By (2) we have the following commutative diagram:

\[
\begin{array}{ccc}
C^\text{simp}_n(K) & \xrightarrow{u_n} & C^\text{simp}_n(sd(K)) \\
\cong & & \cong \\
\downarrow & & \downarrow \\
C^\text{simp}_n(K) & \xrightarrow{u_n} & C^\text{simp}_n(sd(K)).
\end{array}
\]

By Lemma 63.40 we know that the top horizontal maps form a chain homotopy equivalence and that a chain homotopy inverse is given by the stretching maps. It follows that the analogous statements hold for the bottom horizontal maps. Finally Statement (5) follows from (2) and (4) together with Corollary 42.3.

In the remainder of this section we want to discuss the relationship of the stretching map and the simplicial division map with various maps on the topological realizations. First we recall that given an abstract simplicial complex \( K \) we gave in Lemma 62.3 (3) an explicit natural homeomorphism \( \tilde{\Omega}: |sd(K)| \to |K| \). This allows us to formulate the following lemma.

**Lemma 63.42.** Let \( (K, \leq) \) be an abstract simplicial complex. We denote by \( \sigma: sd(K) \to K \) the stretching map from Lemma 63.38. The map \( |\sigma| \circ \tilde{\Omega}^{-1}: |K| \to |K| \) is homotopic to the identity.

**Proof.** Since we will not make use of Lemma 63.42 we outsource the proof thereof to Exercise 63.17.

We recall some more maps and statements from earlier on.

(1) Let \( K \) be an ordered abstract simplicial complex. By Theorem 63.25 we know that the maps

\[
\Theta_K: C^\text{simp}_n(K) \to C_n(|K|)
\]

\( s \mapsto (\Phi^\leq_s: \Delta^n \to |K|) \)

are a natural chain homotopy equivalence.

(2) Given a topological space \( X \) and \( n \in \mathbb{N}_0 \) we denote by \( u_n: C_n(X) \to C_n(X) \) the singular subdivision map as defined in page 1135.

Now we can formulate the following proposition.
**Proposition 63.43.** For every ordered abstract simplicial complex \((K, \leq)\) and every \(n \in \mathbb{N}_0\) the following diagram commutes:

\[
\begin{array}{ccc}
C_n^{\text{simp}, \leq}(K) & \xrightarrow{\partial_n} & C_n^{\text{simp}, \leq}(\text{sd}(K)) \\
\downarrow{\Theta_K} & & \downarrow{\Theta_{\text{sd}(K)}} \\
C_n(|K|) & \xrightarrow{\partial_n} & C_n(|\text{sd}(K)|)
\end{array}
\]

Furthermore all maps form natural chain homotopy equivalences.

The key step in proving Proposition \([63.43]\) is to give an alternative description of the simplicial subdivision map that resembles the definition of the singular subdivision map which we gave on page \([1135]\). We start out with the following definition.

**Definition.** Let \((K, \leq)\) be an ordered abstract simplicial complex.

1. Given a \(k\)-simplex \(s\) of \(K\) we define the “coning map”
   \[
c_s : C_i^{\text{simp}, \leq}(\text{sd}(\partial s)) \to C_{i+1}^{\text{simp}, \leq}(\text{sd}(s)) \\
   \implies \{\emptyset\} \cup t.
\]
   We refer to Figure \([960]\) for an illustration.

2. We define \(\tilde{u}_0 : C_0^{\text{simp}, \leq}(K) \to C_0^{\text{simp}, \leq}(\text{sd}(K))\) to be the obvious inclusion. Furthermore, for \(n \geq 1\) we define inductively the following maps:
   \[
   \tilde{u}_n : C_n^{\text{simp}, \leq}(K) \to C_n^{\text{simp}, \leq}(\text{sd}(K)) \\
   s \mapsto (-1)^n \cdot c_s\left(\partial_{n-1}(s)\right) \in C_{n-1}^{\text{simp}, \leq}(\text{sd}(\partial s)).
   \]
   The definition is illustrated in Figure \([961]\).

The following lemma gives the promised alternative description of the simplicial subdivision maps.

\(^{984}\)Recall that in Lemma \([62.2]\) (2) we saw that \(\text{sd}(K)\) is naturally an ordered abstract simplicial complex.
Lemma 63.44. Let \((K, \leq)\) be an ordered abstract simplicial complex. Given any \(n\)-simplex \(s\) of \(K\) we have \(\tilde{u}_n(s) = u_n(s)\).

Proof of Lemma 63.44. Let \((K, \leq)\) be an ordered abstract simplicial complex. We prove the lemma by induction on \(n\). For \(n = 0\) the statement is basically obvious. Now suppose that the statement holds for some \(n \in \mathbb{N}_0\). Let \(s = \{v_0 < \cdots < v_{n+1}\}\) be some \((n+1)\)-simplex. Given \(i \in \{0, \ldots, n+1\}\) we write \(s(i) := \{v_0, \ldots, \hat{v}_i, \ldots, v_{n+1}\}\). We calculate that

\[
\begin{align*}
\tilde{u}_{n+1}(s) &= (-1)^{n+1} \cdot c_s(\tilde{u}_n(\partial s)) \\
&= (-1)^{n+1} \cdot c_s\left(u_n\left(\sum_{i=0}^{n+1} (-1)^i \cdot s(i)\right)\right) \\
&= (-1)^{n+1} \cdot \sum_{i=0}^{n+1} (-1)^i \cdot \sum_{\sigma \in \text{Bij}\{0, \ldots, n\}} \text{sign}(\sigma) \cdot \{s, s(i)\}_{\sigma} \\
&= \sum_{\tau \in \text{Bij}\{0, \ldots, n+1\}} \text{sign}(\tau) \cdot s_\tau = u_n(s).
\end{align*}
\]

Here we use the following bijection:
\[
\Psi: \{0, \ldots, n+1\} \times \text{Bij}\{0, \ldots, n\} \to \text{Bij}\{0, \ldots, n+1\}
\]

\[
(i, \sigma) \mapsto \begin{cases} 
0, \ldots, n+1 & \mapsto 0, \ldots, n+1 \\
0 & \mapsto \begin{cases} 
0, \ldots, i-1 & \text{if } i \in \{0, \ldots, n+1\} \\
j & \text{if } j \in \{0, \ldots, i-1\} \\
0 & \text{if } j = n+1 \\
0, \ldots, n+1 & \text{if } j \in \{i, \ldots, n\} \\
\end{cases} \end{cases}
\]

and we use that \(\text{sign}(\Psi(i, \sigma)) = (-1)^{i+1} \cdot (-1)^{n+2} \cdot \text{sign}(\sigma)\).

We have thus proved the induction step. 

Now we can easily prove Proposition 63.43.

Proof of Proposition 63.43. It follows immediately from Lemma 63.44 together with the definitions of the various maps that the diagram commutes.

By Lemmas 63.40 and 43.27 we know that the horizontal maps form chain homotopy equivalences. Furthermore by Theorem 63.25 the top vertical maps also form chain homotopy equivalences. Finally the map \(\mathcal{O}\) is a homeomorphism. Thus the bottom vertical maps \(\mathcal{O}_*\) also form a chain homotopy equivalence.

We conclude with the following “unordered” version of Proposition 63.43.

Proposition 63.45. For every abstract simplicial complex \(K\) and every \(n \in \mathbb{N}_0\) the following diagram commutes:

\[
\begin{align*}
H_n^{\text{simp}}(K) \xrightarrow{u_n} H_n^{\text{simp}}(\text{sd}(K)) \\
\Theta_K \downarrow \mathcal{O}_* \downarrow \\
H_n(|K|) \xrightarrow{u_n} H_n(|\text{sd}(K)|)
\end{align*}
\]
Furthermore all maps are natural.

Proof. The proposition follows easily from the fact that every abstract simplicial complex admits an order together with Lemma 63.3 and Proposition 63.45 and together with Proposition 63.28.

Remark. For the record we point out that some of the definitions and results in this section are at least implicit in [Deo18, Theorem 4.9.1] and [Mun66a, p. 99].

Exercises for Chapter 63

Exercise 63.1. Let $K = (V, S)$ be an abstract simplicial complex and let “$\leq$” and “$\lessgtr$” be two orders on $K$. Show that the maps

$$
C_n^{\text{simp}, \leq} (K) \to C_n^{\text{simp}, \lessgtr} (K),
$$

$$
\{ v_0 < \cdots < v_n \} \mapsto \text{sign}(\sigma) \cdot \{ v_{\sigma(0)} \lessgtr \cdots \lessgtr v_{\sigma(n)} \}
$$

where $\sigma \in S_n$ is the unique permutation such that $v_{\sigma(0)} \lessgtr \cdots \lessgtr v_{\sigma(n)}$ defines an isomorphism of chain complexes.

Exercise 63.2. Let $K$ be a non-empty abstract simplicial complex, let $n \in \mathbb{N}_0$ and let $S_n$ be the abstract simplicial complex that we introduced on page 1480. Show that for every $k \in \mathbb{N}_0$ there exists a natural isomorphism

$$
\tilde{H}_k^{\text{simp}} (K \ast S_n) \cong \tilde{H}_{k-(n+1)}^{\text{simp}} (K).
$$

Exercise 63.3. Let $K = (V, S)$ be an abstract simplicial complex. Recall that on page 1516 we said that $K = (V, S)$ is connected if given any $v, v' \in V$ there exist 1-simplices $s_0, \ldots, s_k \in S$ such that $v \in s_0$, such that for every $i \in \{0, \ldots, k-1\}$ we have $s_i \cap s_{i+1} \neq \emptyset$ and such that $v' \in s_k$. Show that if $K$ is a non-empty connected abstract simplicial complex, then given any abelian group $G$ the map

$$
H_k^{\text{simp}} (K; G) \to G
$$

$$
\left[ \sum_{i=0}^{k} \{ v_i \} \otimes g_i \right] \mapsto \sum_{i=0}^{k} g_i
$$

is a natural isomorphism

Remark. This is the simplicial analogue of Proposition 41.5.

Exercise 63.4. In this exercise we give a down-to-earth proof of the Simplicial K"unneth Theorem 63.14 in the special case that we are dealing with 1-dimensional abstract simplicial complexes.

(a) Let $K$ and $L$ be two ordered 1-dimensional abstract simplicial complexes. Show that the tensor product of the chain complexes $C_\ast^{\text{simp}} (K)$ and $C_\ast^{\text{simp}} (L)$, as defined on page 1433 is chain homotopy equivalent to the chain complex $C_\ast^{\text{simp}} (K \times L)$.

(b) Prove (a) for arbitrary finite dimensional abstract simplicial complexes.

\footnote{Here the vertical maps $\Theta$ are the natural isomorphisms introduced on page 1565}
(c) Prove (a) for arbitrary abstract simplicial complexes.

*Remark.* Together with the Künneth Theorem 63.7 for chain complexes this exercise makes it possible to calculate the simplicial homology groups of $K \times L$ directly in terms of the simplicial homology groups of $K$ and $L$.

Exercise 63.5. Let $p,q \in \mathbb{N}_0$. We consider the product $D_p \times D_q$ of the ordered abstract simplicial complexes defined on page 1480. Show that

$$H_i^{\text{simp}}(D_p \times D_q) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{otherwise}. \end{cases}$$

*Remark.* This exercise goes into the proof of the Simplicial Künneth Theorem 63.14. In particular you are not allowed to use this theorem.

Exercise 63.6. Show that for any abstract simplicial complex $K$ and any simplex $s$ of $K$ we have for every $i \in \mathbb{N}$ that $H_i^{\text{simp}}(\text{St}(K, s)) = 0$.

Exercise 63.7.

(a) Formulate and prove a Mayer–Vietoris style theorem for simplicial homology, along the lines of the Mayer–Vietoris Theorem 46.5

(b) Use the exact sequence from (a) to provide a new solution to Exercise 63.2

Exercise 63.8. Let $K$ be a simplicial complex and let $A$ and $B$ be two subcomplexes with $A \cup B = K$. Show that for each $k \in \mathbb{N}_0$ the natural map $H_k^{\text{simp}}(A, A \cap B) \to H_k^{\text{simp}}(X, B)$ is an isomorphism.

*Remark.* This statement can be viewed as the Simplicial Excision Theorem. The biggest difference to the singular setting is that in the simplicial setting the proof is almost embarrassingly easy.

Exercise 63.9. Let $K$ be an abstract simplicial complex and let $L$ be a subcomplex of $K$. Show that for each $k \in \mathbb{N}_0$ there exists a natural isomorphism

$$H_k^{\text{simp}}(K, L) \cong \tilde{H}_k^{\text{simp}}(K \cup_L \text{Cone}(L)).$$

Exercise 63.10. Compute the simplicial homology groups of an abstract simplicial complex $K$ such that $|K|$ is homeomorphic to the surface $\Sigma$ of genus two.

*Hint.* As we saw in Figure 220 we can view $\Sigma$ as the connected sum of two tori and you could use Exercise 63.7.
Exercise 63.11. Show that the two simplicial complexes $X = |S_2|$ and $Y = |\Sigma(\Sigma(S_0))|$ which are shown in Figure 963 admit subdivisions $X'$ and $Y'$ which are simplicially isomorphic.

![Figure 963. Illustration of Exercise 63.11](image)

Exercise 63.12. Let $K = (V, S)$ be an abstract simplicial complex. Let $\mathcal{U} = \{\mathcal{S}(v)\}_{v \in V}$ be the open cover of the topological realization $|K|$ that is given by the open stars. What is the relationship between the original abstract simplicial complex $K$ and the nerve complex $N(\mathcal{U})$?

Exercise 63.13. Formulate and prove a simplicial analogue of the Mayer-Vietoris Theorem 46.5.

Remark. The proof is significantly easier than the original proof of the Mayer-Vietoris Theorem 46.5.

Exercise 63.14. Let $K$ and $L$ be two ordered abstract simplicial complexes. Show that for each $k \in \mathbb{N}_0$ there exists a short exact sequence of the following form:

$$0 \to \tilde{H}_k^{\text{simp}}(K \ast L) \to \tilde{H}_{k-1}(K) \oplus \tilde{H}_{k-1}(L) \to \tilde{H}_{k-1}(K \times L) \to 0.$$  

Remark. This statement is the simplicial analogue of Exercise 46.20. In fact at least if $K$ and $L$ are finite, then we can reduce the simplicial statement to the singular statement. The challenge is to give a purely combinatorial argument.

Exercise 63.15. Let $n \in \mathbb{N}_0$.

(a) Let $W$ be an open subset of $\mathbb{R}^n$ that is the union of finitely many convex open subsets. Show that $H_k(W) = 0$ for $k \geq n$.

Hint. Use the Mayer-Vietoris Theorem 46.5 and do an induction argument on the number of convex open subsets. As on many other occasions we point out the convenient fact that the intersection of convex subsets of $\mathbb{R}^n$ is again convex.

(b) Let $M$ be an open subset of $\mathbb{R}^n$ and let $\sigma \in \mathcal{C}_n(M)$ be a cycle. Show that there exists an open subset $W$ of $\mathbb{R}^n$ that is the union of finitely many convex open subsets such that $\sigma \in \mathcal{C}_n(W)$ and such that $W \subset M$.

(c) Let $M$ be an open subset of $\mathbb{R}^n$. Show that $H_k(M) = 0$ for $k \geq n$.

![Figure 964. Illustration of Exercise 63.15](image)
Exercise 63.16. Let $P_1, \ldots, P_s$ be points in $\mathbb{R}^2$ with $s \geq 3$. We assume that any three of those points are contained in an open disk of radius $r$. Show that all the given points are contained in an open disk of radius $r$.

Exercise 63.17. Let $(K, \leq)$ be an abstract simplicial complex. Let $\sigma : \text{sd}(K) \to K$ be the stretching map from Lemma 63.38. Show that the map $|\sigma| \circ U^{-1} : |K| \to |K|$ is homotopic to the identity.

Remark. Use Corollary 36.9 to overcome any continuity anxieties that might arise.

Exercise 63.18. Let $K$ be an abstract simplicial complex. Show that the maps

$$C^\text{simp}_k(K) \otimes \mathbb{Q} \to C_k(|K|) \otimes \mathbb{Q}$$

$$[v_0, \ldots, v_k] \otimes r \mapsto \frac{1}{(k+1)!} \cdot \sum_{\sigma \in S_{k+1}} \left( \Delta^k \mapsto |K| \right) \cdot \left( (t_0, \ldots, t_k) \mapsto \sum_{i=0}^k t_i \cdot v_{\sigma(i)} \right) \otimes r$$

are a natural chain homotopy equivalence.
64. Simplicial and PL-structures on manifolds

In this chapter we will see that smooth manifolds admit a simplicial structure. In fact we will see that they admit particularly nice simplicial structures. There will be many benefits. For example we can almost immediately draw conclusions on the homology groups and homotopy groups of smooth manifolds.

64.1. Simplicial structures on smooth manifolds. We recall the following definition from page 1497.

Definition. A simplicial structure for a given topological space $X$ is defined as a pair $(K = (V, S), \Theta: |K| \to X)$ where the following holds:

1. $K$ is an abstract simplicial complex,
2. $\Theta$ is a homeomorphism between the topological realization $|K|$ of $K$ and the topological space $X$.

Given a simplex $s \in S$ we refer to $\Theta(|s|)$ as a simplex of $X$ and we refer to $\Theta(\langle s \rangle)$ as an open simplex of $X$.

In this section we want to consider simplicial structures on smooth manifolds. Since the smooth structure on smooth manifolds is important for many arguments and constructions it is reasonable to consider simplicial structures that reflect the smooth structure. In the following the idea is to consider simplicial structures $(K, \Theta)$ such that for each $k$-simplex the characteristic map $\Theta \circ \Phi_k: \Delta^k \to M$ is a smooth embedding. Since $\Delta^k$ is not a smooth manifold it takes a little bit of an effort to explain what a “smooth embedding” is supposed to be in this case.

We start out with the following definition. The first part just recalls the definitions introduced on pages 5 and 272.

Definition. Let $n \in \mathbb{N}_0$ and let $A$ be a subset of $\mathbb{R}^n$ for which there exists an open subset $U$ of $\mathbb{R}^n$ with $U \subset A \subset \overline{U}$. Furthermore let $M$ be a smooth manifold.

1. We say a map $f: A \to M$ is smooth at a point $P \in A$, if there exists an open neighborhood $V$ of $P$ in $\mathbb{R}^n$ and a smooth map $\tilde{f}: V \to \mathbb{R}^m$ which coincides with $f$ on $A \cap V$. We define $Df_P := D\tilde{f}_P: \mathbb{R}^n \to T_{f(P)} M$. We refer to Figure 965 for an illustration.
2. We say a map $f: A \to M$ is an immersion if $f$ is smooth at every $P \in A$ and if given any $P \in A$ the differential $Df_P$ has rank $n$.
3. We say a map $f: A \to M$ is a smooth embedding if it is an immersion and an embedding.

\footnote{We leave it to the reader to verify, using our restrictive choice of domain $A$ and using Exercise 2.30 (1), that the definition of $Df_P$ does not depend on the choice of the smooth extension $\tilde{f}$.}

\footnote{If $A$ is in fact an open subset of $\mathbb{R}^n$, then this definition of an immersion agrees of course with the definition given on page 342.}
Example. Given $k \in \mathbb{N}_0$ we consider the map

$$\Xi_k: \Delta_k := \left\{ (t_1, \ldots, t_k) \in [0, 1]^k \left| \sum_{j=1}^k t_j \in [0, 1] \right. \right\} \to \mathbb{R}^{k+1}$$

$$(t_1, \ldots, t_k) \mapsto \left( t_1, \ldots, t_k, 1 - \sum_{j=1}^k t_j \right).$$

This map has two interesting properties:

1. By picking the obvious extension of $\Xi_k$ to a map $\mathbb{R}^k \to \mathbb{R}^{k+1}$ we see that $\Xi_k$ is an immersion.
2. It follows easily from Proposition 2.43 (3) that the map $\Xi_k$ defines a homeomorphism $\Xi_k: \Delta_k \rightarrow \Delta^k$.

The combination of (1) and (2) shows that $\Xi_k$ is an embedding.

This leads us to the following definition.

**Definition.** Let $M$ be a smooth manifold.

1. Let $k \in \mathbb{N}_0$. We say that a map $\Phi: \Delta^k \to M$ is a smooth embedding if the composition $\Phi \circ \Xi_k: \Delta_k \to M$ is a smooth embedding.
2. We say that a given simplicial structure $(K, \Theta: |K| \to M)$ is smooth if for each $k$-simplex $s$ the corresponding characteristic map $\Theta \circ \Phi_s: \Delta^k \to M$ is a smooth embedding.

Remark. At first glance there are different definitions of “smooth simplicial structure” in the literature. For example our definition of a “smooth simplicial structure” is at first glance different from the one given in [Mun66a, p. 81]. But [Mun66a, Theorem 8.4] shows that our definition is in fact equivalent to the definition used in Munkres’ book. Also, it is not difficult to see that our definition is equivalent to the one used in Whitney’s book [Why57].

Example. In Figure 967 we show smooth simplicial structures for the closed disk, the annulus, the 2-dimensional sphere and for the torus minus an open disk.

The following lemma contains two basic statements about (smooth) simplicial structures of smooth manifolds.
Lemma 64.1. Let $M$ be a smooth manifold which is equipped with a smooth simplicial structure. If $M$ is $n$-dimensional, then the dimension of each simplex is at most $n$.

Remark. In Proposition 66.1 we will prove several other statements regarding simplicial structures on smooth manifolds. In particular we will give an alternative proof of Lemma 64.1. Furthermore we will show that any (smooth) simplicial structure on a manifold $M$ restricts to a (smooth) simplicial structure on the smooth manifold $\partial M$.

Proof. Let $s$ be a $k$-simplex of the given smooth simplicial structure. Combining the characteristic map of the simplex with a chart we obtain a map from a non-empty open subset of $\mathbb{R}^k$ to $\mathbb{R}^n$. If the simplicial structure is smooth this map is in fact an embedding. It follows almost immediately from the invariance of domain, see Theorem 6.19 that $k \leq n$.

Now we can formulate the following theorem.

Theorem 64.2.

1. Every smooth manifold admits a countable smooth simplicial structure.
2. If $M$ is a smooth manifold with boundary $\partial M$, then any smooth simplicial structure for $\partial M$ can be extended to a smooth simplicial structure for $M$.
3. If $M$ is a smooth manifold and if $N$ is a proper submanifold of $M$, then there exists a smooth simplicial structure for $M$ that restricts to a smooth simplicial structure on $N$.
4. If $M = A \cup B$ is a decomposition into two $n$-dimensional submanifolds such that $A \cap B$ is a union of boundary components of $A$ and a union of boundary components of $B$, then we can find a smooth simplicial structure on $M$ such that $A$ and $B$ are subcomplexes.

Remark.

1. Note that the conclusion of Theorem 64.2 (3) is somewhat weaker than the conclusion of Theorem 64.2 (2), it does not say that we can extend a given smooth simplicial structure on $N$ to a smooth simplicial structure on $M$.
2. By [Bin83, Theorem XVIII.3.C] any PL-structure on the boundary of a 3-dimensional topological manifold can be extended to a PL-structure on the 3-dimensional topological manifold.
3. Many more subtle results on finding smooth simplicial structures on smooth manifolds can be found in [Ve84r, Chapter 7].
Proof. We start out with giving precise references for the three statements.

(1) This statement is contained in [Mun66a, Theorem 10.6]. For smooth manifolds without boundary the statement is also shown in [Why57, Chapter IV.12]. For closed smooth manifolds, with a slightly weaker conclusion, the statement was first proved by Whitehead [WhdJ40, Theorem 7] in 1940, building on earlier work of Cairns [Cai34]. Other proofs for (some types of) smooth manifolds are given in [Cai61, Freu39] and [Muk15, Theorem 9.5.1]. A sketch of an argument is also given in [Thu97, Theorem 3.10.2].

(2) This statement is also contained in [Mun66a, Theorem 10.6], alternatively see the discussion on [WhdJ40, p. 822f].

(3) If $N$ is a closed submanifold of $M$, then this statement can be proved by solving [Mun66a, Problem 10.14]. The general case can be deduced from [Ve84r, Theorem 7.8], once one has unraveled the statement [Ve84r, Theorem 7.8].

(4) First we apply (1) to equip the smooth manifold $A \cap B$ with a simplicial structure. Next we use (2) to extend the smooth simplicial structure to $A$ and $B$. It is fairly straightforward to verify that putting these two smooth simplicial structures together we obtain a smooth simplicial structure for $M = A \cup B$.

To give the reader a sense of how one can possibly construct smooth simplicial structures on smooth manifolds we provide a sketch for the proof of statement (1). The sketch is partially inspired by the argument given by Whitney [Why57, Chapter IV.12].

For simplicity let $M$ be a closed $n$-dimensional smooth manifold. Recall that by Proposition 9.1 and Proposition 8.1 we can view $M$ as a submanifold of $\mathbb{R}^m$ for some $m \geq n$. By the General Tubular Neighborhood Theorem 10.5 we can pick a tubular neighborhood $p: W \rightarrow M$. (For the purpose of this sketchy proof we might as well assume that the tubular neighborhood is given by $W = \overline{B}^{m-n} \times M$ and that $p: \overline{B}^{m-n} \times M \rightarrow M$ is the obvious projection.) We equip $\mathbb{R}^m$ with the canonical simplicial structure defined in Lemma 61.17.

We make the following, ever so slightly vague observation.

**Observation.** Using a suitable generalization of the Transversality Theorem 9.10 and using the definition of a smooth map and a smooth submanifold (“locally everything is close to being linear”) we can shrink the cubes to a suitably small size and we can find an isotopy of $M$ such that the resulting simplicial structure $(V, S)$ for $\mathbb{R}^m$ satisfies the following two conditions:

(a) For every simplex $s \in S$ the intersection of $s$ with $M$ is “close” to the transverse intersection of an $n$-dimensional affine space with $s$.\(^\text{888}\)

\(^\text{888}\)In our notation we blur the difference between the abstract simplices of the simplicial structure and the corresponding simplices in $\mathbb{R}^n$.

\(^\text{889}\)Here by “transverse” we mean the following: if $s$ is an $l$-dimensional simplex, then it is contained in an $l$-dimensional affine subspace. The transverse intersection of an $n$-dimensional affine space with an $l$-dimensional affine space in $\mathbb{R}^m$ is of dimension $m + l - n$, where negative dimension is understood to be the empty set.
(b) Every simplex \( s \) with \( s \cap M \neq \emptyset \) is contained in the tubular neighborhood \( W \) and the restriction of the projection \( p: W \to M \) to \( s \) is “close” to being an affine linear map.

We refer to Figure 968 for an illustration.

We set \( k := m - n \). In the following we spell out two consequences of (a).

1. No simplex of dimension less than \( k \) intersects \( M \).
2. If a \( k \)-simplex \( s \) intersects \( M \), then it does so in a unique point \( P = P_s \), which we know by (1) lies necessarily in the interior of \( s \).

Next we make the following constructions.

3. For each \( l \)-simplex \( t \) with \( l > k \) which has the property that the corresponding open simplex \( \langle t \rangle \) intersects \( M \) we pick a point \( P_t \) that lies in the intersection of \( M \) with the interior of \( t \).
4. We consider the abstract simplicial complex

\[
L := (W, T) \quad \text{where} \quad W := \{ s \in S \mid \langle s \rangle \cap M \neq \emptyset \} \quad \text{and} \quad T := \{ (w_0, \ldots, w_l) \mid w_0, \ldots, w_l \in S \text{ and } w_0 \subseteq \ldots \subseteq w_l \}.
\]

5. Let \( \Theta: |L| \to \mathbb{R}^m \) be the unique map with \( \Theta(w) = P_w \) for \( w \in W \) and which is affine linear on each simplex \( |t| \).

Some of these definitions are illustrated in Figure 969. We continue with the following

2-simplex \( \{ w_0, w_1, w_2 \} \) of \( (W, T) \)
observations:

(6) It follows from (a) and (b) that the map \( p: W \to M \) restricts to a homeomorphism \( \Theta(|L|) \to M \). Furthermore, for each simplex \( t \in T \) the map \( p: \Theta(|t|) \to M \) is a submersion, i.e. at each point the differential has full rank.

(7) By (6) we now know that \( (L = (W,T), p \circ \Theta: |L| \to M) \) is a smooth simplicial structure for \( M \).

We refer to Figure 970 for a more “global” illustration of the above argument. Evidently this outline has several serious issues. For example we never made it clear what we mean by “close”. Nonetheless we feel that with enough effort one can turn the above sketch of an argument into a proper proof.

We refer to [Why57, Chapter IV.12] for a very detailed discussion how a variation on the above approach can be made to work.

![simplicial structure for \( \mathbb{R}^m \)](image)

\[ M \] tubular neighborhood \( W \)

\( \text{projection } p \)

\( \text{simplicial complex } \Theta(|L|) \)

\text{Figure 970. Proof of Theorem 64.2 with } n = 1, \ m = 2 \text{ and } k = 1.

Just for fun we mention that in our sketch of a proof of Theorem 64.2 we basically proved the following proposition which says that any submanifold of \( \mathbb{R}^m \) can be “arbitrarily” approximated by a linear simplicial subcomplex of \( \mathbb{R}^m \). We will not make use of this proposition, hence we have no qualms about the rather sketchy proof.

\textbf{Proposition 64.3.}\ Let \( M \) be a closed smooth submanifold of \( \mathbb{R}^m \). Given any \( \epsilon > 0 \) there exists a linear simplicial complex \( (L = (W,T), \Theta: |L| \to X) \) with \( X \subset \mathbb{R}^m \) and an isotopy \( F: X \times [0,1] \to \mathbb{R}^m \) with the following properties:

1. We have \( F_0 = \text{id} \).
2. The map \( F_1 \) is a homeomorphism \( F_1: X \to M \) and it has the property that \( F_1 \circ \Theta \) defines a smooth simplicial structure for \( M \).
3. For every \( x \in X \) the map \( [0,1] \to \mathbb{R}^m \) given by \( t \mapsto F(x,t) \) is affine linear.
4. For every \( x \in X \) we have \( \|x - F_1(x)\| < \epsilon \).

\textbf{Example.}\ Proposition 64.3 says in particular that we can approximate any knot \( M \) in \( \mathbb{R}^3 \) by a “simplicial knot” \( X \). We refer to Figure 971 for an illustration.
We continue with the notation and results in the proof of Theorem 64.2. The \( \epsilon > 0 \) corresponds to a suitable interpretation of “close” in the formulation of (a) and (b). We set \( X := \Theta(|L|) \). The isotopy \( F \) is the map which interpolates the identity \( \text{id}_X \) and the projection \( p : X \to M \).

In Theorem 63.20 we saw that there exist compact topological spaces which admit two “inequivalent” simplicial structures, in other words, in Theorem 63.20 we saw that the Hauptvermutung 63.19 is false in general. Interestingly, the “smooth” analogue of the Hauptvermutung 63.19 is actually correct. More precisely, the following theorem holds.

**Theorem 64.4.** Let \( M \) and \( N \) be smooth manifolds and suppose we are given two smooth simplicial structures \( (K, \Theta : |K| \to M) \) and \( (L, \Omega : |L| \to N) \). If \( M \) and \( N \) are diffeomorphic, then there are subdivisions of \( K \) and \( L \) which are simplicially isomorphic.

**Proof.** This statement is shown in [WhdJ40, Theorem 8] and alternatively in [Mun66a, Theorem 10.5] (see also [Mun75, Theorem 10.13]). It is perhaps worth pointing out that we do not need to assume that \( M \) is compact.

Theorem 64.4 will come in handy at a later stage. But for the foreseeable future it is of no real interest to us.

We conclude this section with picking up some low-hanging fruit that we obtain almost for free from Theorem 64.2. First we have the following theorem.

**Theorem 64.5.** Every (compact) \( n \)-dimensional smooth manifold \( M \) admits a (finite) CW-structure with the following properties:

1. every cell has dimension at most \( n \),
2. the boundary \( \partial M \) is a subcomplex.

Furthermore, if \( M = A \cup B \) is a decomposition into two \( n \)-dimensional submanifolds such that \( A \cap B \) is a union of boundary components of \( A \) and a union of boundary components of \( B \), then we can find a CW-structure on \( M \) which has all the above properties and such that \( A \) and \( B \) are subcomplexes.

**Remark.**

1. Theorems 64.2 and 64.5 can be viewed as a significant strengthening of Corollary 63.37. Later on, in Theorem 85.12 Proposition 119.12 Proposition 104.12 and Propositions 105.8 we will get to know two more methods for equipping a smooth manifold with CW-structure (possibly up to a homotopy equivalence).

2. Note that Theorem 64.5 is stated for smooth manifolds and not for topological manifolds. The situation for topological manifolds is in fact much more complicated and we will deal with it later on in Section 85.6.
Proof. The theorem follows immediately from Theorem \text{64.2} together with Lemma \text{64.1} and Lemma \text{61.24}.

Almost for free we now obtain the following proposition which gives us some control over the “size” of invariants of smooth manifolds.

\textbf{Proposition 64.6.} Let \( M \) be an \( n \)-dimensional \( \theta \)-connected smooth manifold.

1. For every \( k > n \) and for every abelian group \( G \) we have \( H_k(M; G) = 0 \).
2. The higher homotopy groups of \( M \) are countable.

If \( M \) is compact then the following further statements hold:

3. The fundamental group of \( M \) is finitely presented.
4. All homology groups of \( M \) are finitely generated abelian groups. Furthermore, given any field \( \mathbb{F} \) the homology groups \( H_k(M; \mathbb{F}) \) are finite-dimensional.

Remark.

1. Note that in Exercise \text{54.10} we saw that there exists a closed smooth manifold \( M \) such that \( \pi_2(M) \) is infinitely generated as an abelian group. In other words, Proposition \text{64.6} \( (2) \) is in a sense optimal.
2. On page \text{2514} we will give an alternative proof for some of the statements of Proposition \text{85.13} using “handle decompositions”.
3. In Proposition \text{85.13} we will extend Proposition \text{64.6} to compact topological manifolds.

Proof.

(1) This statement follows from Theorem \text{64.5} together with Proposition \text{48.5} \( (1) \) and the discussion on page \text{1402}.

(2) This statement follows from Theorem \text{64.2} together with Proposition \text{62.9}.

(3) This statement follows from Theorem \text{64.5} together with Proposition \text{37.13} \( (3) \).

(4) It follows from Theorem \text{64.5} together with Proposition \text{48.5} \( (2) \) that all homology groups are finitely generated. Furthermore it follows from the discussion on page \text{1402} that each \( H_k(M; \mathbb{F}) \) is finite-dimensional.

In fact in Chapter \text{66} we will see that the existence of smooth simplicial structures on smooth manifolds can be used to extract even more information on homology groups of compact smooth manifolds.

On several occasions we will also study relative homology groups of a compact smooth manifold \( M \), for example we will be interested in the relative homology groups \( H_k(M, \partial M) \). The following lemma, together with Proposition \text{64.6} \( (4) \), gives us some control over these invariants.

\textbf{Lemma 64.7.} (* \( \) ) Let \( X \) be a topological space, let \( A \subset X \) be a subset and let \( k \in \mathbb{N}_0 \).

1. If the homology groups \( H_k(X) \) and \( H_{k-1}(A) \) are finitely generated, then so is the relative homology group \( H_k(X, A) \).

2. Let \( \mathbb{F} \) be a field. If the homology groups \( H_k(X; \mathbb{F}) \) and \( H_{k-1}(A; \mathbb{F}) \) are finite dimensional, then so is the relative homology group \( H_k(X, A; \mathbb{F}) \).
Proof (*). The first statement follows from the long exact sequence of the pair \((X, A)\) together with Lemma [19.6]. The second statement is proved in a similar fashion.

64.2. PL-manifolds. Throughout these notes we have so far only encountered two flavors of manifolds, namely topological manifolds and smooth manifolds. In this section we will introduce a new variety of manifolds, namely we will introduce the concept of PL-manifolds. In a nutshell a PL-manifold is a topological manifold together with a well-behaved simplicial structure.

For the reader’s convenience we recall the following definition from page 1554.

**Definition.** We say that a simplicial complex \(Y\) is a *subdivision* of some simplicial complex \(X\) if the following three conditions are satisfied:

1. The underlying topological spaces are the same,
2. Every simplex of \(Y\) is contained in some simplex of \(X\),
3. For every \(l\)-simplex \(t\) of \(Y\) and every \(k\)-simplex \(s\) of \(X\) which contains \(t\) the map \(\Phi^{-1}_s \circ \Phi_t : \Delta^l \to \Delta^k\) is affine linear.

**Remark.** Let \(X\) be a simplicial complex and let \(Y\) be a subdivision. In Exercise 64.3 we will see that every \(k\)-simplex of \(X\) is the union of finitely many simplices of \(Y\) of dimension \(\leq k\). This shows that our definition of a subdivision agrees with the definition given in [Mun66a, p. 83]. It also shows that if we use Lemma 61.24 to view \(X\) and \(Y\) as CW-complexes, then the identity map \(X \to Y\) is cellular.

We continue with the following definition.

**Definition.** Let \(X\) and \(Y\) be simplicial complexes. We say a map \(f: X \to Y\) is *piecewise linear*, if there exist subdivisions \(X'\) and \(Y'\) such that \(f: X' \to Y'\) is simplicial.

**Remark.** The definition of a piecewise linear map is the one given in [Ze63b, p. 6] and [Gla70, p. 13]. It follows from [RS72 Theorem 2.14] and [RS72 Example 1.5(4)] that the definition of a piecewise linear map on [RS72, p. 5] is equivalent to the above definition. Furthermore, by [Ze63b, Lemma I.7] the definition of a piecewise linear map on [Hud69, p. 2] is also equivalent to the above definition.

**Warning.** Many of our favorite reference, e.g. [Ze63b], mostly deals with finite simplicial complexes. Thus on several occasions we will also restrict to the case of finite simplicial complex. We leave it to the unadventured reader to figure out to what degree the results of this section also generalize to infinite simplicial complexes.

We start out with some examples of piecewise linear maps.

**Examples.**

1. In Figure 972 we show a map \(f: X \to Y\) between two finite linear simplicial complexes which is not simplicial, but which is piecewise linear.

2. Let \(f: X \to Y\) be a map between linear simplicial complexes. If \(X\) is a finite linear simplicial complex, then it follows from the Simplicial Approximation Theorem 62.8 that \(f\) is homotopic to a piecewise linear map.

990 Colloquially one usually says “PL” instead of “piecewise linear.”
From the definitions it is not entirely clear that the composition of two piecewise linear maps is again piecewise linear. Fortunately, with some effort one can show that this is indeed the case.

**Proposition 64.8.** The composition of two piecewise linear maps between finite simplicial complexes is again piecewise linear.

**Proof.** The proposition is proved in [Ze63b, Lemma I.2] and [Gla70, Theorem I.6].

**Remark.** As we hinted at above, both references for the proof of Proposition 64.8 do indeed assume that the simplicial complexes involved are finite. It is not clear to me whether the statement holds for maps between arbitrary simplicial complexes.

We move on to the following basically self-explanatory definition.

**Definition.** Let $X$ and $Y$ be two simplicial complexes.

1. A map $f : X \to Y$ is called a **PL-homeomorphism** if $f$ is piecewise linear, if $f$ is a bijection and if $f^{-1}$ is also piecewise linear.$^{99}$

2. We say $X$ and $Y$ are **PL-homeomorphic** if there exists a PL-homeomorphism $X \to Y$.

We continue with two examples of PL-homeomorphisms.

**Examples.**

1. If $X'$ is a subdivision of a simplicial complex $X$, then it follows immediately from the definition that the map $X' \to X$ is a PL-homeomorphism.

2. If $f : X \to Y$ is a map such that there exists subdivision $X'$ of $X$ and $Y'$ of $Y$ such that the map $f : X' \to Y'$ is a simplicial isomorphism, then $f$ is evidently a PL-homeomorphism.

3. (a) In Figure 973 to the left we show 2-dimensional linear simplicial complexes $X_1$ and $Y_1$ which are related by adding a vertex to a 2-dimensional simplex. It follows from (1) that $X_1$ and $Y_1$ are PL-homeomorphic.

   (b) In Figure 973 to the right we show 2-dimensional simplicial complexes $X_2$ and $Y_2$. If we subdivide $X_2$ and $Y_2$ by adding the intersection point of the two diagonals, then the resulting two linear simplicial complexes are simplicially isomorphic. By (2) this shows that $X_2$ and $Y_2$ are PL-homeomorphic.

4. Let $n \in \mathbb{N}$. We consider the two linear simplicial complexes $\text{Cone} (\partial \Delta^n)$ and $\Delta^n$.

   It follows from the discussion on page 1555 that $\Delta^n$ admits a subdivision, given by

---

$^{99}$For the record we state that it follows from Proposition 61.7 that every piecewise linear map is continuous.
adding a single vertex, which is simplicially isomorphic to \( \text{Cone}(\partial \Delta^n) \). By (1) this shows that \( \text{Cone}(\partial \Delta^n) \) and \( \Delta^n \) are PL-homeomorphic.

(5) By Proposition 63.17 (1) we know that any two finite linear simplicial complexes \( X \) and \( Y \) with \( |X| = |Y| \) are PL-homeomorphic.

Later on we will need the following elementary lemma.

**Lemma 64.9.** If \( f_1 : X_1 \rightarrow Y_1 \) and \( f_2 : X_2 \rightarrow Y_2 \) are two PL-homeomorphisms between two finite simplicial complexes, then the map

\[
  f_1 \ast f_2 : X_1 \ast X_2 \rightarrow Y_1 \ast Y_2
\]

is also a PL-homeomorphism.

**Proof.** We leave it to the reader to provide the proof. \( \square \)

Before we give the definition of a PL-manifold let us introduce the following convention.

**Convention.** Let \( n \in \mathbb{N}_0 \). On page 1480 we introduced the abstract simplicial complexes

1. \( D_n := (V, S) \) with \( V = \{0, \ldots, n\} \) and \( S = \mathcal{P}(V) \setminus \{\emptyset\} \), and
2. \( S_{n-1} := (V, T) \) with \( V = \{0, \ldots, n\} \) and \( T = \mathcal{P}(V) \setminus \{\emptyset, V\} \).

On page 1492 we saw that there exists a canonical homeomorphism \( f : |D_n| \rightarrow \Delta^n \) which restricts to a homeomorphism \( |S_{n-1}| \rightarrow \partial \Delta^n \). Unless we say explicitly something else we will always use these homeomorphisms to view \( \Delta^n \) and \( \partial \Delta^n \) as simplicial complexes.

The above convention leads us to our next definition.

**Definition.** Let \( n \in \mathbb{N} \).

1. A PL \( n \)-ball is defined as a simplicial complex that is PL-homeomorphic to the simplicial complex \( \Delta^n \).
2. A PL \( n \)-sphere is defined as a simplicial complex that is PL-homeomorphic to the simplicial complex \( \partial \Delta^{n+1} \).

**Example.** Let \( n \in \mathbb{N}_0 \). In Exercise 64.2 we will show that \( \text{Cone}(\partial \Delta^n) \) is a PL \( n \)-ball.

**Remark.** In practice it can be a little tricky to show that a given simplicial complex is in fact a PL \( n \)-ball or a PL \( n \)-sphere. But in most cases one can verify, with enough patience
and dexterity, that if a simplicial complex “looks” like an $n$-ball or an $n$-sphere, then it is in fact a PL $n$-ball respectively a PL $n$-sphere. For example it is entertaining to show that all the simplicial complexes shown in Figure 975 are in fact PL 2-balls. Shortly we will get to know a more systematic way for finding PL-homeomorphisms.

![Figure 975](image)

Now we can provide the definition of a PL-manifold. The definition is modelled on the definition of a topological manifold that we gave on page 262. The key difference is that we replace the words “neighborhood”, “ball” and “homeomorphic” by “simplicial neighborhood”, “PL-ball” and “PL-homeomorphic”.

**Definition.**

1. Let $X$ be a simplicial complex and $P \in X$. A *simplicial neighborhood* is a subcomplex of $X$ that is a neighborhood of $P$ in the usual sense as defined on page 89.
2. An $n$-dimensional PL-structure on a topological space $X$ is defined as a simplicial structure $(K = (V, S), \Theta : |K| \to X)$ such that every point $P \in X$ admits a simplicial neighborhood that is a PL $n$-ball.
3. An $n$-dimensional PL-manifold is a pair $(X, \Theta)$ where $X$ is a topological space and $\Theta$ is an $n$-dimensional PL-structure with countably many simplices.

**Examples.**

1. In Figure 976 to the left we show a simplicial structure for the annulus $S^1 \times [0, 1]$. The illustrations to the right of Figure 976 should convince the reader that the simplicial structure for the annulus is a PL-structure.

![Figure 976](image)

2. Let $n \in \mathbb{N}_0$. The canonical simplicial structure on $\Delta^n$ is basically by definition a PL-structure. Recall that in Lemma 41.1 we gave an explicit homeomorphism $\Phi : B^n \to \Delta^n$. Thus $(D_n, \Phi^{-1} : \Delta_n = |D_n| \to B^n)$ is a PL-structure for $B^n$. Similar to the discussion on page 1500 we will refer to it as the canonical PL-structure of $B^n$. 

![Figure 976](image)
(3) Let \( n \in \mathbb{N} \). We consider \( \partial \Delta^{n+1} \) with the usual simplicial structure defined on page \[1598\]. Given any vertex \( v \) the star \( \text{St}(\partial \Delta^n, v) \) is, basically by definition, simplicially isomorphic to \( \text{Cone}(\partial \Delta^n) \). It follows from the example on page \[1598\] that \( \text{St}(\partial \Delta^n, v) \) is a PL \( n \)-ball. This shows that \( \partial \Delta^n \) is an \( n \)-dimensional PL-manifold. Recall that in Lemma \[41.1\] we gave an explicit homeomorphism \( \Phi: S^n \to \partial \Delta^{n+1} \). This shows that \( (S_n, \Phi^{-1}: \partial \Delta_{n+1} = |S_n| \to S^n) \) defines a PL-structure on \( S^n \). We refer to it as the canonical PL-structure on \( S^n \).

**Proposition 64.10.** Let \( X \) and \( Y \) be two simplicial complexes. If \( X \) is an \( n \)-dimensional PL-manifold and if \( X \) and \( Y \) are PL-homeomorphic, then \( Y \) is also an \( n \)-dimensional PL-manifold.

**Example.** It follows from Proposition \[64.10\] that any PL \( n \)-ball and any PL \( n \)-sphere is indeed an \( n \)-dimensional PL-manifold.

**Proof.** This proposition is less trivial than it might appear initially. Fortunately a proof is given in [Gla70, Theorem II.2].

The following proposition gives an alternative characterization of PL-manifolds.

**Proposition 64.11.** Let \( (K = (V, S), \Theta: |K| \to X) \) be a simplicial complex. The following statements are equivalent:

1. \( (X, \Theta) \) is an \( n \)-dimensional PL-manifold.
2. For every vertex \( v \in V \) the link \( \text{Lk}(K, v) \) is a PL \((n-1)\)-sphere or a PL \((n-1)\)-ball.
3. For every vertex \( v \in V \) the star \( \text{St}(K, v) \) is a PL \( n \)-ball.
4. For every \( k \)-simplex \( s \in S \) the link \( \text{Lk}(K, s) \) is a PL \((n-k-1)\)-sphere or a PL \((n-k-1)\)-ball.
5. For every \( k \)-simplex \( s \in S \) the star \( \text{St}(K, s) \) is a PL \((n-k)\)-ball.

![Figure 977. Illustration of Proposition 64.11](image)

**Proof.**

1. \( \Rightarrow \) (2) This implication is shown in [Hud69, p. 26] (alternatively see also [Ze63b, p. III.2]).

2. \( \Rightarrow \) (3) Let \( v \in V \). First we consider the case that the link \( \text{Lk}(v) \) is a PL \((n-1)\)-sphere. In this case we have the following PL-homeomorphisms:

\[
\text{St}(v) \cong \{v\} \ast \text{Lk}(v) \cong \{v\} \ast \text{PL} \ (n-1)\text{-sphere} \cong \{v\} \ast \partial \Delta^n \cong \Delta^n.
\]

Lemma \[62.8\](1c) since (2) holds Lemma \[64.9\] see page \[1598\]

The case that the link \( \text{Lk}(v) \) is a PL \((n-1)\)-ball is dealt with the same way, except that this time we use the basically trivial fact, first pointed out on page \[1506\] that...
\{v\} \ast \Delta^{n-1} is in fact simplicially isomorphic to \Delta^n. We have thus shown that (2) implies (3).

(3) \Rightarrow (1) This implication follows immediately from Lemma 62.5 (1).

(2) \Rightarrow (4) We prove the statement by induction on \(k\). Note that the case \(k = 0\) is precisely Statement (2). Now suppose that the statement holds for some \(k - 1\). Let \(K = (V, S)\) be an abstract simplicial complex and let \(t = \{v_0, \ldots, v_k\}\) be a \(k\)-simplex. We consider the \((k-1)\)-simplex \(s = \{v_0, \ldots, v_{k-1}\}\). By induction hypothesis we know that \(\text{Lk}(K, s)\) is a PL \((n-k)\)-sphere or a PL \((n-k)\)-ball. As we pointed out on page 1600, it follows from Proposition 64.10 that \(\text{Lk}(K, s)\) is in fact an \((n-k)\)-dimensional PL-manifold. Now we see that

\[
\text{Lk}(K, t) = \text{Lk}(\text{Lk}(K, s), v_k) = \text{Lk}\left((n-k)\text{-dimensl. PL-manifold}, v_k\right) = \text{PL} \((n-k-1)\)-sphere or a PL \((n-k-1)\)-ball.
\]

\(\uparrow\) follows easily from the definitions

\(\uparrow\) by induction hypothesis

\(\uparrow\) by (1) \Rightarrow (2)

(4) \Rightarrow (5) The proof of this statement is basically identical to the proof of (2) \Rightarrow (3).

(5) \Rightarrow (3) This implication holds for the trivial reason that every vertex is in particular a 0-simplex.

\[\Box\]

Remark.

(1) The notion of a PL-manifold gets defined differently by different authors. There is the usual question whether or not one wants a manifold to be second-countable or not which in our case translates into the question whether or not one wants the simplicial complex to be countable. But if we ignore this rather technical issue, then we see the following:

(a) The above definition above is basically the one given in [Hud69], p. 20 and [Ze63b], p. II.10.

(b) It follows from Proposition 64.11 (1) \iff (2) that our definition is equivalent to the definition provided in [Bry02], p. 223 and [Stal67], Definition 4.4.9.

(c) It follows from Proposition 64.11 (1) \iff (5) that our definition is equivalent to the definition given in [Geo08], p. 134.

(d) It is a consequence of [RS72], Theorem 2.2 that our definition is equivalent to the one given in [RS72], p. 7.

(e) In the literature an \(n\)-dimensional PL-manifold is sometimes defined as a pair \((X, \{\Phi_i: U_i \rightarrow V_i\})\) where \(X\) is an \(n\)-dimensional topological manifold and where \(\{\Phi_i: U_i \rightarrow V_i\}\) is an atlas for \(X\) such that for given any \(i, j \in I\) the corresponding transition map \(\Phi_j \circ \Phi_i^{-1}: V_i \cap \Phi_i(U_j) \rightarrow V_j \cap \Phi_j(U_j)\) is “piecewise linear”. Here, in this context we say that a map \(f: U \rightarrow V\) between open subsets of \(\mathbb{R}^n\) is piecewise linear if any point \(P \in U\) there exists a linear simplicial complex \(X \subset U\) which is a neighborhood of \(P\) such that the restriction of \(f\) to each simplex of \(X\) is linear. This definition is for example used in [GoS99], p. 7, [Rudy16], p. 16, and [HM74], p. 8. It seems to me that the discussions on [Hud69], p. 82 and [Ded62], p. 370 show that these two concepts of PL-manifolds basically agree. It would be nice though to have a more direct reference for this statement.
(2) A PL-structure for a topological space is sometimes called a piecewise linear triangulation, or shorter, a PL-triangulation.

Proposition 64.11 and drawing enough pictures, shows that the following definition captures the right intuition.

**Definition.** We say a PL-manifold is *closed* if $X$ is compact and for every vertex the link $\text{Lk}(v)$ is a PL-sphere.

We have no intention of going deep into the theory of PL-manifolds. Instead we refer the interested reader to [Hud69, Ze63c, Gla70, RS72] for a much more detailed introduction to PL-manifolds. For example these references contain the definition of the boundary a PL-manifold and a discussion of PL-submanifolds and the existence of “regular neighborhoods” (see also the next section) of subcomplexes.

As an aside we mention only one result, namely suppose that $M$ is a PL-manifold. Similar to the statements of Theorem 64.2 (2) and (3), one can extend a given PL-structure on the boundary to a PL-structure on $M$ and one can extend a given PL-structure on a proper submanifold to a PL-structure of $M$. We refer to [Arm67] for the precise statements and proofs.

64.3. **Regular Neighborhoods** (*). In this short section we introduce the notion of a regular neighborhood of a subcomplex of a simplicial complex. This is an object that gets used commonly in topology and thus we want to give a definition and we want state to some of the main properties of regular neighborhoods. Otherwise we will barely make use of this concept.

First we give a slight generalization of the concept of the barycentric subdivision of an abstract simplicial complex.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex and let $J = (U, R)$ be a finite subcomplex. We define the *barycentric subdivision* $\text{sd}_J(K)$ of $K$ away from $J$ by barycentric subdividing every simplex that is not contained in $J$. More formally, and much less readably, $\text{sd}_J(K)$ is defined as follows:

- vertices of $\text{sd}_J(K) := U \cup \{s\}_{s \in S \setminus \emptyset}$
- simplices of $\text{sd}_J(K) := \{ r \cup \{s_0, \ldots, s_k\} | r \in R \cup \{\emptyset\} \text{ and } s_0, \ldots, s_k \in S \text{ such that } r \not\subseteq s_0 \subseteq \cdots \subseteq s_k \}$.

It follows immediately from the definitions that $\text{sd}_J(K)$ is an abstract simplicial complex and that for $J = \emptyset$ we obtain the usual barycentric subdivision $\text{sd}(K)$.

![Regular Neighborhoods](image)

**Figure 978**

The obvious generalization of Lemma 62.3 holds in the above context. But there is certainly no need for formulating the generalizations. Let us move on to the definition of regular neighborhoods.
**Definition.** Let \( (K = (V, S), \Theta : |K| \to X) \) be a simplicial complex and let \( J = (U, R) \) be a subcomplex. We set
\[
S_K(J) := \{ s \in \text{sd}_J(\text{sd}_J(K)) \mid \text{there exists an } r \in R \text{ with } r \subset s \}.
\]
Now we define
\[
N_K(J) := \bigcup_{s \in S_K(J)} \Theta(|s|) \text{ and } \hat{N}_K(J) := \bigcup_{s \in S_K(J)} \Theta(\langle s \rangle).
\]
We refer to \( N_K(J) \) as the regular neighborhood of \( J \) in \( K \).

![Figure 979](image)

**Remark.** The notion of a regular neighborhood gets defined differently by different authors. Our definition of the regular neighborhood of \( J \) in \( K \) is an example of a regular neighborhood as introduced in [RS72, p. 33] or alternatively in [Gla70, Theorem II.15n].

The following proposition states a few key properties of regular neighborhoods of subcomplexes of PL-manifolds.

**Proposition 64.12.** Let \( (K = (V, S), \Theta : |K| \to M) \) be a compact PL-manifold and let \( J = (U, R) \) be a subcomplex, and let \( \Theta(|J|) \subset M \setminus \partial M \).

1. \( N_K(J) \) is a compact PL-manifold and it is a submanifold of the topological manifold \( M \).
2. \( \hat{N}_K(J) \) is an open subset of \( M \).
3. The boundary of \( N_K(J) \) as a subset of \( M \) equals \( N_K(J) \setminus \hat{N}_K(J) \).
4. \( N_K(J) \) and \( \hat{N}_K(J) \) are both neighborhoods of \( \Theta(|J|) \).
5. \( \Theta(|J|) \) is a deformation retract of \( N_K(J) \).
6. \( \partial N_K(J) \) is a deformation retract of \( N_K(J) \setminus \Theta(|J|) \).

**Sketch of proof.** Evidently we can just assume that \( M = |K| \) and that \( \Theta = \text{id} \). As mentioned above, our definition of the regular neighborhood is an example of a regular neighborhood as defined in [RS72, p. 33]. Thus we can use the results from [RS72].

1. This statement is explicitly and implicitly proved in [RS72, Proposition 3.10].
2. We leave the fairly routine verification of these statements to the reader.
3. This statement is proved in [RS72, Corollary 3.30 (ii)], see also [Gla70, p. 77].
4. We only provide an outline of a proof. First we define a sequence of abstract simplicial complexes via setting \( K_0 := K \) and iteratively via setting \( K_{n+1} := \text{sd}_J(K_n) \) for \( n \in \mathbb{N} \). Similarly to Lemma 62.3 (3) we see that these abstract simplicial complexes define again naturally simplicial structures for \( M \). Using a suitable variation
on Lemma 62.7 one can show that $\bigcap_{n \in \mathbb{N}_0} N_{K_n}(J) = |J|$. The key input at this point is [RS72, Corollary 3.18] which implies that for every $n \in \mathbb{N}_0$ there exists a homeomorphism $F_n : N_{K_n}(J) \times [0,1] \to N_{K_n}(J) \setminus \hat{N}_{K_{n+1}}(J)$ such that for every $P \in N_{K_n}(J)$ we have $F_n(P, 0) = P$ and $F_n(P, 1) \in \partial N_{K_{n+1}}(J)$. Next we want to combine all these maps $F_n$ to obtain a homeomorphism $\partial N_{K_n}(J) \times [0,1] \to N_{K_n}(J) \setminus |J|$. To do so we set $s_0 = 0$, $s_1 = \frac{1}{2}$, $s_2 = \frac{3}{4}$, $s_3 = \frac{7}{8}$ and so on. Furthermore, given $n \in \mathbb{N}_0$ we define $\Xi_n : \partial N_{K_n}(J) \to \partial N_{K_{n+1}}(J)$ via $\Xi_n(P) = F_n \cdots (F_0(P, 1), 1, \ldots, 1)$. Finally we consider the map

$$
\partial N_{K_n}(J) \times [0,1] \to \partial N_{K_{n+1}}(J)
(P, t) \mapsto F_n(\Xi_n(P), 2^{n+1} \cdot (t - s_n)), \quad \text{if } t \in [s_n, s_{n+1}) \text{ for some } n \in \mathbb{N}_0.
$$

Some thought shows that this map is actually a homeomorphism. The desired statement follows from the observation that $\partial N_{K_n}(J) = \partial N_{K_n}(J) \times \{0\}$ is a deformation retract of $N_{K_n}(J) \times [0,1)$. The more carefully one looks at this outline, the less little exercises one detects which need to be carried out to turn this argument into a proper proof. \hfill \blacksquare

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure}
\caption{Illustration for the proof of Proposition 64.12 (4).}
\end{figure}

This concludes our discussion of regular neighborhoods. This concept is discussed in much greater detail in [WhdJ39], [RS72, Chapter 3], [Gla70, Chapter II. B], [Hud69, Chapter 2] and [Ze63b, Chapter 3]. Some properties are also discussed in [Hem76, p. 7f]. In particular we refer to [RS72, Theorems 3.8 and 3.24] and [Gla70, Theorem II.16] for some uniqueness theorems which explain to what degree the regular neighborhood depends on the choice of simplicial structures on a given PL-manifold. Unfortunately it is not always immediately apparent that the various definitions in the above literature are mutually compatible.

64.4. The interplay between topological, smooth and PL-manifolds. Now that the PL-manifolds joined the playground, let us see how they interact with our old friends, the topological and smooth manifolds. Since morally speaking topological manifolds have the least amount of structure it is not surprising that PL-manifolds are indeed topological manifolds:

**Proposition 64.13.** Let $X$ be an $n$-dimensional PL-manifold. The following statements hold:

1. $X$ is an $n$-dimensional topological manifold.
2. A vertex $v$ of the PL-structure lies on the boundary of the topological manifold $X$ if and only if the link $\text{Lk}(v)$ is a PL-ball.
Remark. Let \( X \) be a PL-manifold and let \( s \) be a simplex such that all vertices lie on the boundary \( \partial X \) of \( X \), viewed as a topological manifold. As we see in Figure 981 this piece of information does not imply that \( s \) is actually contained in \( \partial X \).

\[ \Theta = \text{id} \]

\[ \partial X \]

**Figure 981**

Proof. Let \((K = (V, S), \Theta: |K| \to X)\) be an \( n \)-dimensional PL-manifold. Without loss of generality we can assume that \( \Theta = \text{id} \), in particular we can assume that \(|K| = X|\).

1. In the following we will show that \( X \) is an \( n \)-dimensional topological manifold.
   
   a. By Lemma 61.5 we know that \( X \) is Hausdorff.
   
   b. By definition of a PL-manifold we know that \( S \) is countable, in particular \( V \) is countable. Furthermore note that Proposition 64.11 says that for each \( v \in V \) the open star \( \overset{\circ}{\text{St}}(v) \) is homeomorphic to a subset of \( \mathbb{R}^n \). From Lemma 6.1 (1) we obtain that each open star is second-countable. Thus it follows from Lemma 62.5 (2) that \( X \) is the countable union of countably many second-countable open subsets. Hence we obtain from Lemma 6.1 (4) that \( X \) itself is second-countable.
   
   c. By definition of a PL-manifold we know that for each \( P \in X \) there exists in particular a neighborhood \( U \) of \( P \) and a homeomorphism \( \Phi: U \to \overline{B}^n \). On page 263 we showed that \( \overline{B}^n \) itself is an \( n \)-dimensional topological manifold. It is now elementary to see that there exists a chart, in the sense of the definition on page 261, for \( X \) at \( P \).

We have thus verified that \( X \) is indeed an \( n \)-dimensional topological manifold.

2. Let \( v \in V \) be a vertex. We calculate that

\[
\begin{align*}
\text{H}_n(X, X \setminus \{v\}) & \cong \text{H}_n(\text{St}(v), \text{St}(v) \setminus \{v\}) \\
& \cong \text{H}_n(\text{St}(v), \text{Lk}(v)) \\
& \cong \text{H}_{n-1}(\text{Lk}(v)) \\
& \cong \mathbb{Z}, \text{ if } \text{Lk}(v) \text{ is a PL } (n-1)\text{-sphere,}\\
& \cong 0, \text{ if } \text{Lk}(v) \text{ is a PL } (n-1)\text{-ball.}
\end{align*}
\]

by the excision theorem 43.20 which can be used by Lemma 62.5 (1d) and Corollary 43.18 (2a) together with Lemma 62.5 (1g)

It follows from Lemma 44.1 that \( v \in \partial X \) if and only if \( \text{Lk}(v) \) is a PL \((n-1)\)-ball.

Next we turn to the relationship between smooth manifolds and PL-manifolds. The following theorem says that any smooth manifold admits an essentially natural PL-structure.

**Theorem 64.14.**

1. Every smooth simplicial structure on an \( n \)-dimensional smooth manifold is an \( n \)-dimensional PL-structure.
(2) If $M$ is a closed smooth manifold, then for every smooth simplicial structure the corresponding PL-manifold is also closed.

(3) Every smooth manifold admits the structure of a PL-manifold.

(4) Any two smooth simplicial structures on a smooth manifold are PL-homeomorphic.

**Proof.**

(1) It follows from [WhdJ40, Theorem 5] (see also the argument of [Mun66a, p. 82]) together with Proposition 64.11 that every smooth simplicial structure on a smooth manifold is a PL-structure in the above sense.

(2) This statement follows immediately from Proposition 64.13 together with fact, proved in Proposition 44.2 (2), that a smooth manifold is closed as a smooth manifold if and only if it is closed as a topological manifold.

(3) This statement follows from (1) together with Theorem 64.2 where we showed that every smooth manifold admits a countable smooth simplicial structure.

(4) This statement follows immediately from Theorem 64.4.

Theorem 64.14 says in particular that given any $n \in \mathbb{N}_0$ the map

$$\varphi_n : \left\{ \begin{array}{c} \text{diffeomorphism classes of closed} \\ \text{n-dimensional smooth manifolds} \end{array} \right\} \to \left\{ \begin{array}{c} \text{PL-homeomorphism classes of closed} \\ \text{n-dimensional PL-manifolds.} \end{array} \right\}$$

$[M] \mapsto [(M, \text{smooth simplicial structure})]$ is well-defined. It is natural to ask whether $\varphi_n$ is a bijection. It turns out that the answer is complicated. More precisely, we have the following theorem.

**Theorem 64.15.**

(1) For $n = 1, \ldots, 6$ the map $\varphi_n$ is a bijection.

(2) For $n = 7$ (and many other dimensions) the map $\varphi_n$ is not a monomorphism.

(3) For $n = 10$ (and many other dimensions) the map $\varphi_n$ is not an epimorphism. In fact there exists a closed 10-dimensional PL-manifold that does not admit a single smooth structure.

**Proof.** The theorem is a combination of several major results in topology. Later in Section ?? we will discuss this theorem in much greater detail and we will give all the necessary references.

We turn our focus back to the relationship between topological and PL-manifolds. In light of Proposition 64.13 it is perhaps tempting to think that a PL-manifold is the same as a topological manifold together with some simplicial structure. But it turns out that the situation is more delicate.

**Theorem 64.16.** There exists a simplicial structure on $S^5$ that is not a PL-structure.

The key to proving Theorem 64.16 is the following very subtle and very difficult theorem which was proved independently by Jim Cannon [Cann79] and Richard Edwards [Edw80, Edw06] in the late 1970s. We also refer to [Dav86, Corollary VII.2,C] and [Lat79] for alternative accounts of the proof.
Theorem 64.17. (Double Suspension Theorem) Let \( Y \) be an \( n \)-dimensional PL-manifold. If \( Y \) is a homology sphere, i.e. if \( H_k(Y; \mathbb{Z}) \cong H_k(S^n; \mathbb{Z}) \) for all \( k \), then the double suspension \( \Sigma(\Sigma(Y)) \) is homeomorphic to \( S^{n+2} \).

The proof of Theorem 64.16 also requires the following lemma.

Lemma 64.18. Let \( n \in \mathbb{N}_{\geq 2} \) and let \( M \) be a closed 0-connected \( n \)-dimensional topological manifold. If \( \pi_1(M) \) is non-trivial, then the suspension \( \Sigma(M) \) is not an \( (n+1) \)-dimensional topological manifold.

Proof. We outsourced the proof to the very amusing Exercise 45.9.

With these preparations it is now quite easy to provide a proof of Theorem 64.16.

Proof of Theorem 64.16

1. By Proposition 66.11 we know that there exists a closed orientable 3-dimensional smooth manifold \( Y \) that is a homology 3-sphere, but such that \( \pi_1(Y) \) is a non-trivial group.
2. By Theorem 64.14 we can equip \( Y \) with a PL-structure.
3. It follows from (2) and the Double Suspension Theorem 64.17 that \( \Sigma(\Sigma(Y)) \) is homeomorphic to \( S^5 \).
4. By (2) we know that \( Y \) is equipped with a simplicial structure. We equip the double suspension \( \Sigma(\Sigma(Y)) \) with the simplicial structure given by “the double suspension” of the simplicial structure. More precisely, we equip \( \Sigma(\Sigma(Y)) \) with the simplicial structure given by applying Corollary 61.21 twice.
5. Let \( N \) be the “North Pole” of the second suspension. It follows from the discussion on page 1523 that \( \text{Lk}(\Sigma(\Sigma(Y)), N) = \Sigma(Y) \).
6. Since \( \pi_1(Y) \) is non-trivial we obtain from Lemma 64.18 that \( \Sigma(Y) \) is not even a 4-dimensional topological manifold. Therefore we obtain from Proposition 64.13 that \( \text{Lk}(\Sigma(\Sigma(Y)), N) = \Sigma(Y) \) is not a 4-dimensional PL-manifold, let alone a PL 4-sphere.
7. We obtain from the above, together with Proposition 64.11 that \( \Sigma(\Sigma(Y)) \) admits a simplicial structure that is not a PL-structure.
8. In (3) we saw that \( \Sigma(\Sigma(Y)) \) is homeomorphic to \( S^5 \). It follows from (7) that \( S^5 \) admits a simplicial structure that is not a PL-structure.

Illustration for the proof of Theorem 64.16.

Figure 982. Illustration for the proof of Theorem 64.16.

Towards the end of these notes, in Section ??, we will study the relationship between topological manifolds, smooth manifolds and PL-manifolds in greater detail.
64.5. **Stellar subdivisions and the Alexander-Newman Theorem.** The notion of a PL-homeomorphism, and thus also the notion of a PL-manifold, relies on the notion of a subdivision which, as discussed on page 1555, is not combinatorial. In the final two sections of this chapter we will discuss how one can turn the theory of PL-homeomorphisms and PL-manifolds into a purely combinatorial theory.

First, given an abstract simplicial complex we introduce, inspired by the definition on page 1522 and by Lemma 62.5 (1b), the combinatorial notion of the star and the link of a simplex.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex. We introduce the following three subcomplexes $^992$ of $K$:

\[
\begin{align*}
\text{St}(K, s) & := \left( \bigcup_{t \in S \text{ with } s \subset t} \{ t \in S \mid s \cup t \in S \} \right) \\
\text{Lk}(K, s) & := \left( \bigcup_{t \in S \text{ with } s \subset t} \left( t \setminus s, \{ t \in S \mid s \cup t \in S \text{ and } s \cap t = \emptyset \} \right) \right) \\
K \setminus \text{St}(K, \emptyset) & := \begin{cases} 
(V \setminus \{v\}, \{ t \in S \mid s \not\subset t \}), & \text{if } s = \{v\} \text{ is a 0-simplex,} \\
(V, \{ t \in S \mid s \not\subset t \}), & \text{otherwise.}
\end{cases}
\end{align*}
\]

We refer to Figure 983 for an illustration of the definition of $K \setminus \text{St}(K, \emptyset)$.

![Figure 983](image)

**Remark.** Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$.

1. The vigilant reader will have noticed that we defined $\text{St}(K, s)$ and $\text{Lk}(K, s)$ twice, namely on page 1522 as suitable subsets of $|K|$ and now as abstract subcomplexes.

The vigilant reader surely will have no troubles in figuring out which of the two definitions we are working with at any given moment.

2. The notation \textquotedblleft $K \setminus \text{St}(K, \emptyset)$\textquotedblright\ is meant to be suggestive, but note that on its own \emptyset makes no sense.

Next we recall the following definitions from page 1482 and page 1518.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex.

1. (a) If $s$ is a 0-simplex, then we define $\partial s = (\emptyset, \emptyset)$.

   (b) If $s$ is not a 0-simplex, then we define $\partial s$ to be the abstract simplicial complex $(s, \mathcal{P}(s) \setminus \{\emptyset, s\})$.

2. We denote by $\underline{s} := \sum_{v \in s} \frac{1}{\dim(v) + 1} \cdot v \in |K|$ the barycenter.$^993$

The following lemma summarizes several basic relations between the objects we just introduced.

---

$^992$ One can easily verify that all three are indeed subcomplexes.

$^993$ The meticulous reader will notice that in this section, on several occasions, we will use Lemma 62.1.
Lemma 64.19. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. The following statements hold:

1. $\text{St}(K, s) = \text{Lk}(K, s) \ast s$.
2. The union of the subcomplexes $K \setminus \text{St}(K, s)$ and $\text{St}(K, s) = \text{Lk}(K, s) \ast s$ equals $K$ and the intersection equals $\text{Lk}(K, s) \ast \partial s$.
3. The intersection of the abstract simplicial complexes $K \setminus \text{St}(K, s)$ and $\text{Lk}(K, s) \ast \partial s \ast s$ also equals $\text{Lk}(K, s) \ast \partial s$.

Proof. We leave it to the reader to verify that all the statement follow indeed immediately from the definitions. □

![Illustration for Lemma 64.19](image)

Now we define the notion of a “stellar subdivision at a simplex $s$”. The basic idea is to add a vertex in the interior of $s$ and subdivide all the simplices that contain $s$ accordingly. Slightly more precisely, the “stellar subdivision at a simplex $s$” is defined as replacing the subcomplex $\text{St}(K, s) = \text{Lk}(K, s) \ast s$ by the abstract simplicial complex $\text{Lk}(K, s) \ast \partial s \ast s$.

Even more precisely, it is defined as follows.

Definition.

1. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. We define the stellar subdivision of $K$ at $s$ to be the abstract simplicial complex $^{994}$

   $\sigma_s(K) := (K \setminus \text{St}(K, s)) \cup \text{Lk}(K, s) \ast \partial s \ast s$.

2. Let $K$ be an abstract simplicial complex. If $K'$ is a stellar subdivision of $K$, then we say that $K$ is a stellar weld of $K'$.

3. We say two abstract simplicial complexes $K$ and $L$ are stellar equivalent if there exists a finite sequence $K = K_0, K_1, \ldots, K_m = L$ of abstract simplicial complexes such that each $K_{i+1}$ is simplicially isomorphic to either a stellar subdivision or a stellar weld of $K_i$.

We illustrate the definition of a stellar subdivision at a 1-simplex in Figure 985 and we illustrate the definition of a stellar subdivision at a 2-simplex in Figure 986.

Remark.

$^{994}$It follows from Lemma 61.2 (1) that $\sigma_s(K)$ is indeed an abstract simplicial complex.
(1) We follow the naming conventions used in [Lic99] which differ slightly from the ones used in say [Hud69, Ze63b, RS72]. More precisely, what we call a stellar subdivision is called an elementary stellar subdivision in [Hud69, Ze63b, RS72].

(2) It follows easily from the definitions and Lemma 62.1 (3) that the stellar subdivision at a 0-simplex is the identity.

Lemma 64.20. Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$. If $\text{Lk}(K, s)$ is finite, then there exists a natural PL-homeomorphism $|K| \rightarrow |\sigma_s(K)|$.

Remark. The proof of Lemma 64.20 shows that $|\sigma_s(K)|$ is essentially a subdivision of $|K|$. This shows that the name “stellar subdivision” is justified.

Proof (*). Let $K = (V, S)$ be a finite abstract simplicial complex and let $s \in S$. Recall that on page 1598 we saw that there exists a natural PL-homeomorphism $\varphi: |s| \rightarrow |\partial s \ast s|$ which is the identity on the common subset $|\partial s|$. It follows from Lemmas 61.20 and 64.9 together with our hypothesis that $\text{Lk}(K, s)$ is finite, that the map $\text{id}_{\text{Lk}(K, s)}$ and $\varphi$ give rise to a natural PL-homeomorphism $f: |\text{Lk}(K, s) \ast s| \rightarrow |\text{Lk}(K, s) \ast \partial s \ast s|$ which has the following property:

(*) The map $f$ is the identity on the common subset $|\text{Lk}(K, s) \ast \partial s|$.

Next we consider the two maps

$\Phi: |K| \rightarrow |\sigma_s(K)|$

$P \mapsto \begin{cases} P \text{, if } P \in |K \setminus \text{St}(K, \hat{s})|, \\ f(P) \text{, if } P \in |\text{St}(K, s)| \end{cases}$

$\Psi: |\sigma_s(K)| \rightarrow |K|$

$P \mapsto \begin{cases} f^{-1}(P) \text{, if } P \in |\text{Lk}(K, s) \ast \partial s \ast s|. \\ P \text{, if } P \in |K \setminus \text{St}(K, \hat{s})|, \end{cases}$
We make the following observations:

1. It follows from Lemma 64.19 (2) and (3) together with (*) that both maps are well-defined.
2. By Lemma 61.8 together with Lemma 2.35 we know that both maps are continuous.
3. Basically by construction the maps are inverses of one another.

In summary we have shown that both maps are homeomorphisms. It remains to show that $\Phi : |K| \to |\sigma_s(K)|$ is in fact a PL-homeomorphism. To do so, note that it follows easily from the definition of the map $\Phi$ that the simplicial complex $(\sigma_s(K), \Phi^{-1} : |\sigma_s(K)| \to |K|)$ is a subdivision of $|K|$. With respect to this subdivision the map $\Phi$ is evidently a simplicial isomorphism. Thus we see that $\Phi$ is in fact a PL-homeomorphism. ■

The following rather amazing theorem is one of the key bridges between topology and combinatorics.

**Theorem 64.21. (Alexander-Newman Theorem)** Let $K$ and $L$ be two finite abstract simplicial complexes. The following two statements are equivalent:

1. The abstract simplicial complexes $K$ and $L$ are stellar equivalent.
2. The simplicial complexes $|K|$ and $|L|$ are PL-homeomorphic.

**Proof.** The “$(1) \Rightarrow (2)$”-direction is just the combination of Lemma 64.20 and Proposition 64.8. The much harder “$(2) \Rightarrow (1)$”-direction was first proved by James Alexander [Al30, Theorem 15:1] in 1930, building on work of Max Newman [New26]. More modern expositions of the proof are given in [Gla70, Theorem II.7] and in [Lic99, Theorem 4.5]. ■

According to [Lic99, p. 311] and [Mel18, p. 1] the following question, posed in particular in [Hud69, p. 14] and [Pac91, Problem 3.3], is still open. An affirmative answer for 2-dimensional abstract simplicial complexes was given by Jürgen Ewald [Ewa86] in 1986.

**Question 64.22.** Let $K$ and $L$ be two finite abstract simplicial complexes such that the simplicial complexes $|K|$ and $|L|$ are PL-homeomorphic. Do there exist iterated stellar subdivisions of $K$ and $L$ which are simplicially isomorphic?

64.6. Combinatorial manifolds and Pachner’s Theorem. The Alexander-Newman Theorem 64.21 and Propositions 64.11 and 64.13 (2) motivate the following definitions.

**Definition.**

1. We say that two finite abstract simplicial complexes $K$ and $L$ are combinatorially homeomorphic if $K$ and $L$ are stellar equivalent.
2. Let $n \in \mathbb{N}_0$. We say that a finite abstract simplicial complex is a *combinatorial $n$-ball* if it is combinatorially homeomorphic to $D_n$ and we say it is a *combinatorial $n$-sphere* if it is combinatorially homeomorphic to $S^n_{n-1}$.
3. Let $K$ be a finite abstract simplicial complex. We say $K$ is an *$n$-dimensional combinatorial manifold* if for every vertex $v$ the link $\text{Lk}(K, v)$ is a combinatorial $(n-1)$-sphere or a combinatorial $(n-1)$-ball.
4. We say an $n$-dimensional combinatorial manifold $K$ is *closed* if for every vertex $v$ the link $\text{Lk}(K, v)$ is a combinatorial $(n-1)$-sphere.
Examples. Let $n \in \mathbb{N}$. We consider the abstract simplicial complexes $D_n$ and $S_n$.

1. For every vertex $v$ of $D_n$ we have, basically by definition, that $\text{Lk}(D_n, v)$ is simplicially isomorphic to $D_{n-1}$. Thus we see that $D_n$ is an $n$-dimensional combinatorial manifold.
2. Similarly, for every vertex $v$ of $S_n$ we have, again basically by definition, that $\text{Lk}(S_n, v)$ is simplicially isomorphic to $S_{n-1}$. Thus we obtain that $S_n$ is a closed $n$-dimensional combinatorial manifold.

Remark.

1. From what I can see, there is no combinatorial analogue of the notion that a map between two finite abstract simplicial complexes is piecewise linear.
2. In the literature, see e.g. [Hud69, p. 26] and [Gla70, p. 18], a combinatorial manifold is often defined as a PL-manifold. Even though the concept of a “wrong definition” does not exist, it seems to me that it is more appropriate to define a combinatorial manifold as above, namely to define it immediately as a purely combinatorial object.

The statement of the following proposition, which can be viewed as an analogue of Proposition 64.10 does not come as a surprise.

Proposition 64.23. Let $K$ and $L$ be two finite abstract simplicial complexes. If $K$ is a (closed) $n$-dimensional combinatorial manifold and if $L$ is combinatorially homeomorphic to $K$, then $L$ is a (closed) $n$-dimensional combinatorial manifold.

Example. It follows from Proposition 64.23 and the previous examples that every combinatorial $n$-ball is indeed an $n$-dimensional combinatorial manifold and that every combinatorial $n$-sphere is indeed a closed $n$-dimensional combinatorial manifold.

Proof. A short moment’s thought shows that this statement does indeed need a proof, it does not follow immediately from the definitions. In fact the proposition is a consequence of [Gla70, Lemma on p. 19].

By definition the link of any 0-simplex in a closed combinatorial manifold is a combinatorial sphere. The following lemma, which is an analogue of Proposition 64.11 (2) $\Rightarrow$ (4), generalizes this statement to higher dimensional simplices.

Lemma 64.24. Let $K$ be a closed $n$-dimensional combinatorial manifold. If $s$ is a $k$-simplex, then the link $\text{Lk}(K, s)$ is a combinatorial $(n-k-1)$-sphere.
Proof. The proof of this lemma is almost the same as the proof of Proposition 64.11 (2) ⇒ (4). The only slight difference is that now we need to use the fact, mentioned above, that every combinatorial $k$-sphere is a closed $k$-dimensional combinatorial manifold.

By definition two combinatorially homeomorphic combinatorial manifolds are related by a sequence of stellar subdivisions and stellar welds. In the following we will see that they are also related by the more elegant “bistellar moves”.

To introduce the notion of a bistellar move we need the following basic definition.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex and let $s \in S$ be a simplex.

1. Let $m \in \mathbb{N}_0$. We say that $\text{Lk}(K, s) =: (U, R)$ is a *non-trivial* $m$-sphere in $K$ if the following two conditions are satisfied:
   a. we have $\#U = m + 2$ and $R = \mathcal{P}(U) \setminus \{\emptyset, U\}$.
   b. the vertex set $U$ is not a simplex of $K$.
   In this case we denote by $B(K, s)$ the abstract simplicial complex $(U, \mathcal{P}(U) \setminus \{\emptyset\})$. We illustrate the definition in Figure 988.

2. We say that $\text{Lk}(K, s)$ is a *non-trivial* $(-1)$-sphere in $K$ if it is the empty subcomplex.
   In this case we define $B(K, s)$ to be abstract simplicial complex consisting of the single vertex $s$.

As usual, if $K$ is understood then we write $B(s)$ instead of $B(K, s)$.

![Figure 988](image_url)

We move on to the next lemma which can be viewed as the fourth part of Lemma 64.19.

**Lemma 64.25.** Let $K = (V, S)$ be a closed $n$-dimensional combinatorial manifold and let $s \in S$ be a $k$-simplex. We suppose that the link $\text{Lk}(K, s)$ is a non-trivial $(n - k - 1)$-sphere in $K$. Then the intersection of the abstract simplicial complexes $K \setminus \text{St}(K, s)$ and $\partial s \ast B(K, s)$ equals $\text{Lk}(K, s) \ast \partial s$.

Proof. Again we leave the task of verifying the lemma to the reader.

Suppose we are in the setting of Lemma 64.25. Loosely speaking the *bistellar move along* $s$ is defined as the result of replacing the subcomplex

$$\text{St}(K, s) = s \ast \text{Lk}(K, s) \quad \text{by the abstract simplicial complex} \quad \partial s \ast B(K, s).$$

More precisely, we have the following definition.

---

996 This just means that $\text{Lk}(K, s)$ is simplicially isomorphic to the abstract simplicial complex $S_m$. It is worth recalling that Lemma 64.24 says that the link of a $k$-simplex in a closed $n$-dimensional combinatorial manifold is combinatorially homeomorphic to $S_{n-k-1}$, which is a much weaker condition than demanding that the link is simplicially isomorphic to $S_{n-k-1}$. 

---
Definition. Let $K = (V, S)$ be a closed $n$-dimensional combinatorial manifold and let $s \in S$ be a $k$-simplex such that $\text{Lk}(K, s)$ is a non-trivial $(n - k - 1)$-sphere in $K$. We define

$$\tau_s(K) := (K \setminus \text{St}(K, \bar{s})) \cup \partial s \ast B(K, s).$$

We refer to the unique $(n - k)$-simplex in $B(K, s)$ as the dual simplex. We say $\tau_s(K)$ is obtained from $K$ by a bistellar move along $s$.

Examples.

1. In Figure 989 we show a bistellar move along a 1-simplex $s$ in a 2-dimensional combinatorial manifold.

2. In Figure 990 we show a bistellar move along a 2-simplex $s$ in a 3-dimensional combinatorial manifold.

3. In Figure 991 we show a bistellar move along a 2-simplex $s$ in a 2-dimensional combinatorial manifold. In this case $\text{Lk}(s) = \varnothing$, which by the above convention, is a non-trivial $(-1)$-sphere.

Note that in each example we see that the bistellar move along the dual simplex actually gets us back to the original abstract simplicial complex. In the next lemma we will see that this is not a coincidence.

The following lemma summarizes a few key properties of bistellar moves.
Lemma 64.26. Let $K = (V, S)$ be a closed $n$-dimensional combinatorial manifold and let $s \in S$ be a $k$-simplex such that $\text{Lk}(K, s)$ is a non-trivial $(n - k - 1)$-sphere in $K$. We denote by $t$ the dual simplex. The following statements hold:

1. The dual simplex $t$ is an $(n - k)$-simplex in $\tau_s(K)$ with the following properties:
   - (a) $\partial t = \text{Lk}(K, s)$,
   - (b) $\text{Lk}(\tau_s(K), t) = \partial s$,
   - (c) (i) if $s = \{v\}$ is a 0-simplex, then $B(\tau_s(K), t) = (\{t\}, \{t\})$,
   - (ii) if $s$ is not a 0-simplex, then $B(\tau_s(K), t) = s$.

2. $\tau_s(K) \setminus \text{St}(\tau_s(K), \hat{t}) = K \setminus \text{St}(K, \hat{s})$.

Furthermore $\partial s$ is a non-trivial $(k - 1)$-sphere in $\tau_s(K)$.

3. $\tau_s(K)$ is a closed $n$-dimensional combinatorial manifold which is naturally combinatorially homeomorphic to $K$.

4. $\tau_t(\tau_s(K))$ is naturally simplicially isomorphic to $K$.

Remark. Lemma 64.26 shows that in particular that if two closed $n$-dimensional combinatorial manifold are bistellar equivalent, then they are also stellar equivalent. Furthermore Lemma 64.26 gives us also the justification for the name “bistellar move”.

Proof.

(1) We leave the elementary verification of these statements to the reader. Note that the slightly awkward fact that we need to deal with 0-simplices separately is due to

\[997^\text{Here we view the simplex } s \text{ as an abstract simplicial complex in its own right.}\]  
\[998^\text{It follows from (1) that we can form } \tau_t(\tau_s(K)).\]
the fact that already in the definitions on page 1613 and page 1608 we were forced to treat 0-simplices slightly differently.

(2) This statement follows easily from (1). Indeed, we see that

\[
\sigma_t(\tau_s(K)) = (\tau_s(K) \setminus \text{St}(\tau_s(K), t)) \cup \text{Lk}(\tau_s(K), t) \ast \partial t \ast t \xrightarrow{\sim} \sigma_s(K).
\]

by definition by Lemma 64.19 the map \( s \mapsto t \) defines a simplicial isomorphism

(3) It follows from (2) that \( \tau_s(K) \) is naturally stellar equivalent to \( K \). In other words, \( \tau_s(K) \) is naturally combinatorially homeomorphic to \( K \). It follows from Proposition 64.23 that \( \tau_s(K) \) is also a closed \( n \)-dimensional combinatorial manifold.

(4) First assume that \( s \) is not a 0-simplex. In this case we see that

\[
\tau_t(\tau_s(K)) = (\tau_s(K) \setminus \text{St}(\tau_s(K), t)) \cup \partial t \ast B(\tau_s(K), t) = K.
\]

by definition Lemma 64.19

Finally we deal with the case that \( s = \{v\} \) is a 0-simplex. Note that in this case the vertex set of \( \tau_t(\tau_s(K)) \) equals \( (V \setminus \{v\}) \cup \{t\} \). The obvious bijection between the vertex sets of \( \tau_t(\tau_s(K)) \) and of \( K \), i.e. the map given by \( t \mapsto v \), induces, by the same argument as above, a simplicial isomorphism \( \tau_t(\tau_s(K)) \rightarrow K \). ■

Note that Lemma 64.26 (4) implies in particular that “being related by a sequence of bistellar moves” is an equivalence relation. This observation motivates the following definition.

**Definition.** We say that two closed \( n \)-dimensional combinatorial manifold are **bistellar equivalent** if one can be obtained from the other via a finite sequence of bistellar moves and simplicial isomorphisms.

The following theorem can be viewed as a refinement of the Alexander-Newman Theorem 64.21 for closed combinatorial manifolds. The theorem was proved in 1991 by Udo Pachner [Pac91].

**Theorem 64.27. (Pachner’s Theorem)** Let \( K \) and \( L \) be two closed combinatorial manifolds. The following two statements are equivalent:

1. The abstract simplicial complexes \( K \) and \( L \) are bistellar equivalent.
2. The abstract simplicial complexes \( K \) and \( L \) are combinatorially homeomorphic (i.e. they are stellar equivalent).

**Remark.**

1. Pachner’s Theorem 64.27 is the reason why bistellar moves are often called **Pachner moves**.
2. An analogue of Pachner’s Theorem 64.27 for combinatorial manifolds that are not closed is given in [Pac91, Theorem 6.3] and [Lic97b, Theorem 5.10].
(3) The Alexander-Newman Theorem 64.21 and Pachner’s Theorem 64.27 can be viewed as an analogue of Theorem 27.21 which says that any two knot diagrams for a given knot are related by a finite sequence of Reidemeister moves.

**Proof.** The “(1)⇒(2)”-direction is an immediate consequence of Lemma 64.26. The much more interesting “(2)⇒(1)”-direction is proved in [Pac91, Theorem 5.5]. An exposition of the proof is also given in [Lic99, Theorem 5.9]. For combinatorial manifolds of dimension \( \leq 3 \) a more elementary proof is given in [BW96, Theorem 4.11] and implicitly in [TV92]. Furthermore for combinatorial manifolds of dimension \( \leq 4 \) a proof is also given in [Pac78].

Let us quickly compare the statements and roles of the Alexander-Newman Theorem 64.21 and Pachner’s Theorem 64.27.

1. The Alexander-Newman Theorem 64.21 is more general in so far as it applies to any two finite simplicial complexes whereas Pachner’s Theorem 64.27 only deals with closed combinatorial manifolds.
2. Now we restrict ourselves to the class of closed \( n \)-dimensional combinatorial manifolds.
   a. A stellar subdivision consists in replacing \( \text{Lk}(K, s) \ast s \) by \( \text{Lk}(K, s) \ast \partial s \ast s \). As should become clear from considering Figure 993 for \( n \geq 3 \) there are infinitely many simplicial isomorphism types of links of simplices that can appear. Thus we see that even for closed \( n \)-dimensional combinatorial manifolds there are infinitely many “combinatorially distinct” stellar subdivisions.
   b. On the other hand a Pachner move can only be applied if the link \( \text{Lk}(K, s) \) is in fact simplicially isomorphic to some \( S_k, k = 0, \ldots, n \). Recall that if a Pachner move is possible, then it replaces \( \text{Lk}(K, s) \ast s \) by \( \partial s \ast B(K, s) \). Thus we see that there are only \( n + 1 \) “combinatorially distinct” moves.

\[\text{Lk}(s)\text{stellar subdivision}\]
\[\text{Lk}(s)\text{bistellar move}\]

**Figure 993**

\[\text{We leave it to the reader to fill the expression “combinatorially distinct” with meaning.}\]
Now, at the end the end of this chapter we have obtained the following sequence of maps:

\[
\begin{align*}
\{\text{diffeomorphism classes of closed } n\text{-dimensional smooth manifolds}\} \\
\mathcal{W}_n &\downarrow \text{by Theorem 64.13} \quad \text{a bijection for } n \leq 6 \\
\{\text{PL-homeomorphism classes of closed } n\text{-dimensional PL-manifolds}\} \\
|K| &\uparrow \\
\uparrow_k \quad \text{a bijection by the Alexander-Newman Theorem 64.21} \\
\{\text{combinatorial homeomorphism classes of} \\
\{\text{closed } n\text{-dimensional combinatorial manifolds}\} \\
\uparrow \quad \text{the identity by Pachner's Theorem 64.27} \\
\{\text{bistellar equivalence classes of closed } n\text{-dimensional combinatorial manifolds}\}
\end{align*}
\]

This shows in particular that for dimensions \( n \leq 6 \) the classification of closed smooth manifolds boils down to (very difficult!) combinatorics.

In particular the sequence of maps gives us an approach to defining invariants of closed \( n\)-dimensional PL-manifolds (or equivalently smooth manifolds for \( n \leq 6 \)): we “just” need to define an invariant for closed \( n\)-dimensional combinatorial manifolds that is invariant under the \( n+1 \) bistellar moves. This approach to defining invariants has been used by Vladimir Turaev and Oleg Viro [TV92] and John Barrett and Bruce Westbury [BW96] in the 3-dimensional setting and by Christopher Douglas and David Reutter [DR18] in the 4-dimensional setting.

Finally we mention that the significance of Pachner’s Theorem 64.27 in mathematics and theoretical physics (“loop quantum gravity theory”) is nicely explained in [Lic97b, Lic99] and [Kle18].

---

**Exercises for Chapter 64**

**Exercise 64.1.** We equip the smooth manifold \( \overline{B^2} \) with the canonical simplicial structure \( \Phi: \Delta^2 \to \overline{B^2} \) introduced on page 1500. Is this a smooth simplicial structure for the smooth manifold \( \overline{B^2} \)?

**Figure 994. Illustration of Exercise 64.1**

**Exercise 64.2.** Let \( n \in \mathbb{N}_0 \). Show that \( \text{Cone}(\partial \Delta^n) \) is \( \text{PL-homeomorphic} \) to \( \Delta^n \). We refer to Figure 974 for an illustration.

**Exercise 64.3.** Let \( X \) be a simplicial complex and let \( Y \) be a subdivision. Show that every \( k\)-simplex of \( X \) is the union of finitely many simplices of \( Y \) of dimension \( \leq k \).
**Exercise 64.4.** We consider the triangle \( \triangle_{ABC} \) shown in Figure 995. Let \( P \in \overline{AC} \) and \( Q \in \overline{BC} \) be two points such that the segment \( \overline{PQ} \) is not parallel to the segment \( \overline{AB} \). Let \( p \) be the radial projection from \( C \) of the segment \( \overline{PQ} \) to the base \( \overline{AB} \) of the triangle. We equip \( \overline{PQ} \) and \( \overline{AB} \) with the obvious simplicial structures. Show that the map \( p \) is not piecewise linear.

*Remark.* The fact that the radial projection map \( p \) is not piecewise linear is called the “standard mistake” in [Ze63b, p. I.6] and [RS72, p. 6].

![Figure 995. Illustration of Exercise 64.4](image)

**Exercise 64.5.** We consider the two abstract simplicial complexes \( K \) and \( L \) shown in Figure 996.

(a) Show that \( L \) is not a stellar subdivision of \( K \).

(b) Show “by hand” that \( K \) and \( L \) are stellar equivalent.

![Figure 996. Illustration for Exercise 64.5](image)

**Exercise 64.6.** Use the Alexander-Newman Theorem 64.21 to prove Pachner’s Theorem 64.27 in the 2-dimensional case.

**Exercise 64.7.** Let \( K \) be an abstract simplicial complex. Show that if \( K \) is a closed \( n \)-dimensional combinatorial manifold, then the maximal dimension of a simplex of \( K \) is precisely \( n \).

*Hint.* You could do an induction on \( n \).
In this chapter we will state and prove the Lefschetz Fixed Point Theorem which gives a criterion for a self-map to have a fixed point. This theorem can be viewed as a far reaching generalization of the Brouwer Fixed Point Theorem 43.8.

65.1. The trace of an endomorphism. In the formulation of the Lefschetz Fixed Point Theorem we need the notion of the trace of suitable endomorphisms. Even though this notion is surely well-known to the reader we recall the definition and a few properties of the trace of an endomorphism. This short section will facilitate the discussion below. Nonetheless, the author will not hold it against the reader if the reader decides to skip this section.

**Definition.** Let $R$ be a ring. Given an $(n \times n)$-matrix $A = (a_{ij})$ over $R$ we define its trace to be

$$\text{tr}(A) := \sum_{i=1}^{n} a_{ii}.$$ 

**Lemma 65.1.** Let $R$ be a ring and let $A$ and $B$ be two $(n \times n)$-matrices over $R$. If $R$ is commutative, then we have

$$\text{tr}(A \cdot B) = \text{tr}(B \cdot A).$$

**Proof.** We perform the following simple calculation:

$$\text{tr}(A \cdot B) = \text{tr} \left( \text{matrix with } (i, j)\text{-entry } \sum_{k=1}^{n} a_{ik} \cdot b_{kj} \right) = \sum_{i=1}^{n} \sum_{k=1}^{n} a_{ik} \cdot b_{kj} = \sum_{i=1}^{n} \sum_{k=1}^{n} b_{ki} \cdot a_{ik} \overset{\text{same calculation backwards}}{=} \text{tr}(B \cdot A).$$

since $R$ is commutative

**Lemma 65.2.** Let $R$ be a commutative domain, let $V$ be a free $R$-module of rank $n$ and let $\varphi : V \to V$ be an endomorphism. We pick a basis for $V$. Then

$$\text{tr}(\varphi) := \text{trace of the matrix representing } \varphi \text{ with the respect to the given basis}$$

does not depend on the choice of the basis. We refer to $\text{tr}(\varphi)$ as the trace of the endomorphism.

**Notation.** Given a commutative domain $R$, a free $R$-module $V$ of finite rank and an endomorphism $\varphi : V \to V$, depending on the amount of space we have, we use one of the following three notations:

$$\text{tr}(\varphi) = \text{tr}(\varphi : V \to V) = \text{tr}(\varphi \circ V).$$

**Example.** Let $R$ be a commutative domain and let $V$ be a free $R$-module of finite rank. It follows immediately from the definitions that $\text{tr}(\text{id}_V) = \text{rank}(V)$.

**Proof.** Let $R$ be a commutative domain. Let $\{v_1, \ldots, v_m\}$ and $\{w_1, \ldots, w_n\}$ be two bases for $V$. Since $R$ is a commutative domain the rank of $V$ is well-defined, see page 82. Thus we see that $m = n$. Now let $P = (p_{ij})$ be the base change matrix, i.e. $P = (p_{ij})$ is the matrix that is uniquely determined by the condition that given any $i \in \{1, \ldots, n\}$ we have
$v_i = \sum_{j=1}^{n} p_{ji} \cdot w_j$. The “opposite” base change matrix is evidently an inverse to $P$, in particular we see that $P$ is invertible. We denote by $A$ and $B$ the matrices representing $\varphi$ with respect to the two bases. We see that
\[
\text{tr}(B) = \text{tr}(P \cdot A \cdot P^{-1}) = \text{tr}(P^{-1} \cdot P \cdot A) = \text{tr}(A).
\]

\[
\uparrow\text{an elementary calculation by Lemma 65.1 since } R \text{ is commutative and since all matrices are square matrices of the same size}
\]

In many of the applications below we will consider the case that $R$ is a field. But on several occasions the case $R = \mathbb{Z}$ is also of interest.

**Lemma 65.3.** Let $\varphi: V \to V$ be an endomorphism of a finitely generated free abelian group and let $R$ be a commutative domain. Let $\gamma: \mathbb{Z} \to R$ be the natural ring homomorphism with $\gamma(1_\mathbb{Z}) = 1_R$ from page 490. Then
\[
\gamma \left( \text{tr} \left( \varphi: V \to V \right) \right) = \text{tr} \left( \varphi \otimes \text{id}_R: V \otimes R \to V \otimes R \right) \in R.
\]

**Proof.** Let $\{v_1, \ldots, v_n\}$ be a basis for the free abelian group $V$ and let $A$ be the $(n \times n)$-matrix that represents $\varphi$ with respect to this basis. It is straightforward to verify that $v_1 \otimes 1, \ldots, v_n \otimes 1$ is a basis for the $R$-module $V \otimes R$ and that $\gamma(A)$ is the matrix that represents the endomorphism $\varphi \otimes \text{id}$. Since the trace commutes with ring homomorphisms we obtain the desired equality $\gamma(\text{tr}(A)) = \text{tr}(\gamma(A))$. $\blacksquare$

Sometimes it is also convenient to consider the trace of an endomorphism of a finitely generated abelian group. This leads us to the following definition.

**Definition.**

1. Given a finitely generated abelian group $H$ we refer to
   \[
   FH := H/\text{Tor}(H)
   \]
   as the maximal torsion-free quotient of $H$.

2. Given a homomorphism $\alpha: A \to B$ between two finitely generated abelian groups we denote the obvious induced map $FA \to FB$ by $\alpha$ as well.

**Lemma 65.4.** Given a finitely generated abelian group $H$ the maximal torsion-free quotient $FH = H/\text{Tor}(H)$ of $H$ is a free abelian group.

**Proof.** A very elementary exercise shows that $FH = H/\text{Tor}(H)$ is a torsion-free abelian group. Since $H$ is finitely generated we obtain from Theorem 19.4 that $FH$ is in fact a free abelian group. $\blacksquare$

**Remark.**

1. It follows easily from the definition that the map $H \to FH$ defines a functor from the category of finitely generated abelian groups to the category of free abelian groups.
It might sound silly to mention Theorem 19.4 explicitly in the proof of Lemma 65.4, but it is worth noting that for commutative rings $R$ which are not PIDs there is usually no meaningful functor from the category of finitely generated $R$-modules to the category of free $R$-modules.

The hypothesis that $H$ is finitely generated is of course necessary, for example the maximal torsion-free quotient of the abelian group $(\mathbb{Q}, +)$ is again $(\mathbb{Q}, +)$, which is certainly not a free abelian group.

**Definition.** Given an endomorphism $\varphi: H \to H$ of a finitely generated abelian group we define
\[
\text{tr}(\varphi) = \text{tr} \left( \begin{array}{c} FH \to FH \\ [h] \mapsto [\varphi(h)] \end{array} \right).
\]

We conclude this elementary section with the following basic lemma which is a variation on Lemma 65.3.

**Lemma 65.5.** Let $H$ be a finitely generated abelian group and let $\varphi: H \to H$ be an endomorphism. Then the following equality holds:
\[
\text{tr}(\varphi: H \to H) = \text{tr}(\varphi \otimes \text{id}: H \otimes \mathbb{Q} \to H \otimes \mathbb{Q}) \in \mathbb{Q}.
\]

**Proof.** By the classification of finitely generated abelian groups, see Theorem 19.4, we can write $H = F \oplus T$ where $F$ is a free abelian group and $T$ is a torsion group. We denote by $\psi$ the map $F \xrightarrow{f \mapsto f \oplus 0} F \oplus T \xrightarrow{\varphi} F \oplus T \xrightarrow{f \mapsto \varphi(f)} F$. Then we see that
\[
\text{tr}(\varphi: H \to H) = \text{tr}(\psi: F \to F) = \text{tr}(\psi \otimes \text{id}: F \otimes \mathbb{Q} \to F \otimes \mathbb{Q}) = \text{tr}(\varphi \otimes \text{id}: H \otimes \mathbb{Q} \to H \otimes \mathbb{Q}).
\]

It follows easily from the definitions by Lemma 65.3 and by Lemma 37.3. $\blacksquare$

**65.2. The Lefschetz number.** In this section we return to topology.

**Definition.** Let $\mathbb{F}$ be a field.

1. Let $X$ be a topological space. We say the homology of $X$ is $\mathbb{F}$-finite if all homology groups $H_i(X; \mathbb{F})$ with $\mathbb{F}$-coefficients are finite-dimensional vector spaces and if all but finitely many homology groups $H_i(X; \mathbb{F})$ are zero.

2. Let $X$ be a topological space such that the homology is $\mathbb{F}$-finite. Let $\varphi: X \to X$ be a map. We define the $\mathbb{F}$-Lefschetz number of $\varphi$ to be$^\text{1000}
\Lambda(\varphi, \mathbb{F}) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\varphi_*: H_n(X; \mathbb{F}) \to H_n(X; \mathbb{F})).$

**Remark.** In Exercise 65.4 we will see that the $\mathbb{F}$-Lefschetz number depends only rather mildly on the choice of the field $\mathbb{F}$.

In general it can be tricky to determine (the trace of) an induced map on homology. The following lemma gives us some basic (partial) calculations of Lefschetz numbers.

---

$^\text{1000}$Recall that on page 1400 we pointed out that the induced map $\varphi_*: H_n(X; \mathbb{F}) \to H_n(X; \mathbb{F})$ is an endomorphism of an $\mathbb{F}$-vector space. Since the vector space $H_n(X; \mathbb{F})$ is by hypothesis finite-dimensional we see that the trace is in fact defined.
Lemma 65.6.

(1) If $X$ is a finite CW-complex, then for any field $\mathbb{F}$ we have $\Lambda(\text{id}_X, \mathbb{F}) = \chi(X)$.

(2) Let $X$ be a 0-connected topological space and let $\varphi : X \to X$ be a map. For every field $\mathbb{F}$ we have $\text{tr} (\varphi_* : H_0(X; \mathbb{F}) \to H_0(X; \mathbb{F})) = 1$.

(3) Let $\mathbb{F}$ be a field and let $X$ be a 0-connected topological space with $\mathbb{F}$-finite homology. If $\varphi : X \to X$ is a constant map, then $\Lambda(\varphi, \mathbb{F}) = 1$.

Proof. (*)

(1) We calculate that

$$\Lambda(\text{id}_X, \mathbb{F}) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\text{id}_* \circ H_n(X; \mathbb{F})) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \dim_{\mathbb{F}}(H_n(X; \mathbb{F})) = \chi(X).$$

(2) This statement follows immediately from the obvious generalizations of Proposition 41.5 and the discussion on page 1088 to homology with $\mathbb{F}$-coefficients.

(3) This statement follows immediately from (2).

The following lemma is an immediate and quite useful consequence of Proposition 42.5 and the discussion on page 1401.

Lemma 65.7. Let $\mathbb{F}$ be a field and let $X$ be a topological space such that the homology is $\mathbb{F}$-finite. Let $\varphi, \psi : X \to X$ be two maps. If $\varphi$ and $\psi$ are homotopic, then the Lefschetz numbers agree, i.e. $\Lambda(\varphi, \mathbb{F}) = \Lambda(\psi, \mathbb{F})$.

At times it is more efficient to work with the “usual” homology groups, i.e. the homology groups with $\mathbb{Z}$-coefficients. This leads to the following unexciting definition.

**Definition.**

(1) Let $X$ be a topological space. We say the homology of $X$ is $\mathbb{Z}$-finite if all homology groups $H_i(X)$ are finitely generated abelian groups and if all but finitely many homology groups $H_i(X)$ are zero.

(2) Let $X$ be a topological space such that the homology is $\mathbb{Z}$-finite. Let $\varphi : X \to X$ be a map. We define the **Lefschetz number of $\varphi$** to be

$$\Lambda(\varphi) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\varphi_* : H_n(X) \to H_n(X)).$$

The following lemma relates the above Lefschetz number $\Lambda(\varphi)$ to the Lefschetz number $\Lambda(\varphi, \mathbb{Q})$.

Lemma 65.8. Let $X$ be a topological space and let $\varphi : X \to X$ be a map.

(1) Let $k \in \mathbb{N}_0$. We have $\text{rank}(H_k(X)) = \dim(H_k(X; \mathbb{Q}))$. Furthermore, if $H_k(X)$ is finitely generated, then we have

$$\text{tr}(\varphi_* : H_k(X) \to H_k(X)) = \text{tr}(\varphi_* : H_k(X; \mathbb{Q}) \to H_k(X; \mathbb{Q})).$$

(2) If the homology of $X$ is $\mathbb{Z}$-finite, then the homology of $X$ is also $\mathbb{Q}$-finite and we have the equality $\Lambda(\varphi) = \Lambda(\varphi, \mathbb{Q})$. 
Proof. Statement (2) is an immediate consequence of Statement (1). Thus let us prove the first statement. Let \( k \in \mathbb{N}_0 \). The equality \( \text{rank}(H_k(X)) = \dim(H_k(X; \mathbb{Q})) \) was shown in Corollary [57.21](2). Now assume that \( H_k(X) \) is finitely generated. We have the following equalities:

\[
\text{tr} \left( H_k(X) \xrightarrow{\varphi} H_k(X) \right) = \text{tr} \left( H_k(X) \otimes \mathbb{Q} \xrightarrow{\varphi \otimes \text{id}} H_k(X) \otimes \mathbb{Q} \right) = \text{tr} \left( H_k(X; \mathbb{Q}) \xrightarrow{\varphi} H_k(X; \mathbb{Q}) \right).
\]

by Lemma [65.5] by the naturality of the short exact sequence of the Universal Coefficient Theorem [57.19] and the observation that by Lemma [57.17](4) the Tor-groups with \( \mathbb{Q} \)-coefficients vanish.

65.3. The formulation of the Lefschetz Fixed Point Theorems. Now we can finally formulate the long promised Lefschetz Fixed Point Theorem. This theorem, with somewhat different language, was first proved in 1926 by Solomon Lefschetz [Lef26] p. 48.\(^{1001}\)

**Theorem 65.9. (Lefschetz Fixed Point Theorem I)** Let \( X \) be a finite simplicial complex and let \( \varphi : X \to X \) be a map. If there exists a field \( \mathbb{F} \) such that the \( \mathbb{F} \)-Lefschetz number \( \Lambda(\varphi, \mathbb{F}) \) is non-zero, then \( \varphi \) has a fixed point.

We will prove the Lefschetz Fixed Point Theorem 65.9 in the next section. First we will see that one of our earlier great successes, namely Theorem 45.13, is just a special case of the Lefschetz Fixed Point Theorem 65.9.

**Theorem 45.13.** Let \( n \in \mathbb{N} \) and let \( \varphi : S^n \to S^n \) be a map. If \( \deg(\varphi) \neq (-1)^{n+1} \), then \( \varphi \) has a fixed point.

**Proof.** We consider the topological space \( S^n \). By the discussion on page 1500 we know that \( S^n \) admits the structure of a finite simplicial complex. Let \( \varphi : S^n \to S^n \) be a map. We calculate that

\[
\Lambda(\varphi, \mathbb{Q}) = \text{tr} \left( H_0(S^n) \xrightarrow{\varphi} H_0(S^n) \right) + (-1)^n \cdot \text{tr} \left( H_n(S^n) \xrightarrow{\varphi} H_n(S^n) \right) = 1 + (-1)^n \cdot \deg(\varphi).
\]

by Lemma [65.6](2) = 1 by definition of the degree

The Lefschetz Fixed Point Theorem 65.9 thus says that if \( 1 + (-1)^n \cdot \deg(\varphi) \neq 0 \), then \( \varphi \) has a fixed point. But that is exactly what we wanted to show. \( \blacksquare \)

For many applications the following variation on the Lefschetz Fixed Point Theorem 65.9 is particularly useful.

**Theorem 65.10. (Lefschetz Fixed Point Theorem II)** Let \( M \) be a compact smooth manifold and let \( \varphi : M \to M \) be a map. If there exists a field \( \mathbb{F} \) such that the \( \mathbb{F} \)-Lefschetz number \( \Lambda(\varphi, \mathbb{F}) \) is non-zero, then \( \varphi \) has a fixed point.

**Remark.**

(1) Later on in Theorem 85.11 we will prove the Lefschetz Fixed Point Theorem also for finite CW-complexes and compact topological manifolds. In fact not only is the statement of Theorem 85.11 more general than the statement of Theorem 65.10 the

\(^{1001}\)Solomon Lefschetz (1884-1972) was an American mathematician.
proof of Theorem 65.11 will also be self-contained, since we will not make use of Theorem 64.2 for which we provided only a sketch of a proof.

(2) Reading (1) one might be tempted to think that the conclusion of the Lefschetz Fixed Point Theorem holds for every compact topological space. But in Exercise 65.5 we will see that this is certainly not the case.

(3) We will prove a generalization of the Lefschetz Fixed Point Theorem 65.10 in the Lefschetz-Hopf Theorem 96.5.

**Proof.** Let $M$ be a compact smooth manifold. By Theorem 64.2 we know that $M$ admits a finite simplicial structure. Thus we can apply the Lefschetz Fixed Point Theorem 65.9 and we are done. ■

**Corollary 65.11.** Let $M$ be a compact connected smooth manifold such that $H_n(M)$ is torsion for all $n \geq 1$. Then every map $\varphi : M \to M$ has a fixed point.

**Proof.** Let $M$ be a compact connected smooth manifold such that $H_n(M)$ is torsion for all $n \geq 1$. We calculate that

$$\Lambda(\varphi, Q) \overset{\downarrow}{=} \text{tr}(\varphi_* : H_0(M) \to H_0(M)) + \sum_{n \in \mathbb{N}} (-1)^n \cdot \text{tr}(\varphi_* : H_n(M) \to H_n(M)) = 1.$$  

It follows from the Lefschetz Fixed Point Theorem 65.10 that $\varphi$ has a fixed point. ■

**Examples.**

(1) If we apply Corollary 65.11 to the compact connected smooth manifold $M = B^n$, then we recover the Brouwer Fixed Point Theorem 43.8.

(2) In Proposition 48.10 we computed the homology groups of the real projective spaces $\mathbb{R}P^n$. These calculations show in particular that the hypotheses of Corollary 65.11 are satisfied for even-dimensional real projective spaces $\mathbb{R}P^{2n}$. Thus we see that every self-map $f : \mathbb{R}P^{2n} \to \mathbb{R}P^{2n}$ has a fixed point. (This gives an alternative solution of Exercise 45.12.) We will consider the case of odd-dimensional real projective spaces in Exercise 65.3.

In the next section we will provide a proof of the Lefschetz Fixed Point Theorem 65.9 and afterwards we will consider two more elaborate applications of the Lefschetz Fixed Point Theorem 65.9. There are many other pretty consequences of the Lefschetz Fixed Point Theorem 65.9 which we cannot mention in these modest notes. In fact the book by Brown [BrownR71] is completely dedicated to the proof of the Lefschetz Fixed Point Theorem 65.9 and its numerous applications and generalizations.

65.4. **Proof of the Lefschetz Fixed Point Theorem 65.9** One of the keys to proving the Lefschetz Fixed Point Theorem 65.9 is the following result in linear algebra which is a not-so-distant relative to Lemma 55.3.

**Theorem 65.12.** (Hopf Trace Formula)
Let $\mathbb{F}$ be a field. If
\[
C_* := 0 \to C_k \xrightarrow{\partial_k} C_{k-1} \xrightarrow{\partial_{k-1}} \cdots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0
\]
is a chain complex of finite-dimensional $\mathbb{F}$-vector spaces, then given any chain map $\varphi_* : C_* \to C_*$ we have
\[
\sum_{i=0}^k (-1)^i \cdot \text{tr}(\varphi_i : C_i \to C_i) = \sum_{i=0}^k (-1)^i \cdot \text{tr}(\varphi_* : H_i(C_*) \to H_i(C_*)).
\]

The analogue of (1) also holds if we start out with a chain complex of finitely generated free abelian groups.

The key to proving the Hopf Trace Formula 65.12 is the following lemma.

**Lemma 65.13.** Let $\mathbb{F}$ be a field. Suppose we are given a commutative diagram of homomorphisms of finite-dimensional $\mathbb{F}$-vector spaces of the following type:
\[
\begin{array}{ccc}
0 & \to & A \\
\alpha & \downarrow & p \\
B & \to & C \\
\downarrow & & \downarrow \\
0 & \to & 0
\end{array}
\]
\[
\begin{array}{ccc}
0 & \to & A \\
\iota & \downarrow & \beta \\
B & \to & C \\
\downarrow & & \downarrow \\
0 & \to & 0
\end{array}
\]
If the horizontal sequences are exact, then
\[
\text{tr}(\beta : B \to B) = \text{tr}(\alpha : A \to A) + \text{tr}(\gamma : C \to C).
\]

**Proof.** Let $a_1, \ldots, a_m$ be a basis for $A$ and let $c_1, \ldots, c_n$ be a basis for $C$. For $i = 1, \ldots, n$ we pick a $\bar{c}_i \in B$ with $p(\bar{c}_i) = c_i$. It follows easily from our hypothesis that the horizontal sequences are exact that $i(a_1), \ldots, i(a_m), \bar{c}_1, \ldots, \bar{c}_n$ form a basis for $B$. Furthermore it is elementary to show, using the hypothesis that the diagram commutes, that the matrix of $\beta$ with respect to this basis is of the following form:
\[
\begin{pmatrix}
\text{matrix that represents } \alpha & * & * \\
0 & 0 & * & * \\
0 & 0 & \text{matrix that represents } \gamma
\end{pmatrix}
\]
where each "*" indicates some element in $\mathbb{F}$.

It is now clear that $\text{tr}(\beta) = \text{tr}(\alpha) + \text{tr}(\gamma)$. \qed

Now that Lemma 65.13 is in our toolbox the proof of the Hopf Trace Formula 65.12 is almost embarrassingly similar to the proof of Lemma 55.3.

**Proof of Hopf Trace Formula 65.12.** First we note that Statement (2) follows almost immediately from Statement (1) applied to $\mathbb{F} = \mathbb{Q}$, together with Lemma 65.5 and the Universal Coefficient Theorem 57.18. We leave it to the reader to fill in the details.

Thus it remains to prove Statement (1). For the given chain complex $(C_*, \partial_*)$ over some field $\mathbb{F}$ we write for each $n \in \mathbb{N}_0$
\[
Z_n := \ker(\partial_n), \quad B_n := \text{im}(\partial_{n+1}) \quad \text{and} \quad H_n = Z_n / B_n.
\]
We write $\varphi_{B_n} := \varphi_n|_{B_n}$ and $\varphi_{Z_n} := \varphi_n|_{Z_n}$. For symmetry reasons we also write $\varphi_{C_n} := \varphi_n$ and $\varphi_{H_n} := \varphi_* : H_n \to H_n$. These $\mathbb{F}$-vector spaces and homomorphisms form the following
two types of commutative diagrams of short exact sequences

(a)  
\[
\begin{array}{c}
0 \to Z_n \to C_n \to B_{n-1} \to 0 \\
\downarrow \varphi_{Zn} \downarrow \varphi_{Cn} \downarrow \varphi_{Bn-1} \\
0 \to Z_n \to C_n \to B_{n-1} \to 0
\end{array}
\]

and

(b)  
\[
\begin{array}{c}
0 \to B_n \to Z_n \to H_n \to 0 \\
\downarrow \varphi_{Bn} \downarrow \varphi_{Zn} \downarrow \varphi_{Hn} \\
0 \to B_n \to Z_n \to H_n \to 0
\end{array}
\]

Now we see that

by (a) and Lemma 65.13 we know that

\[ \sum_{n=0}^{k} (-1)^n \cdot \text{tr}(\varphi_{C_n}) = \sum_{n=0}^{k} (-1)^n \cdot (\text{tr}(\varphi_{Z_n}) + \text{tr}(\varphi_{B_{n-1}})) \]

by (b) and Lemma 65.13 we know that

\[ \sum_{n=0}^{k} (-1)^n \cdot (\text{tr}(\varphi_{B_n}) + \text{tr}(\varphi_{H_n})) \]

we do the substitution \( m = n - 1 \) and we use that \( B_k = 0 \) and \( B_{-1} = 0 \)

Now we are fully prepared for tackling the proof of the Lefschetz Fixed Point Theorem 65.

**Proof of the Lefschetz Fixed Point Theorem 65.9** Let \( X \) be a finite simplicial complex and let \( \varphi : X \to X \) be a map without a fixed point. Furthermore let \( \mathbb{F} \) be a field. We need to show that

\[ \Lambda(\varphi, \mathbb{F}) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\varphi : H_n(X; \mathbb{F}) \to H_n(X; \mathbb{F})) = 0. \]

The basic idea for the proof is quite simple:

We need to upgrade the fact that \( \varphi(x) \neq x \) for every \( x \in X \) to the statement that for a suitable chain complex \( C_* \) that calculates \( H_*(X) \) we also have \( \varphi(\sigma) \neq \sigma \) for every element \( \sigma \) of a suitable basis. This implies that the trace on the chain group level is zero, hence we get the desired statement from the Hopf Trace Formula 65.12 (1).

For better or worse turning the idea into a proper proof requires a substantial effort. First of all we note that since \( X \) is a finite simplicial complex we can use Lemma 61.9 to view \( X \) as a subspace of some \( \mathbb{R}^n \). In particular we can and will equip \( X \) with the usual Euclidean metric \( d(x, y) := \|x - y\|_{\mathbb{R}^n} \).
Claim 1. There exists an iterated barycentric subdivision \( Y \) of \( X \) such that for every vertex \( w \) of \( Y \) we have \( \varphi(\text{St}(Y, w)) \cap \text{St}(Y, w) = \emptyset \).

The claim is proved in several easy steps:

1. Since \( X \) is a finite simplicial complex we know by Lemma 61.9 that \( X \) is compact.
2. From the compactness of \( X \) together with our hypothesis that for every \( x \in X \) we have \( \varphi(x) \neq x \) we obtain through some elementary arguments, as provided in Exercise 3.11 (b), that there exists an \( \epsilon > 0 \) such that for every \( x \in X \) we have \( d(\varphi(x), x) \geq \epsilon \).

3. By Lemma 62.7 there exists a \( j \in \mathbb{N}_0 \) such that for every vertex \( v \) of the iterated barycentric subdivision \( \text{sd}^j(X) \) we have \( \text{diam}(\text{St}(\text{sd}^j(X), v)) < \frac{\epsilon}{2} \).

4. It follows from (2) and (3) that \( \varphi(\text{St}(\text{sd}^j(X), w)) \cap \text{St}(\text{sd}^j(X), w) = \emptyset \). Indeed, let \( x, y \in \text{St}(\text{sd}^j(X), w) \). We calculate that

\[
d(\varphi(x), y) \geq d(\varphi(x), x) - d(x, y) \geq \epsilon - \frac{\epsilon}{2} \geq \frac{\epsilon}{2} > 0.
\]

This implies that \( \varphi(\text{St}(\text{sd}^j(X), w)) \cap \text{St}(\text{sd}^j(X), w) = \emptyset \).

Thus the iterated barycentric subdivision \( Y := \text{sd}^j(K) \) has the desired property.

Next we apply the Simplicial Approximation Theorem 62.8 to the map \( \varphi : Y \to Y \). We obtain an \( i \in \mathbb{N}_{\geq 0} \) and a simplicial map \( \psi : Z := \text{sd}^i(Y) \to Y \) with the following properties:

(A) The map \( \psi \) is homotopic to \( \varphi \) as a map \( Y \to Y \).

(B) For every vertex \( w \) of \( Z = \text{sd}^i(Y) \) we have \( \varphi(\text{St}(\text{sd}^i(Y), w)) = \text{St}(Y, \psi(w)) \).

It follows from (A) and Lemma 65.7 that the Lefschetz numbers of \( \varphi \) and \( \psi \) agree.

The map \( \psi : Z \to Y \) is a simplicial map between two different simplicial complexes. The following claim gets as close as possible to saying that \( \psi \) does not fix a simplex.

Claim 2. For every simplex \( s \) of \( Y \) and every simplex \( t \) of \( Z \) with \( t \subset s \) we have \( \psi(t) \neq s \).
Let $s$ be a simplex of $Y$ and let $t$ be a simplex of $Z$ with $t \subset s$. Let $v$ be a vertex of $t$. (It might be helpful to consider Figure 998) We make the following deductions:

$v$ a vertex of the simplex $t$ of $Z$  \[ \implies t \subset \text{St}(Z, v) \implies \varphi(t) \subset \varphi(\text{St}(Z, v)) \implies \varphi(t) \subset \text{St}(Y, \psi(v)) \]

by the definition of $\text{St}(Z, v)$, see page 1522 by (B)

\[ \implies \varphi(t) \cap \varphi(\text{St}(Y, \psi(v))) = \emptyset \implies t \cap \text{St}(Y, \psi(v)) = \emptyset \]

by Claim 1

\[ \implies t \cap \text{St}(Y, \psi(t)) = \emptyset \]

since $\psi(v)$ is a vertex of $\psi(t)$ we have $\text{St}(Y, \psi(t)) \subset \text{St}(Y, \psi(v))$

we have $t \subset \text{St}(Y, s)$, indeed this follows from $t \subset s$ and from $s \subset \text{St}(Y, s)$, which in turn holds by definition of $\text{St}(Y, s)$.

\[ \text{Figure 998. Illustration for the proof of Claim 2.} \]

Next, given $n \in \mathbb{N}_0$ let

\[ u_n : C_n^{\text{simp}}(Y) \to C_n^{\text{simp}}(\text{sd}^i(Y)) \]

be the $i$-fold iterated simplicial subdivision map that we introduced in Lemma 63.41.

Claim 3. For each $n \in \mathbb{N}_0$ the map $u_n \circ \psi_* : C_n^{\text{simp}}(Z) \to C_n^{\text{simp}}(Z)$ has trace zero.

Let $T_n$ be the set of $n$-simplices of $Z$. It follows from Lemma 63.5 that $T_n$, with some choice of ordering for each $t \in T_n$, is a basis of $C_n^{\text{simp}}(Z)$. Now let $t \in T_n$. If $\psi(t)$ is not an $n$-simplex of $Y$, then by definition we have $\psi_*(t) = 0$. Now suppose that $\psi(t)$ is an $n$-simplex of $Y$.

by definition of the simplicial subdivision map

\[ (u_n \circ \psi_*)(t) = \text{linear combination of } n\text{-simplices of } Z \text{ contained in } \psi(t) \]

\[ = \text{linear combination of } n\text{-simplices of } Z \text{ not equal to } t. \]

here we need to distinguish two cases:

1. If $t$ is contained in some $n$-simplex $s$ of $Y$, then the conclusion follows from Claim 2.
2. If $t$ is not contained in any $n$-simplex of $Y$, then it is in particular not contained in the $n$-simplex $\psi(t)$ of $Y$

\[ = \text{linear combination of elements in } T_n \setminus \{t\}. \]
This calculation shows that, with respect to the basis $T_n$, each diagonal entry of the map $u_n \circ \psi_*$ is zero. In particular the trace of the map $u_n \circ \psi_* : C_n^{\text{simp}}(Z) \to C_n^{\text{simp}}(Z)$ is zero. \(\square\)

\[
\begin{array}{ccc}
Z & \xrightarrow{\psi} & Y \\
\text{simplicial} & & \text{simplicial} \\
\end{array}
\]

\[
\begin{array}{ccc}
& & (u_2 \circ \psi)(t) \\
& & \text{simplicial} \\
\end{array}
\]

\[
\begin{array}{ccc}
& & Z \\
\end{array}
\]

\[\text{Figure 999. Illustration for the proof of Claim 3.}\]

In the following we will use simplicial homology with $\mathbb{F}$-coefficients. The definition should be clear to the reader and it should be clear that some of the statements which we cite below, which were formulated for homology without coefficients, also have obvious generalizations to homology with $\mathbb{F}$-coefficients.

Claim 4. The following diagram commutes:

\[
\begin{array}{ccc}
H_n^{\text{simp}}(Z; \mathbb{F}) & \xrightarrow{\psi_*} & H_n^{\text{simp}}(Y; \mathbb{F}) \\
\downarrow & & \downarrow \\
H_n(Z; \mathbb{F}) & \xrightarrow{\psi_*} & H_n(Z; \mathbb{F}) \\
\end{array}
\]

Here the vertical maps are the natural isomorphism defined on page 1565.

It turns out that there is not much to say. The rectangle to the left commutes by the naturality of the vertical maps and the rectangle to the right commutes by Proposition 63.45. \(\square\)

\[\text{\textsuperscript{1002}}\text{The two cases are illustrated in Figure 999}\]
Now we can quickly conclude the proof of the Lefschetz Fixed Point Theorem \[65.9\]. Indeed, we see that by Lemma \[43.28\] the singular subdivision maps \(u_*\) are chain homotopic to the identity, thus the induced map on homology is the identity
\[
\Lambda(\varphi, \mathbb{F}) = \Lambda(\psi, \mathbb{F}) = \sum_{i \in \mathbb{N}_0} (-1)^i \cdot \text{tr}(u_* \circ \psi_* \circ H_i(Z; \mathbb{F})) = \sum_{i \in \mathbb{N}_0} (-1)^i \cdot \text{tr}(u_* \circ \psi_* \circ C^\text{simp}_i(Z))
\]
by Claim 4 by the Hopf Trace Formula \[65.12\](1)
\[
= \sum_{i \in \mathbb{N}_0} (-1)^i \cdot \text{tr}(u_* \circ \psi_* \circ C^\text{simp}_i(Z)) = 0.
\]
by Claim 3 and since by definition \(C^\text{simp}_i(Z; \mathbb{F}) = C^\text{simp}_i(Z) \otimes \mathbb{F}\)

We have thus proved that if \(\varphi\) has no fixed points, then \(\Lambda(\varphi, \mathbb{F}) = 0\). \(\blacksquare\)

65.5. Vector fields on smooth manifolds. In this section we will apply the Lefschetz Fixed Point Theorem \[65.9\] to the study of the (non-)existence of certain vector fields on smooth manifolds.

Let \(M \subset \mathbb{R}^n\) be a submanifold without boundary. On page \[1185\] we defined the notion of a vector field on \(M\). Now we define the notion of a vector field on any smooth manifold.

**Definition.** Let \(M\) be an \(n\)-dimensional smooth manifold.

1. A vector field on \(M\) is a map \(v\) which assigns to each \(P \in M\) a vector \(v(P) \in T_P M\) such that the following condition is satisfied: For every chart \(\Phi: U \rightarrow V\) from an open set \(U\) of \(M\) to an open set \(V\) of \(\mathbb{R}^n\) the map \(V \rightarrow \mathbb{R}^n, P \mapsto D\Phi_{\Phi^{-1}(P)}(v(\Phi^{-1}(P))) \subset T_P V = \mathbb{R}^n\) is continuous. We say that the vector field \(v\) is smooth if for every chart the above map is smooth.

2. Given a vector field \(v\) on \(M\) we say that \(x \in M\) is a zero of \(v\) if \(v(x) = 0\).

**Remark.** Let \(M \subset \mathbb{R}^n\) be a submanifold without boundary. It follows easily from the definitions that under the usual natural isomorphisms of the tangent spaces \(V_P M \cong T_P M\) from page \[294\] and page \[491\] the two notions of vector fields introduced on page \[1185\] and above coincide.

On several occasions we will make use of the following basic lemma.

**Lemma 65.14.** Let \(f: M \rightarrow N\) be a map between two smooth manifolds and let \(v\) be a vector field on \(N\). If \(f\) is a local diffeomorphism, then for each \(x \in M\) we can define

\(\text{Recall that for a smooth manifold we mean by a “chart” a chart from the given smooth structure.}\)
\[(f^*v)(x) = (Df_x)^{-1}(v(f(x))) \in T_x M.\] These vectors define a vector field \(f^*v\) on \(M\). We refer to \(f^*v\) as the pullback of \(v\) under \(f\).

**Proof.** The lemma follows easily from the definitions. We do not feel like filling in the details. 

One of the goals of this section is to address the following question.

**Question 65.15.** Which closed connected 2-dimensional smooth manifolds admit a nowhere vanishing vector field?

**Example.** In Figure 1000 we show vector fields on the projective plane \(\mathbb{RP}^2\), on the Klein bottle and the surface of genus 2. The vector field on the Klein bottle is nowhere-vanishing, whereas the vector field on \(\mathbb{RP}^2\) and the surface of genus 2 both have zeros.

![Figure 1000](image)

The attentive reader will not have failed to notice that it is the right moment to recall one of the highlights from one of the earlier chapters:

**Theorem 45.14 (Hairy Ball Theorem)** Every vector field on an even-dimensional sphere vanishes on at least one point.

**Sketch of proof.** Let \(v\) be a nowhere vanishing vector field on a sphere \(S^n\). By “traveling along the great circle defined by \(v\)” we can find a homotopy \(F: S^n \times [0, 1] \to S^n\) from the identity to the antipodal map \(\rho: S^n \to S^n\) given by \(\rho(x) = -x\). In particular we see that \((-1)^{n+1} = \deg(\rho) = \deg(\text{id}) = 1\). Thus we see that \(n\) is odd.

**Remark.** Regarding Question 65.15 the Hairy Ball Theorem 45.14 says in particular that \(S^2\) does not admit a nowhere vanishing vector field.

To address Question 65.15 it is also helpful to add a few ways to construct new vector fields to our toolbox.

**Lemma 65.16.**
65. THE LEFSCHETZ FIXED POINT THEOREM

(1) Let \( f : M \to N \) be a map between smooth manifolds which is a local diffeomorphism. Let \( v \) be a vector field on \( N \). The map
\[
P \mapsto (\mathcal{D}_P f)^{-1}(v(f(P))) \in T_{f(P)}(N)
\]
is a vector field on \( M \) that we denote by \( f^*v \). A point \( P \in M \) is a zero of \( f^*v \) if and only if \( f(P) \) is a zero of \( v \).

(2) Let \( M \) be a smooth manifold and let \( v \) be a vector field on \( M \). Suppose \( p : \tilde{M} \to M \) is a covering. Then \( p^*v \) is a vector field on \( \tilde{M} \).

(3) Let \( M \) be a smooth manifold and let \( v \) be a vector field on \( M \). Suppose we are given a group \( G \) that acts freely, properly and smoothly on \( M \) such that for every \( g \in G \) we have \((g \cdot M \to M)^*v) = v\). Then there exists a unique vector field \( u \) on \( M/G \) such that \( v = p^*u \) where \( p : M \to M/G \) is the projection map.

Proof.

(1) The mature reader will have no troubles with providing a proof for this statement.
(2) This statement follows from (1) and Proposition 17.1 (2a).
(3) The proof of this statement is very similar to the proof of (1) and it is also left to the reader.

Lemma 65.16 allows us to answer Question 65.15 in some special cases:

Examples.

(1) If \( v \) is a vector field on \( \mathbb{R}P^2 \) with \( n \) zeros, then it follows from Lemma 65.16 applied to the 2-fold covering \( p : S^2 \to \mathbb{R}P^2 = S^2/x \sim -x \) that \( S^2 \) has a vector field with \( 2n \) zeros. By the Hairy Ball Theorem 45.14 we know that \( 2n > 0 \). In other words, we have just shown that every vector field on \( \mathbb{R}P^2 \) has at least one zero.

(2) On the smooth manifold \( \mathbb{R}^2 \) we consider the constant “horizontal” vector field \( v(x, y) = (1, 0) \in T_{(x,y)}\mathbb{R}^2 = \mathbb{R}^2 \). As discussed in Lemma 3.31 and on page 501 we can view the torus and the Klein bottle as quotients of \( \mathbb{R}^2 \) by a group \( G \) that acts freely, properly and smoothly. Furthermore, in both cases one can easily verify that the given \( G \)-action preserves the vector field \( v \). This shows that the nowhere vanishing vector field \( v \) descends to a nowhere vanishing vector field on the torus and the Klein bottle. For the Klein bottle we obtain precisely the vector field shown in Figure 1000.

The following theorem is the main result of this section.

**Theorem 65.17.** Let \( M \) be a closed smooth manifold. If \( M \) admits a nowhere vanishing vector field, then \( \chi(M) = 0 \).

Remark.

(1) On page 1363 we saw that for even \( n \) the Euler characteristic \( \chi(S^n) \) equals 2. Thus we see that Theorem 65.17 is a generalization of the Hairy Ball Theorem 45.14.

---

\( ^{1004}\) Recall that by Proposition 6.32 we know that \( M/G \) is a smooth manifold and that the projection \( p : M \to M/G \) is a local diffeomorphism.
(2) For 2-dimensional smooth manifolds a low-tech proof of Theorem 65.17 involving “negative, neutral and positive charges” is given in [Thu97, Proposition 1.3.3].

(3) Let $M$ be a closed connected 2-dimensional smooth manifold that is not diffeomorphic to the torus or the Klein bottle. It follows from the calculations on pages 1363 and 1369 that $\chi(M) \neq 0$. Thus we obtain from Theorem 65.17 that $M$ does not admit a nowhere vanishing vector field. Together with the above discussion we now have a complete answer to Question 65.15.

(4) In Proposition 97.4 we will see that the converse to Theorem 65.17 holds. Namely we will see that if $M$ is a closed connected smooth manifold with $\chi(M)$, then $M$ admits a nowhere vanishing vector field.

(5) In Corollary 97.6 we will prove a suitable extension of Theorem 65.17 to the setting of smooth manifolds with non-empty boundary.

The key idea behind the proof of Theorem 65.17 is similar to the proof of the Hairy Ball Theorem 45.14, namely we want to use the nowhere vanishing vector field $v$ on $M$ to construct an interesting self-map of $M$. This is done in the following proposition.

**Proposition 65.18.** Let $M$ be a closed smooth manifold. If there exists a nowhere vanishing vector field, then there exists a map $g: M \to M$ that is homotopic to the identity and which has no fixed points.

**Sketch of proof of Proposition 65.18.** We sketch two different proofs of the proposition. The first proof is much shorter, but requires more input from analysis and it needs a stronger hypothesis. The second proof is somewhat longer but it is makes fewer demands on analysis.

Let us start with the first proof. To simplify the discussion we assume that the vector field is smooth. As discussed in [Lee02, Theorem 17.8], fairly basic results in the theory of differential equations tell us that the vector field $v$ on $M$ defines a flow $\Phi: M \times \mathbb{R} \to M$, i.e. a continuous map with the following two properties:

1. For every $P \in M$ we have $\Phi(P,0) = P$.
2. For every $P \in M$ and for every $t \in \mathbb{R}$ we have $(s \mapsto \Phi(P,t+s))' = v(\Phi(P,t))$.

Since $\Phi: M \times \mathbb{R}$ is continuous we see that all the maps $\Phi_t$ are all homotopic. It follows from the fact that $v(P) \neq 0$ for every $P \in M$ and a compactness argument that there exists an $\epsilon > 0$ such that for every $P \in M$ we have $\Phi(P,\epsilon) \neq P$. In other words, the map $\Phi_\epsilon: M \to M$ has no fixed points and it is homotopic to $\Phi_0 = \text{id}$. This concludes the first proof of the proposition.

![Figure 1001. Second illustration of the proof of Theorem 65.17](image-url)

Now we turn to the second proof of the proposition. By Proposition 9.1 (1) together with Proposition 8.1 we can and will view $M$ as a submanifold of some $\mathbb{R}^n$. It follows
from Proposition 8.25 that there exists an \( \epsilon > 0 \) such that the following two conditions are satisfied:

(a) The subset \( Z := \{ P + w \mid P \in M \text{ and } w \in (V_P M)\perp \text{ with } \|w\| \leq \epsilon \} \) of \( \mathbb{R}^n \) is a neighborhood of \( M \).

(b) The map

\[
q: Z \to M \\
P + w \mapsto P
\]

where \( P \in M \) and \( w \in (V_P M)\perp \text{ with } \|w\| \leq \epsilon \)

is well-defined and continuous.

![Diagram of vector field and map](image)

**Figure 1002.** Second illustration of the proof of Theorem 65.17

Next we consider the map

\[
F: M \times \mathbb{R}_{\geq 0} \to \mathbb{R}^n \\
(P,t) \mapsto P + t \cdot v(P).
\]

We make the following observations:

1. As in Lemma 18.1 we see that \( F \) is, unsurprisingly, continuous.
2. It follows from (a), together with the fact that \( M \) is in particular compact and together with some elementary point-set theoretic arguments along the lines of Exercise 3.6 that there exists a \( \mu > 0 \) such that \( F(M \times [0,\mu]) \subset Z \).
3. We set \( g := q \circ F_\mu: M \to M \).
4. By (1) we know that \( q \circ F: M \times [0,\mu] \to M \) defines a homotopy between the identity and \( g \).
5. It remains to show that \( g \) has no fixed points. Thus let \( P \in M \). By (b) we can write \( F_\mu(P) = P + \mu \cdot v(P) =: Q + w \) with \( Q \in M \) and \( w \in (V_Q M)\perp \text{ with } \|w\| \leq \epsilon \).
   Since \( V_P M \cap V_P M\perp = \{0\} \) and since \( v(P) \) is a non-zero vector in \( V_P M \) we see that \( P \neq Q \). By definition we have \( g(P) = Q \). Thus we have shown that \( g(P) \neq P \).

This concludes the second proof of the proposition.

Now it is straightforward to provide the proof of Theorem 65.17.

**Proof of Theorem 65.17** Let \( M \) be a closed smooth manifold. Suppose there exists a nowhere vanishing vector field \( v \) on \( M \). By Proposition 65.18 there exists a map \( g: M \to M \)
that is homotopic to the identity and which has no fixed points. Now we calculate that

\[ \chi(M) = \Lambda(id: M \to M) = \Lambda(f: M \to M) = \Lambda(f: M \to M, \mathbb{Q}) \]

by Lemma 65.6 since \( f \) and \( id \) are homotopic

**Remark.** The approach we used in the proof of Theorem 65.17 is an antediluvian version of the more sophisticated argument using flows of vector fields on smooth manifolds which is studied in detail in [Lee02, Chapter 9].

As a teaser we state the following proposition which we will prove later on. This proposition is basically the converse to Theorem 65.17.

**Proposition 97.4.** Let \( M \) be a closed connected smooth manifold. If \( \chi(M) = 0 \), then \( M \) admits a nowhere vanishing smooth vector field.

In Chapter 97 we will not only provide a proof of Proposition 97.4 but we will also formulate and prove a significant generalization of Theorem 65.17 namely the Poincaré-Hopf Theorem 97.5 which, given a vector field, relates the type of zeros which occur to the Euler characteristic of the smooth manifold.

65.6. The Borsuk-Ulam Theorem II . In this section we will see how to use the Lefschetz Fixed Point Theorem 65.9 to give an alternative proof of the Borsuk-Ulam Theorem 59.3. First we remind the reader of the statement of the Borsuk-Ulam Theorem 59.3.

**Theorem 59.3 (Borsuk-Ulam)** Let \( n \in \mathbb{N}_0 \). For every map \( g: S^n \to \mathbb{R}^n \) there exists a pair of antipodal points \( x \) and \(-x\) on \( S^n \) with \( g(x) = g(-x) \).

**Remark.** It is worth pointing out that we saw in Sections 59.4 and Section 59.5 that the Borsuk-Ulam Theorem 59.3 has many fascinating consequences.

The key to our second proof of the Borsuk-Ulam Theorem 59.3 is the following proposition.

**Proposition 65.19.** Let \( n \in \mathbb{N} \) and let \( f: S^n \to S^n \) be a map. If \( f(-x) = -f(x) \) for all \( x \in S^n \), then the Lefschetz number \( \Lambda(f) \) is even.

**Examples.**

1. Let \( A \in O(n+1) \). We consider the map \( f: S^n \to S^n \) that is given by \( f(x) := A \cdot x \). Evidently we have \( f(-x) = -f(x) \) for all \( x \in S^n \). Furthermore it follows from Lemma 45.11 (6) together with Lemma 65.6 (2) that \( \Lambda(f) = 1 + (-1)^n \cdot \det(A) \).

2. In Exercise 65.13 we will see that given any \( n \in \mathbb{N} \) and given any even \( m \in \mathbb{Z} \) there exists a map \( f: S^n \to S^n \) with \( \Lambda(f) = m \) and such that \( f(-x) = -f(x) \) for all \( x \in S^n \).

**Remark.** The proof of Proposition 65.19 is an expanded write-up of the arguments in [Deo18, Theorem 4.9.17] and [Arm83, Chapter 9.3].

The following gives us a criterion for showing that a trace is even.
Lemma 65.20. Let $V$ be a finitely generated free $\mathbb{Z}$-module and let $\rho: V \to V$ be an isomorphism with the following two properties:

(i) There exists a subset $T$ of $V$ such that $T \cap \rho(T) = \emptyset$ and such that $T \cup \rho(T)$ is a basis for $V$.
(ii) We have $\rho \circ \rho = \text{id}_V$.

Let $\varphi: V \to V$ be a homomorphism. If $\varphi$ commutes with $\rho$, then $\text{tr}(\varphi: V \to V)$ is even.

Proof. We equip $V$ with the basis $T \cup \rho(T)$. It follows immediately from (ii) that

$$
\text{matrix representing } \rho \text{ with respect to the basis } T \cup \rho(T) = 
\begin{pmatrix}
T & \rho(T) \\
\rho(T) & 0 & \text{id} & 0
\end{pmatrix}.
$$

Now let $\varphi: V \to V$ be a homomorphism that commutes with $\rho$. We write

$$
\text{matrix representing } \varphi \text{ with respect to the basis } T \cup \rho(T) =: 
\begin{pmatrix}
T & \rho(T) \\
\rho(T) & A & B \\
C & D
\end{pmatrix}.
$$

Since $\varphi$ commutes with $g$ we see that

$$
\begin{pmatrix}
A & B \\
C & D
\end{pmatrix} \cdot 
\begin{pmatrix}
0 & \text{id} \\
\text{id} & 0
\end{pmatrix} =
\begin{pmatrix}
0 & \text{id} \\
\text{id} & 0
\end{pmatrix} \cdot 
\begin{pmatrix}
A & B \\
C & D
\end{pmatrix}.
$$

Multiplying out both sides we see in particular that $A = D$. But this implies evidently that the trace of the above matrix representing $\varphi$ is even. Thus we have shown that $\text{tr}(\varphi)$ is even.

Now we can provide the proof of Proposition 65.19.

Proof of Proposition 65.19. Let $f: S^n \to S^n$ be a map which has the property that $f(-x) = -f(x)$ for all $x \in S^n$. We denote by $\rho: S^n \to S^n$ the map that is given by $\rho(x) = -x$. Note that our hypothesis on $f$ is equivalent to the statement that $f$ commutes with $\rho$. We need to show that $\Lambda(f)$ is even. Similar to the proof of the Lefschetz Fixed Point Theorem 65.9 on page 1627 we intend to proceed as follows:

We want to upgrade the hypothesis that $f \circ \rho = \rho \circ f$ to a statement about an induced map on a suitable simplicial chain complex $C_*$ such that we can conclude from Lemma 65.20 and the Hopf Trace Formula 65.12(2) that $\Lambda(f)$ is even.

To carry out this program we equip $S^n$ with the simplicial structure given by the homeomorphisms

$$
S^n \xleftarrow{\cong} S^0 \ast \cdots \ast S^0 \xrightarrow{\downarrow} \left| S_0 \right| \ast \cdots \ast \left| S_0 \right| \xrightarrow{\cong} \left| S_0 \ast \cdots \ast S_0 \right|.
$$

homeomorphism given by Lemma 61.19(1) homeomorphism given by Lemma 61.20

We introduce the following notation:

(1) We write $K := S_0 \ast \cdots \ast S_0$ and we denote by $\Psi: |K| \to S^n$ the above homeomorphism.
(2) Given any $k \in \mathbb{N}_0$ we denote by $\mathcal{U}: |sd^k(K)| \to K$ the natural homeomorphism given by Lemma 62.3 (3).

(3) By a slight abuse of notation we denote by $\rho: K \to K$ the map that is induced by the reflection on the simplices of all the copies of $S_0$.

(4) Note that by Lemma 62.3 (5) the simplicial map $\rho: K \to K$ induces a simplicial map $sd^k(K) \to sd^k(K)$ which we also denote by $\rho$.

Claim 1. There exists a $k \in \mathbb{N}_0$ and a simplicial map $\varphi: sd^k(K) \to K$ with the following properties:

1. the map $\Psi \circ |\varphi| \circ \mathcal{U}^{-1} \circ \Psi^{-1}: S^n \to S^n$ is homotopic to $f$,
2. the map $\varphi$ commutes with the maps $\rho$, more precisely, the following diagram commutes

$$
\begin{array}{ccc}
|sd^k(K)| & \xrightarrow{\varphi} & K \\
\rho \downarrow & & \downarrow \rho \\
|sd^k(K)| & \xrightarrow{\varphi} & K
\end{array}
$$

As we will see, the proof of Claim 1 follows from a careful reading of the proof of the Simplicial Approximation Theorem 62.8.

(a) First note that Claim 1 of the proof of the Simplicial Approximation Theorem 62.8 shows that there exists a $k \in \mathbb{N}_0$ such that for every vertex $v$ of $sd^k(K)$ there exists a vertex $w$ of $K$ with $f((\Psi \circ \mathcal{U})(St(|sd^k(K)|, v))) \subset \Psi(\mathcal{S}t(|K|, w))$. We denote by $V$ the vertex set of $sd^k(K)$ and we denote by $W$ the vertex set of $K$. By the above there exists a map $\varphi: V \to W$ with the following property:

(*) For every vertex $v \in V$ we have $f((\Psi \circ \mathcal{U})(St(|sd^k(K)|, v))) \subset \Psi(\mathcal{S}t(|K|, \varphi(v)))$.

(b) In the proof of the Simplicial Approximation Theorem 62.8 we have shown that every map $\varphi: V \to W$ that satisfies (*) is a simplicial map and that it has the property that $\Psi \circ |\varphi| \circ \mathcal{U}^{-1} \circ \Psi^{-1}$ is homotopic to $f$.

(c) It follows immediately from the definition of $\Psi$ and the naturality of $\mathcal{U}$ that the following two diagrams commute:

$$
\begin{array}{ccc}
|K| & \xrightarrow{\rho} & |K| \\
\psi \downarrow & & \downarrow \psi \\
S^n & \xrightarrow{\rho} & S^n
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
|sd^k(K)| & \xrightarrow{\rho} & |sd^k(K)| \\
\psi \downarrow & & \downarrow \psi \\
|K| & \xrightarrow{\rho} & |K|
\end{array}
$$
(d) Since all maps called \( \rho \) satisfy the condition that \( \rho \circ \rho = \text{id} \) we obtain easily from (a) and (c) that we can pick a map \( \varphi : V \to W \) which satisfies (*) and such that \( \varphi \circ \rho = \rho \circ \varphi \).

(e) By (b) we know that \( \varphi \) satisfies (1). Furthermore, by (d) we know that the simplicial map \( \varphi \) also satisfies (2).

Before we move on to the next claim we introduce and recall some notation:

1. Now we write \( g := \Psi \circ |\varphi| \circ \delta^{-1} \circ \Psi^{-1} \).
2. We denote by \( u_* : C^\text{simp}(|K|) \to C^\text{simp}(|sd^k(K)|) \) the \( k \)-fold iterated singular subdivision map that we introduced in Lemma 63.41.

**Claim 2.** For every \( j \in \mathbb{N}_0 \) there exists an isomorphism \( \mu : H^\text{simp}_j(|sd^k(K)|) \to H_j(S^n) \) such that the following diagram commutes:

\[
\begin{align*}
H^\text{simp}_j(|sd^k(K)|) & \xrightarrow{\varphi_*} H^\text{simp}_j(|K|) & \xrightarrow{\psi_*} H^\text{simp}_j(|sd^k(K)|) \\
\downarrow & \quad \downarrow & \quad \downarrow \\
H_j(S^n) & \xrightarrow{\Theta_{sd^k(K)}} H_j(|K|) & \xrightarrow{\Theta_{sd^k(K)}} H_j(S^n).
\end{align*}
\]

For the proof of Claim 2 we consider the following much more elaborate diagram:

\[
\begin{align*}
H^\text{simp}_j(|sd^k(K)|) & \xrightarrow{\varphi_*} H^\text{simp}_j(|K|) & \xrightarrow{\psi_*} H^\text{simp}_j(|sd^k(K)|) \\
\downarrow & \quad \downarrow & \quad \downarrow \\
H_j(|K|) & \xrightarrow{\Theta_{sd^k(K)}} H_j(|sd^k(K)|) & \xrightarrow{\Theta_{sd^k(K)}} H_j(S^n). \\
\end{align*}
\]

We make the following observations and clarifications:

1. The maps \( \Theta \) are the natural isomorphisms introduced on page 1565.
2. We denote by \( u_* : C_*([K]) \to C_*([|K|]) \) the \( k \)-fold iterated singular subdivision map that we introduced on page 1135.
3. It follows from Proposition 63.45 applied iteratively \( k \) times, that the rectangle to the top right commutes.
4. The quadrilateral at the bottom commutes by definition.
5. The triangle at the bottom right commutes by Lemma 43.28.
6. The square to the top left commutes by the naturality of \( \Theta \).

It follows from the above that the isomorphism \( \mu := \psi_* \circ \Theta_{sd^k(K)} \) has the desired property.
To shorten the notation a little bit we now write $L := \text{sd}^k(K)$. We calculate that

$$\Lambda(f) = \Lambda(g) = \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \text{tr} \left( g_* \otimes H_i(S^n) \right) = \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \text{tr} \left( (u_j \circ \varphi_*) \otimes C_i^{\text{simp}}(L) \right).$$

by Lemma 65.7 and Claim 1 (1)

$$\Lambda(f) = \sum_{j \in \mathbb{N}_0} (-1)^j \cdot \text{tr} \left( (u_j \circ \varphi_*) \otimes C_i^{\text{simp}}(L) \right).$$

by Claim 2

At this point we see that it suffices to prove the following claim.

Claim 3. For each $j \in \mathbb{N}_0$ the trace $\text{tr} \left( (u_j \circ \varphi_*) \otimes C_j^{\text{simp}}(L) \right)$ is even.

Evidently the plan is to apply Lemma 65.20. We make a few more preparations:

1. We consider the following diagram:

$$
\begin{array}{cccc}
C_j^{\text{simp}}(L) & \xrightarrow{g_*} & C_j^{\text{simp}}(K) & \xrightarrow{u_j} & C_j^{\text{simp}}(L) \\
\downarrow{\rho_*} & & \downarrow{\rho_*} & & \downarrow{\rho_*} \\
C_j^{\text{simp}}(L) & \xrightarrow{g_*} & C_j^{\text{simp}}(K) & \xrightarrow{u_j} & C_j^{\text{simp}}(L).
\end{array}
$$

It follows from Claim 1 (2) that the square to the left commutes. It follows from the naturality of the simplicial subdivision maps that the square to the right commutes.

2. Note that it follows immediately from the definition of the map $\rho: K \to K$ that $\rho: K \to K$ does not fix a single simplex of $K$ and that $\rho \circ \rho = \text{id}_K$. Since the map $K \to L = \text{sd}^k(K) = L$ is functorial we see that $\rho: L \to L$ has the same properties, i.e. $\rho: L \to L$ does not fix a single simplex of $L$ and it satisfies $\rho \circ \rho = \text{id}_L$.

3. We denote by $S_j$ the set of $j$-simplices of $L$. It follows immediately from (2) that there exists a subset $T_j$ of $S_j$ with the following properties:

(i) $T_j \cap \rho(T_j) = \emptyset$ and (ii) $T_j \cup \rho(T_j) = S_j$.

We equip each $t \in T_j$ with some order and we use these orders to view $T_j$ as a subset of $C_j^{\text{simp}}(L)$. It follows from (ii) and Lemma 63.5 that $T_j \cup \rho(T_j)$ is a basis of $C_j^{\text{simp}}(L)$.

Now we apply Lemma 65.20 to $V = C_j^{\text{simp}}(L)$, $T = T_j$, $\rho = \rho_*$ and $\varphi = \varphi$. It follows from (1), (2) and (3) that all the hypotheses of Lemma 65.20 are satisfied. Thus we obtain that the trace of $u_j \circ \varphi_*$ is indeed even.

The argument for deducing the Borsuk-Ulam Theorem from Proposition 65.19 is almost identical to the argument on page 1451 for deducing the Borsuk-Ulam Theorem from Proposition 59.4.

**Proof of the Borsuk-Ulam Theorem**. Let $g: S^n \to \mathbb{R}^n$ be a map. Suppose there exists no pair of antipodal points $x$ and $-x$ in $S^n$ with $g(x) = g(-x)$. Put differently, suppose that for any $x \in S^n$ we have $g(x) \neq g(-x)$. We consider the composition of the
following two maps
\[
\Phi : S^{n-1} \times [0,1] \rightarrow S^n_{\geq 0} \rightarrow S^{n-1}.
\]
\[
(y, t) \mapsto (y \cdot \sqrt{1-t^2}, t) \mapsto \frac{g(x)-g(\cdot x)}{\|g(x)-g(\cdot x)\|}
\]
defined since \(g(x) \neq g(\cdot x)\)

Now we see that
by definition we have \(\Phi(-x,0) = -\Phi(x,0)\), thus it follows from Proposition 65.19 that \(\Lambda(\Phi_0)\) is even
\[
\text{even number} \overset{\downarrow}{\Lambda(\Phi_0)} = \Lambda(\Phi_1) = \Lambda(\text{constant map}) = 1.
\]
by Lemma 65.7 since \(\Phi_0\) and \(\Phi_1\) are homotopic by definition of \(\Phi_1\) Lemma 65.6(3)
We have thus obtained a contradiction.

Exercises for Chapter 65

Exercise 65.1. Let \(X\) be a finite simplicial complex, let \(\varphi : X \rightarrow X\) be a map and let \(\mathbb{F}\) be a field. We denote by \(\gamma : \mathbb{Z} \rightarrow \mathbb{F}\) the ring homomorphism that is given by \(\gamma(n) = n \cdot 1_{\mathbb{F}}\). Show that
\[
\Lambda(X, \mathbb{F}) = \gamma(\Lambda(X))
\]
Hint. Use Exercise 57.3.

Exercise 65.2. Let \(n \in \mathbb{N}\). Show that there exists a compact smooth manifold \(M\) and a map \(\varphi : M \rightarrow M\) with Lefschetz number \(\Lambda(\varphi) = n\) such that \(\varphi\) has precisely one fixed point.

Exercise 65.3. Let \(n \in \mathbb{N}\). Does the real projective space \(\mathbb{RP}^{2n+1}\) admit a self-map without fixed points?

Exercise 65.4. We consider the torus \(T := S^1 \times S^1\) embedded in \(\mathbb{R}^3\) as shown in Figure 1004. Let \(f : T \rightarrow T\) be the map that is given by reflection in the \(xy\)-plane. Is \(f\) homotopic to a map without fixed points?

![Figure 1004. Illustration for Exercise 65.4](image)

Exercise 65.5. We consider the topological space \(X = A \cup B \cup C\) that is shown in Figure 1005. Here \(A\) is a circle of radius 3, \(C\) is a circle of radius 1 around the origin and \(B\) is the image of an embedding \(\mathbb{R} \rightarrow \mathbb{R}^2\) which spirals towards \(A\) and \(C\).

(a) Give a rigorous description of \(X\).
(b) Show that \(X\) is compact.
(c) Compute the homology groups of \(X\).

Fix some “angle” \(\gamma \in (0, \pi)\). Let \(f : X \to X\) be the map that is given by rotation by the angle \(\gamma\) on \(A\) and \(C\) and which is given by sending a point \(s \cdot e^{i\phi}\) on \(B\) to the “next” point on \(B\) of the form \(t \cdot e^{i(\phi + \gamma)}\) with \(s > t\).

(d) Show that \(f\) is continuous.

(e) Show that \(f\) has no fixed points.

(f) Show that the Lefschetz number \(\Lambda(f) \neq 0\).

This long but fun exercise shows that in the formulation of the Lefschetz Fixed Point Theorems it does not suffice to work with compact topological spaces that are say \(\mathbb{Q}\)-homology finite. We need the topological space to be “sufficiently nice”.

**Exercise 65.6.** We consider the topological space \(X = A \cup B\) that is shown in Figure 1006.

Let \(\varphi : X \to X\) be the map that is given by \(z \mapsto z^2\) on \(A\) and that is given by reflection along the \(x\)-axis on \(B\).

(a) Show that the Lefschetz number \(\Lambda(\varphi, \mathbb{F}) = 0\) for every field \(\mathbb{F}\).

(b) Show that any map \(\psi\) that is homotopic to \(\varphi\) actually has a fixed point.

*Remark.* It is easy to see that \(X\) admits a simplicial structure. Thus the exercise shows that the converse to the Lefschetz Fixed Point Theorem 65.9 does not hold.

**Exercise 65.7.**

1. Let \(A \in \text{GL}(n, \mathbb{C})\) be a matrix. We denote by \(\varphi_A : \mathbb{CP}^{n-1} \to \mathbb{CP}^{n-1}\) the induced map given by \(\varphi_A([P]) := [A \cdot P]\).

(a) Show that the Lefschetz number \(\Lambda(\varphi_A) = n\).

*Hint.* Use Lemma 2.65 (4). The super conscientious reader might also want to consult the discussion on page 558 to show that a certain map is indeed continuous.
(b) Use (a) to show that $A$ has an eigenvalue.

(2) What does the approach in (1) say about the existence of real eigenvalues of real matrices?

**Exercise 65.8.** Let $n \in \mathbb{N}_0$ be even.

(a) Show that the complex projective space $\mathbb{C}P^n$ admits a self-map without fixed points. 

Remark. In Exercise 90.9 we will prove the much more interesting converse, namely we will show that for every odd $n$ every self-map of $\mathbb{C}P^n$ has a fixed point.

(b) Does there exist a nowhere vanishing vector field on $\mathbb{C}P^n$?

**Exercise 65.9.** For which $n \in \mathbb{N}$ does the real projective space $\mathbb{R}P^n$ admit a nowhere vanishing vector field?

**Exercise 65.10.** Does the Klein bottle $K$ admit two vector fields $v$ and $w$ such that at every point $P \in K$ the two vectors $v(P), w(P) \in T_P K$ are linearly independent?

**Exercise 65.11.** In Figure 1000 we saw that the surface $\Sigma$ of genus 2 supports a vector field with two zeros. What does such a vector field look like if we consider $\Sigma$ as a submanifold of $\mathbb{R}^3$ in the usual way?

**Exercise 65.12.** Does the surface of genus 2 admit a vector field with a single zero?

**Exercise 65.13.** Let $m \in \mathbb{Z}$ be even.

(a) Show that there exists a map $f : S^1 \to S^1$ with Lefschetz number $\Lambda(f) = m$ and such that for every $x \in S^1$ we have $f(-x) = -f(x)$.

(b) Now prove (a) for higher-dimensional spheres.

**Exercise 65.14.** Let $X$ be a finite CW-complex and let $\varphi : X \to X$ be a self-map. Furthermore let $p : \tilde{X} \to X$ be a finite covering. By Lemma 29.11 we know that there exists a map $\tilde{\varphi} : \tilde{X} \to \tilde{X}$ such that the following diagram commutes:

$$
\begin{array}{ccc}
\tilde{X} & \xrightarrow{j} & \tilde{X} \\
\downarrow p & & \downarrow p \\
X & \xrightarrow{f} & X
\end{array}
$$

Show that

$$
\Lambda(\tilde{\varphi} : \tilde{X} \to \tilde{X}) = [\tilde{X} : X] \cdot \Lambda(\varphi : X \to X).
$$

Hint. Use cellular homology and use the Hopf Trace Formula, i.e. use Theorem 65.12.

**Exercise 65.15.** Let $M$ be a compact topological manifold. Suppose we are given two compact codimension-zero submanifolds $A$ and $B$ such that $A \cap B = \partial A = \partial B$. Furthermore let $f : M \to M$ be a map that restricts to self-maps of $A$ and $B$. Show that

$$
\Lambda(f : M \to M) = \Lambda(f : A \to A) + \Lambda(f : B \to B) - \Lambda(f : A \cap B \to A \cap B).
$$

Hint. Use the Mayer–Vietoris Theorem for Manifolds and use the Hopf Trace Formula, i.e. use Theorem 65.12.

Remark. In Proposition 85.13 we will see that the homology groups of $A$, $B$ and $M$ are finitely generated and that there exists an $n$ such that they vanish in dimension $> n$. 

Exercise 65.16. Let $M$ be a smooth manifold and let $v$ be a vector field on $M$. Show that the zero set $\{x \in M \mid v(x) = 0\}$ is a closed subset of $M$.

Hint. Use Lemma 2.6 (2b).

Exercise 65.17. A Lie group is a smooth manifold $X$ with empty boundary together with a group structure such that the two maps

$$
X \times X \rightarrow X \quad \text{and} \quad X \rightarrow X
$$

$$(x, y) \mapsto x \cdot y \quad \text{and} \quad x \mapsto x^{-1}
$$

are smooth. For example it is not difficult to show that the matrix groups $\text{SO}(n)$ and $\text{U}(n)$ and $\text{SU}(n)$ with the usual multiplication are Lie groups. Show that the Euler characteristic of any closed Lie group of dimension $\geq 1$ is zero.
66. HOMOLOGY GROUPS OF PSEUDOMANIFOLDS AND SMOOTH MANIFOLDS

Let $M$ be an $n$-dimensional smooth manifold. By Theorem 64.2, we know that $M$ admits a smooth simplicial structure. In Proposition 64.6, we used this fact to show that for every $k > n$ we have $H_k(M) = 0$. In this chapter, we will squeeze more information out of the existence of a simplicial structure. In particular, this will allow us to calculate $H_n(M; \mathbb{Z})$ and it will allow us to make some statements regarding $H_{n-1}(M; \mathbb{Z})$.

66.1. The top-dimensional homology group of a pseudomanifold. In this chapter, we will see that any simplicial structure of an $n$-dimensional topological manifold has several special properties. This will lead us to the notion of an $n$-dimensional pseudomanifold, which can be viewed as a simplicial analogue of a manifold. We will then prove several statements regarding the simplicial homology groups of an $n$-dimensional pseudomanifold. In the subsequent section, we will then use the calculations from this chapter to prove the promised results on homology groups of smooth manifolds.

First, we recall and introduce some definitions.

**Definition.** Let $K = (V, S)$ be an abstract simplicial complex.

1. Let $t$ be a simplex of $K$. As on page 1481, we define a face of $t$ to be a simplex $s$ with $s \subseteq t$. In this setting, we also say that $t$ cobounds $s$.
2. Let $s \in S$ be a $k$-simplex of $K$. We say $s$ has order $r$, if there exist precisely $r$ simplices of dimension $k + 1$ which contain $s$ as a face.

As before, we sometimes use the same terms when we talk about topological realizations and simplicial complexes.

![Figure 1007](image.png)

**Proposition 66.1.** Let $M$ be an $n$-dimensional topological manifold that is equipped with a simplicial structure.

1. There is no simplex of dimension $> n$ and every simplex is the face of an $n$-simplex.
2. The simplicial structure has finitely many simplices if and only if it has finitely many $n$-simplices.
3. The simplicial structure on $M$ restricts to a simplicial structure on the $(n - 1)$-dimensional topological manifold $\partial M$. If $M$ is a smooth manifold and if we are given a smooth simplicial structure, then the restriction of the simplicial structure to the smooth manifold $\partial M$ is also a smooth simplicial structure.
Let $s$ be an $(n-1)$-simplex of $M$. Then
\[
\text{order of } s = \begin{cases} 
1, & \text{if } s \text{ lies on the boundary,} \\
2, & \text{otherwise.}
\end{cases}
\]

If $M$ is connected, then given any two $n$-simplices $t$ and $t'$ there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of $n$-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face.

Remark.

1. In Lemma 64.1 we gave a different proof why the maximal dimension of a simplex of a smooth simplicial structure of an $n$-dimensional smooth manifold equals $n$.
2. A rather different proof of Proposition 66.1 (5) is given in [Mun84] Corollary 65.2.

The key idea behind the proof of Proposition 66.1 is to squeeze the maximal amount of information out of the local homology groups. To do so we first recall the following definition from page 1151.

**Definition.** Given a topological space $X$ and given a point $P \in X$ the relative homology group $H_j(X, X \setminus \{P\})$ is called the $n$-th local homology group of $X$ at the point $P$.

We recall the calculation of the local homology groups of a topological manifold.

**Lemma 44.1** Let $M$ be an $n$-dimensional topological manifold and let $P \in M$. For every $j \in \mathbb{N}_0$ we have
\[
H_j(M, M \setminus \{P\}) \cong \begin{cases} 
\mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and } j = n, \\
0, & \text{otherwise.}
\end{cases}
\]

**Proof.** Since in a minute we will calculate a different local homology group it is perhaps helpful to remind us of the proof of the lemma. For simplicity we only consider the case that $P \in M \setminus \partial M$. In this case we can pick a chart $\Phi: U \to B^n$ for $P$ with $\Phi(P) = 0$. We then have
\[
H_j(M, M \setminus \{P\}) \leftarrow H_j(U, U \setminus \{P\}) \xrightarrow{\Phi_*} H_j(B^n, B^n \setminus \{0\}) \xrightarrow{\partial} \widetilde{H}_{j-1}(B^n \setminus \{0\}) \leftarrow \widetilde{H}_{j-1}(S^{n-1}).
\]

Excision Theorem 43.20 isomorphism by the long exact sequence in reduced homology of the pair $(B^n, B^n \setminus \{0\})$ and the fact that $H_*(B^n) = 0$ by page 1106 isomorphism since $S^{n-1}$ is homotopy equivalent to $B^n \setminus \{0\}$. 

Figure 1008. Illustration of Proposition 66.1.
The statement now follows from the calculation of the reduced homology groups of spheres given in Proposition 43.4.

The next proposition calculates the local homology groups of a simplicial complex. This calculation is also interesting in its own right.

Proposition 66.2. Let $K = (V, S)$ be an abstract simplicial complex and let $P \in |K|$. By Lemma 61.11 there exists a unique simplex $s \in S$ such that $P$ is a point in the open simplex $\langle s \rangle$. We set $m := \dim(s)$. If $\operatorname{Lk}(K, s)$ is a finite simplicial complex, then for every $j \in \mathbb{N}_0$ we have

$$H_j(|K|, |K| \setminus \{P\}) \cong \tilde{H}_{j-1-m}(\operatorname{Lk}(K, s)).$$

Proof. We perform the following calculation:

by the long exact sequence in reduced homology of the pair $(\operatorname{St}(s), \operatorname{St}(s) \setminus \{P\})$ and the observation, see Lemma 62.5 (1f), that $\operatorname{St}(s)$ is contractible, which implies that its reduced homology vanishes

$$H_j(|K|, |K| \setminus \{P\}) \xrightarrow{\cong} H_j(\operatorname{St}(s), \operatorname{St}(s) \setminus \{P\}) \xrightarrow{\delta} \tilde{H}_{j-1}(\operatorname{St}(s) \setminus \{P\}) \cong \tilde{H}_{j-1}(\partial s \ast \operatorname{Lk}(s))$$

by Lemma 62.5 (1d) we know that $\operatorname{St}(s)$ is a neighborhood, by Lemma 62.5 (1g) together with Corollary 42.8 we can apply the Excision Theorem 43.20 (2)

$$\cong \tilde{H}_{j-1}(S^{m-1} \ast \operatorname{Lk}(s)) \cong \tilde{H}_{j-1-m}(\operatorname{Lk}(s)).$$

since $s$ is an $m$-simplex we know by Lemma 61.3 and Lemma 41.1 (3) that $\partial s$ is homeomorphic to $S^{m-1}$, by Corollary 45.8 we have $\tilde{H}_{l+m}(S^{m-1} \ast X) \cong \tilde{H}_l(X)$ whenever $X$ is compact and Hausdorff, we can apply this result since $\operatorname{Lk}(s)$ is by hypothesis finite.

\[\text{Figure 1009. Illustration for the proof of Proposition 66.2}\]

Now we can finally provide the proof of Proposition 66.1

Proof of Proposition 66.1. Basically by definition of a simplicial structure it suffices to consider the case that the $n$-dimensional topological manifold $M$ is the topological realization $M = |K|$ of some abstract simplicial complex $K = (V, S)$. Note that by Lemma 62.6 we know that the topological manifold $M = |K|$ is regionally compact. Thus it follows from Proposition 62.9 that the abstract simplicial complex $K$ is locally finite and that the link of any vertex is a finite simplicial complex. This implies in particular that we can apply Proposition 66.2 without worries.

(1) It suffices to prove the following claim.

Claim. Given any simplex $s$, the maximal dimension of a simplex that contains $s$ is precisely given by $n$.

\[\text{\textsuperscript{1005}It can happen that } \operatorname{Lk}(K, s) = \emptyset. \text{ Recall that by definition we have } \tilde{H}_{-1}(\emptyset) \cong \mathbb{Z}. \]
\[\text{\textsuperscript{1006}I do not know whether the statement holds in general without the condition that } \operatorname{Lk}(K, s) \text{ is finite.}\]
Let $s$ be a simplex of $K$. As we mentioned in the beginning of the proof, we know that $K$ is locally finite. This implies that there exists a simplex $t$ of maximal dimension that contains $s$. We set $m := \dim(t)$. Now let $P \in (t)$ be a point. We calculate that

\[
\begin{align*}
\text{Proposition 66.2 applied to the } m\text{-simplex } t & \quad \text{Lemma 44.1 applied to } |K| = M \\
\downarrow & \quad \downarrow \\
\mathbb{Z} \cong \tilde{H}_{-1}(\text{Lk}(K, t)) & \cong H_m(|K|, |K| \setminus \{P\}) \cong \left\{ \begin{array}{ll}
\mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and } m=n, \\
0, & \text{otherwise.}
\end{array} \right.
\end{align*}
\]

since there are no simplices of dimension $> m$ which contain $t$ we see that $\text{Lk}(K, t) = \emptyset$.

Comparing the left-hand side with the right-hand side shows that $m = n$. $\square$

(2) This statement is an almost immediate consequence of (1). Indeed, we only have to show that if $K$ has finitely many $n$-simplices, then it has only finitely many simplices. But every $n$-simplex has only finitely many faces and by (1) we see that every simplex of $K$ is the face of an $n$-simplex. Thus we are done.

(3) First note that if we are given a smooth simplicial structure on a smooth manifold that restricts to a simplicial structure on $\partial M$, then it follows easily from the definitions that this simplicial structure on $\partial M$ is actually a smooth simplicial structure. Thus, to prove (3), it remains to show that the simplicial structure on $|K| = M$ restricts to a simplicial structure on the topological manifold $\partial M$.

If $M$ is a smooth manifold, then we know by Proposition 6.27(3a) that $\partial M$ is a closed subset of $M$. In the general case that $M$ is a topological manifold the same statement follows from Proposition 44.2.

Now that we know that $\partial M$ is a closed subset of $M$ we obtain the desired statement from Lemma 61.13 together with the following claim.

**Claim.** Let $s$ be an $m$-simplex of $K$. Either $\langle s \rangle \cap \partial M = \emptyset$ or $\langle s \rangle \subset \partial M$.

Let $s$ be a simplex. For any point $P \in \langle s \rangle$ we perform almost the same calculation as in (1):

\[
\begin{align*}
\text{Proposition 66.2 applied to the } m\text{-simplex } s & \quad \text{Lemma 44.1 applied to } |K| = M \\
\downarrow & \quad \downarrow \\
\tilde{H}_{n-1-m}(\text{Lk}(K, s)) & \cong H_n(|K|, |K| \setminus \{P\}) \cong \left\{ \begin{array}{ll}
\mathbb{Z}, & \text{if } P \in M \setminus \partial M, \\
0, & \text{otherwise.}
\end{array} \right.
\end{align*}
\]

It follows from this calculation that $\langle s \rangle \cap \partial M = \emptyset$ if $\tilde{H}_{n-1-m}(\text{Lk}(K, s)) \cong \mathbb{Z}$ and that $\langle s \rangle \subset \partial M$ if $\tilde{H}_{n-1-m}(\text{Lk}(K, s)) = 0$. $\square$

(4) Let $s$ be an $(n-1)$-simplex of $M$. We denote by $r$ the order of $s$. We pick a point $P \in \langle s \rangle$. Similar to (1) we calculate that

\[
\begin{align*}
\text{Proposition 66.2 applied to the } (n-1)\text{-simplex } s & \quad \text{Lemma 44.1 applied to } |K| = M \\
\downarrow & \quad \downarrow \\
\mathbb{Z}^{r-1} \cong \tilde{H}_0(\text{Lk}(K, s)) & \cong H_n(|K|, |K| \setminus \{P\}) \cong \left\{ \begin{array}{ll}
\mathbb{Z}, & \text{if } P \in M \setminus \partial M, \\
0, & \text{otherwise.}
\end{array} \right.
\end{align*}
\]

since $s$ is an $(n-1)$-simplex and since there are no simplices of dimension $> n$ we see that $\text{Lk}(K, s)$ consists of $r$ points, the isomorphism now follows from Lemma 43.1(5).
Comparing the left-hand side with the right-hand side gives us the desired statement. (5) Now we assume that \( M \) is in fact connected. We say that two \( n \)-simplices \( t \) and \( t' \) of \( K \) are **equivalent** if there exists a sequence \( t = s_0, s_1, \ldots, s_k = t' \) of \( n \)-simplices such that any two consecutive simplices have a common \((n-1)\)-dimensional face. Recall that our task is to show that any two \( n \)-simplices are equivalent in the above sense.

The key to doing so is the following claim:

**Claim.** Let \( t \) and \( t' \) be two \( n \)-simplices. If \( t \cap t' \neq \emptyset \), then \( t \) and \( t' \) are actually equivalent in the above sense.

Given \( m \in \{0, \ldots, n-1\} \) we say that two \( n \)-simplices \( x \) and \( x' \) are \( m \)-**equivalent** if there exists a sequence \( x = s_0, s_1, \ldots, s_k = x' \) of \( n \)-simplices such that any two consecutive simplices have a common face of dimension \( \geq m \). It suffices to show that if we are given \( m \in \{0, \ldots, n-2\} \) such that any two \( n \)-simplices in \( K \) are \( m \)-equivalent, then any two \( n \)-simplices in \( K \) are also \((m+1)\)-equivalent. In fact evidently it suffices to show that if we are given two \( n \)-simplices \( x \) and \( x' \) which have an \( m \)-simplex \( s \) in common, then \( x \) and \( x' \) are \((m+1)\)-equivalent. To do so we first note that since \( \dim(x) > \dim(s) \) we can pick a vertex \( w \) of \( x \cap \text{Lk}(K, s) \) and similarly we can pick a vertex \( w' \) of \( x' \cap \text{Lk}(K, s) \).

Now we want to show that \( \text{Lk}(K, s) \) is connected. To do so we pick a point \( P \in \langle s \rangle \) and we perform basically the same calculation as in the previous arguments:

\[
\tilde{H}_0(\text{Lk}(K, s)) \cong \tilde{H}_{m+1}(|K|, |K| \setminus \{P\}) = \tilde{H}_{m+1}(M, M \setminus \{P\}) = 0.
\]

Proposition \[66.2\] applied to the \( m \)-simplex \( s \) and \( j = m+1 \) by Lemma \[4.1\] since \( m \leq n-2 \)

It follows from this calculation together with Lemma \[43.1\] and Exercise \[61.11\] that the abstract simplicial complex \( \text{Lk}(K, s) \) is in fact connected in the sense of the definition on page \[1516\]. This means in our setting that there exist \( 1 \)-simplices \( e_1, \ldots, e_k \in S \) of \( \text{Lk}(K, s) \) such that the following holds:

(*) We have \( w \in e_1 \), for every \( i \in \{1, \ldots, k-1\} \) we have \( e_i \cap e_{i+1} \neq \emptyset \) and we have \( w' \in e_k \).

Let \( i \in \{1, \ldots, k\} \). Since \( e_i \) is a simplex in \( \text{Lk}(K, s) \) there exists a simplex \( f_i \) of \( K \) with \( e_i \cup s \subset f_i \). By (1) we can in fact find an \( n \)-simplex \( \tilde{f}_i \) of \( K \) with \( e_i \cup s \subset f_i \subset \tilde{f}_i \). We set \( f_0 := x \) and \( f_{k+1} := x' \). Note that it follows from (*) that any two consecutive \( \tilde{f}_i \) and \( \tilde{f}_{i+1} \) have \( s \) and a vertex of \( \text{Lk}(K, s) \) in common, i.e. they have an \((m+1)\)-simplex in common. This shows that \( x \) and \( x' \) are in fact \((m+1)\)-connected.  

**Figure 1010.** Illustration for the proof of Proposition \[66.1\] (5).
We pick an equivalence class of $n$-simplices of $K$ and we denote by $J$ the subcomplex of $K$ given by the union of the $n$-simplices in said equivalence class. Since $J$ is a subcomplex we know by Lemma 61.8 that $|J|$ is a closed subset of $|K| = M$. Furthermore it follows from the claim together with Exercise 61.10 that $|J|$ is also an open subset of $|K| = M$. By hypothesis $|K| = M$ is connected. Thus we see that $K = J$, which implies that any two $n$-simplices in $K$ are in fact equivalent. ■

Our main goal is to say something meaningful about homology groups of smooth manifolds. The idea is to use Proposition 66.1 and the fact that we can calculate singular homology groups via simplicial homology groups. Since we will only use the information given by Proposition 66.1 it is convenient to introduce the following definition.

**Definition.** Let $n \in \mathbb{N}_0$. An $n$-dimensional pseudomanifold is a non-empty abstract simplicial complex $K$ such the following conditions are satisfied:

1. Every simplex of $K$ is a face of an $n$-simplex of $K$.
2. Every $(n-1)$-simplex has order one or two.
3. Given any two $n$-simplices $t$ and $t'$ there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of $n$-simplices such that any two consecutive simplices have a common $(n-1)$-dimensional face.

Given a pseudomanifold $K$ we define $\partial K$ to be the subcomplex that is given by the union of all $(n-1)$-simplices of order 1. We say a pseudomanifold $K$ is closed if $\partial K = \emptyset$ and if $K$ is finite.

**Examples.**

1. In Figure 1011 we illustrate the definition of a 2-dimensional pseudomanifold.

2. In Figure 1012 we show an abstract simplicial complex that satisfies (1) and (2) but that does not satisfy (3). This example shows that Condition (3) is stronger than requiring ordinary connectedness.

**Remark.**

---

Note that this condition implies that $K$ is necessarily $n$-dimensional.
(1) The definition of a pseudomanifold we give seems to be the one which is most frequently used, it goes back to work of Luitzen Brouwer [Brou76] in 1912.

(2) Proposition 66.1 says that if we are given a simplicial structure \((K, \Theta: |K| \to M)\) of a connected non-empty \(n\)-dimensional topological manifold \(M\), then \(K\) is an \(n\)-dimensional pseudomanifold.

(3) In Exercise 66.4 we will show that if \(K\) is an \(n\)-dimensional pseudomanifold with \(n \in \{1, 2\}\), then \(|K|\) is a closed \(n\)-dimensional smooth manifold.

(4) Let \(K\) be a finite \(n\)-dimensional pseudomanifold. As usual we denote by \(\Sigma(K)\) the suspension as defined on page 1506. As we will see in Exercise 66.1, it follows very easily from the definitions that \(\Sigma(K)\) is an \((n+1)\)-dimensional pseudomanifold with \(\partial \Sigma(K) = \Sigma(\partial K)\).

Now assume that the fundamental group \(\pi_1(|K|)\) of the topological realization \(|K|\) is non-trivial. It follows from Corollary 61.21 together with Lemma 64.18 that the topological realization \(|\Sigma(K)|\) of the suspension \(\Sigma(K)\) is not a topological manifold. This shows that for \(n \geq 3\) not all \(n\)-dimensional pseudomanifolds arise from topological manifolds.

(5) In the literature there exist several, not always entirely equivalent, notions of a pseudomanifold. In general, as we just saw in (3), the topological realizations of pseudomanifolds are not topological manifolds. But many tools and results on topological manifolds can be generalized to the context of (topological realization of) pseudomanifolds, see e.g. [KiW06, Chapter 4]. Also note that in the literature an \(n\)-dimensional pseudomanifold is sometimes called an \(n\)-circuit.

Next we recall and expand a definition from page 1544.

**Definition.** Let \(K = (V, S)\) be an abstract simplicial complex.

1. Let \(n \in \mathbb{N}_0\). An ordered \(n\)-simplex of \(K\) is an \((n+1)\)-tuple \((v_0, \ldots, v_n) \in V^{n+1}\) such that \(\{v_0, \ldots, v_n\} \in S\). We write \(\lfloor (v_0, \ldots, v_n) \rfloor := \{v_0, \ldots, v_n\}\).

2. An oriented \(n\)-simplex is a pair \((\epsilon, s)\) where \(\epsilon \in \{\pm 1\}\) and \(s\) is an ordered \(n\)-simplex of \(K\). As in (1) we write \(\lfloor (\epsilon, s) \rfloor := \lfloor s \rfloor\) and we refer to \(\lfloor (\epsilon, s) \rfloor\) as the underlying simplex. Sometimes we also say that \((\epsilon, s)\) is an orientation of the \(n\)-simplex \(s\).

3. We say two oriented \(n\)-simplices \((\mu, s = (v_0, \ldots, v_n))\) and \((\nu, t = (w_0, \ldots, w_n))\) are equivalent if \(\mu = \nu \cdot \text{sign}(\sigma)\) where \(\sigma \in \text{Bij}\{0, \ldots, n\}\) with \(v_i = w_{\sigma(i)}\) for \(i = 0, \ldots, n\).

It follows immediately from Lemma 63.1 that this is indeed an equivalence relation on the set of oriented \(n\)-simplices.

4. An orientation of an \(n\)-simplex \(s\) is an equivalence class of oriented \(n\)-simplices with underlying simplex \(s\).

**Definition.** Let \(K = (V, S)\) be an abstract simplicial complex and let \((\epsilon, t = (v_0, \ldots, v_n))\) be an oriented \(n\)-simplex. Let \(s\) be a codimension-one face of \(t\). If \(v_i\) is the one vertex of \(t\)
Lemma 63.1. We leave it to the reader to fill in the details. This statement follows easily from the properties of the sign of a bijection, see Proof. We leave it to the reader to fill in the details.

Example. In Figure [1013] we show the oriented 2-simplex \((+1, (v_0, v_1, v_2))\) together with the orientations induced on all of the three codimension-one faces.

\[
\begin{align*}
\text{the oriented 2-simplex} & \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad 
In the discussion below, we will often not distinguish in the notation between an ordered simplex and the element it represents in $\tilde{C}_{\Delta}^\text{simp}(K)$. The boundary map is given by
\[
\partial_n : C_n^\text{simp}(K) \to C_{n-1}^\text{simp}(K)
\]
\[
(v_0, \ldots, v_n) \mapsto \sum_{i=0}^n (-1)^i \cdot (v_0, \ldots, v_{i-1}, v_i, v_{i+1}, \ldots, v_n).
\]

Now we can provide the promised theorem.

**Theorem 66.4.** Let $K$ be an $n$-dimensional pseudomanifold. The following statements hold:

1. We have an isomorphism as follows:
\[
H_n^\text{simp}(K) \cong \begin{cases} \mathbb{Z}, & \text{if } K \text{ is closed and orientable,} \\ 0, & \text{otherwise.} \end{cases}
\]

Furthermore, if $K$ is closed and orientable, and if $\{(\epsilon_w, Y_w)\}_{w \in W}$ is an orientation of $K$ (here $W$ denotes the set of $n$-simplices of $K$), then a generator of $H_n^\text{simp}(K) \cong \mathbb{Z}$ is represented by the simplicial cycle $\sum_{w \in W} \epsilon_w \cdot Y_w \in C_n^\text{simp}(K)$.

2. If $K$ is finite, then we also have an isomorphism as follows:
\[
H_{n-1}^\text{simp}(K) \cong \begin{cases} \text{free abelian group}, & \text{if } K \text{ is orientable or if } \partial K \neq \emptyset, \\ \text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } K \text{ is non-orientable and } \partial K = \emptyset. \end{cases}
\]

3. If $K$ is finite, then
\[
H_n^\text{simp}(K; \mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } K \text{ is closed, regardless whether or not } K \text{ is orientable,} \\ 0, & \text{otherwise.} \end{cases}
\]

Furthermore, if $K$ is in fact closed and if $Y_1, \ldots, Y_m$ is a set of ordered $n$-simplices of $K$ such that for each $n$-simplex $s$ there exists a unique $i \in \{1, \ldots, m\}$ with $s = [Y_i]$, then the unique non-zero element of $H_n^\text{simp}(K; \mathbb{F}_2) \cong \mathbb{F}_2$ is represented by the simplicial cycle $Y_1 \otimes 1 + \cdots + Y_m \otimes 1 \in C_n^\text{simp}(K; \mathbb{F}_2) = C_n^\text{simp}(K) \otimes \mathbb{F}_2$.

Theorem [66.4] leads us to the following definition.

**Definition.** Let $K$ be a closed $n$-dimensional pseudomanifold.

1. If $K$ is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in W}$, then we refer to the simplicial homology class
\[
[K] := \left[ \sum_{w \in W} \epsilon_w \cdot Y_w \right] \in H_n^\text{simp}(K)
\]
as the fundamental class of $K$.

2. We refer to the unique non-zero element in $H_n^\text{simp}(K; \mathbb{F}_2) \cong \mathbb{F}_2$ as the $\mathbb{F}_2$-fundamental class $[K]_{\mathbb{F}_2}$.

For clarity we break the proof of Theorem [66.4] into three parts. For the proof of the first part it is convenient to introduce the following definitions which we will use on a few other occasions.
Definition. Let $K = (V, S)$ be an $n$-dimensional abstract simplicial complex such that every $(n-1)$-simplex has order $\leq 2$.

1. We denote by $W$ the set of $n$-simplices of $K$.
2. We denote by $E_2$ the set of $(n-1)$-simplices of order 2.
3. Let $\Gamma = (W, E_2, \varphi)$ be the undirected abstract graph with vertex set $W$, with edge set $E_2$ and where $\varphi: E_2 \rightarrow \mathcal{P}(W)$ is the map that associates to each edge $e \in E_2$ the set $\{w \in W \mid e \text{ is a face of } w\}$. Note that for $e \in E_2$ the set $\varphi(e)$ has precisely two elements. This means that $\Gamma$ is indeed an undirected abstract graph in the sense of the definition on page 226. We call $\Gamma$ the dual graph of the abstract simplicial complex $K$. We refer to Figure 1015 for an illustration.

![Figure 1015](image)

Proof of Theorem 66.4 (1). Let $K$ be an $n$-dimensional pseudomanifold. Our goal is to calculate $H_n^{\text{simp}}(K)$. We start out with the following easy but useful observation which we will use throughout this proof without referring to it again explicitly:

$$H_n^{\text{simp}}(K) = \ker \left( \partial_n: C_n^{\text{simp}}(K) \rightarrow C_{n-1}^{\text{simp}}(K) \right).$$

Since $K$ has no simplices of dimension $n+1$, hence $C_{n+1}^{\text{simp}}(K) = 0$

To determine the right hand side of the above we need to introduce some notation.

1. We denote by $E$ the set of $(n-1)$-simplices of $K$. Furthermore we denote by $E_1$ the set of $(n-1)$-simplices of order 1 and similarly we denote by $E_2$ the set of $(n-1)$-simplices of order 2. Note that it follows from the hypothesis that $K$ is an $n$-dimensional pseudomanifold that $E = E_1 \sqcup E_2$.
2. We denote by $W$ the set of $n$-simplices of $K$.
3. Let $\Gamma = (W, E_2, \varphi)$ be the dual graph of $K$. Note that part (3) of the definition of a pseudomanifold implies that the undirected abstract graph $\Gamma$ is connected in the sense of the definition on page 227.
4. For each $(n-1)$-simplex $e \in E$ we pick, once and for all, an ordered $(n-1)$-simplex $X_e$ with $[X_e] = e$. We use Lemma 63.5 to view $\{X_e\}_{e \in E}$ as a basis for $C_{n-1}^{\text{simp}}(K)$.
5. We consider the two obvious projections

$$p_1: \bigoplus_{e \in E} \mathbb{Z} \cdot X_e \rightarrow \bigoplus_{e \in E_1} \mathbb{Z} \cdot X_e \quad \text{and} \quad p_2: \bigoplus_{e \in E} \mathbb{Z} \cdot X_e \rightarrow \bigoplus_{e \in E_2} \mathbb{Z} \cdot X_e$$

Since $E = E_1 \sqcup E_2$ we see for $s \in C_{n-1}^{\text{simp}}(K)$ that $s = 0$ if and only if $p_1(s) = 0$ and $p_2(s) = 0$. 
Now suppose that for each $w \in W$ we are given an oriented $n$-simplex $Y_w$ with $[Y_w] = w$. We introduce the following conventions.

(6) As above we use Lemma 63.5 to view $\{Y_w\}_{w \in W}$ as a basis for $C_n^{\text{simp}}(K)$.

(7) Given $e \in E$ and $w \in W$ we set

$$\mu_{ew} = \begin{cases} 
0, & \text{if } e \text{ is not a face of } w, \\
+1, & \text{if } e \text{ is a face of } w \text{ and } [(+1, Y_w)] \text{ induces } [(+1, X_e)], \\
-1, & \text{if } e \text{ is a face of } w \text{ and } [(+1, Y_w)] \text{ induces } [(-1, X_e)].
\end{cases}$$

The following figure illustrates the proof of Theorem 66.4.

![Illustration for the proof of Theorem 66.4](image)

**Claim 1.** Given $\sum_{w \in W} a_w \cdot Y_w \in C_n^{\text{simp}}(K)$ we have

(a) $p_1(\partial_n(\sum_{w \in W} a_w \cdot Y_w)) = 0 \iff$ for all $w \in W$ that cobound an $e \in E_1$ we have $a_w = 0$

(b) $p_2(\partial_n(\sum_{w \in W} a_w \cdot Y_w)) = 0 \iff$ for all $w \neq w' \in W$ that cobound some $e \in E_2$ we have $\mu_{ew} \cdot a_w = -\mu_{ew'} \cdot a_{w'}$.

We start out our proof of Claim 1 with the following calculation:

$$\partial_n(\sum_{w \in W} a_w \cdot Y_w) = \sum_{w \in W} a_w \cdot \partial_n(Y_w) = \sum_{w \in W} a_w \cdot \sum_{e \in E \text{ such that } e \text{ is a face of } w} \mu_{ew} \cdot X_e = \sum_{e \in E} X_e \cdot \sum_{w \in W \text{ such that } e \text{ is a face of } w} \mu_{ew} \cdot a_w.$$ 

This follows immediately from the definition of $\partial_n$, see page 1653, the definition of induced orientations, see page 1652, and the above definition of $\mu_{ew}$.

Now we consider the two projections.

(a) Note that an element $s \in C_{n-1}^{\text{simp}}(K)$ lies in the kernel of $p_1$ if and only if for all $e \in E_1$ the $X_e$-coefficient of $s$ vanishes. Thus let $e \in E_1$. Let $w \in W$ be the unique $n$-simplex that cobounds $e$. Using the above calculation we see that

$$\text{X}_e\text{-coefficient of } \partial_n\left(\sum_{w \in W} a_w \cdot Y_w\right) = \mu_{ew} \cdot a_w.$$ 

The promised result follows from this discussion.

(b) Next let $e \in E_2$. Let $w \neq w'$ be the two $n$-simplices that cobound $e$. Similar to the above we see that

$$\text{X}_e\text{-coefficient of } \partial_n\left(\sum_{w \in W} a_w \cdot Y_w\right) = \mu_{ew} \cdot a_w + \mu_{ew'} \cdot a_{w'}.$$ 

Note that if $e$ is a face of $w$, then precisely one of the two cases does indeed occur.
As in (a) we see that this calculation gives us the desired result.

Now note that Claim 1 follows almost immediately from the above discussion.

**Claim 2.** Every element \(\sum_{w \in W} a_w \cdot Y_w\) that lies in the kernel of the map

\[
C_n^\text{simp}(K) \xrightarrow{\partial_n} C_{n-1}^\text{simp}(K) = \bigoplus_{e \in E} \mathbb{Z} \cdot X_e \xrightarrow{p_2} \bigoplus_{e \in E_2} \mathbb{Z} \cdot X_e
\]

has the property that for all \(w, w' \in W\) we have \(|a_w| = |a_{w'}|\).

We consider the map

\[
f : W \to \mathbb{N}_0 \quad w \mapsto |a_w|.
\]

It follows from Claim 1 that for every \(e \in E_2\) and \(w, w' \in \varphi(e)\) we have \(|a_w| = |a_{w'}|\). Since the abstract graph \((W, E_2, \varphi)\) is connected we obtain from Lemma 4.5 that \(f : W \to \mathbb{N}_0\) is constant.

**Claim 3.** Given any \(w_0 \in W\) the map

\[
\Theta_{w_0} : \ker(\partial_n : C_n^\text{simp}(K) \to C_{n-1}^\text{simp}(K)) \to \mathbb{Z} \quad \sum_{w \in W} a_w \cdot Y_w \mapsto a_{w_0}
\]

is a monomorphism.

It is clear that the given map is a homomorphism. It follows immediately from Claim 2 that the map \(\Theta_{w_0}\) is a monomorphism.

Now we can prove Statement (1) of the proposition.

(i) We need to show that if \(K\) is infinite, then \(H_n^\text{simp}(K) = 0\). So suppose that \(K\) is infinite. It follows from the fact that \(K\) is finite-dimensional and the fact that every simplex is contained in an \(n\)-simplex that \(W\) is also infinite. Now let \(\sum_{w \in W} a_w \cdot Y_w\) be an element in \(\ker(\partial_n : C_n^\text{simp}(K) \to C_{n-1}^\text{simp}(K))\). Since \(W\) is infinite and since by definition every element in \(C_n^\text{simp}(K)\) is a finite linear combination of ordered simplices we see that there exists a \(w_0 \in W\) with \(a_{w_0} = 0\). But then it follows from Claim 2 that \(a_w = 0\) for all \(w \in W\).

(ii) We need to show that if \(\partial K \neq \varnothing\), then \(H_n^\text{simp}(K) = 0\). Thus suppose that \(\partial K \neq \varnothing\). By definition of \(\partial K\) this implies that \(E_1 \neq \varnothing\). We pick some \(e_0 \in E_1\). Let \(w_0\) be the unique \(n\)-simplex that cobounds \(e_0\). Now let \(\sum_{w \in W} a_w \cdot Y_w\) be an element in \(\ker(\partial_n : C_n^\text{simp}(K) \to C_{n-1}^\text{simp}(K))\). By Claim 1 we have \(a_{w_0} = 0\). But then it follows from Claim 2 that \(a_w = 0\) for all \(w \in W\).

(iii) Now assume that \(H_n^\text{simp}(K) \neq 0\). We need to show that \(K\) is actually orientable. To do so it suffices to prove the following claim.
Claim. If \( \sum_{w \in W} a_w \cdot Y_w \) is a non-zero element in \( \ker \left( \partial_n : C_n^{\text{simp}}(K) \to C_{n-1}^{\text{simp}}(K) \right) \), then the orientations \( \{(\text{sign}(a_w), Y_w)\}_{w \in W} \) define an orientation of \( K \).

Let \( \sum_{w \in W} a_w \cdot Y_w \) be a non-zero element in \( \ker \left( \partial_n : C_n^{\text{simp}}(K) \to C_{n-1}^{\text{simp}}(K) \right) \). Let \( e \) be an \((n-1)\)-simplex of order 2, i.e., let \( e \in E_2 \). Let \( w \neq w' \) be the two cobounding \( n \)-simplices of \( e \). By Claim 1 we know that \( \mu_{ew} \cdot a_w = -\mu_{ew'} \cdot a_{w'} \). It follows from Claim 2 that we also have the equality \( \mu_{ew} \cdot \text{sign}(a_w) = -\mu_{ew'} \cdot \text{sign}(a_{w'}) \). But basically by definition that means that \((\text{sign}(a_w), Y_w)\) and \((\text{sign}(a_{w'}), Y_{w'})\) induce opposite orientations on the \((n-1)\)-simplex \( e \).

(iv) Finally we suppose that \( K \) is closed and orientable. Let \( \{(\mu_w, Y_w)\}_{w \in W} \) be an orientation of \( K \). We need to show that \( H_n^{\text{simp}}(K) \cong \mathbb{Z} \) and that \( \sum_{w \in W} \mu_w \cdot Y_w \) is a generator of \( H_n^{\text{simp}}(K) \).

Since \( K \) is by definition non-empty we can pick some \( w_0 \in W \). We consider the maps

\[
\mathbb{Z} \xrightarrow{\Psi} \ker(\partial_n : C_n^{\text{simp}}(K) \to C_{n-1}^{\text{simp}}(K)) \xrightarrow{\Theta_{w_0}} \mathbb{Z}
\]

\[
r \mapsto r \cdot \sum_{w \in W} \mu_w \cdot Y_w
\]

It follows almost immediately from Claim 1 that the map \( \Psi \) to the left is well-defined, in the sense that it takes values in \( \ker(\partial_n : C_n^{\text{simp}}(K) \to C_{n-1}^{\text{simp}}(K)) \). Furthermore it is clear that the composition \( \Theta_{w_0} \circ \Psi \) is given by multiplication by \( \mu_{w_0} \), in particular the composition \( \Theta_{w_0} \circ \Psi \) is an isomorphism. By Claim 3 we know that \( \Theta_{w_0} \) is a monomorphism. It follows from this discussion that \( \Psi \) is an isomorphism. But that is exactly what we needed to show. \( \blacksquare \)

The proof of Statement (2) of Theorem 66.4 will require the following elementary lemma.

**Lemma 66.5.** Let \( A, B, C \) and \( D \) be abelian groups. We denote by \( p_1 : B \oplus C \to B \) the projection. Now suppose we are given an exact sequence

\[
A \xrightarrow{\alpha} B \oplus C \xrightarrow{\varphi} D
\]

of homomorphisms such that the following conditions are satisfied:

1. the group \( B/p_1(\alpha(A)) \) is torsion,
2. the group \( D \) is torsion-free,
3. the map \( p_1 \circ \alpha : A \to B \) is a monomorphism.

Then the map

\[
\Theta : B/p_1(\alpha(A)) \oplus \ker(C \xrightarrow{\varphi} D) \to \frac{\ker(\varphi : B \oplus C \to D)}{\Im(\alpha : A \to B \oplus C)}
\]

\[
([b], c) \mapsto [([b], c)]
\]

is an isomorphism.

---

1009 Here recall that given a non-zero integer \( a \in \mathbb{Z} \setminus \{0\} \) we denote by \( \text{sign}(a) := \frac{a}{|a|} \in \{\pm 1\} \) its sign. Also note that we know by hypothesis that at least one \( a_w \neq 0 \), but then it follows from Claim 2 that all \( a_w \neq 0 \), in particular it makes sense to consider the signs of the \( a_w \).
Proof of Lemma 66.5. From our hypotheses (1) and (2) and the exactness of the sequence we easily deduce the following statement:

(*) The map \( B \xrightarrow{\varphi((b,0))} D \) is the zero map.

Note that (*) implies that if \( \varphi(b,c) = 0 \), then we also have \( \varphi((0, c)) = 0 \). From this observation it follows immediately that \( \Theta \) is an epimorphism. Now suppose we are given \( b \in B \) and \( c \in \ker(C \to D) \) with \( \Theta([b], c) = 0 \). This means that there exists an \( a \in A \) with \( \alpha(a) = (b,c) \). By the exactness of the sequence and by (*) we know that there exists an \( \tilde{a} \in A \) with \( \alpha(\tilde{a}) = (b,0) \). From (3) we obtain that \( a = \tilde{a} \). Thus we see that \( (b, c) = \alpha(a) = \alpha(\tilde{a}) = (b,0) \). This shows that \( [b] = 0 \in B/p_1(\alpha(A)) \) and \( c = 0 \). In other words, we have shown that \( \Theta \) is a monomorphism.

We move on to the proof of Statement (2) of Theorem 66.4.

Proof of Theorem 66.4 (2). Let \( K \) be a finite \( n \)-dimensional pseudomanifold. Recall that we need to prove the following statements:

(a) If \( K \) is orientable and closed, then \( H_{n-1}^{\text{simp}}(K) \) is a free abelian group.

(b) If \( K \) is non-orientable and if \( \partial K \neq \emptyset \), then \( H_{n-1}^{\text{simp}}(K) \) is a free abelian group.

In the following we will use freely the notation that we introduced in the proof of Statement (1). In particular we consider again the abstract graph \( \Gamma = (W, E_2, \varphi) \). Since \( K \) is finite we know that \( \Gamma \) is finite, hence by Proposition 4.8 (1) we know that there exists a spanning tree \( T \) of \( \Gamma \). Recall that this means that \( T \) is connected, that \( \chi(T) = 1 \) and, by Proposition 4.8 (2) it means that \( T \) contains every vertex. We pick \( \bar{w} \in W \). By Corollary 4.7 we know that we can write \( W = \{ \bar{w}, w_1, \ldots, w_k \} \) and \( E_2 = \{ e_1, \ldots, e_k \} \) such that the following statements hold:

1. For each \( i \in \{1, \ldots, k\} \) the vertex \( w_i \) is an endpoint of the edge \( e_i \).
2. If some vertex \( w_i \) is an endpoint of some \( e_j \), then \( j \leq i \).

We introduce the following notation. We denote by

\[
\begin{align*}
p_1 &: C_{n-1}^{\text{simp}}(K) \to \bigoplus_{i=1}^k \mathbb{Z} \cdot e_i \\
p_2 &: C_{n-1}^{\text{simp}}(K) \to \bigoplus_{e \in E_2 \setminus \{e_1, \ldots, e_k\}} \mathbb{Z} \cdot e_i
\end{align*}
\]

the obvious projection maps.

The key to the proof of Theorem 66.4 (2) is the following observation, which is an immediate consequence of Claim 1 together with the clever choice of \( w_1, \ldots, w_k \) and \( e_1, \ldots, e_k \).

Observation. The map \( \bigoplus_{i=1}^k \mathbb{Z} \cdot w_i \xrightarrow{\partial_n} C_{n-1}^{\text{simp}}(K) \xrightarrow{p_1} \bigoplus_{i=1}^k \mathbb{Z} \cdot e_i \) is represented by a matrix of the form

\[
D := \begin{pmatrix}
\pm 1 & * & \ldots & * \\
0 & \pm 1 & * & : \\
0 & 0 & \pm 1 & * \\
0 & 0 & 0 & \pm 1
\end{pmatrix}
\]
(a₁) First we assume that $K$ is orientable and closed. Let $\{(w, Y_w)\}_{w \in W}$ be an orientation of $K$. We set $\mu := \sum_{w \in W} \epsilon_w \cdot Y_w$. Since $\epsilon_w \in \{\pm 1\}$ we see that $Y_{w_1}, \ldots, Y_{w_k}, \mu$ is a basis for $C^n_{\text{simp}}(K)$. This time we consider the following maps

$$
\begin{array}{cccc}
\bigoplus_{i=1}^k \mathbb{Z} \cdot Y_{w_i} & \xrightarrow{\partial_n} & \bigoplus_{i=1}^k \mathbb{Z} \cdot X_{e_i} & \xrightarrow{\partial_{n-1}} \\
\mu \xrightarrow{\text{projection}} & \approx & \text{matrix } D & \xrightarrow{\text{projection } p_2} \\
& & & \\
\bigoplus_{i=1}^k \mathbb{Z} \cdot X_{e_i} & \xrightarrow{\partial_{n-1}} & C^n_{\text{simp}}(K) &
\end{array}
$$

As we already discussed in the proof of Statement (1), since $K$ is closed we obtain from Claim 1 that $\partial_n(\mu) = 0$. Thus the image of $\partial_n$ equals the image of the diagonal map. Furthermore, the bottom horizontal map is represented by the matrix $D$ from the observation, in particular we see that the bottom horizontal map is an isomorphism. From Lemma [66.5] we now obtain the following isomorphism:

$$
\ker \left( \bigoplus_{\epsilon \neq e_1, \ldots, e_k} \mathbb{Z} \cdot X_\epsilon \xrightarrow{\partial_{n-1}} C^n_{\text{simp}}(K) \right) \approx \ker \left( C^n_{\text{simp}}(K) \xrightarrow{\partial_{n-1}} C^n_{\text{simp}}(K) \right) = \ker \left( C^n_{\text{simp}}(K) \xrightarrow{\partial_{n-1}} C^n_{\text{simp}}(K) \right).
$$

(a₂) Now we assume that $\partial K \neq \emptyset$, i.e. we assume that $E_1 \neq \emptyset$. We pick an $\tilde{e} \in E_1$. Let $\tilde{w} \in W$ be the unique $n$-simplex that cobounds $\tilde{e}$. We pick $w_1, \ldots, w_k$ and $e_1, \ldots, e_k$. 

**Figure 1017.** Illustration for the proof of Theorem 66.4 (3).
accompanying. We consider the following maps

\[
\begin{array}{cccc}
\bigoplus_{i=1}^{k} \mathbb{Z} \cdot Y_{w_{i}} \oplus \mathbb{Z} \cdot Y_{\bar{w}} & \to & \bigoplus_{i=1}^{k} \mathbb{Z} \cdot X_{e_{i}} \oplus \mathbb{Z} \cdot \bar{X}_{\bar{e}} & \to & \bigoplus_{i=1}^{k} \mathbb{Z} \cdot X_{\bar{e}} \\
\partial_{n} & & \partial_{n-1} & & \partial_{n-1}
\end{array}
\]

projection

It follows easily from the Observation and Claim 1 that the diagonal map is an isomorphism. It now follows from Lemma 66.5 that

\[
\ker \left( \bigoplus_{e \neq e_{1}, \ldots, e_{k}, \bar{e}} \mathbb{Z} \cdot X_{e} \right) \xrightarrow{\partial_{n-1}} \mathcal{C}_{n-2}^{\text{simp}}(K) \cong \ker \left( \mathcal{C}_{n-1}^{\text{simp}}(K) \xrightarrow{\partial_{n-1}} \mathcal{C}_{n-2}^{\text{simp}}(K) \right).
\]

But the group on the right hand side is the subgroup of a finitely generated free abelian group, so it follows from Lemma 19.8(3) that it is itself a finitely generated free abelian group.

(b) Finally we assume that \( K \) is closed and non-orientable. First we consider the following maps:

\[
\begin{array}{cccc}
\bigoplus_{w \in W} \mathbb{Z} \cdot Y_{w} & \to & \bigoplus_{i=1}^{k} \mathbb{Z} \cdot X_{e_{i}} \oplus \bigoplus_{e \neq e_{1}, \ldots, e_{k}} \mathbb{Z} \cdot X_{e} & \to & \bigoplus_{i=1}^{k} \mathbb{Z} \cdot X_{e_{i}} \\
\partial_{n} & & \text{projection } p_{2} & & \partial_{n}
\end{array}
\]

By our hypothesis that \( K \) is closed and non-orientable, together with Statement (1), we know that \( \mathcal{H}_{n}^{\text{simp}}(K) = 0 \). This means that the horizontal map is a monomorphism. On the other hand, for rank reasons the diagonal map \( p_{2} \circ \partial_{n} \) has a kernel. In other words, there exists some non-zero \( \mu = \sum_{w \in W} a_{w} \cdot Y_{w} \in \mathcal{C}_{n}^{\text{simp}}(K) \) with \( p_{2}(\partial_{n}(\mu)) = 0 \). By Claim 2 we know that the value \( |a_{w}| \) is constant. Thus after dividing by this constant (which is non-zero since \( \mu \) is non-zero) we can arrange that each \( |a_{w}| = 1 \).

Since \( K \) is by hypothesis closed, i.e. since each edge has order 2, we see, say by the calculation in the proof of Claim 1 or by direct inspection, that for each \( e \in E \) the \( X_{e} \)-coefficient of \( \partial_{n}(\mu) \) lies in \( \{0, \pm 2\} \). Furthermore since \( \partial_{n} \) is a monomorphism we know that \( \partial_{n}(\mu) \neq 0 \). Thus there exists some \( f \in E \) such that the \( f \)-coefficient of \( \partial_{n}(\mu) \) equals \( \pm 2 \). From \( p_{2}(\partial_{n}(\mu)) = 0 \) we obtain that \( f \neq e_{1}, \ldots, e_{k} \). Next we
consider the following maps:

\[ \bigoplus_{i=1}^{k} \mathbb{Z} \cdot Y_{w_i} \oplus \mathbb{Z} \cdot \mu^c \xrightarrow{\partial_n} \bigoplus_{i=1}^{k} \mathbb{Z} \cdot X_{e_i} \oplus \mathbb{Z} \cdot X_f \oplus \bigoplus_{e \neq e_1, \ldots, e_k, f} \mathbb{Z} \cdot X_e \xrightarrow{\partial_{n-1}} \mathbb{C}^{\text{simp}}_{n-2}(K) \]

Finally we note that it follows from the above together with Lemma 66.5 that the following is an isomorphism:

\[ \ker \left( \bigoplus_{e \neq e_1, \ldots, e_k, f} \mathbb{Z} \cdot X_e \rightarrow \mathbb{C}^{\text{simp}}_{n-2}(K) \right) \oplus \mathbb{Z}^{k+1} \left/ \left( D \ast_0 \mathbb{Z}^{k+1} \right) \right. \xrightarrow{\approx} \mathbb{Z}_2 \text{ by the observation} \]

We have thus finished the proof of Theorem 66.4 (2). \[ \blacksquare \]

![Diagram](image)

**Figure 1018.** Illustration for the proof of Theorem 66.4 (2).

Finally we get to the proof of the last statement of Theorem 66.4 (3).

**Proof of Theorem 66.4 (3).** Let \( K \) be a finite \( n \)-dimensional pseudomanifold. First we point out that it would be a fun exercise to modify the proof of (1) to obtain the promised result. But in these notes we will not pursue this approach. Instead we will do a little trick. First we consider the case that \( K \) is closed. In this case we perform the following calculation:

\[ \mathbb{H}^{\text{simp}}_n(K; \mathbb{F}_2) \cong \mathbb{H}^{\text{simp}}_n(K) \otimes \mathbb{F}_2 \oplus \text{Tor}(\mathbb{H}^{\text{simp}}_{n-1}(K), \mathbb{F}_2) \cong \begin{cases} \mathbb{Z} \otimes \mathbb{F}_2 \oplus \text{Tor}(\mathbb{Z}_l, \mathbb{F}_2) & \text{if } K \text{ is orientable} \\ 0 \otimes \mathbb{F}_2 \oplus \text{Tor}(\mathbb{Z}_l \oplus \mathbb{Z}_2, \mathbb{F}_2) & \text{if } K \text{ is non-orientable} \end{cases} \cong \mathbb{F}_2. \]

by the Algebraic Universal Coefficient Theorem 57.18 by (1) and (3)Lemma 57.3 and 57.17

Now suppose that \( Y_1, \ldots, Y_m \) is a set of ordered \( n \)-simplices of \( K \) such that for each \( n \)-simplex \( s \) of \( K \) there exists a unique \( i \in \{1, \ldots, m\} \) with \( s = [Y_i] \). One easily verifies that the simplicial chain \( Y_1 \otimes 1 + \cdots + Y_m \otimes 1 \in \mathbb{C}^{\text{simp}}_n(K; \mathbb{F}_2) = \mathbb{C}^{\text{simp}}_n(K) \otimes \mathbb{F}_2 \) is a simplicial cycle. Since it is non-zero we see that it equals necessarily the unique non-zero element of \( \mathbb{H}^{\text{simp}}_n(K; \mathbb{F}_2) = \ker(\mathbb{H}^{\text{simp}}_n(K; \mathbb{F}_2) \rightarrow \mathbb{H}^{\text{simp}}_{n-1}(K; \mathbb{F}_2)) \cong \mathbb{F}_2. \)
Finally if the pseudomanifold $K$ is not closed, then the above approach shows almost immediately that $H_n^\text{simp}(K; \mathbb{F}_2) = 0$. With a slight sigh of relief we note that we have now finally managed to prove all three statements of Theorem 66.4.

66.2. The top-dimensional homology group of a smooth manifold. As the reader surely expected, the main application of Theorem 66.4 is the following theorem which gives us lots of interesting extra information on the homology groups of smooth manifolds.

**Theorem 66.6.** Let $M$ be a connected non-empty $n$-dimensional smooth manifold. The following statements hold:

1. We have an isomorphism as follows:
   $$H_n(M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ is closed and orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

2. If $M$ is compact, then we also have an isomorphism as follows:
   $$H_{n-1}(M; \mathbb{Z}) \cong \begin{cases} \text{free abelian group,} & \text{if } M \text{ is orientable or if } \partial M \neq \emptyset, \\ \text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable and closed.} \end{cases}$$
   In both cases the free abelian group is finitely generated.

3. If $M$ is compact, then
   $$H_n(M; \mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } M \text{ is closed, regardless whether or not } M \text{ is orientable,} \\ 0, & \text{otherwise.} \end{cases}$$

**Examples.**

1. Let $k \in \mathbb{N}$. We consider $k \cdot \mathbb{R}P^2$, i.e. we consider the connected sum of $k$ copies of $\mathbb{R}P^2$. By Exercise 8.17 we know that $k \cdot \mathbb{R}P^2$ is non-orientable. In Proposition 48.9 we showed that
   $$H_1(k \cdot \mathbb{R}P^2; \mathbb{Z}) \cong \mathbb{Z}^{k-1} \oplus \mathbb{Z}_2 \text{ and } H_2(k \cdot \mathbb{R}P^2; \mathbb{Z}) = 0.$$ This is reassuringly consistent with Theorem 66.6.

2. Recall that the Möbius band $M$ is a compact non-orientable 2-dimensional smooth manifold with non-empty boundary. Since $M$ is homotopy equivalent to $S^1$ we see that $H_1(M; \mathbb{Z}) \cong H_1(S^1; \mathbb{Z}) \cong \mathbb{Z}$. This example illustrates that in Theorem 66.6 the "$\mathbb{Z}_2$"-term for a non-orientable smooth manifold only appears if $M$ is closed.

3. In Chapter 86 we will make sense of the notion of an orientable topological manifold. We will prove the generalization of Theorem 66.6 to the setting of topological manifolds in Theorems 87.1, 87.2 and 87.3 and Proposition 87.22. These new results completely subsume Theorem 66.6. Nonetheless it is worth covering the above proof since it is fairly geometric, whereas the latter proofs for topological manifolds are rather unintuitive.

**Proof of Theorem 66.6.** Let $M$ be a connected non-empty $n$-dimensional smooth manifold. Note that by Theorem 64.2 we know that $M$ admits a smooth simplicial structure $(K = (V, S), \Theta: |K| \to M)$. By Proposition 66.1 we know that $K$ is an $n$-dimensional pseudomanifold. Evidently now we would like to apply Theorem 66.4 and call it a day.
But to do so we need to show that the hypotheses on the smooth manifolds do indeed match the corresponding hypotheses for pseudomanifolds. Let us start with the good news:

(1) By Lemma 61.9 (1) and Proposition 61.12 we know that $M$ is compact if and only if $K$ is finite.

(2) From Proposition 66.1 (1), (3) and (4) we obtain that $\partial M = \emptyset$ if and only if $\partial K = \emptyset$.

Here is the bad news: We still have to relate the (non-) orientability of the smooth manifold $M$ to the (non-) orientability of the abstract simplicial complex $K$. This will be done in the subsequent Proposition 66.7.

The following proposition gives us the last piece of the proof of Theorem 66.6.

**Proposition 66.7.** Let $n \in \mathbb{N}$ and let $M$ be a connected non-empty $n$-dimensional smooth manifold. Furthermore let $(K = (V, S), \Theta : |K| \to M)$ be a smooth simplicial structure. The map

$$
\begin{align*}
\{ \text{orientations of the smooth manifold } M \text{ in the sense of the definition on page 297} \} & \xrightarrow{\cong} \{ \text{orientations of the pseudomanifold } K \text{ in the sense of the definition on page 1652} \}. \\
\text{orientation of } M & \mapsto \left( \epsilon_s \right)
\end{align*}
$$

for each $n$-simplex $s$ we pick a corresponding ordered simplex $Y_s$ and we consider the oriented $n$-simplex $[(\epsilon_s, Y_s)]$ where $\epsilon_s = +1$ if $\Theta \circ \Phi_{Y_s}^{\leq} : \tilde{\Delta}^n \to M$ is orientation-pres. $\epsilon_s = -1$ if $\Theta \circ \Phi_{Y_s}^{=} : \tilde{\Delta}^n \to M$ is orientation-rev. is a natural bijection. In particular the smooth manifold $M$ is orientable if and only if the pseudomanifold $K$ is orientable.

Proof of Proposition 66.7 (*). In the following we will provide a proof of Proposition 66.7. To preserve the author’s sanity we will skip a few technical calculations. We leave it to the reader to fill in the details.

Throughout the proof let $M$ be a non-empty $n$-dimensional smooth manifold and let $(K = (V, S), \Theta : |K| \to M)$ be a smooth simplicial structure. First note that the case $n = 0$ is trivial, since every 0-dimensional smooth manifold and every 0-dimensional pseudomanifold is orientable. Thus in the following we assume that $n > 0$. Before we do anything else we recall and introduce a few definitions and we make a few basic comments regarding these definitions.

(a) Let $k \in \mathbb{N}_0$. On page 1075 we introduced

$$
\tilde{\Delta}^k := \{(t_0, \ldots, t_k) \in \Delta^k \mid \text{all coordinates are non-zero}\}.
$$

Now we also define

$$
\tilde{\Delta}^k := \{(t_0, \ldots, t_k) \in \Delta^k \mid \text{at least two coordinates are non-zero}\}.
$$

---

1010 We do not impose any other conditions, in particular neither do we assume that $M$ is compact nor do we assume that $\partial M = \emptyset$.

1011 We leave it to the reader to figure out what “natural” means in this context.
(b) Similar to the discussion on page 1075 we view $\check{\Delta}^k$ and $\check{\Delta}^k$ in the obvious way as smooth manifolds. Note that $\check{\Delta}^k$ has no boundary and that the boundary of $\check{\Delta}^k$ equals $\check{\Delta}^k \cap \partial \Delta^k$. We equip the smooth manifolds $\check{\Delta}^k$ and $\check{\Delta}^k$ with the orientation where for each $P \in \check{\Delta}^k$ a basis $v_1, \ldots, v_k$ of $V_P \check{\Delta}^k$ is positive if the vectors $\{(1, \ldots, 1), v_1, \ldots, v_k\}$ are a positive basis for $\mathbb{R}^{k+1}$. As always we endow the boundary $\partial \check{\Delta}^k$ of the oriented smooth manifold $\check{\Delta}^k$ with the orientation given by Lemma 6.50.

(c) Note that for any $j \in \{0, \ldots, k\}$ the usual $j$-th face map $i_j^k: \Delta^{k-1} \rightarrow \Delta^k$ restricts to an embedding $i_j^k : \check{\Delta}^{k-1} \rightarrow \partial \check{\Delta}^k \subset \check{\Delta}^k$. Using Lemma 6.46 (2) it is straightforward to verify that the map $i_j^k : \check{\Delta}^{k-1} \rightarrow \partial \check{\Delta}^k$ is orientation-preserving if and only if $j$ is even.

Figure 1019

(d) Let $k \in \mathbb{N}_0$ and let $Y = (v_0, \ldots, v_k)$ be an ordered $k$-simplex of $K = (V, S)$. On page 1487 we introduced the corresponding characteristic map

$$\Phi^\leq_Y : \Delta^k = \{(t_0, \ldots, t_k) \in \mathbb{R}_{\geq 0}^{k+1} \mid \sum_{i=0}^k t_i = 1\} \rightarrow |K|$$

$$(t_0, \ldots, t_k) \mapsto \sum_{i=0}^k t_i \cdot v_i.$$

(e) It follows almost immediately from the definition of a "smooth" simplicial structure, see page 1589 that for every ordered $k$-simplex $Y = (v_0, \ldots, v_k)$ the map $\Theta \circ \Phi^\leq_Y : \check{\Delta}^n \rightarrow M$ is an immersion.

Now we turn to the actual proof of the proposition.

First we assume that we are given an orientation of the smooth manifold $M$. We need to equip the pseudomanifold $K = (V, S)$ with a natural orientation. We say that an ordered $n$-simplex $Y = (v_0, \ldots, v_n)$ is positive if the map $\Theta \circ \Phi^\leq_Y : \check{\Delta}^n \rightarrow M$ is orientation-preserving in the sense of the definition on page 299. Since $n \geq 1$ we see easily that, by possibly swapping the order of two vertices, we can find for each $n$-simplex $s \in S$ a positive ordered $n$-simplex $Y_s$ with $[Y_s] = s$. It remains to prove the following claim.

Claim 1. The oriented $n$-simplices $[(+1, Y_s)]$ form an orientation of the pseudomanifold $K$.

Let $e$ be an $(n-1)$-simplex of $K$ of order 2 and let $s, t$ be the two $n$-simplices that cobound $e$. We need to show that the orientations $[(+1, Y_s)]$ and $[(+1, Y_t)]$ induce opposite

---

1012Slightly more precisely, a smooth atlas for $\check{\Delta}^k$ is given by projection to the first $k$ coordinates, and for $\check{\Delta}^k$ we obtain a smooth atlas by the same projection and an affine linear map that sends points on a component of $\Delta^k \cap \partial \Delta^k$ into the $(k-1)$-hyperplane.
orientations on \( e \). We write \( Y_s = (v_0, \ldots, v_n) \) and we write \( Y_t = (w_0, \ldots, w_n) \). Let \( v_k \) be the vertex missing in \( e \) and let \( w_l \) be the vertex missing in \( e \). We consider the maps

\[
\tilde{\Delta}^{n-1} \xrightarrow{i_k^n} \tilde{\Delta}^n \xrightarrow{\Theta \circ \Phi \leq (v_0, \ldots, v_n)} M \xleftarrow{\Theta \circ \Phi \leq (w_0, \ldots, w_n)} \tilde{\Delta}^n \xleftarrow{i_l^n} \tilde{\Delta}^{n-1}.
\]

The two maps \( \tilde{\Delta}^{n-1} \rightarrow M \) are immersions and the images coincide, thus we obtain a self-diffeomorphism of \( \tilde{\Delta}^{n-1} \). A little bit of thought, using (c) and using Lemma 6.46 (2), shows that this map is orientation-preserving if and only if \( k + l + 1 \) is even.\footnote{Also note that the fact that \( \tilde{\Delta}^n \) is dense in \( \tilde{\Delta}^n \) implies that the map \( \Theta \circ \Phi \leq \gamma \); \( \tilde{\Delta}^n \rightarrow M \) is also orientation-preserving.} Next we need to associate to each orientation of the pseudomanifold \( K \) an orientation of the smooth manifold \( M \). Thus suppose we are given an orientation \( \{(\mu_s, Y_s)\}_{s \in S} \) of the pseudomanifold \( K \). Since \( n > 0 \) we can and will assume that for each \( n \)-simplex \( s \) we have \( \mu_s = 1 \).

Claim 2. The smooth manifold \( M \setminus \Theta(K^{n-2}) \) has a natural orientation.\footnote{Note that by Lemma 61.8 we know that \( M \setminus \Theta(K^{n-2}) \) is an open subset of \( M \), in particular it is a smooth submanifold of \( M \).}

Let \( P \in M \setminus \Theta(K^{n-2}) \). Since every \( (n-1) \)-simplex is the face of an \( n \)-simplex we see that there exists an \( n \)-simplex \( s \) with \( P \in \Theta(|s|) \). Since \( P \notin \Theta(K^{n-2}) \) we see that there exists a \( Q \in \tilde{\Delta}^n \) such that \( P = \Phi \leq (Q) \). Since \( \Phi \leq (Q) : \tilde{\Delta}^n \rightarrow M \) is an immersion we know that the induced map \( T_Q \tilde{\Delta}^k \rightarrow T_P M \) is an isomorphism. Thus it makes sense to equip \( T_P M \) with the image of the positive orientation of \( \tilde{\Delta}^n \) under the above isomorphism. We need to show that the definition of the orientation does not depend on the choice of \( s \). If \( P \in M \setminus \Theta(K^{n-1}) \), then we know from Lemma 61.11 that \( s \) is unique, hence we are done. Otherwise there exists an \( (n-1) \)-simplex \( e \) such that \( P \in \Theta(|e|) \). If the order of \( e \) equals one, then \( s \) is again unique and again we are done. Finally if the order of \( e \) equals two, then it follows from the hypothesis that \( \{(\mu_s, Y_s)\}_{s \in S} \) is an orientation of \( K \). A reasonably elementary calculation shows that the orientation on \( T_P M \) does not depend on the choice of the bounding \( n \)-simplex. Finally we note that it is fairly straightforward to show that these orientations of the tangent spaces define an orientation, in the sense of the definition on page 297 of the smooth submanifold \( M \setminus \Theta(K^{n-2}) \).

We move on to the next claim.

Claim 3. For every open connected subset \( U \) of \( M \) the following holds:
(a) The set \( U \cap (M \setminus \Theta(K^{n-2})) \) is connected.
(b) The closure of \( U \cap (M \setminus \Theta(K^{n-2})) \) equals \( U \).

For \( i = 0, \ldots, n-2 \) we set \( N_i = U \cap (M \setminus \Theta(K^{i-1})) \) and we set \( Y_i = \Theta(K^i) \cap N_i \). Note that for each \( i \in \{1, \ldots, n-2\} \) we have \( N_i = N_{i-1} \setminus Y_{i-1} \). It follows easily from the definition of a smooth simplicial structure together with Lemma \( \ref{lem:smoothstructure} \) that each \( N_i \) is an \( n \)-dimensional smooth manifold and that each \( Y_i \) is a proper \( i \)-dimensional smooth submanifold of \( N_i \). Since \( i \leq n-2 \) we obtain iteratively from the future Corollary \( \ref{cor:submanifold} \) and the hypothesis that \( N_0 = U \) is path-connected that each \( N_i \) is path-connected. Finally note that we know by Exercise \( \ref{exer:orientability} \) and the fact that \( \dim(Y_i) = i < n = \dim(N_i) \) that the closure of \( N_i \setminus Y_i \) is \( N_i \). Note that the statements of Claim 3 follow almost immediately from these considerations.

\[
\begin{array}{c}
\text{Figure 1021. Second illustration for the proof of Proposition \ref{prop:orientability}}
\end{array}
\]

Finally let \( P \in M \). It follows quite easily from Claim (3a) that we can find a chart \( \Psi: U \to V \) around \( P \) such that \( V \) is a connected open subset of \( \mathbb{R}^n \) or \( H_n \) and such that \( \Psi \) is orientation-preserving for some \( Q \in M \setminus \Theta(K^{n-2}) \). Furthermore it follows from Claim (3a) and Lemma \( \ref{lem:orientation} \) (2) that the restriction of \( \Psi \) to \( U \setminus \Theta(K^{n-2}) \) is orientation-preserving at every point. Now we equip all \( Q \in U \) with the orientation induced by \( \Psi \) and the standard orientation of \( \mathbb{R}^n \) respectively \( H_n \). It follows easily from Claim (3b) that these orientations do not depend on the choice of \( \Psi \) and that these orientations of the tangent spaces define an orientation of the smooth manifold \( M \).

In the above discussion we constructed natural maps

\[
\{\text{orientations of the smooth manifold } M \} \leftrightarrow \{\text{orientations of the pseudomanifold } K \}
\]

in both directions. It follows reasonably easily from the definitions that the two maps are inverses of one another, thus both maps are natural bijections. \( \blacksquare \)

For manifolds with non-empty boundary the following theorem contains lots of extra information.

**Theorem 66.8.** Let \( M \) be a connected non-empty \( n \)-dimensional smooth manifold. The following statements hold:

1. We have an isomorphism as follows:
   \[
   H_n(M, \partial M; \mathbb{Z}) \cong \begin{cases} 
   \mathbb{Z}, & \text{if } M \text{ is orientable and compact,} \\
   0, & \text{otherwise.} 
   \end{cases}
   \]

2. If \( M \) is compact, then we also have an isomorphism as follows:
   \[
   H_{n-1}(M, \partial M; \mathbb{Z}) \cong \begin{cases} 
   \text{free abelian group,} & \text{if } M \text{ is orientable,} \\
   \text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable.}
   \end{cases}
   \]
Remark.

1. Note that if $M$ is a connected non-empty smooth manifold with $\partial M = \emptyset$, then the statements of Theorem 66.8 are contained in Theorem 66.6.

2. We will prove the generalization of Theorem 66.6 to the setting of topological manifolds in Theorems 87.1 and 87.2 and Proposition 87.22.

Example. Let $M$ be the Möbius band. Recall that $M$ is a compact non-orientable 2-dimensional smooth manifold. In Exercise 43.7 we already saw that

$$H_k(M, \partial M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}_2, & \text{if } k = 1, \\ 0, & \text{otherwise.} \end{cases}$$

This calculation is of course consistent with Theorem 66.8.

**Figure 1022**

Proof. Let $M$ be a connected non-empty $n$-dimensional smooth manifold. We dealt with the case $\partial M = \emptyset$ in Theorem 66.6; so we might as well assume that $\partial M \neq \emptyset$.

In the following we first sketch what we think should be the “correct” proof of Theorem 66.8 (1). Afterwards we will give the full details for an alternative proof.

(a) As before one uses Theorem 64.2 to equip $M$ with some smooth simplicial structure $(K, \Theta: |K| \to M)$. It follows from Proposition 66.1 that $K$ is an $n$-dimensional pseudomanifold such that $\partial M$ corresponds precisely to $\partial K$.

(b) By Lemma 63.30 we have a natural isomorphism $H_n^{\text{simp}}(K, \partial K) \cong H_n(|K|, |\partial K|; \mathbb{Z})$.

(c) It is fairly straightforward to modify the argument of Theorem 66.4 to show that one has an isomorphism

$$H_n^{\text{simp}}(K, \partial K) \cong \begin{cases} \mathbb{Z}, & \text{if } K \text{ is orientable and finite,} \\ 0, & \text{otherwise.} \end{cases}$$

(d) By Proposition 66.7 we know that $M$ is orientable if and only if $K$ is orientable. The desired statement (1) now follows from the combination of all of the above.

The above approach is surely convincing and it is relatively straightforward to work out the details. Furthermore the same approach can also be employed to settle Statements (2) and (3).

Now we turn to our second approach to proving the proposition. This second approach has the advantage that this time we can provide all the details. Given $M$ we consider its double $D M = M \cup_{\partial M = \partial M'} M'$ where $M'$ is a second copy of $M$. We refer to page 1163.
for details and we refer to Figure 1023 for an illustration. Recall that by Lemma 44.12 we know the following:

(a) The double $DM$ is also an $n$-dimensional smooth manifold such that $M \subset DM$ is a smooth submanifold.
(b) The boundary of the double $DM$ is empty.
(c) $M$ is orientable if and only if $DM$ is orientable.
(d) $M$ is connected if and only if $DM$ is connected.
(e) $M$ is compact if and only if $DM$ is compact.

![Diagram](image)

**Figure 1023**

In the following we denote by $i: M \to DM$ the natural inclusion and we denote by $r: DM \to M$ the folding map that we introduced on page 1164. Given $k \in \mathbb{N}_0$ we consider the following maps:

$$H_k(M, \partial M) \xrightarrow{i_*} H_k(DM) \xrightarrow{\partial} H_{k-1}(DM) \xrightarrow{r_*} H_{k-1}(M) \xrightarrow{i_*} H_k(DM) \xrightarrow{\partial} H_{k-1}(DM) \xrightarrow{r_*} H_{k-1}(M) \xrightarrow{i_*} H_k(DM) \xrightarrow{\partial} H_{k-1}(DM) \xrightarrow{r_*} H_{k-1}(M) \xrightarrow{i_*} H_k(DM) \xrightarrow{\partial} H_{k-1}(DM) \xrightarrow{r_*} H_{k-1}(M) \xrightarrow{i_*} H_k(DM) $$

We make the following observations:

(f) The horizontal sequence is the long exact sequence in homology corresponding to the pair $(DM, M)$.

(g) Since $r \circ i = \text{id}_M$ we have $r_* \circ i_* = \text{id}_{H_k(M)}$, which implies that $i_* : H_k(M) \to H_k(DM)$ is a monomorphism.

(h) By Lemma 44.12 we know that the vertical map is an isomorphism.

Next we recall some of our earlier calculations:

(i) Since $\partial M \neq \emptyset$ we obtain from Theorem 66.6 that $H_n(M) = 0$ and that $H_{n-1}(M)$ is a free abelian group.

(j) By Theorem 66.6 we have

$$H_n(DM) \cong \begin{cases} \mathbb{Z}, & \text{if } DM \text{ is closed and orientable}, \\ 0, & \text{otherwise} \end{cases} $$

(k) By Theorem 66.6 and since $\partial(DM) = \emptyset$ we have

$$H_{n-1}(DM) \cong \begin{cases} \text{free abelian group}, & \text{if } DM \text{ is orientable}, \\ \text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } DM \text{ is non-orientable} \end{cases}$$
Now we turn to the actual proofs of the three statements of the proposition.

(1) By the above we have an exact sequence

\[ 0 \rightarrow H_n(M) \xleftarrow{i_*} H_n(DM) \rightarrow H_n(DM, M) \xrightarrow{\partial} 0. \]

The desired statement now follows from (a)–(h) together with (i) and (j).

(2) By the above we have an exact sequence:

\[ 0 \rightarrow H_{n-1}(M) \xleftarrow{i_*} H_{n-1}(DM) \rightarrow H_{n-1}(DM, M) \xrightarrow{\partial} 0. \]

Since \( r_* \circ i_* = \text{id}_{H_{n-1}(M)} \) we obtain from Splitting Lemma 46.2 and the above discussion that \( H_{n-1}(DM) \cong H_{n-1}(M, \partial M) \oplus \) free abelian group. The desired statement follows from (a)–(h) together with (k) and Lemma 19.8.

(3) We can deduce this statement from Theorem 66.6 (3) using a slight variation on the above arguments. Alternatively we can deduce (3) from (1) and (2) using the Universal Coefficient Theorem 57.19 in the same way that we deduced Theorem 66.6 (3) from Theorem 66.6 (1) and (2). \[\blacksquare\]

66.3. Homology groups of lens spaces. In this section we will apply the results from the previous sections to complete the long overdue calculation of the homology groups of lens spaces.

**Lemma 66.9.** Let \( p \in \mathbb{N} \) and let \( q \in \mathbb{Z} \) be coprime to \( p \). For the corresponding lens space \( L(p, q) \) we have

\[ H_n(L(p, q); \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases} \]

**Remark.** An alternative approach to computing the homology groups of lens spaces will be given in Exercise ??.

The calculation of this lemma is rather disappointing, it shows that homology groups cannot distinguish between two lens spaces of the form \( L(p, q) \) and \( L(p, r) \). In particular we have made no progress at all on Question 16.7.

**Proof.** We start out with the following observations:

1. It follows from Proposition 16.9 and the definition of a lens space that \( L(p, q) \) is finitely covered by \( S^3 \). It follows from \( \chi(S^3) = 0 \) together with Proposition 37.4 that \( \chi(L(p, q)) = 0 \).
2. Note that on page 502 we pointed out that every lens space \( L(p, q) \) is a closed orientable connected 3-dimensional smooth manifold.
3. We already know from Proposition 41.5 that \( H_0(L(p, q)) \cong \mathbb{Z} \).
4. By Corollary 52.6 we know that \( H_1(L(p, q)) \cong \mathbb{Z}_p \).
(5) By (2) and Proposition 64.6 (or alternatively Theorem 87.3) we know that $H_n(L(p, q)) = 0$ for $n \geq 4$.

(6) By Theorem 66.6 (1) and (2) (or alternatively by Theorem 87.1) we know that $H_3(L(p, q)) \cong \mathbb{Z}$.

Thus at the moment we are still missing $H_2(L(p, q))$. Now note that

$$\text{rank } H_2(L(p, q)) = \chi(L(p, q)) - \text{rank } H_0(L(p, q)) + \text{rank } H_1(L(p, q)) + \text{rank } H_3(L(p, q)) = 0.$$ 

Furthermore we know by Theorem 66.6 (2) that $H_2(L(p, q))$ is a finitely generated free abelian group. Therefore we see that $H_2(L(p, q)) = 0$.

66.4. The Poincaré Homology Sphere. We start out with the following almost self-explanatory definition of a homology sphere.

**Definition.**

(1) We say that an $n$-dimensional topological manifold $X$ is a **topological homology $n$-sphere** if for every $k \in \mathbb{N}_0$ we have $H_k(X; \mathbb{Z}) \cong H_k(S^n; \mathbb{Z})$. Sometimes we also just say **homology $n$-sphere**.

(2) Sometimes, for disambiguation we also refer to such a topological manifold as an **integral homology $n$-sphere**.

(3) If $X$ is actually a smooth manifold, then we refer to $X$ as a **smooth homology sphere**.

For the record we state the following lemma which is an immediate consequence of Proposition 41.5 and Theorem 66.6.

**Lemma 66.10.** Let $M$ be a smooth manifold. If $M$ is a homology $n$-sphere, then $M$ is connected and orientable.

It follows from the classification of 1-dimensional and 2-dimensional topological manifolds that we have stated in Theorem 7.1 and the Surface Classification Theorem 23.4 and the calculation of homology groups in Proposition 48.9 that for $n = 1, 2$ every homology $n$-sphere is homeomorphic to the standard sphere $S^n$. In 1900 Henri Poincaré [Poi1900, PGL53, p. 370] claimed that the same statement also holds for $n = 3$, i.e. he claimed that every homology 3-sphere is in fact homeomorphic to $S^3$. Shortly afterwards, in 1904, Henri Poincaré [Poi1904, PGL53] himself found a counterexample to this claim. More precisely, he proved the following proposition.

**Proposition 66.11.** There exists a 3-dimensional smooth manifold $M$ that is a homology 3-sphere, but such that $\pi_1(M)$ is a non-trivial group.

**Remark.** In Exercise 66.13 and in Proposition 107.5 we will prove the higher-dimensional analogue of Proposition 66.11.

1015 In fact in [PGL53, p. 498] he wrote “Pour ne pas trop allonger ce travail, je me bornerai à énoncer le théorème suivant dont la démonstration demanderait quelques développements: Tout polyèdre qui a tous ses nombres de Betti égaux à si et tous ses tableaux $T_q$ bilatères est simplement connexe, c’est-à-dire homéomorphe à l’hypersphère.
Now we turn to the proof of Proposition 66.11. By now there are many proofs. In the following we will give Poincaré’s example of such a smooth manifold. Later on in Exercise 68.4 we will give a different proof of Proposition 66.11.

To construct Poincaré’s example we need to recall a few definitions and results from earlier on.

**Definition.**

1. Let \( z := 1 + \sqrt{\frac{5}{2}} \) be the golden ratio. As on page 1382 let \( D \) be the regular dodecahedron that is the convex hull of the 20 vertices \((\pm 1, \pm 1, \pm 1), (0, \pm z, \pm \frac{1}{z}), (\pm \frac{1}{z}, 0, \pm z), \) and \((\pm z, \pm \frac{1}{z}, 0)\).

   Furthermore let \( \text{Sym}(D) \) be the subgroup of \( \text{SO}(3) \) that preserves the regular dodecahedron, i.e. that preserves the set of these 20 vertices.

2. Let \( T := \{ A \in M(2 \times 2, \mathbb{C}) \mid A = A^T \text{ and } \text{tr}(A) = 0 \} \). This is a 3-dimensional real vector space which we equip with the basis that is given by the matrices

   \[
   E_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad E_3 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}.
   \]

   Furthermore we equip \( T \) with the form \( (A, B) \mapsto g(A, B) := \frac{1}{2} \text{tr}(AB^T) \). Next recall that on page 1302 we showed that the map \( T \to \mathbb{R}^3 \) given by \( E_i \to e_i \) defines an isometry \( (T, g) \to (\mathbb{R}^3, \langle , \rangle) \) which we now use to make the identification \( \text{SIsom}(T, g) = \text{SO}(3) \). Furthermore, in Lemma 51.1 we showed that that map

   \[
   q: \text{SU}(2) \to \text{SIsom}(T, g) = \text{SO}(3)
   \]

   is a well-defined group homomorphism, that it is an epimorphism and that the kernel is given by \( \pm \text{id} \).

3. We make the identification \( S^3 = \{ z \in \mathbb{H} = \mathbb{R}^4 \mid ||z|| = 1 \} \), i.e. we view \( S^3 \) as the set of quaternions of length 1. By Proposition 60.2 (3) we know that the following map is a diffeomorphism and a group isomorphism:

   \[
   f: S^3 \to \text{SU}(2), \quad (z, w) = z + j \cdot w \mapsto \begin{pmatrix} z & -w \\ w & \bar{z} \end{pmatrix}
   \]

   The matrix that represents left-multiplication by \( z + j \cdot w \) with respect to the complex basis \( \{1, j\} \) of \( \mathbb{H} \).

4. We refer to \( \Gamma := (q \circ f)^{-1}(\text{Sym}(D)) \subset S^3 \) as the binary icosahedral group.

**Remark.** It might be a little confusing that we refer to \( \Gamma \) as the binary icosahedral group. As we discussed on page 1383, the symmetry group of a regular icosahedron \( I \) equals the symmetry group of a regular dodecahedron \( D \). Therefore in the above definition of the binary icosahedral group we could replace \( \text{Sym}(D) \) by \( \text{Sym}(I) \), which is more logical and more common. But since it is a little easier to describe \( \text{Sym}(D) \) geometrically we prefer to work with the regular dodecahedron.
Sphere. In the following we outline a few of these alternative descriptions of the Poincaré Homology Sphere are discussed in detail in [KSc79].

**Remark.** The Poincaré Homology Sphere is ubiquitous in topology and can be described in many different ways. The different avatars and also the history of the Poincaré Homology Sphere are discussed in detail in [SW33], [Rolf90], Chapter 10.E], [Vol13], and [KSc79]. In fact [KSc79] provides altogether eight different ways to construct the Poincaré Homology Sphere. In the following we outline a few of these alternative descriptions of the Poincaré Homology Sphere.

1. In 1904, when Henri Poincaré discovered the eponymous sphere, he gave a different description in terms of gluing two “handlebodies”. It is shown in [SW33] that this topological space is homeomorphic to the topological space we describe next in (2).
2. Let $D$ be the “solid” regular dodecahedron. Now identify each pentagon on the boundary with the opposite pentagon via a $\pi/5$ twist in the “clockwise” direction. As is explained in [KSc79], the resulting topological space is in fact homeomorphic to the Poincaré Homology Sphere as we defined it above.

3. On page ?? we will give two descriptions of the Poincaré Homology Sphere as the result of a “surgery” on a knot respectively a link.

**Proof.**
(1) Let \( z := 1 + \frac{\sqrt{5}}{2} \) be the golden ratio. Recall that \( D \) is the polyhedron that is spanned by the 20 vertices
\[
(\pm 1, \pm 1, \pm 1), \quad (0, \pm z, \pm \frac{z}{2}), \quad (\pm \frac{1}{2}, 0, \pm z), \quad \text{and} \quad (\pm z, \pm \frac{1}{2}, 0).
\]
In Figures 858 and 1024 we show that one can inscribe five cubes \( C_1, \ldots, C_5 \) into the regular dodecahedron. As we already mentioned on page 1383, it is shown in \([\text{Arm88}], \text{p. 40}\) that the map
\[
\text{Sym}(D) \rightarrow A_5 \cong \text{positive permutations of } \{C_1, \ldots, C_5\}
\]
\[A \mapsto \{C_i \mapsto A \cdot C_i\}\]
is an isomorphism. We consider the maps \( \text{SU}(2) \rightarrow \text{SIsom}(T,g) = \text{SO}(3) \) and \( f: S^3 \rightarrow \text{SU}(2) \) that we defined above and we recall that the binary icosahedral group is defined as \( \Gamma := (q \circ f)^{-1}(\text{Sym}(D)) \subset S^3 \). As we mentioned above, in Lemma 51.1 we showed that \( \ker(q \circ f) = \pm 1 \in S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 | \|z\| = 1\} \). Furthermore it follows from Theorem 51.2 (1) that \( q \circ f \) is an epimorphism. Since \( \text{Sym}(D) \cong A_5 \) has \( \frac{1}{2}5! = 60 \) elements and since \( q \circ f \) has a kernel with two elements we see that \( \Gamma \) is a group with 120 elements.

(2) We need to show that the abelianization of \( \Gamma \) is trivial. By (1) we know that the group \( \Gamma \subset S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 | \|z\| = 1\} \) fits into a short exact sequence
\[
1 \rightarrow \{\pm 1\} \xrightarrow{\rho} \Gamma \xrightarrow{q \circ f} \text{Sym}(D) \rightarrow 1.
\]
By Proposition 21.20 we get an induced exact sequence
\[
\{\pm 1\} \xrightarrow{\rho} \Gamma_{ab} \xrightarrow{(q \circ f)_{ab}} (\text{Sym}(D))_{ab} \rightarrow 1.
\]
Almost every algebra book worth its money shows that \( A_5 \cong \text{Sym}(D) \) is a simple group, see e.g. \([\text{Bog08}], \text{Theorem 11.3}\). This fact implies that the abelianization of \( \text{Sym}(D) \) is trivial. Thus it suffices to prove the following claim.

**Claim.** The quaternion \(-1 \in S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 | \|z\| = 1\} \) represents the trivial element in \( \Gamma_{ab} \).

First recall that a straightforward explicit calculation, which you and I carried out in Exercise 51.1 and on page 1462, shows that
\[
(q \circ f)(i) = q\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \quad \text{and} \quad (q \circ f)(j) = q\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.
\]

It follows immediately from the explicit description of the vertices of the regular dodecahedron \( D \) in (1) that the two matrices \( A \) and \( B \) to the right actually lie in \( \text{Sym}(D) \). Next note that it follows from the above calculation, that \( i = (q \circ f)^{-1}(A) \) and \( j = (q \circ f)^{-1}(B) \). In particular we see that that \( i, j \in (q \circ f)^{-1}(\text{Sym}(D)) = \Gamma \).

\[\text{An argument similar to our proof of (2) is also provided in } [\text{Bre93}] \text{ p. 354} \text{ and in } [\text{Toen17}] \text{ p. 133} \text{.}\]
By definition of the quaternion multiplication on page 1462 we have

\[ [i, j] = i \cdot j \cdot i^{-1} \cdot j^{-1} = -j \cdot i \cdot i^{-1} \cdot j^{-1} = -1. \]

We have thus shown that $-1$ is a commutator of elements in $\Gamma$. By definition of $\Gamma_{ab}$ this implies that $-1$ represents indeed the trivial element in $\Gamma_{ab}$. 

Recall that it follows from Proposition 60.2 (3) that $\Gamma := (q \circ f)^{-1}(\text{Sym}(D))$ is a finite subgroup of the group $S^3 = \{ z \in \mathbb{H} = \mathbb{R}^4 \mid |z| = 1 \}$. Since subgroups act freely on groups we see that $\Gamma$ acts freely on $S^3$. Since $\Gamma$ is a finite subgroup it now follows from Proposition 6.32 that $M := S^3/\Gamma$ is a closed 3-dimensional smooth manifold. It remains to show that $M = S^3/\Gamma$ is a homology sphere. First we perform the following calculation:

\[
\begin{align*}
H_1(S^3/\Gamma) &\cong \pi_1(S^3/\Gamma)_{ab} \cong \Gamma_{ab} = 0. \\
\text{by the Hurewicz} & \quad \text{by Proposition 14.14 by (2)} \\
\text{Theorem 62.20} & \quad \text{and Theorem 16.16}
\end{align*}
\]

Next note that by Proposition 64.6 we have $H_i(M) = 0$ for $i \geq 4$. Furthermore note that by construction $\Gamma$ is contained in $\text{SU}(2)$. Thus we see that the action of $\Gamma$ on $S^3$ is orientation-preserving. Therefore it follows from Proposition 6.47 that $M = S^3/\Gamma$ is actually orientable. This implies in turn by Theorem 66.6 that $H_3(M) \cong \mathbb{Z}$. Thus it remains to show that $H_2(M) = 0$. By Theorem 66.6 (2) we know that $H_2(M)$ is a free abelian group. So it suffices to show that $b_2(M) = 0$. In fact we have

\[
b_2(M) = \chi(M) = \frac{1}{k} \cdot \chi(S^3) = 0.
\]

since $b_0(M) = b_3(M) = 1$ and $b_1(M) = 0$ 

\[ \text{Proposition 37.4 page 1363} \]

Remark. Let $M$ be a homology 3-sphere with finite fundamental group. As is pointed out in [Kerv69, p. 67], it follows from the work of Michio Suzuki [Su55] or alternatively John Milnor [Miln57b] that $\pi_1(M)$ is isomorphic to the binary icosahedral group. In fact, it follows from the much more fancy Elliptisation Theorem ?? that such $M$ is actually diffeomorphic to the Poincaré Homology Sphere.

We conclude this section with the statement of a conjecture that was formulated by Henri Poincaré [PGL53, p. 498] [Poi1904].

**Conjecture 66.13. (Poincaré Conjecture)** If $M$ is a homology 3-sphere that is simply connected, then $M$ is homeomorphic to $S^3$.

We will discuss the Poincaré Conjecture and various variations thereof in Chapter ??.

\[ \text{Since the action of $\Gamma$ is free it follows also from Exercise 3.28 that the action is orientation-preserving.} \]
66.5. The topology of smooth manifolds. In this section we provide two results on the
topology of smooth manifolds. Let us formulate our first result.

**Proposition 66.14.** Let $M$ be a connected non-empty $n$-dimensional smooth manifold. If
$M$ is non-compact or if $M$ has non-empty boundary, then $M$ is homotopy equivalent to
an $(n - 1)$-dimensional simplicial complex, in particular $M$ is homotopy equivalent to an
$(n - 1)$-dimensional CW-complex.

**Examples.**

(1) Given $g \in \mathbb{N}_0$ and $k \in \mathbb{N}_0$ we denote as usual by $\Sigma_{g,k}$ the surface of genus $g$ with $k$
open disks removed. In Figure 1026 we sketch a deformation retraction from $\Sigma_{2,2}$ to
a CW-complex of Euler characteristic $-4$.

More generally, almost the same argument shows that $\Sigma_{g,k}$ with $k \geq 1$ admits a
deformation retraction to a CW-complex with $k$ 0-cells and $2g + 2(k - 1)$ 1-cells, i.e.
a 1-dimensional CW-complex of Euler characteristic $k - (2g + 2(k - 1)) = -2g - k + 2$.

Using Proposition 37.8 (2) we also see that $\Sigma_{g,k}$ is homotopy equivalent to the wedge
of $2g + k - 1$ circles.

(2) The non-compact smooth manifold that is given by removing a point from the torus
is easily seen to be homotopy equivalent to the wedge of two circles.

(3) In Figure 1027 we show the surface $M$ of infinite genus, which is non-compact, and
a 1-dimensional CW-complex that is deformation retract of $M$. It is admittedly not
overly obvious why the 1-dimensional CW-complex is indeed a deformation retract
of $M$.

**Remark.** Let $M$ be a compact connected $n$-dimensional smooth manifold with non-empty
boundary. By Proposition 66.14 we now know that $M$ is homotopy equivalent to a finite
(n − 1)-dimensional CW-complex which implies by Proposition 48.5 that \( H_n(M) = 0 \) and that \( H_{n-1}(M) \) is a finitely generated free abelian group. This is of course consistent with Theorem 66.6.

The proof of Proposition 66.14 requires some preparations.

**Definition.** Let \( K = (V, S) \) be an \( n \)-dimensional abstract simplicial complex such that every \((n - 1)\)-simplex has order \( \leq 2 \). We denote by \( W \) the set of \( n \)-simplices and we denote by \( E \) the set of \((n - 1)\)-simplices.

1. We say an \( n \)-simplex is free if it admits a codimension one face of order 1. Otherwise we say that the \( n \)-simplex is unfree.
2. A boundary route is a subgraph \( \Gamma = (W, \tilde{F}, \varphi) \) of the dual graph \( \Gamma = (W, E, \varphi) \) with the following property: every \( n \)-simplex of \( K \), i.e. every vertex of the dual graph, is connected in \( \tilde{\Gamma} \) to a free \( n \)-simplex.
