**Lemma 66.15.** Let \( K = (V, S) \) be an \( n \)-dimensional abstract simplicial complex that admits a boundary route. There exists a subcomplex \( K' = (V', S') \) of \( K = (V, S) \) with the following three properties:

1. \( K' = (V', S') \) admits a boundary route.
2. \(|K'| \) is a deformation retract of \(|K|\).
3. The number of \( n \)-simplices of \( K' \) is less than the number of \( n \)-simplices of \( K \).

**Proof of Lemma 66.15** Let \( K = (V, S) \) be an \( n \)-dimensional abstract simplicial complex that admits a boundary route \( \tilde{\Gamma} = (W, \tilde{F}, \varphi) \). Since \( K \) is \( n \)-dimensional we know that it contains at least one \( n \)-simplex and since \( K \) admits a boundary route we see that there exists an \( n \)-simplex \( w \) that is free. By definition this means that \( w \) admits a codimension-one face \( e \) of order 1. We denote by \( f_1, \ldots, f_n \) the remaining codimension-one faces of \( w \). We set

\[
K' := (V, S \setminus \{w, e\}).
\]

Note that \( K' \) is indeed a subcomplex of \( K \). A slight generalization of Exercise 18.24 shows that there exists a deformation retraction from \(|w|\) to \( \bigcup_{i=1}^{n} |f_i| \). It follows from Lemma 61.8 together with Lemma 3.10 that this deformation retraction together with the constant homotopy on \(|K'|\) defines a deformation retraction from \(|K|\) to \(|K'|\).

\[^{1018}\text{We refer to page 1654 for the definition of the dual graph.}\]
Since every \((n-1)\)-simplex of \(K\) has order \(\leq 2\) we see that every \(n\)-simplex of \(K'\) that contains one of the \(f_i\) as a face is a free \(n\)-simplex of \(K'\). Using this observation it is now straightforward to see a boundary route for \(K'\) is given by \((W\setminus \{w\}, \{\tilde{f} \in \tilde{F} \mid \tilde{f} \neq w\}, \varphi)\).

**Figure 1029.** Illustration for the proof of Lemma 66.15

Now we can provide the proof of Proposition 66.14.

**Proof of Proposition 66.14 in the compact case.** Let \(M\) be a compact connected non-empty \(n\)-dimensional smooth manifold with non-empty boundary. Recall that by Theorem 64.2 we know that \(M\) admits a simplicial structure \((\mathcal{K} = (V, S), \vartheta) : |\mathcal{K}| \to M\) such that \(\partial M\) is a subcomplex. We need to show that \(|\mathcal{K}|\) is homotopy equivalent to a finite \((n-1)\)-dimensional simplicial complex.

Let \(\Gamma = (W, E, \varphi)\) be the dual graph of \(\mathcal{K}\). By Proposition 66.1 (5) we know that \(\Gamma\) is connected. Thus it follows from Proposition 4.8 (1) that \(\Gamma\) admits a spanning tree \(T\). By definition \(T\) is connected and by Proposition 4.8 we know that a spanning tree contains all vertices. Since \(\partial M \neq \emptyset\) we know by Proposition 66.1 that \(\partial |\mathcal{K}| \neq \emptyset\). Thus we see that \(T\) is in fact a boundary route for \(\mathcal{K}\). This means that we can start up the machine given by Lemma 66.15. Iteratively applying Lemma 66.15 we get the desired deformation retraction.

**Figure 1030.** Illustration for the proof of Proposition 66.14

simplicial structure for the surface of genus one
with one boundary component

1-dimensional simplicial complex
Proof of Proposition 66.14 in the non-compact case. Let $M$ be a non-compact connected $n$-dimensional smooth manifold. It follows from [NR04, Theorem 2.2], or alternatively [WhdJ61b, Lemma 2.1], together with Proposition 62.12 that $M$ is homotopy equivalent to an $(n - 1)$-dimensional simplicial complex.

We will not attempt to give a full proof of our own, but we will sketch an outline of a proof. Evidently we again use the fact that by Theorem 64.2 we know that we can equip $M$ with a simplicial structure $(K = (V, S), \Theta: |K| \to M)$. It is fairly straightforward to show that there exists a sequence $Y_1, Y_2, \ldots$ of non-empty subcomplexes of $K$ with the following properties:

1. The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $Y_i \subset Y_{i+1}$.
2. Each $X_i$ is a finite $(n-1)$-dimensional pseudomanifold.
3. We have $\bigcup_{i \in \mathbb{N}} X_i = K$.

Now, with a considerable effort one can modify the above arguments used in the compact case to show that there exists a sequence of $(n - 1)$-dimensional subcomplexes $X_i \subset Y_i$ with the following properties:

4. For each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
5. Each $|X_i|$ is a deformation retract of $|Y_i|$.

Finally we set $X := \bigcup_{i \in \mathbb{N}} X_i$. Note that $X$ is an $(n - 1)$-dimensional subcomplex of $Y$. It remains to show that $X$ is a deformation retract of $Y$.

We pick a base point $\ast \in \mathbb{N}$. Using the above one can show, reasonably easily, that the inclusion induced map $\pi_n(X, \ast) \to \pi_n(Y, \ast)$ is an isomorphism for every $n \in \mathbb{N}$. It follows from Proposition 119.10 (which is a variation on the Whitehead Theorem 119.9, that $X$ is indeed a deformation retract of $Y$. We leave it as a charming challenge to the reader to turn this idea into a rigorous proof.

We give a new proof of the following proposition.

Proposition 31.5. Let $M$ be a connected 2-dimensional smooth manifold. If $M$ is non-compact, then $\pi_1(M)$ is a free group.

Proof. Let $M$ be a connected 2-dimensional smooth manifold that is non-compact. By Proposition 66.14 we know that $M$ is homotopy equivalent to a 1-dimensional CW-complex. It follows from Proposition 18.16 (2) and Proposition 37.9 (1) that $\pi_1(M)$ is a free group.

We conclude this chapter with the following proposition.

Proposition 66.16. Let $M$ be a compact connected $n$-dimensional smooth manifold. There exists a CW-structure for $M$ with a single $n$-cell.

Remark. For fans of small CW-complexes we also recall Proposition 39.11 which says that any 0-connected CW-complex $X$ is homotopy equivalent to a CW-complex $Y$ with a single 0-cell which has the property that for any $n \geq 2$ the number of $n$-cells of $X$ equals the number of $n$-cells of $Y$.

1019 My apologies for referring to a future result.
In the proof of Proposition 66.16 we will make use of the following lemma.

**Lemma 66.17.** Let \( L \) be an \( n \)-dimensional pseudomanifold that contains two subcomplexes \( J \) and \( K \). If \( K \) consists of a single \( n \)-simplex, if \( J \cap K \) consists of a single \((n-1)\)-simplex \( e \) and if \( e \) has order 1 in \( J \), then there exists a homeomorphism \((|L|, \partial L|) \rightarrow (|J|, \partial J|)\) of pairs of topological spaces.

**Sketch of a proof of Lemma 66.17.** Let \( w \) be the one \( n \)-simplex of \( J \) that cobounds \( e \). It is elementary, albeit ever-so-slightly painful, to write down an explicit homeomorphism \(|w| \cup |K| \rightarrow |w|\) that is the identity on \( \partial w \setminus (|\partial w| \cap |K|) \). Together with the identity on \( |J| \setminus |w|\) this homeomorphism gives us the desired homeomorphism from \(|L|\) to \(|J|\). It follows almost immediately from the definitions that this homeomorphism restricts to a homeomorphism \( \partial L| \rightarrow \partial J|\). We leave it to the reader to fill in the details. 

![Figure 1031. Illustration of Lemma 66.17](image)

**Sketch of a proof of Proposition 66.16.** We sketch a proof of the proposition. The statement is also proved with fewer details but more authority in [Mc02, Theorem 5.1].

Let \( M \) be a closed connected non-empty \( n \)-dimensional smooth manifold. By Theorem 64.2 we know that \( M \) admits a simplicial structure \((K = (V,S), \Theta : |K| \rightarrow M)\). We need to show that \(|K|\) admits a CW-structure with a single \( n \)-cell.

Let \( \Gamma = (W, E_2, \varphi) \) be the dual graph of \( K \). By Proposition 66.1 (5) we know that \( \Gamma \) is connected. Thus it follows from Proposition 4.8 (1) that \( \Gamma \) admits a spanning tree \( T \). Note that by Proposition 4.8 (2) we know that \( T \) contains every vertex of \( \Gamma \).

Let \( X \) be the subcomplex of \( K \) that is given by removing all \( n \)-simplices and by removing all \((n-1)\)-dimensional simplicial complex. Furthermore let \( L \) be the abstract simplicial complex that is given by the "disjoint union of the \( n \)-simplices of \( K \) and gluing them along the \((n-1)\)-simplices corresponding to the edges of \( T \). It is not difficult, but also not particularly instructive, to write down a completely rigorous definition of \( L \). Note that \( L \) comes with a natural simplicial map \( f : L \rightarrow K \).

Next note that using an induction argument based on Lemma 66.17 and which also makes use of Lemma 41.1 it is rather straightforward to show that there exists a homeomorphism \( \Psi : (\overline{B^n}, S^{n-1}) \rightarrow (\Delta^n, \partial \Delta^n) \rightarrow (|L|, \partial L|) \). Finally, using Proposition 2.43 (3) one can verify that the map

\[
\begin{align*}
&x \sim (\Psi \circ f|)(x) \text{ for every } x \in S^{n-1} \\
&\downarrow \\
&(\overline{B^n} \cup |X|)/ \sim \rightarrow |K| \\
&[P] \mapsto \begin{cases} 
(\Psi \circ f|)(P), & \text{if } P \in \overline{B^n}, \\
\\ 
\end{cases} \quad \text{if } P \in |X| \subset |K|
\end{align*}
\]
is a homeomorphism. The left-hand side admits an obvious CW-structure with a single $n$-cell. Thus we have shown that $|K|$ admits a CW-structure with a single $n$-cell.

Exercise 66.1. Let $K$ be a finite $n$-dimensional pseudomanifold.  
(a) Show that the suspension $\Sigma(K)$, as defined on page 1506, is an $(n + 1)$-dimensional pseudomanifold.
(b) Show that if $K$ is closed, then $\Sigma(K)$ is closed.
(c) Show that if $K$ is orientable in the sense of the definition on page 1652 then $\Sigma(K)$ is orientable.

Exercise 66.2. Let $K$ be an $n$-dimensional pseudomanifold such that $\partial K$ is an $(n - 1)$-dimensional pseudomanifold. Let $i: \partial K \to K$ be the inclusion map. We consider the cone $K \cup_{\partial K} \text{Cone}(\partial K)$. Show that $\text{Cone}(i: \partial K \to K)$ is a closed $n$-dimensional pseudomanifold.

Exercise 66.3. Let $K$ be an $m$-dimensional pseudomanifold and let $L$ be an $n$-dimensional pseudomanifold. We equip $K$ and $L$ with a total order and we define the product $K \times L$ as on page 1501.

(a) Show that $K \times L$ is an $(m + n)$-dimensional pseudomanifold.
(b) Show that $K \times L$ is closed if and only if both $K$ and $L$ are closed.
(c) Show that $K \times L$ is orientable if and only if both $K$ and $L$ are orientable.

Exercise 66.4.
(a) Let $K$ be a 1-dimensional pseudomanifold. Show that $|K|$ is a closed 1-dimensional smooth manifold.
(b) Let $K$ be a 2-dimensional pseudomanifold. Show that $|K|$ is a closed 2-dimensional smooth manifold.

Remark. Part (a) is fairly straightforward. The proof of part (b) is more delicate. One way to prove part (b) is to imitate the proof, given in Propositions 6.8 and 6.21, that the surface $\Sigma_g$ of genus $g$ is closed 2-dimensional smooth manifold.

Exercise 66.5. Let $K = (V, S)$ be an $n$-dimensional pseudomanifold.
(a) Show that the barycentric subdivision $\text{sd}(K)$ is an $n$-dimensional pseudomanifold.
(b) Suppose that $K$ is equipped with an orientation. Let $t = \{s_0, \ldots, s_n\}$ be an $n$-simplex of $\text{sd}(K)$. For $i = 0, \ldots, n$ we denote by $v_i$ the vertex of $s_i$ that is not contained in $s_{i-1}$. Let $\epsilon \in \{-1, 1\}$ be the sign such that $(\epsilon, (v_0, \ldots, v_n))$ matches the given orientation of $K$. We equip the $n$-simplex $t$ of $\text{sd}(K)$ with the orientation given by $(\epsilon, (s_0, \ldots, s_n))$. Show that the above orientations of the $n$-simplices of $\text{sd}(K)$ define an orientation for $\text{sd}(K)$.

We refer to Figure 1033 for an illustration.

**Exercise 66.6.** Let $M$ be a compact connected non-empty smooth manifold. Furthermore let $(K = (V, S), \Theta: |K| \rightarrow M)$ be a simplicial structure for $M$. Let $\Gamma$ be the dual graph as defined on page 1654. Is there a relationship between the homology groups $H_1(\Gamma; \mathbb{Z})$ and the groups $H_1(M; \mathbb{Z})$ or $H_1(M, \partial M; \mathbb{Z})$? For example is there a relationship between the ranks or the minimal number of generators?

**Exercise 66.7.** Let $M$ be a compact orientable $n$-dimensional smooth manifold. Suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. Show that $H_{n-1}(M, A)$ is a free abelian group.

**Exercise 66.8.** Let $M$ be a compact connected $n$-dimensional smooth manifold and let $p \neq 2$ be a prime. Determine $H_n(M, \partial M; \mathbb{F}_p)$ and $H_n(M; \mathbb{F}_p)$.

**Exercise 66.9.** Let $k, l \in \mathbb{N}$ and let $N_{k,l}$ be $N_k = k \cdot \mathbb{R}P^2$ minus $l$ open disks. Determine $H_1(N_{k,l}, \partial N_{k,l}; \mathbb{Z})$.

**Exercise 66.10.** Let $K$ be an infinite $n$-dimensional pseudomanifold such that $\partial K = \emptyset$. Show that $H_{n-1}^\text{simp}(K)$ is a free abelian group.

*Remark.* This exercise will require a serious effort.

**Exercise 66.11.** Let $p, q \in \mathbb{N}$ be coprime. Show that every orientation-reversing diffeomorphism of the lens space $L(p, q)$ has at least one fixed point.

**Exercise 66.12.** Let $X$ be a connected 2-dimensional smooth manifold with infinite fundamental group. Show that $X$ is aspherical, i.e.
show that $\pi_i(X) = 0$ for $i \geq 2$.

*Hint.* First use the Hurewicz Theorem \[53.5\] and the results from this section to show that $\pi_2(X) = 0$.

*Remark.* This exercise gives in particular a new proof of the fact that given a surface $\Sigma_g$ of genus $g \geq 1$ we have $\pi_i(\Sigma_g) = 0$ for $i \geq 2$. We had initially proved this statement on page \[1070\] using the rather difficult results from Chapter \[33\].

**Exercise 66.13.** Let $M$ be a 3-dimensional smooth homology 3-sphere with non-trivial fundamental group. Furthermore let $n \geq 4$. We pick a smooth embedding $\varphi: \mathbb{B}^3 \to M$ and we consider $W := (M \setminus \varphi(\mathbb{B}^3)) \times \mathbb{B}^{n-3}$. By Proposition \[80.9\] we can equip $W$ with the structure of an orientable $n$-dimensional smooth manifold. Show that the double $D W$ is an $n$-dimensional smooth homology $n$-sphere with non-trivial fundamental group.

**Exercise 66.14.** Let $\Sigma$ be a compact oriented connected 2-dimensional smooth manifold. We consider the product $N := \Sigma \times [0, 1]$ and we consider the subset $A := \partial \Sigma \times [0, 1] \subset N$. Let $\varphi: \Sigma \to \Sigma \times \{0\} \subset N$ be the obvious inclusion map. Now let $g: S \to N$ be a map from a compact oriented connected 2-dimensional smooth manifold with $g(\partial S) \subset A$ such that $\varphi_*([\Sigma]) = g_*([S])$. Show that $\chi(S) \leq \chi(\Sigma)$.

*Remark.* In a slightly simplified version the exercise says that the surface $\Sigma \times \{0\}$ is the “simplest” surface in $N$ representing the homology class $[\Sigma \times \{0\}]$.

---

Footnote: By Proposition \[66.11\] we know that such $M$ exists.
67. Simplicial cohomology

In this chapter we will introduce the simplicial cohomology groups of an (ordered) abstract simplicial complex. This chapter can be seen as a continuation of our discussions of abstract simplicial complexes in Chapters 61, 62 and 63. The objects in this chapter are for the most part purely combinatorial and for the most part this chapter can be read independently of the chapters on singular cohomology. We will only make use of the purely algebraic statements in Sections 73.1, 73.2 and 73.3.

As for simplicial homology, the study of simplicial cohomology is great fun in its own right. But as we will see, it is also a very convenient tool for calculating singular cohomology groups and for determining the often intractable cup and cap products.

In Chapter 71 we will prove the Simplicial Poincaré Duality Theorem 71.4 for pseudo-manifolds, which gives us in particular a Poincaré Duality theorem for smooth manifolds.

67.1. Simplicial chain complexes. In the following section we will introduce simplicial cohomology groups. Before we do so it is convenient to recall several definitions and results on simplicial chain complexes.

We start out with the following definition from page 1542.

**Definition.** Let $K = (V,S)$ be an ordered abstract simplicial complex. Given $k \in \mathbb{N}_0$ we define

$$C_{\leq k}(K) := \text{free abelian group generated by the set of } k\text{-simplices of } K.$$ 

Furthermore we consider the boundary map

$$\partial_k : C_{\leq k}(K) \rightarrow C_{k-1}(K)$$

$$\{v_0 < \cdots < v_k\} \mapsto \sum_{i=0}^{k} (-1)^i \cdot \{v_0, \ldots, v_{i-1}, \hat{v}_i, v_{i+1}, \ldots, v_k\}.$$ 

By Lemma 63.2 we know that $(C_{\leq k}(K), \partial_k)$ is a chain complex, thus we can define the corresponding simplicial homology groups $H_{\leq k}(K)$.

The above definition is straightforward, but it does have the major disadvantage that it requires the choice of an order on $K$. In most situations there is no natural choice of an order. In the absence of an order we are led to the following more elaborate definition which initially we gave on page 1544 and in Lemma 63.6.

**Definition.** Let $K = (V,S)$ be an abstract simplicial complex.

1. Let $k \in \mathbb{N}_0$. An ordered $k$-simplex of $K$ is a $(k+1)$-tuple $(v_0, \ldots, v_k) \in V^{k+1}$ such that $\{v_0, \ldots, v_k\}$ is an $k$-simplex of $K = (V,S)$. In the following we write $[v_0, \ldots, v_k] := \{v_0, \ldots, v_k\}$.

Recall that, according to the definition on page 1484, an order on an abstract simplicial complex $(V,S)$ is a partial order on $V$ that has the property that the restriction to each simplex is actually a total order.
(2) Let \( k \in \mathbb{N}_0 \). We define the \( k \)-th simplicial chain group

\[
\mathbb{C}_k^{\text{simp}}(K) := \text{free abelian group on the set of ordered } k\text{-simplices of } K / (v_0, \ldots, v_k) - \text{sign}(\sigma) \cdot (v_{\sigma(0)}, \ldots, v_{\sigma(k)}) \text{ where } \sigma \in S_{k+1} = \text{Bij}\{0, \ldots, k\}.
\]

(3) Given an ordered simplex \((v_0, \ldots, v_k)\) we denote its image in \(\mathbb{C}_k^{\text{simp}}(K)\) by \([v_0, \ldots, v_k]\).

(4) We consider the map

\[
\partial_k: \mathbb{C}_k^{\text{simp}}(K) \to \mathbb{C}_{k-1}^{\text{simp}}(K)
\]

\[
[v_0, \ldots, v_k] \mapsto \sum_{i=0}^{k} (-1)^i \cdot [v_0, \ldots, v_{i-1}, \hat{v}_i, v_{i+1}, \ldots, v_k].
\]

(5) By Lemma 63.6 we know that \((\mathbb{C}_*^{\text{simp}}(K), \partial_*)\) is a chain complex, thus we can define the corresponding simplicial homology groups \(\mathbb{H}_*(K)\).

\textbf{Notation.} In pictures we denote the ordering of the simplices of a 1-simplex in the obvious way by an arrow pointing from the first to the second vertex. Furthermore, given an ordered 2-simplex we indicate the first vertex by a dot and the ordering of the remaining vertices by an oriented 3/4-circle. We refer to Figure 1035 for an illustration.

\textbf{Figure 1035}

We recall the following lemma.

\textbf{Lemma 63.6.} Let \( K \) be an abstract simplicial complex. If we choose for each \( k \)-simplex \( s \in S \) an ordered \( k \)-simplex \( \bar{s} \) with \( [\bar{s}] = s \), then the [\( \bar{s} \)] form a basis for \(\mathbb{C}_k^{\text{simp}}(K)\).

We conclude this short section with the following proposition that combines several earlier statements on the relationship between the above two simplicial chain complexes and also the singular chain complex of the topological realization.

\textbf{Proposition 67.1.}

(1) Let \((K = (V, S), \leq)\) be an ordered abstract simplicial complex.

(a) We consider the following maps:

\[
\begin{array}{ccc}
\mathbb{C}_k^{\text{simp}}(K) & \overset{\Omega_{\leq, k}}{\leftarrow} & \mathbb{C}_k^{\text{simp, \leq}}(K) \\
[v_0, \ldots, v_k] & \iff & s = \{v_0 < \cdots < v_k\} \quad \overset{\Theta_{\leq, k}}{\longrightarrow} \quad \mathbb{C}_k(|K|) \\
\end{array}
\]

\text{map given by sending } e_i \text{ to } v_i

The maps \(\Omega_{\leq, k}\) to the left define a natural isomorphism of chain complexes whereas the maps \(\Theta_{\leq, k}\) to the right define a natural chain homotopy equivalence.

(b) There exist maps

\[
\pi_k: \mathbb{C}_k(|K|) \to \mathbb{C}_k^{\text{simp, \leq}}(K)
\]
which have the following two properties:

(i) The maps $\pi_k$ form a chain map which form a chain homotopy equivalence.

(ii) For each $k \in \mathbb{N}_0$ we have $\pi_k \circ \Theta_k = \text{id}_{C_{k}^{\text{simp}, \leq}(K)}$.

(2) Let $K$ be an abstract simplicial complex and let “$\leq$” and “$\subset$” be two orders on $K$. The two chain maps

$$C_{k}^{\text{simp}}(K) \xrightarrow{\Omega_{\leq,k}^{-1}} C_{k}^{\text{simp}, \leq}(K) \xrightarrow{\Theta_{\leq,k}} C_{k}(|K|)$$

and

$$C_{k}^{\text{simp}}(K) \xrightarrow{\Omega_{\subset,k}^{-1}} C_{k}^{\text{simp}, \subset}(K) \xrightarrow{\Theta_{\subset,k}} C_{k}(|K|)$$

are chain homotopic.

(3) Let $G$ be an abelian group. The chain homotopy equivalence class of (2) induces a natural isomorphism

$$\Xi_k^*: H_{k}^{\text{simp}}(K; G) \rightarrow H_{k}(|K|; G).$$

**Proof.**

(1) (a) This statement is the combination of Lemma 63.8 and Theorem 63.25.

(b) It follows almost immediately from the definitions that for each $k \in \mathbb{N}_0$ the map $C_k^{\text{simp}, \leq}(K) \rightarrow C_k(|K|)$ is a monomorphism and that the image is a summand. The desired statement is now an immediate consequence of (a) and Proposition 49.3.

(2) This statement is the content of Lemma 63.26.

(3) It follows immediately from (2) and a slight generalization of Lemma 42.2 that any choice of order on $K$ induces the same map on homology with $G$-coefficients, i.e. the map $\Xi_k^*$ is well-defined. It follows easily from (1) and Corollary 42.3 that the map $\Xi_k^*$ is a natural isomorphism.

67.2. The definition of the simplicial cohomology groups. In this section we will introduce the simplicial cohomology groups of an (ordered) abstract simplicial complex. The discussion in the previous section also shows that it will be necessary to consider two slightly different types of simplicial cohomology groups.

We start out with a decidedly dull definition.

**Definition.** Let $K$ be an (ordered) abstract simplicial complex and let $G$ be an abelian group. For each $k \in \mathbb{N}_0$ we write

$$C_k^{\text{simp}}(K; G) := \text{Hom}(C_{k}^{\text{simp}}(K), G) \quad \text{and} \quad C_k^{\text{simp}, \leq}(K; G) := \text{Hom}(C_k^{\text{simp}, \leq}(K), G).$$

Elements of $C_k^{\text{simp}}(K; G)$ and $C_k^{\text{simp}, \leq}(K; G)$ are called simplicial $k$-cochains.

**Remark.** Let $G$ be an abelian group, let $K$ be an ordered abstract simplicial complex and let $k \in \mathbb{N}_0$.

(1) It follows from Lemma 73.1 that a simplicial $k$-cochain in $C_k^{\text{simp}, \leq}(K; G)$ is the same data as assigning an element of $G$ to every $k$-simplex. Note that in contrast to the setting of singular cochains one can actually hope to “see” simplicial cochains. For example see Figure 1036 for a simple-minded illustration.
In contrast, it follows easily from Lemma 57.3 that a chain in $C^\text{simp;}_k(K) \otimes G$ is the same data as assigning an element of $G$ to finitely many $k$-simplices.

(2) Now we introduce the following notation.

\textbf{Notation.}

\begin{enumerate}
\item Let $K$ be an order abstract simplicial complex and let $s$ be an ordered $k$-simplex. We denote by $s^*: C^\text{simp;}_k(K) \to \mathbb{Z}$ the map that is given by $s^*(s) = 1$ and $s^*(t) = 0$ for any $k$-simplex $t \neq s$.
\item Let $K$ be an abstract simplicial complex and let $s = (v_0, \ldots, v_k)$ be an ordered $k$-simplex. It follows immediately from the definitions that

$$s^*: C^\text{simp}_k(K) \to \mathbb{Z}, \quad [w_0, \ldots, w_k] \mapsto \begin{cases} 0, & \text{if } \{v_0, \ldots, v_k\} \neq \{w_0, \ldots, w_k\}, \\ \text{sign}(\sigma), & \text{if there exists a } \sigma \in \text{Bij}\{0, \ldots, k\} \\ \text{with } w_i = v_{\sigma(i)} \text{ for } i = 0, \ldots, k \end{cases}$$

\[\text{is well-defined, in other words, } s^* \text{ is a well-defined cochain in } C^k_{\text{simp}}(K; \mathbb{Z}).\]
\end{enumerate}

In the following we will mostly study the simplicial cohomology of finite (ordered) abstract simplicial complexes. In this context the following lemma is very helpful.

\textbf{Lemma 67.2.} Let $k \in \mathbb{N}_0$.

\begin{enumerate}
\item Let $K = (V, S)$ be an ordered abstract simplicial complex. If $K$ is finite, then the set $\{s^* \mid s \text{ a } k\text{-simplex}\}$ is a basis for $C^k_{\text{simp}; \leq}(K; \mathbb{Z})$.
\item Let $K = (V, S)$ be an abstract simplicial complex. We choose for each $k$-simplex $s$ an ordered $k$-simplex $\tilde{s}$ with $[\tilde{s}] = s$. If $K$ is finite, then the $\tilde{s}^*$ form a basis for $C^k_{\text{simp}}(K; \mathbb{Z})$.
\end{enumerate}

\textbf{Proof.} This follows immediately from Lemma 73.1 together with the definition of $C^\text{simp;}_k(K)$ and together with Lemma 63.6.

Now that we have gained a little bit of familiarity with cochains let us move on to the definition of the simplicial cochain complex and the simplicial cohomology groups.
**Definition.** Let $K$ be an abstract simplicial complex and let $G$ be an abelian group. For each $k \in \mathbb{N}_0$ we refer to

$$
\delta_k := \partial_{k+1} : \operatorname{Hom}(C^k(G), G) \to \operatorname{Hom}(C^{k+1}_k(G), G)
$$

as the **coboundary map**. Any simplicial $k$-cochain in $\ker(\delta_k : C^k_k(G) \to C^{k+1}_k(G))$ is called a **simplicial $k$-cocycle**. We refer to the cochain complex

$$
... \leftarrow C^{k+1}_k(G) \leftarrow C^k_k(G) \leftarrow C^{k-1}_k(G) \leftarrow ... \leftarrow C^0_k(G) \leftarrow 0
$$

as the **simplicial cochain complex of $K$ with $G$-coefficients**. We define the $k$-th **simplicial cohomology group of $K$ with $G$-coefficients** as follows:

$$
H^k_k(G) := \ker(\delta_k : C^k_k(G) \to C^{k+1}_k(G)) / \operatorname{im}(\delta_{k-1} : C^{k-1}_k(G) \to C^k_k(G)).
$$

If $K$ is actually an ordered abstract simplicial complex, then we define the cochain complex $C^*_{\operatorname{simp}, \leq}(G)$ and the simplicial cohomology groups $H^k_{\operatorname{simp}, \leq}(G)$ in the obvious way.

**Example.** We consider the “simplicial circle” $C$ with vertex set $V = \{a, b, c\}$ shown in Figure 1037. We consider the ordered 1-simplices $s := (a, b)$, $t := (b, c)$ and $u := (c, a)$. We see that the simplicial chain complex $C^*_{\operatorname{simp}}(C; \mathbb{Z})$ is of the following form:

$$
0 \to C^1_{\operatorname{simp}}(C) \xrightarrow{\partial} C^0_{\operatorname{simp}}(C) \to 0 \quad \text{thus the dual} \quad 0 \leftarrow C^1_{\operatorname{simp}}(C; \mathbb{Z}) \xleftarrow{\partial_0} C^0_{\operatorname{simp}}(C; \mathbb{Z}) \leftarrow 0
$$

$s \mapsto b - a$  
$t \mapsto c - b$  
$u \mapsto a - c$.

An elementary calculation shows that

$$
H^0_{\operatorname{simp}}(C; \mathbb{Z}) = \ker(\delta_0) = \mathbb{Z} \cdot (a^* + b^* + c^*).
$$

We turn to the slightly more tricky calculation of $H^1_{\operatorname{simp}}(C; \mathbb{Z})$. First note that it is elementary to show that

$$
\operatorname{im}(\delta_0 : C^0_{\operatorname{simp}}(C; \mathbb{Z}) \to C^1_{\operatorname{simp}}(C; \mathbb{Z})) = \{k \cdot s^* + l \cdot t^* + m \cdot u^* | k + l + m = 0\}.
$$

**References:**

- **Remark.** Usually it takes a while to get used to coboundaries. Thus let us show in detail that we have $\delta_0(a^*) = u^* - s^* \in C^0_{\operatorname{simp}}(C; \mathbb{Z}) = \operatorname{Hom}(C^1_{\operatorname{simp}}(C; \mathbb{Z})$. We need to show that $\delta_0(a^*) = u^* - s^*$ are the same homomorphism. By Lemma 63.6 we know that $\{s, t, u\}$ is a basis for $C^1_{\operatorname{simp}}(C)$. So we need to show that the two homomorphisms take the same values on $s, t$ and $u$. We calculate that

$$
\delta_0(a^*)(s) = a^*(\partial_1 s) = a^*(b - a) = a^*(b) - a^*(a) = -1 = u^*(s) - s^*(s) = (u^* - s^*)(s).
$$

The same way we proceed with $t$ und $u$.
Now let us consider the cochain \( \theta = t^* : C_1^{\text{simp}}(C) \to \mathbb{Z} \). (In other words, \( \theta \) is the cochain that is given by \( \theta(s) = 0, \theta(t) = 1 \) and \( \theta(u) = 0 \).) An elementary argument, see e.g. Exercise 41.11, shows that the map

\[
\mathbb{Z} \xrightarrow{\sim} H_1^{\text{simp}}(C; \mathbb{Z}) = \text{coker}(\delta_0)
\]

is an isomorphism.\(^{1023}\) Note that on several occasions throughout this chapter we will make use of the above simplicial cocycle \( \theta = t^* \in C_1^{\text{simp}}(C; \mathbb{Z}) \).

---

\( C \)

\( s \)

\( t \)

\( u \)

\( b \)

\( c \)

\( a \)

\( 0 \)

\( 1 \)

\( \text{cocycle } \theta : C_1^{\text{simp}}(K) \to \mathbb{Z} \text{ represents a generator of } H_1^{\text{simp}}(K; \mathbb{Z}) \)

---

We state the next example as a lemma.

**Lemma 67.3.** Let \( G \) be an abelian group and let \( K = (V, S) \) be an abstract simplicial complex.

1. Given any \( g \in G \) the constant cochain \( \varphi_g : C_0^{\text{simp}}(K) \to G \) given by \( \varphi_g(v) = g \) for every \( v \in V \) is a cocycle.
2. If \( K \) is non-empty and connected in the sense of the definition on page 1516, then \( H_0^{\text{simp}}(K; G) = \{ \varphi_g | g \in G \} \). In particular \( H_0^{\text{simp}}(K; G) \cong G \).

**Proof.**

1. Let \( g \in G \). We need to show that \( \delta_0(\varphi_g) = 0 \in C_1^{\text{simp}}(K) = \text{Hom}(C_1^{\text{simp}}(K), G) \).

In other words, by definition of \( C_1^{\text{simp}}(K) \) we need to show that for every ordered 1-simplex \((v_0, v_1)\) of \( K \) we have \( (\delta_0 \varphi_g)([v_0, v_1]) = 0 \). Indeed, we calculate that

\[
\delta_0(\varphi_g)([v_0, v_1]) = \varphi_g(\partial_1([v_0, v_1])) = \varphi_g(v_1 - v_0) = \varphi_g(v_1) - \varphi_g(v_0) = g - g = 0.
\]

2. We will prove the second statement in Exercise 67.2. \( \square \)

We conclude this section with the following explicit calculation of the coboundary map. This result will come in handy in the following chapter.

**Lemma 67.4.** Let \( K = (V, S) \) be an abstract simplicial complex and let \((v_0, \ldots, v_k)\) be an ordered \( k \)-simplex of \( K \). We have

\[
\delta_k([v_0, \ldots, v_k]^*) = (-1)^{k+1} \sum_{w \in V \text{ such that } \{v_0, \ldots, v_k, w\} \text{ is a } (k+1)-\text{simplex}} [v_0, \ldots, v_k, w]^* \in C_{k+1}^{\text{simp}}(K; \mathbb{Z}).
\]

---

\(^{1023}\)Of course there are many other choices of a cochain \( \theta \) that would work. We picked this particular one since later on it works well in the pictures.
Proof. We need to show that both sides define the same map $C_k^{\text{simp}}(K) \to \mathbb{Z}$. Basically by definition of $C_k^{\text{simp}}(K)$ this means that we need to show both sides provide the same value for any given $[y_0, \ldots, y_k]$. So suppose we are given an ordered $(k+1)$-simplex $(y_0, \ldots, y_{k+1})$ of $K$. After possibly reordering the $y_i$ we can arrange that there exists an $m \in \{0, \ldots, k\}$ such that $y_i = v_i$ for $i = 0, \ldots, m-1$ and such that $\{y_m, \ldots, y_k\} \cap \{v_m, \ldots, v_k\} = \emptyset$. We calculate that

$$
\begin{align*}
(\delta_k([v_0, \ldots, v_k]^*)([y_0, \ldots, y_{k+1}]) &= [v_0, \ldots, v_k]^*(\partial_{k+1}([y_0, \ldots, y_{k+1}])) \\
&= \sum_{i=0}^{k+1} (-1)^i [v_0, \ldots, v_k]^*([y_0, \ldots, \hat{y}_i, \ldots, y_{k+1}]) \\
&= \sum_{i=0}^{k+1} \begin{cases} 0, & \text{if } i < k+1 \text{ or if } m \neq k \\ (-1)^{k+1}, & \text{if } i = k+1 \text{ and if } m = k. \end{cases}
\end{align*}
$$

It follows easily from the definitions that the cochain on the right hand side of the lemma leads to the same result. $
$

Properties of simplicial cohomology groups. In the following lemma we will see that simplicial cohomology groups define contravariant functors. Before we can formulate that lemma let us recall a definition from Lemmas 63.3 and 63.7. Namely, given a simplicial map $f : K = (V, S) \to L = (W, T)$ between abstract simplicial complexes we consider the following chain map:

$$
f_* : C_k^{\text{simp}}(K) \to C_k^{\text{simp}}(L)
[v_0, \ldots, v_k] \mapsto \begin{cases} [f(v_0), \ldots, f(v_k)], & \text{if } f(v_0), \ldots, f(v_k) \text{ are pairwise different}, \\
0, & \text{otherwise}. \end{cases}
$$

When we are dealing with an order-preserving simplicial map between ordered abstract simplicial complexes, then we define the induced map $C_k^{\text{simp}, \leq}(K) \to C_k^{\text{simp}, \leq}(L)$ in the analogous way.

**Lemma 67.5.** Let $k \in \mathbb{N}_0$ and let $G$ be an abelian group.
(1) The maps

\[ (K, \leq) \mapsto H^k_{\text{simp,} \leq}(K; G) \]
\[ (f: (K, \leq) \to (L, \leq)) \mapsto \begin{pmatrix} f_*: H^k_{\text{simp,} \leq}(K; G) \to H^k_{\text{simp,} \leq}(L; G) \\ [\varphi: C^k_{\text{simp}}(K) \to G] \mapsto [\varphi \circ f_*] \end{pmatrix} \]

define a contravariant functor from the category \( \text{OrdAbsCplx} \) of ordered abstract simplicial complexes to the category \( \text{AbGr} \) of abelian groups.

(2) The maps

\[ K \mapsto H^k_{\text{simp}}(K; G) \]
\[ (f: K \to L) \mapsto \begin{pmatrix} f_*: H^k_{\text{simp}}(K; G) \to H^k_{\text{simp}}(L; G) \\ [\varphi: C^k_{\text{simp}}(K) \to G] \mapsto [\varphi \circ f_*] \end{pmatrix} \]

define a contravariant functor from the category \( \text{AbsCplx} \) of abstract simplicial complexes to the category \( \text{AbGr} \) of abelian groups.

**Proof.** The lemma is an immediate consequence of Lemmas 63.3, 63.7 and 73.8.

**Example.** In Figure 1039 we show the “simplicial annulus” \( A \) together with the obvious projection map \( p \) to the simplicial circle \( C \). Furthermore we show the simplicial cocycle \( \theta \in C^1_{\text{simp}}(C; \mathbb{Z}) \) that we introduced on page 1688 and we show the corresponding cocycle \( p^*(\theta) \in C^1_{\text{simp}}(A) \).

![Figure 1039](image)

The following proposition relates the two flavors of simplicial cohomology groups to one another and it relates them to the singular cohomology groups of the topological realization.

**Proposition 67.6.** Let \( G \) be an abelian group.

1. Let \( (K, \leq) \) be an ordered abstract simplicial complex.
   a. The natural maps

\[ \Theta^*_\leq k: C^k(|K|; G) \to C^k_{\text{simp,} \leq}(K; G) \]
\[ (\varphi: C_k(|K|) \to G) \mapsto \left( C^k_{\text{simp}}(K) \xrightarrow{\Theta^*_\leq k} C_k(|K|) \xrightarrow{\varphi} G \right) \]

are a cochain homotopy equivalence. In particular the maps induce natural isomorphisms

\[ \Theta^*_\leq k: H^k(|K|; G) \to H^k_{\text{simp,} \leq}(K; G) \]
(b) Every simplicial cocycle \( \varphi \in C^k_{\text{simp}}(K; G) \) "extends" to a singular cocycle of \( C^k(|K|; G) \). More precisely, there exists a cocycle \( \psi \in C^k(|K|; G) \) such that 
\[
\Theta^*_{\leq, k}(\psi) = \varphi, \quad \text{i.e. such that} \quad \psi \circ \Theta_{\leq, k} = \varphi : C^k_{\text{simp}}(K) \to G.
\]

(2) Let \( K \) be an abstract simplicial complex. We pick an order "\( \leq \)" for \( K \). The composition of the two maps 
\[
H^k(|K|; G) \xrightarrow{\Theta^*_{\leq}} H^k_{\text{simp}, \leq}(K; G) \xrightarrow{\Omega_{\leq, k}^{-1}} H^k_{\text{simp}}(K; G)
\]
does not depend on the choice of "\( \leq \)" and it defines a natural isomorphism 
\[
\Xi^*_k : H^k(|K|; G) \to H^k_{\text{simp}}(K; G).
\]

**Proof.**

(1) (a) This statement follows immediately from Proposition \[67.1\] (1) and Lemma \[73.8\].

(b) Let \( \varphi \in C^k_{\text{simp}, \leq}(K; G) \) be a simplicial cocycle. By Proposition \[67.1\] (2) there exist maps \( \pi_k : C^k(|K|) \to C^k_{\text{simp}, \leq}(K) \) which have the following two properties:

(i) The maps \( \pi_k \) form a chain map.

(ii) For each \( k \in \mathbb{N}_0 \) we have \( \pi_k \circ \Theta_k = \text{id}_{C^k_{\text{simp}, \leq}(K)} \).

We set \( \psi := \pi^*_k(\varphi) \). By (i) this is a cocycle and by (ii) we have \( \psi \circ \Theta_{\leq, k} = \varphi \).

(2) This statement follows immediately from Proposition \[67.1\] (1) and Lemma \[73.8\]. □

**Example.** Let us rephrase the statement of Proposition \[67.6\] (1b). It says that given any simplicial cocycle \( \varphi \in C^k_{\text{simp}, \leq}(K; G) \) there exists a singular cocycle \( \psi \in C^k(|K|; G) \) with 
\[
[\Theta^*_{\leq, k}(\psi)] = [\varphi] \in H^k_{\text{simp}, \leq}(K; G)
\]
and which, restricted to the singular simplices provided by the simplices of \( K \), coincides with \( \varphi \). We try to illustrate this statement in Figure 1040.

![Figure 1040](image)

"annulus" \( A \) 

the simplicial cocycle \( \varphi = p^*(\theta) \) extends to a singular cocycle \( \psi \)

**Figure 1040**

We continue with the following lemma which is just a special case of Lemma \[74.6\].

**Lemma 67.7.** Let \( G \) be an abelian group and let \( k \in \mathbb{N}_0 \).

(1) Given any abstract simplicial complex \( K \) the map 
\[
\langle \ , \ \rangle : H^k_{\text{simp}}(K; G) \times H^k_{\text{simp}}(K) \to G \quad \langle [\varphi], [\sigma] \rangle \mapsto \langle [\varphi], [\sigma] \rangle_K := \varphi(\sigma),
\]
called the Kronecker pairing, is well-defined and bilinear.

(2) Given any simplicial map \( f : K \to L \) between two abstract simplicial complexes, given any \( \sigma \in H^k_{\text{simp}}(K) \) and given any \( \varphi \in H^k_{\text{simp}}(L; G) \) we have 
\[
\langle f^*(\varphi), \sigma \rangle_K = \langle \varphi, f_*(\sigma) \rangle_L.
\]
With the above lemma we can now formulate the following theorem which is an immediate consequence of the purely algebraic Universal Coefficient Theorem \[75.12\] for Cohomology Groups.

**Theorem 67.8. (Universal Coefficient Theorem for Simplicial Cohomology)** Let $K$ be an abstract simplicial complex and let $G$ be an abelian group. For each $k \in \mathbb{N}_0$ there exists a short exact sequence

$$0 \longrightarrow \text{Ext}(H_{k-1}^{\text{simp}}(K), G) \longrightarrow H_k^{\text{simp}}(K; G) \overset{\text{ev}}{\longrightarrow} \text{Hom}(H_k^{\text{simp}}(K), G) \longrightarrow 0$$

which is natural in the abstract simplicial complex $K$ and natural in the abelian group $G$. This short exact sequence splits and there exists therefore an isomorphism

$$H_k^{\text{simp}}(K; G) \cong \text{Ext}(H_{k-1}^{\text{simp}}(K), G) \oplus \text{Hom}(H_k^{\text{simp}}(K), G).$$

The analogous statement for ordered abstract simplicial complexes and the corresponding simplicial homology and cohomology groups also holds.

**Remark.**

1. The Universal Coefficient Theorem \[67.8\] for Simplicial Cohomology is a double-edged sword. It allows us to compute the isomorphism types of simplicial cohomology groups in terms of the much more friendly simplicial homology groups. But it also says, somewhat disappointingly, that the isomorphism types of simplicial cohomology groups do not contain any information that is not already contained in the isomorphism types of the simplicial homology groups.

2. The Universal Coefficient Theorem \[67.8\] for Simplicial Cohomology is also somewhat less powerful than it might appear. The theorem can be very convenient for determining the isomorphism types of simplicial cohomology groups. But if the Ext-terms are non-zero, then the theorem does not provide an approach to finding explicit cocycles representing cohomology classes.

**67.4. The simplicial cup product.** We had seen that one the remarkable features of singular cohomology is that it comes with a cup product and that it interacts with singular homology via the cap product. Before we attempt to introduce simplicial analogues let us remind us of the definitions from pages \[1970\], \[1981\] and \[2019\].

**Definition.**

1. For $i = 0, \ldots, n$ we write $v_i := (0, \ldots, 1, 0, \ldots, 0) \in \mathbb{R}^{n+1}$.

2. For $a_0, \ldots, a_k \in \Delta^n$ we consider the map

$$[a_0, \ldots, a_k] : \Delta^k \longrightarrow \Delta^n \quad (\lambda_0, \ldots, \lambda_k) \mapsto \sum_{j=0}^k \lambda_j \cdot a_j.$$
(3) Let $X$ be a topological space and let $R$ be a commutative ring.

(a) Let $\varphi \in C_p^q(X; R)$ and $\psi \in C^n(X; R)$ be cochains. We define the \textit{cup product} of $\varphi$ and $\psi$ to be the singular cochain $\varphi \cup \psi : C_{p+q}^n(X) \to R$

\[
(\sigma : \Delta^{p+q} \to X) \mapsto \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]).
\]

(b) Given a singular cochain $\varphi \in C^k(X; R)$ and a singular simplex $\sigma : \Delta^n \to X$ with $k \leq n$ we define the \textit{cap product} of $\varphi$ and $\sigma$ to be the singular chain $\varphi \cap \sigma := \varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, v_n].$

For $k > n$ we define $\varphi \cap \sigma = 0.$

In this and in the coming section we will introduce simplicial analogues of the above definitions. Evidently the idea is to imitate the above definitions and to define the cup and cap products on the level of simplicial (co-) chains. A short moment’s thought shows that on the (co-) chain level one needs to work with \textit{ordered} abstract simplicial complexes.

First we have the following definition which is clearly inspired by our second definition of the cup product in singular cohomology that we gave on page \[1981\].

\textbf{Definition.} Let $(K, \leq)$ be an ordered abstract simplicial complex and let $R$ be a commutative ring. Given $\varphi \in C^{p}_{\text{simp}, \leq}(K; R)$ and $\psi \in C^{q}_{\text{simp}, \leq}(K; R)$ we consider the \textit{cup product}

\[
\varphi \cup \psi : C^{p+q}_{\text{simp}, \leq}(K) \to R \quad \{v_0 < \cdots < v_p < \cdots < v_{p+q}\} \mapsto \varphi(\{v_0 < \cdots < v_p\}) \cdot \psi(\{v_p < \cdots < v_{p+q}\}).
\]

The following lemma is the analogue of Lemma \[81.2\].

\textbf{Lemma 67.9.} Let $(K, \leq)$ be an ordered abstract simplicial complex and let $R$ be a commutative ring. Furthermore let $\varphi \in C^p_{\text{simp}, \leq}(K; R)$ and $\psi \in C^q_{\text{simp}, \leq}(K; R).$ Then

\[
\delta(\varphi \cup \psi) = \delta \varphi \cup \psi + (-1)^p \cdot \varphi \cup \delta \psi \in C^{p+q+1}_{\text{simp}, \leq}(K; R).
\]

In the following we will state several lemmas that are the simplicial counterparts of earlier results on the singular cup product. In most cases the proofs are, with an appropriate change of notation, basically identical. For sake of illustration we provide the proof of Lemma \[67.9\] and we invite the reader to compare the proof to the proof of Lemma \[81.2\].

\textbf{Proof (\*)}. Let $\varphi \in C^p_{\text{simp}, \leq}(K; R)$ and $\psi \in C^q_{\text{simp}, \leq}(K; R)$ be simplicial cochains. We have to prove the following equality:

\[
\delta(\varphi \cup \psi) = \delta \varphi \cup \psi + (-1)^p \cdot \varphi \cup \delta \psi \in C^{p+q+1}_{\text{simp}, \leq}(K; R) = \text{Hom}(C^p_{\text{simp}, \leq}(K), R).
\]
So let \( s = \{ v_0 < \cdots < v_{p+q+1} \} \) be a simplicial \((p + q + 1)\)-simplex. We have the following three equalities in \( R^{1694}_\text{simplex} \):

(a) \((\partial(\varphi \cup \psi))(s) = (\varphi \cup \psi)\biggl( \sum_{j=0}^{p+q+1} (-1)^j \cdot \{ v_0 < \cdots < v_j < \cdots < v_{p+q+1} \} \biggr) \)

\[
= \sum_{j=0}^{p} (-1)^j \cdot (\varphi \cup \psi)(\{ v_0 < \cdots < v_j < \cdots < v_{p+q+1} \}) \\
+ (-1)^p \cdot \sum_{j=0}^{q+1} (-1)^j \cdot (\varphi \cup \psi)(\{ v_0 < \cdots < v_j < \cdots < v_{p+q+1} \}) \\
= \sum_{j=0}^{p} (-1)^j \cdot \varphi(\{ v_0 < \cdots < v_j < \cdots < v_{p+1} \}) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) \\
+ (-1)^p \cdot \sum_{j=0}^{q+1} (-1)^j \cdot \varphi(\{ v_0 < \cdots < v_j < \cdots < v_{p+1} \}) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) 
\]

and

(b) \((\partial \varphi \cup \psi)(s) = (\partial \varphi)(\{ v_0 < \cdots < v_{p+1} \}) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) \)

\[
= \varphi\biggl( \sum_{j=0}^{p+1} (-1)^j \cdot \{ v_0 < \cdots < v_j < \cdots < v_{p+1} \} \biggr) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) \\
= \sum_{j=0}^{p+1} (-1)^j \cdot \varphi(\{ v_0 < \cdots < v_j < \cdots < v_{p+1} \}) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) 
\]

(c) \((-1)^p \cdot (\varphi \cup \partial \psi)(s) = (-1)^p \cdot \varphi(\{ v_0 < \cdots < v_p \}) \cdot (\partial \psi)(\{ v_p < \cdots < v_{p+q+1} \}) \)

\[
= (-1)^p \cdot \varphi(\{ v_0 < \cdots < v_p \}) \cdot \psi\biggl( \sum_{k=0}^{q+1} (-1)^k \cdot \{ v_k < \cdots < v_{p+q+1} \} \biggr) \\
= (-1)^p \cdot \sum_{k=0}^{q+1} (-1)^k \cdot \varphi(\{ v_0 < \cdots < v_p \}) \cdot \psi(\{ v_p < \cdots < v_{p+q+1} \}) 
\]

Now we observe that if we take the sum of (b) and (c), then the \((j = p + 1)\)-summand in (b) cancels with the \((k = 0)\)-summand in (c). But after this observation it is obvious that the desired equality \((b)+(c)=(a)\) holds.

In light of Lemma 67.9, it is now straightforward to see that the cup product descends to a map on simplicial cohomology.

**Lemma 67.10.** Let \( R \) be a commutative ring. For every ordered abstract simplicial complex \((K, \leq)\) the map

\[
\cup : H^p_{\text{simp}, \leq}(K; R) \times H^q_{\text{simp}, \leq}(K; R) \to H^{p+q}_{\text{simp}, \leq}(K; R) 
\]

\[
([\varphi], [\psi]) \mapsto [\varphi \cup \psi] := [\varphi \cup \psi] 
\]

is well-defined. We refer to this map again as the cup product.

**Proof.** This lemma follows almost immediately from Lemma 67.9. For more details we refer to the proof of Lemma 81.3. In that proof we just need to replace Lemma 81.2 by Lemma 67.9. \(\blacksquare\)

\(^{021}\)Here in the argument we use on several occasions that for a simplicial \(n\)-cochain \(\phi\) and an \((n+1)\)-simplex \(t = \{ w_0 < \cdots < w_{n+1} \} \) we have by definition

\[
(\delta_{n+1} \phi)(t) = \phi(\partial_t t) = \phi\biggl( \sum_{l=0}^{n+1} (-1)^l \cdot \{ w_0 < \cdots < w_l < \cdots < w_{n+1} \} \biggr) .
\]
The simplicial cup product is an interesting invariant in its own right and as we will see shortly, for finite abstract simplicial complexes it can be computed effectively. As for simplicial homology the question arises whether the isomorphism type of the simplicial cup product is an invariant of the topological realization. As we discussed in Sections 63.4 and 63.5, arguably the cleanest way of showing this is by proving that the simplicial cup product corresponds to the singular cup product. This is precisely what we will do in the first part of the following proposition, which can be viewed as an addendum to Proposition 67.6.

**Proposition 67.11.** Let $K$ be an abstract simplicial complex and let $R$ be a commutative ring.

1. Let “≤” be an order on $K$. Let $\Theta_{\leq,k}: C_{k}^{\text{simp,} \leq}(K) \to C_{k}(\mid K\mid)$ be the natural chain map that we introduced in Proposition 67.1. The following diagram commutes:

\[
\begin{array}{ccc}
H^{p}(\mid K\mid; R) \times H^{q}(\mid K\mid; R) & \to & H^{p+q}(\mid K\mid; R) \\
\Theta_{\leq} & \cong & \Theta_{\leq} \\
H_{\text{simp,} \leq}(K; R) \times H_{\text{simp,} \leq}(K; R) & \to & H_{\text{simp,} \leq}^{p+q}(K; R).
\end{array}
\]

2. There exists a unique map

\[
H_{\text{simp,} \leq}^{p}(K; R) \times H_{\text{simp,} \leq}^{q}(K; R) \to H_{\text{simp,} \leq}^{p+q}(K; R)
\]

such that for every choice of order “≤” for $K$ the following diagram commutes:

\[
\begin{array}{ccc}
H_{\text{simp,} \leq}^{p}(K; R) \times H_{\text{simp,} \leq}^{q}(K; R) & \to & H_{\text{simp,} \leq}^{p+q}(K; R) \\
\Omega_{\leq} & \cong & \Omega_{\leq} \\
H_{\text{simp,} \leq}^{p}(K; R) \times H_{\text{simp,} \leq}^{q}(K; R) & \to & H_{\text{simp,} \leq}^{p+q}(K; R).
\end{array}
\]

In other words, we can define the cup product on $H_{\text{simp}}^{*}(K; R)$ in a way that is independent of the choice of an order “≤”.

3. The following diagram commutes:

\[
\begin{array}{ccc}
H^{p}(\mid K\mid; R) \times H^{q}(\mid K\mid; R) & \to & H^{p+q}(\mid K\mid; R) \\
\Xi_{\leq} & \cong & \Xi_{\leq} \\
H_{\text{simp}}^{p}(K; R) \times H_{\text{simp}}^{q}(K; R) & \to & H_{\text{simp}}^{p+q}(K; R).
\end{array}
\]

**Remark.** Let $K$ be an abstract simplicial complex. In the presence of an order on $K$ we have, by definition, a natural simplicial cup product on the cochain groups $C_{k}^{*}(K; R)$. In the absence of an order we do not have a natural simplicial cup product on the cochain groups $C_{k}^{*}(K; R)$. But Proposition 67.11 says that we do have a natural simplicial cup product on the cohomology groups $H_{\text{simp}}^{*}(K; R)$.

**Proof.**

1. It follows follows immediately from the definitions of the simplicial cup product and the definition of the singular cup product that we gave on page 1981 and that we
recalled on page 1693 that the following diagram commutes:

$$
\begin{array}{ccc}
C^p(\langle K \rangle; R) \times C^q(\langle K \rangle; R) & \stackrel{\cup}{\rightarrow} & C^{p+q}(\langle K \rangle; R) \\
\theta^*_p \downarrow \quad \downarrow \theta^*_q & & \downarrow \theta^*_p \\
C^p_{\text{simp}, \leq}(K; R) \times C^q_{\text{simp}, \leq}(K; R) & \stackrel{\cup}{\rightarrow} & C^{p+q}_{\text{simp}, \leq}(K; R).
\end{array}
$$

The desired statement follows immediately from this observation.

(2) Surely there is a heroic proof for this statement that does not involve singular cohomology. But to lessen the pain let us give a proof that makes the most use of our previous results. Thus we consider the following diagram:

$$
\begin{array}{ccc}
H^p_{\text{simp}}(K; R) \times H^q_{\text{simp}}(K; R) & \stackrel{\cup}{\rightarrow} & H^{p+q}_{\text{simp}}(K; R) \\
(\alpha^*_\leq)^* \uparrow \cong \quad \cong \uparrow (\alpha^*_\leq)^* & & \cong \uparrow (\alpha^*_\leq)^* \\
H^p_{\text{simp}, \leq}(K; R) \times H^q_{\text{simp}, \leq}(K; R) & \stackrel{\cup}{\rightarrow} & H^{p+q}_{\text{simp}, \leq}(K; R) \\
\theta^*_p \uparrow \cong \quad \cong \uparrow \theta^*_q & & \cong \uparrow \theta^*_p \\
H^p(\langle K \rangle; R) \times H^q(\langle K \rangle; R) & \stackrel{\cup}{\rightarrow} & H^{p+q}(\langle K \rangle; R).
\end{array}
$$

By Proposition 67.1 together with Lemma 73.5 we see that the composition of the two vertical maps does not depend on the choice of “≤”. By (1) we know that the lower square commutes. Now we define the cup product on $H^*_{\text{simp}}(K; R)$ via the singular cup product and we see that it makes the upper square commute for any choice of “≤”.

(3) This statement follows immediately from the definition of the natural isomorphisms $\Xi^*$, see Proposition 67.6 (3).

\[\boxed{\text{Remark.}}\] Proposition 67.11 shows in particular that if we are given a simplicial complex $(X, \Theta: |K| \to X)$, then we can compute the initially intractable singular cup product on $H^*(X; R)$ via the simplicial cup product on $H^*_{\text{simp}}(K; R)$. If $K$ is finite and explicitly given, then at least in principle one can compute the simplicial cup product on $H^*_{\text{simp}}(K; R)$ by brute force. This approach though is not a cure-all. For example given any $n \in \mathbb{N}$ we will want to determine the cup product on $H^* (\mathbb{C}P^n; \mathbb{Z})$ and $H^* (\mathbb{R}P^n; \mathbb{F}_2)$. By Theorem 64.2 we know that the complex projective spaces $\mathbb{C}P^n$ and the real projective spaces $\mathbb{R}P^n$ admit simplicial structures. But we run into the following issues:

(1) It seems to be difficult to find explicit simplicial structures for the complex projective spaces $\mathbb{C}P^n$. So we cannot even get started.

(2) Explicit simplicial structures for smooth manifolds tend to have many simplices. For example in Exercise 62.5 we gave an explicit simplicial structure for the real projective space $\mathbb{R}P^n$ with $2^{n+1} - 1$ vertices and it seems difficult to find simplicial structures with a significantly smaller number of vertices.

Later on, in Propositions 90.7 and 90.7 we will compute these cup products using the Simplicial Poincaré Duality Theorem 71.4.

To do calculations of cup products we need to deal with specific cohomology classes and in fact also with explicit cocycles. In the next lemma we will see that closed oriented
pseudomanifolds are a rich source of interesting explicit cocycles. Before we can state this lemma it is convenient to recall some definitions from page 1652 and page 1653.

Definition. Let $K = (V, S)$ be an $n$-dimensional pseudomanifold.

1. We denote by $S_n$ the set of $n$-simplices of $K$.
2. An orientation of an $n$-simplex $s$ of $K$ is an equivalence class of a pair $(\epsilon, \tilde{s})$ where $\epsilon \in \{-1, 1\}$ and $\tilde{s}$ is an ordered $n$-simplex with $[\tilde{s}] = s$.
3. An orientation of $K$ is a choice of an orientation for each $n$-simplex of $K$ such that for any $(n-1)$-simplex $s$ of order 2 the two bounding $n$-simplices induce opposite orientations on $s$.
4. If $K$ is a closed pseudomanifold that is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in S_n}$, then we refer to the simplicial homology class

$$[K] := \left[ \sum_{w \in S_n} \epsilon_w \cdot Y_w \right] \in H_n^{\text{simp}}(K)$$

as the fundamental class of $K$.

We illustrate the definitions for the simplicial torus in Figure 1041

![Simplicial Torus](image)

**Figure 1041**

Now we can formulate the following lemma.

**Lemma 67.12.** Let $K = (V, S)$ be a closed connected $n$-dimensional pseudomanifold that is equipped with an orientation $\{(\epsilon_w, Y_w)\}_{w \in S_n}$ in the sense of the definition on page 1652.

1. (a) For any $s, t \in S_n$ we have $[\epsilon_s \cdot Y^*] = [\epsilon_t \cdot Y^*] \in H_n^{\text{simp}}(K; \mathbb{Z})$. We refer to this cohomology class as the dual fundamental class $[K]^* \in H_n^{\text{simp}}(K; \mathbb{Z})$.
   
   (b) We have $H_n^{\text{simp}}(K; \mathbb{Z}) = \mathbb{Z} \cdot [K]^*$.

2. We have $\langle [K]^*, [K] \rangle_K = 1$.

**Proof.**

1. It follows from Theorem 66.4 and the discussion on page 1659 that the simplicial chain complex of $K$ is of the form

$$
\begin{align*}
0 & \rightarrow \mathbb{Z} \cdot \left[ \sum_{w \in S_n} \epsilon_w \cdot Y_w \right] \oplus \tilde{C}_n \xrightarrow{\partial_n} \tilde{C}_{n-1} \oplus \tilde{C}_{n-1} \quad \rightarrow \ldots \\
& = \epsilon_n^{\text{simp}}(K) \quad \epsilon_{n-1}^{\text{simp}}(K)
\end{align*}
$$
such that $D : \tilde{C}_n \to \tilde{C}_{n-1}$ is an isomorphism. It follows easily that the map
\[
H^n_{\text{simp}}(K; \mathbb{Z}) = \operatorname{coker}(\delta_{n-1}) \to \operatorname{Hom} \left( \mathbb{Z} \cdot \left[ \sum_{w \in S_n} \epsilon_w \cdot Y_w \right], \mathbb{Z} \right) \to \mathbb{Z}
\]
\[
\varphi \mapsto \text{restriction of } \varphi \quad \varphi \mapsto \varphi \left( \sum_{w \in S_n} \epsilon_w \cdot Y_w \right)
\]
is an isomorphism. The desired statements follow almost immediately from this observation.  \[\text{(2) This statement follows immediately from the definitions.} \]

Now let us try to determine the simplicial cup product of the simplicial torus.

**Example.** We consider the simplicial circle $C$ with vertex set $V = \{a, b, c\}$ and the simplicial circle $D = \{x, y, z\}$ with the obvious total order on the vertex sets. Furthermore we consider the simplicial torus $T = C \times D$, where we define the product as on page 1501. We equip $T$ with the orientation shown in Figure 1041. We denote by $p : C \times D \to C$ and $q : C \times D \to D$ the natural projections. We equip the vertex set of $T = C \times D$ with the lexicographic ordering. In Figure 1042 we show $T = C \times D$ together with the projections.

Let us first consider the simplicial cohomology of $T$. Let $\theta \in C^1_{\text{simp}}(C)$ be the simplicial cocycle that we introduced on page 1688. We have the following equalities:
\[
H^i_{\text{simp}}(T; \mathbb{Z}) = \begin{cases} 
\mathbb{Z} \cdot \text{constant cochain } v \mapsto 1, & \text{if } i = 0, \\
\mathbb{Z} \cdot [p^* \theta] \oplus \mathbb{Z} \cdot [q^* \theta], & \text{if } i = 1, \\
\mathbb{Z} \cdot [T]^*, & \text{if } i = 2, \\
0, & \text{if } i > 2.
\end{cases}
\]

This can be obtained either through a slightly heroic linear algebra exercise, or, more systematically, through the combination of Lemma 67.12, the Simplicial Künneth Theorem 63.14 and the Universal Coefficient Theorem 67.8 for Simplicial Cohomology. Now we can calculate our first interesting simplicial cup product:
\[
[p^* \theta] \cup [q^* \theta] = [p^* \theta] \cup [q^* \theta] = \left[ \left( \begin{array}{c} (b, y), (c, y), (c, z) \end{array} \right) \right]^* = [T]^* \in H^2_{\text{simp}}(T; \mathbb{Z}).
\]

Similar calculations gives us the following table for the cup product:
\[
\begin{pmatrix}
[p^* \theta] & [p^* \theta] \\
[q^* \theta] & [q^* \theta]
\end{pmatrix}
\begin{pmatrix}
[p^* \theta] & [q^* \theta] \\
[p^* \theta] & [q^* \theta]
\end{pmatrix}
= \begin{pmatrix}
0 & [T]^* \\
-[T]^* & 0
\end{pmatrix}.
\]

This is the simplicial analogue of the calculation performed in Lemma 81.14.

In the following we state several properties of the simplicial cup product that are the analogues of the corresponding properties of the singular cup product. First let us start with the analogue of Proposition 81.17.

---

1025 The above argument is related to the content of Exercise 73.1.
1026 In fact the remaining three entries of the matrix can also be obtained easily from Proposition 67.14 and Lemma 67.15.
we equip the vertices of \( T \) with the lexicographic ordering

\[
\text{torus } T = C \times D
\]

the ordered 2-simplex \(((b, y), (c, y), (c, z))\)

\[
\begin{array}{c}
\text{circle } C \quad 0 \quad 1 \quad 0 \quad \text{projection } p
\end{array}
\]

\[
\text{projection } q
\]

\[
\begin{array}{c}
\text{circle } D
\end{array}
\]

\[
\text{simplicial cocycle } \theta \in C^1_{\text{simp}}(C; \mathbb{Z})
\]

\[\text{Figure 1042}\]

**Proposition 67.13.** Let \( K = (V, S) \) be an abstract simplicial complex and let \( R \) be a commutative ring. The following statements hold:

1. The cup product on \( H^*(_{\text{simp}}(K; R) \) is \( R \)-bilinear and associative.
2. The abelian group \( H^*_{\text{simp}}(K; R) = \bigoplus_{n \in \mathbb{N}_0} H^*_{\text{simp}}(K; R) \) together with the map

\[
\cup : H^*_{\text{simp}}(K; R) \times H^*_{\text{simp}}(K; R) \rightarrow H^*_{\text{simp}}(K; R)
\]

is a ring where the multiplicatively neutral element is given by

\[
1_K := \left[ \text{map } V \rightarrow R \text{ given by } v \mapsto 1 \right] \in H^0_{\text{simp}}(K; R).
\]

**Proof.** We pick an order "\( \leq \)" for \( K \). As in the proof of Proposition 81.7 we see that the cup product on the cochain level is associative. It now follows easily that all the given statements hold for \( (H^*_{\text{simp}, \leq}(K; R), \cup) \). By Proposition 67.11 (2) the statements now also hold for \( (H^*_{\text{simp}}(K; R), \cup) \).

The following proposition is the analogue of Proposition 81.8

**Proposition 67.14.** Let \( K \) be an abstract simplicial complex and let \( R \) be a commutative ring. For any \( \varphi \in H^p_{\text{simp}}(K; R) \) and any \( \psi \in H^q_{\text{simp}}(K; R) \) we have

\[
\varphi \cup \psi = (-1)^{pq} \cdot \psi \cup \varphi \in H^{p+q}_{\text{simp}}(K; R).
\]

**Proof.** We pick an order "\( \leq \)" for \( K \). By Proposition 67.11 (2) it suffices to prove the following claim.

**Claim.** For any \( \varphi \in H^p_{\text{simp}, \leq}(K; R) \) and \( \psi \in H^q_{\text{simp}, \leq}(K; R) \) we have

\[
\varphi \cup \psi = (-1)^{pq} \cdot \psi \cup \varphi \in H^{p+q}_{\text{simp}, \leq}(K; R).
\]

The proof of the claim happens at the "cochain level". The argument is basically identical to the proof of Proposition 81.8. The only real difference is that one needs to replace the product topological space \( \Delta^n \times [0, 1] \) by the product of the ordered abstract simplicial
complexes $D_n = (\{0, \ldots, n\}, \mathcal{P}(\{0, \ldots, n\} \setminus \emptyset))$ and $D_1 = (\{0, 1\}, \{\{0\}, \{1\}\})$, as defined in Lemma 61.16. We leave it to the reader to make the necessary modifications to the argument.

Finally we have the following lemma which is the simplicial analogue of Lemma 81.10.

**Lemma 67.15.** Let $R$ be a commutative ring.

1. Let $f : K \to L$ be a simplicial map between two abstract simplicial complexes. For any $\varphi \in H^p_{\text{simp}}(L; R)$ and $\psi \in H^q_{\text{simp}}(L; R)$ we have
   \[f^*(\varphi) \cup f^*(\psi) = f^*(\varphi \cup \psi) .\]

   In particular the map
   \[f^* : H^*_{\text{simp}}(L; R) \to H^*_{\text{simp}}(K; R)\]
   is a homomorphism of graded rings which satisfies $f^*(1_L) = 1_K$.

2. The maps
   \[K \mapsto (H^*_{\text{simp}}(K; R), \cup)\]
   \[(f : K \to L) \mapsto (f^* : H^*_{\text{simp}}(L; R) \to H^*_{\text{simp}}(K; R))\]
   define a contravariant functor from the category $\text{AbsSimpCplx}$ of abstract simplicial complexes to the category $\text{GrRing}$ of graded rings.

**Proof (**) .

1. Let $f : K = (V, S) \to L = (W, T)$ be a simplicial map between two abstract simplicial complexes. By Exercise 1.2 we can pick total orders “$\leq_K$” on $K$ and “$\leq_L$” on $L$ such that the map $f : V \to W$ is order-preserving. It follows basically immediately from the definitions that for $\varphi \in C^p_{\text{simp}, \leq_L}(L; R)$ and $\psi \in C^q_{\text{simp}, \leq_L}(L; R)$ we have the equality $f^*(\varphi) \cup f^*(\psi) = f^*(\varphi \cup \psi) \in C^{p+q}_{\text{simp}, \leq_K}(K)$. The statements now follow from Proposition 67.11(2).

2. This statement follows from (1) together with Lemma 67.5(2). ■

67.5. **The simplicial cap product.** In this section we will introduce the simplicial cap product. In contrast to the simplicial cup product it is perhaps less immediately clear what the simplicial cap product is good for. But it will have its moment of glory in Chapter 68 when we state and prove the Simplicial Poincaré Duality Theorem 71.4.

The following definition of the simplicial cap product is an adaptation of the definition of the singular cap product that we gave on page 2019 and that we recalled on page 1693.

**Definition.** Let $(K, \leq)$ be an ordered abstract simplicial complex and let $R$ be a commutative ring. Given an $n$-simplex $s = \{v_0 < \cdots < v_n\}$, given $k \leq n$ and given a simplicial cochain $\varphi \in C^k_{\text{simp}, \leq}(K; R)$ we define

\[\varphi \cap s := \varphi(\{v_0 < \cdots < v_k\} \cdot \{v_k < \cdots < v_n\} \in C^{k}_{\text{simp}, \leq}(n-k; R).\]
We extend this definition to simplicial $R$-chains and we obtain the \textit{cap product}

$$\cap: C^k_{\text{simp}, \leq}(X; R) \times C^n_{\text{simp}, \leq}(X; R) \to C^{n-k}_{\text{simp}, \leq}(X; R)$$

$$\varphi \cap r \cdot \sigma \mapsto r \cdot (\varphi \cap \sigma).$$

For $k > n$ we define the cap product to be the zero map.

The next lemma says that the cap product defines a map on simplicial (co-)homology.

**Lemma 67.16.** Let $(K, \leq)$ be an ordered abstract simplicial complex. Given any commutative ring $R$ and given any $k, n \in \mathbb{N}_0$ the map

$$H^k_{\text{simp}, \leq}(K; R) \times H^n_{\text{simp}, \leq}(K; R) \to H^{n-k}_{\text{simp}, \leq}(K; R)$$

$$(\varphi, [\sigma]) \mapsto [\varphi \cap \sigma]$$

is well-defined.

**Proof.** The same argument as in the proof of Lemma \[83.1\] shows that given an $n$-simplex $s = \{v_0 < \cdots < v_n\}$, given $k \leq n$ and given any simplicial cochain $\varphi \in C^k_{\text{simp}, \leq}(K; R)$ we have the following equality:

$$\partial(\varphi \cap \sigma) = (-1)^k \cdot (-\delta \varphi \cap \sigma + \varphi \cap \partial \sigma) \in C_{n-k-1}(X; R).$$

As in the proof of Lemma \[83.2\] we see that the lemma follows easily from this equality. ■

The next proposition is an analogue of Proposition \[67.11\].

**Proposition 67.17.** Let $K$ be an abstract simplicial complex and let $R$ be a commutative ring.

1. Let $\leq$ be an order on $K$. Let $\Theta_{\leq,k}: C^k_{\text{simp}, \leq}(K) \to C_k(|K|)$ be the natural chain map that we introduced in Proposition \[67.1\]. The following diagram commutes:

$$
\begin{array}{ccc}
H^p(|K|; R) \times H_n(|K|; R) & \xrightarrow{\cap} & H_{n-p}(|K|; R) \\
\Theta_{\leq,k}^{\leq} \uparrow \cong \downarrow \Theta_{\leq,k} & & \cong \uparrow \Theta_{\leq,k}^{\leq} \\
H^p_{\text{simp}, \leq}(K; R) \times H^n_{\text{simp}, \leq}(K; R) & \xrightarrow{\cap} & H^{n-p}_{\text{simp}, \leq}(K; R).
\end{array}
$$

2. There exists unique map

$$
\begin{array}{ccc}
H^p_{\text{simp}}(K; R) \times H^n_{\text{simp}}(K; R) & \xrightarrow{\cap} & H^{n-p}_{\text{simp}}(K; R) \\
\Omega_{\leq}^{\leq} \uparrow \cong \downarrow \Omega_{\leq}^{\leq} & & \cong \uparrow \Omega_{\leq}^{\leq} \\
H^p_{\text{simp}, \leq}(K; R) \times H^n_{\text{simp}, \leq}(K; R) & \xrightarrow{\cap} & H^{n-p}_{\text{simp}, \leq}(K; R).
\end{array}
$$

such that for any choice of order $\leq$ for $K$ the following diagram commutes:

$$
\begin{array}{ccc}
H^p_{\text{simp}}(K; R) \times H^n_{\text{simp}}(K; R) & \xrightarrow{\cap} & H^{n-p}_{\text{simp}}(K; R) \\
\Omega_{\leq}^{\leq} \uparrow \cong \downarrow \Omega_{\leq}^{\leq} & & \cong \uparrow \Omega_{\leq}^{\leq} \\
H^p_{\text{simp}, \leq}(K; R) \times H^n_{\text{simp}, \leq}(K; R) & \xrightarrow{\cap} & H^{n-p}_{\text{simp}, \leq}(K; R).
\end{array}
$$

In other words, we can define the cap product on $H^*_\text{simp}(K; R)$ and $H^*_\text{simp}(K; R)$ in a way that is independent of the choice of an order $\leq$.\[67.11\]
(3) The following diagram commutes:

\[
\begin{array}{ccc}
H_p([K]; R) \times H_n([K]; R) & \xrightarrow{\sim} & H_{n-p}([K]; R) \\
\Xi \downarrow & \cong & \Xi \\
H_{simp}^p(K; R) \times H_{n}^{simp}(K; R) & \xrightarrow{\sim} & H_{simp}^{n-p}(K; R).
\end{array}
\]

Sketch of proof.

(1) It follows almost immediately from the definition that the corresponding diagram on the level of simplicial (co-) chains commutes. This implies that the given diagram commutes.

(2) As in the proof of Proposition 67.11 (2) this statement follows from (1) together with Proposition 67.1, Corollary 42.8 and Lemma 73.5.

(3) This statement follows immediately from the definition of the natural isomorphisms \(\Xi_*\) and \(\Xi^*\), see Propositions 67.1 (3) and 67.6 (3). ■

Example. As on page [1698] we consider again the simplicial torus \(T = C \times D\). We equip \(T = (V,S)\) with the orientation \(\{(\epsilon_w, Y_w)\}_{w \in S_2}\) shown in Figures 1041 and 1043 and we denote by \(p: C \times D \to C\) the natural projection. Furthermore, we again make use of the simplicial cocycle \(\theta \in C^1_{simp}(C; \mathbb{Z})\) that we first encountered on page [1688]. We introduce the following extra notation:

1. We denote by \(j: D \to C \times D\) the simplicial map given by \(v \mapsto (c, v)\).
2. We denote by \(\sigma := \{x, y\} + \{y, z\} + \{z, x\} \in C_{1, simp}^\leq(D)\) the “obvious” simplicial cycle. Note that it represents the simplicial fundamental class \([D] \in H^1_{simp} \leq(D)\).

It follows immediately from the definitions that

\[
p^*(\theta) \cap \sum_{w \in S_2} \epsilon_w \cdot Y_w = j_*(\sigma) \in C^1_{simp} \leq(C \times D)
\]

thus in terms of (co-) homology we have

\[
p^*([\theta]) \cap [T] = j_*([D]) \in H^1_{simp, \leq}(C \times D).
\]

We refer to Figure 1043 for an illustration.

In the following we state three lemmas that summarize the key properties of the simplicial cap product. All of these statements are analogues of singular statements. First, the following lemma is an analogue of Lemma 83.4.

Lemma 67.18. Let \(K\) be a non-empty connected abstract simplicial complex. Given any \(\varphi \in H^p_{simp}(K; R)\) and \(\sigma \in H^p_{simp}(K; R)\) the following equality holds:

\[
\varphi \cap \sigma = \langle \varphi, \sigma \rangle_K \in H^0_{simp}(K; R) = R.
\]

as in Exercise 63.3 there is a natural identification

\[1027\]
Proof. First we pick an order “≤” for the abstract simplicial complex $K$. Next we observe that the statement for $φ ∈ H_p^{\text{simp}, ≤}(K; R)$ and $σ ∈ H_p^{\text{simp}, ≤}(K; R)$ follows immediately from the definitions. Now the statement follows from Proposition 67.17 (2).

The following lemma relates the simplicial cup product to the simplicial cap product. It can be viewed as an analogue of Lemma 83.7.

Lemma 67.19. Let $K$ be an abstract simplicial complex and let $R$ be a commutative ring. For any $φ ∈ H_p^{\text{simp}}(K; R)$, any $ψ ∈ H_q^{\text{simp}}(K; R)$ and any $σ ∈ H_n^{\text{simp}}(K; R)$ we have

$$φ ∩ (ψ ∩ σ) = (ψ ∪ φ) ∩ σ ∈ H_{n-p-q}^{\text{simp}}(K; R).$$

Sketch of proof. We pick an order “≤” for $K$. With basically the same, quite elementary, argument as in the proof of Lemma 83.7 we see that for any $φ ∈ H_p^{\text{simp}, ≤}(K; R)$, any $ψ ∈ H_q^{\text{simp}, ≤}(K; R)$ and any $σ ∈ H_n^{\text{simp}, ≤}(K; R)$ we have

$$φ ∩ (ψ ∩ σ) = (ψ ∪ φ) ∩ σ ∈ H_{n-p-q}^{\text{simp}, ≤}(K; R).$$

The desired statement now follows from Proposition 67.17 (2).

Finally we have the following analogue of Lemma 83.8.

Lemma 67.20. Let $R$ be a commutative ring and let $f : K → L$ be a simplicial map between two abstract simplicial complexes. Given any $p, n ∈ \mathbb{N}_0$ the following diagram commutes

$$
\begin{array}{ccc}
H_p^{\text{simp}}(K; R) × H_n^{\text{simp}}(K; R) & \xrightarrow{f^*} & H_{n-p}^{\text{simp}}(K; R) \\
\uparrow & & \downarrow f_* \\
H_p^{\text{simp}}(L; R) × H_n^{\text{simp}}(L; R) & \xrightarrow{f^*} & H_{n-p}^{\text{simp}}(L; R),
\end{array}
$$

i.e. for any $φ ∈ H_p^{\text{simp}}(L; R)$ and any $σ ∈ H_n^{\text{simp}}(K; R)$ we have

$$φ ∩ f_*(σ) = f_*(f^*(φ) ∩ σ) ∈ H_{n-p}^{\text{simp}}(L; R).$$
Proof. Let \( f: K = (V, S) \to L = (W, T) \) be a simplicial map between two abstract simplicial complexes. By Exercise 1.2 we can pick total orders “\( \leq_K \)” on \( K \) and “\( \leq_L \)” on \( L \) such that the map \( f: V \to W \) is order-preserving. It follows basically immediately from the definitions that for any \( \varphi \in C^p_{\text{simp}, \leq_L}(L; R) \) and \( \sigma \in C^*_n, \leq_K(K; R) \) we have the equality
\[
 f_*(\sigma) = f_*(f^*(\varphi) \cap \sigma).
\]
The promised statement now follows from Proposition 67.17 (2).

We conclude this chapter with a short calculation which in particular shows that at times simplicial cup products can be computed using simplicial cap products.

Example. Let us look one last time at the simplicial torus \( T = C \times D \) with the natural projections \( p: C \times D \to C \) and \( q: C \times D \to D \). We will now see how we can obtain the simplicial cup product \( p^*(\theta) \cup q^*(\theta) \), that we initially computed on page 1698 from the calculation of the simplicial cup product on page 1702. Indeed, under the natural identification \( H_0^{\text{simp}}(T; R) = R = H_0^{\text{simp}}(D; R) \) from Exercise 63.3 we have the following equalities:

\[
 \langle p^*([\theta]) \cup q^*([\theta]), [T] \rangle_T = \langle p^*([\theta]) \cup q^*([\theta]), [T] \rangle_T = q^*([\theta]) \cap (p^*([\theta]) \cap [T]) = q^*([\theta]) \cap j_*([D]) = \langle q^*([\theta]), j_*([D]) \rangle_T = \langle \theta, j_*([D]) \rangle_D = \langle [\theta], [D] \rangle_D = 1.
\]

In Chapter 68 we will state the Simplicial Poincaré Duality Theorem 71.4. Given a closed oriented PL-manifold \( K \) it allows for the calculation of simplicial cap products of the form \( \varphi \cap [K] \). With tricks as above one can use this calculation of a simplicial cap product to determine several interesting simplicial cup products. In particular in Chapter 90 we will use this approach to calculate the (simplicial) cup products of the real and complex projective spaces.

---

Exercises for Chapter 67

Exercise 67.1. We consider the abstract simplicial complex \( K \) shown in Figure 1044. Determine the isomorphism type of \( H^1_{\text{simp}}(K; \mathbb{Z}) \).

Exercise 67.2. Let \( K = (V, S) \) be a non-empty abstract simplicial complex. We assume that \( K \) is connected. Recall that by the definition on page 1516 this means that given any \( v, v' \in V \) there exist 1-simplices \( s_0, \ldots, s_k \in S \) such that \( v \in s_0 \), such that for every \( i \in \{0, \ldots, k - 1\} \) we have \( s_i \cap s_{i+1} \neq \emptyset \) and such that \( v' \in s_k \). Now let \( G \) be an abelian
group. Given any \( g \in G \) we consider the simplicial cochain \( \varphi_g : C^0_\text{simp}(K) \to G \) that is given by \( \varphi_g(v) = g \) for every vertex \( v \in V \). Show that the map

\[
G \to H^0_\text{simp}(K; G) \\
g \mapsto \varphi_g
\]

is a natural isomorphism.

**Remark.** This statement can be viewed is the cohomological analogue of Exercise 63.3.

**Exercise 67.3.** Let \( K \) be an abstract simplicial complex and let \( L \) be a subcomplex of \( K \). Given an abelian group \( G \) and given \( k \in \mathbb{N}_0 \) we define

\[
H^k_\text{simp}(K, L; G) := H^k(C^k_\text{simp}(K, L), G).
\]

Show that there exists a natural isomorphism

\[
H^k_\text{simp}(K, L; G) \cong \tilde{H}^k_{\text{simp}}(K \cup_L \text{Cone}(L); G).
\]

**Exercise 67.4.** In Figure 1045 we show an abstract simplicial complex \( K \) whose topological realization \( |K| \) is homeomorphic to the real projective plane \( \mathbb{R}P^2 \).

(a) Show that for \( i = 0, 1, 2 \) we have \( H^i_\text{simp}(K; \mathbb{F}_2) \cong \mathbb{F}_2 \) and identify in each dimension a cocycle that represents the unique non-zero element.

(b) Compute the simplicial cup product \( H^1_\text{simp}(K; \mathbb{F}_2) \times H^1_\text{simp}(K; \mathbb{F}_2) \xrightarrow{\cup} H^2_\text{simp}(K; \mathbb{F}_2) \). In other words, determine whether it is trivial or non-trivial.

**Figure 1045.** Illustration for Exercise 67.4

**Exercise 67.5.** Let \( g \in \mathbb{N} \). First pick a suitable abstract simplicial complex \( K \) that has the property that its topological realization is homeomorphic to the surface of genus \( g \). Afterwards compute the cup product

\[
H^1_\text{simp}(K; \mathbb{Z}) \times H^1_\text{simp}(K; \mathbb{Z}) \to H^2_\text{simp}(K; \mathbb{Z}).
\]

**Exercise 67.6.** We consider the topological space

\[
X = \mathbb{B}^2 / \sim \quad \text{where} \quad z \sim z \cdot e^{2\pi i/3} \quad \text{for} \quad z \in S^1.
\]

(a) Determine the isomorphism types of \( H_i(X; \mathbb{F}_3) \) and \( H^i(X; \mathbb{F}_3) \).

(b) Give an explicit simplicial structure \( K \) for \( X \).

(c) Compute the simplicial cup product \( H^1_\text{simp}(K; \mathbb{F}_3) \times H^1_\text{simp}(K; \mathbb{F}_3) \xrightarrow{\cup} H^2_\text{simp}(K; \mathbb{F}_3) \).
68. THE FUNDAMENTAL CLASS OF SMOOTH MANIFOLDS

Let $M$ be a compact orientable connected non-empty $n$-dimensional smooth manifold. By Theorem 66.8, we now know that we have $\text{H}_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$. In this chapter, we will see that a choice of an orientation naturally determines a generator $[M]$ of $\text{H}_n(M, \partial M; \mathbb{Z})$, called the fundamental class of $M$. As the name already suggests, this homology class is of fundamental importance in the study of smooth manifolds.

68.1. The definition of the fundamental class. For our definition of fundamental classes, we need to recall the following notation.

**Notation.** Let $n \in \mathbb{N}_0$. As on page 1075, we consider

$$\partial \Delta^n := \{(t_0, \ldots, t_n) \in \Delta^n \mid \text{at least one coordinate is zero}\}$$

$$\Delta^n := \{(t_0, \ldots, t_n) \in \Delta^n \mid \text{all coordinates are non-zero}\}.$$

We view $\Delta^n$ as a smooth manifold and we equip it with the orientation defined on page 1075. Loosely speaking, it is the orientation given by the “outward pointing vector $(1, \ldots, 1)$”.

We move on to the following somewhat technical definition.

**Definition.** Let $M$ be an oriented $n$-dimensional smooth manifold and let $\Psi : \Delta^n \to M$ be a map.

1. We say that a point $x \in \Delta^n$ is admissible for $\Psi$ if $\Psi^{-1}(\Psi(x)) = \{x\}$ and if there exists an open connected neighborhood $U$ of $x \in \Delta^n$ such that the map $\Psi|_U : U \to M$ is a smooth embedding.

2. Given an admissible point $x$ for $\Psi$, we define

$$\text{sign}(\Psi, x) = \begin{cases} +1, & \text{if } \Psi \text{ is orientation-preserving at } x, \\ -1, & \text{if } \Psi \text{ is orientation-reversing at } x. \end{cases}$$

![Figure 1046](image)

**Example.** In many cases, we will consider embeddings $\Psi : \Delta^n \to M$ such that the restriction of $\Psi$ to $\Delta^n$ is a smooth embedding. In this case, every point $x \in \Delta^n$ is admissible for $\Psi$, and we have

$$\text{sign}(\Psi, x) = \begin{cases} +1, & \text{if } \Psi : \Delta^n \to M \text{ is orientation-preserving}, \\ -1, & \text{if } \Psi : \Delta^n \to M \text{ is orientation-reversing}. \end{cases}$$

Also note that it is clear that any non-empty smooth manifold admits such a smooth embedding.

The following theorem is the main technical result of this chapter.
Theorem 68.1. Let \( n \in \mathbb{N} \) and let \( M \) be a compact oriented connected \( n \)-dimensional smooth manifold.

(1) For every \( x \in M \setminus \partial M \) the inclusion induced map

\[
\omega_x: H_n(M, \partial M) \to H_n(M, M \setminus \{x\})
\]

\[\cong \mathbb{Z} \text{ by Theorem 66.8} \cong \mathbb{Z} \text{ by Lemma 44.1}\]

is an isomorphism.

(2) There exists a unique \([M] \in H_n(M, \partial M)\) with the following property: For every map \( \Psi: \Delta^n \to M \) and every admissible \( x \in \Delta^n \) for \( \Psi \) we have the following equality in \( H_n(M, M \setminus \{\Psi(x)\})\):

\[
\omega_{\Psi(x)}([M]) = \text{sign}(\Psi, x) \cdot \left[ \Psi: \Delta^n \to M \right].
\]

the map \( H_n(M, \partial M) \to H_n(M, M \setminus \{\Psi(x)\}) \) as in (1)

(3) The uniquely determined element \([M] \in H_n(M, \partial M)\) from (2) is a generator, in particular we have \( H_n(M, \partial M) = \mathbb{Z} \cdot [M] \).

Proof of Theorem 68.1 (1) for closed manifolds. Let \( n \in \mathbb{N} \) and let \( M \) be a closed oriented connected \( n \)-dimensional smooth manifold. By Theorem 64.2 we can pick a smooth simplicial structure \((K = (V, S); \lambda: |K| \to M)\) for the smooth manifold \( M \). Since \( V \) is finite we can easily pick a total order \( \leq \) on the vertex set \( V \).

In the following we will use the results from Section 66.1 to construct an explicit singular cycle in \( C_n(M) \) which represents a generator of \( H_n(M) \). We will use this cycle to prove (1). Afterwards we will show that the homology class \([M] \) that it represents actually has all the properties stated in (2).

In the following we will make heavy use of the objects we introduced in Section 66.1. Even if the reader might no longer be completely familiar with all the technical definitions, the overall flow of the argument should still be easy to follow. Without further ado, let us construct the promised singular cycle.

(a) Given an \( m \)-simplex \( s \) of \( K \) we consider the embedding

\[
\Phi_s^\leq: \Delta^m \to |K|
\]

\[\begin{array}{c}
(t_0, \ldots, t_m) \\
\mapsto \sum_{i=0}^m t_i \cdot i \text{-th vertex of } s.
\end{array}
\]

here we use the total order on \( V \) to order the vertices of \( s \)

(b) We denote by \( s_1, \ldots, s_k \) the \( n \)-simplices of \( K \).

\[1028\]Note that by definition of a smooth embedding, see page 342, we know that \( \Psi(x) \subset M \setminus \partial M \). This implies that we have an induced map \( H_n(M, \partial M) \to H_n(M, M \setminus \{\Psi(x)\}) \).

\[1029\]Since \( x \) is an admissible point for \( \Psi \) we know that \( \Psi^{-1}(\Psi(x)) = \{x\} \). Note that this implies in particular that \( \Psi(\partial \Delta^n) \subset M \setminus \{\Psi(x)\} \) which in turn implies that \( \Psi \) is a cycle in \( C_n(M, M \setminus \{\Psi(x)\}) \).
(c) Let \( i \in \{1, \ldots, k\} \). It follows from the definition of a smooth simplicial structure, see page 1589 that the map \( \lambda \circ \Phi_{s_i}^\leq : \tilde{\Delta}^n \to M \) is a smooth embedding. Now we set

\[
\epsilon_i := \begin{cases} 
+1, & \text{if } \lambda \circ \Phi_{s_i}^\leq : \tilde{\Delta}^n \to M \text{ is orientation-preserving}, \\
-1, & \text{if } \lambda \circ \Phi_{s_i}^\leq : \tilde{\Delta}^n \to M \text{ is orientation-reversing}.
\end{cases}
\]

(d) By Proposition 66.7 we know that the oriented \( n \)-simplices \([[\epsilon_1, s_1]], \ldots, [[\epsilon_k, s_k]]\) form an orientation, in the sense of the definition on page 1652 for the pseudo-manifold \( K \).

(e) Next we consider the maps

\[
\begin{align*}
C^\text{simp}_m(K) & \twoheadrightarrow C^\text{simp}_{\leq}(K) \rightarrowtail C_m([|K|]) \xrightarrow{\lambda} C_m(M) \\
[v_0, \ldots, v_m] = [s] & \leftrightarrow \{v_0 < \ldots < v_m\} = [s] \xmapsto{\Phi_s} \mathbb{Z}.
\end{align*}
\]

(f) It follows from (d) together with Theorem 66.4 (1) that \( \epsilon_1 \cdot [s_1] + \ldots + \epsilon_k \cdot [s_k] \) is a cycle in the simplicial chain complex \( C^\text{simp}_s(K) \) and we know that it represents a generator of \( H^\text{simp}_n(K) \).

(g) It now follows from (e) and (f) that \( c := \epsilon_1 \cdot \lambda \circ \Phi_{s_1}^\leq + \ldots + \epsilon_k \cdot \lambda \circ \Phi_{s_k}^\leq \in C_n(M) \) is a singular cycle in \( C_s(M) \) and that it represents a generator of \( H_n(M) \).

Now we turn to the actual proof of (1). As a reminder, recall that we need to prove the following claim.

\textbf{Claim.} For every \( x \in M \) the map

\[
\omega_x : H_n(M) \to H_n(M, M \setminus \{x\})
\]

is an isomorphism.

First we take care of the special case of a point \( y \in M \) which can be written as \( y = (\lambda \circ \Phi_{s_i})(P) \) for some \( i \in \{1, \ldots, k\} \) and some \( P \in \tilde{\Delta}^n \). We consider the following two maps:

\[
\begin{align*}
H_n(M) & \xrightarrow{\omega_y} H_n(M, M \setminus \{y\}) \xrightarrow{(\lambda(\Phi_{s_i}^\leq))_*} H_n(\Delta^n, \Delta^n \setminus \{P\}) \cong \mathbb{Z}[\text{id}_{\Delta^n}], \text{ by Exercise 45.1}
\end{align*}
\]

\[
\begin{align*}
[c] & \mapsto [c] = [\lambda \circ \Phi_{s_i}^\leq] \quad \cong [\text{id}_{\Delta^n}]
\end{align*}
\]

since all the other \( \lambda \circ \Phi_{s_i}^\leq \) are zero in \( C_n(M, M \setminus \{y\}) \)

The above data shows that the image of \([c]\) in \( H_n(M, M \setminus \{y\}) \) equals the image of a generator of \( H_n(\Delta^n, \Delta^n \setminus \{P\}) \). Since the map to the right is an isomorphism we see that the map \( \omega_y : H_n(M) \to H_n(M, M \setminus \{y\}) \) is an epimorphism. Since \( M \) is closed orientable connected and non-empty we know by Theorem 66.8 that the group to the left is also isomorphic to \( \mathbb{Z} \). Thus we see that both groups are isomorphic to \( \mathbb{Z} \) we see that the map \( \omega_y \) is actually an isomorphism.
Now let \( x \in M \) be any point. Since \( M \) is connected we obtain from Proposition 8.29 that there exists a diffeomorphism \( f: M \to M \) with \( f(x) = y \). Now we consider the following diagram:

\[
\begin{array}{ccc}
H_n(M) & \xrightarrow{\omega_x} & H_n(M, M \setminus \{x\}) \\
\downarrow{f_*} & \cong & \downarrow{f_*} \\
H_n(M) & \xrightarrow{\omega_y} & H_n(M, M \setminus \{y\}).
\end{array}
\]

By the above we know that the bottom map is an isomorphism. Since \( f \) is a diffeomorphism the vertical maps are isomorphisms. Since the diagram commutes we see that the top horizontal map is also an isomorphism.

\[\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1047.png}
\caption{Illustration for the proof of Theorem 68.1 (1).}
\end{figure}\]

The proof of Theorem 68.1 (2) is a technically more intricate variation on the proof of Theorem 68.1 (1).

**Proof of Theorem 68.1 (2) and (3) for Closed Manifolds.** We continue with the notation of the proof of Theorem 68.1 (1). Note that the uniqueness part of Statement (2) is basically an immediate consequence of Statement (1). Thus to prove Statement (2) it remains to prove existence. In the following we will now show that

\[ [M] := [c] = [\epsilon_1 \cdot \lambda \circ \Phi^\leq_{s_1} + \cdots + \epsilon_k \cdot \lambda \circ \Phi^\leq_{s_k}] \in H_n(M) \]

has the desired properties. Before we do so, note that in (1) we already saw that \([c]\) is a generator of \( H_n(M) \). Thus once we have shown that \([c]\) has the desired properties we have also shown Statement (3).

First let us now prove the following claim.

**Claim.** For every map \( \Psi: \Delta^n \to M \) and every admissible \( x \in \hat{\Delta}^n \) we have

\[ \omega_{\Psi(x)}([M]) = \text{sign}(\Psi, x) \cdot [\Psi: \Delta^n \to M]. \]

Similar to the proof of the claim in Statement (1) we first deal with a special case. We pick an \( n \)-simplex \( s_i \) and we consider the corresponding map \( \Upsilon := \lambda \circ \Phi^\leq_{s_i}: \Delta^n \to M \). Note that since we have given a smooth simplicial structure we know that the restriction of \( \Upsilon = \lambda \circ \Phi^\leq_{s_i}: \Delta^n \to M \) to \( \hat{\Delta}^n \) is a smooth embedding. In particular any \( x \in \hat{\Delta}^n \) is admissible. Next note that we have the following equalities in \( H_n(M, M \setminus \{\Upsilon(x)\}) \):

\[
\omega_{\Upsilon(x)}([M]) = [\epsilon_1 \cdot \lambda \circ \Phi^\leq_{s_1} + \cdots + \epsilon_k \cdot \lambda \circ \Phi^\leq_{s_k}] = [\epsilon_i \cdot \lambda \circ \Phi^\leq_{s_i}] = \text{sign}(\Upsilon, x) \cdot [\Upsilon].
\]

\[\begin{align*}
\text{definition of } [M] & \quad \text{since all other } \Phi^\leq_{s_j} \text{ are zero in } C_n(M, M \setminus \{\Upsilon(x)\}) & \quad & \text{since } \epsilon_i = \text{sign}(\Upsilon, x)
\end{align*}\]
This concludes the proof of the claim for the special case $\Upsilon = \lambda \circ \Phi_{s,1}$ and any $x \in \bar{\Delta}^n$.

Now we turn to the general case. Let $\Psi: \Delta^n \to M$ be a map and let $x \in \bar{\Delta}^n$ be an admissible point. By definition we have $\Psi^{-1}(\Psi(x)) = \{x\}$ and by definition there exists an open connected neighborhood $U$ of $x \in \bar{\Delta}^n$ such that the map $\Psi|_U: U \to M$ is a smooth embedding. We pick an orientation-preserving embedding $\theta: \bar{B}^n \to U$ with $\theta(0) = x$.

Next we consider the embedding $\tilde{\Upsilon} := \Upsilon \circ \theta: \bar{B}^n \to M$, with $\Upsilon = \lambda \circ \Phi_{s,1}$ as above, and we consider the embedding $\tilde{\Psi} = \Psi \circ \theta: \bar{B}^n \to M$. First we make the following assumption:

(*) The maps $\tilde{\Upsilon}$ and $\tilde{\Psi}$ are both orientation-preserving embeddings or they are both orientation-reversing embeddings.

In this case it follows from Theorem 8.36 that there exists a diffeomorphism $f$ of $M$ with the following two properties:

(i) the map $f$ is homotopic to the identity,

(ii) $f \circ \tilde{\Upsilon} = \tilde{\Psi}$.

We consider the following commutative diagram:

$$
\begin{array}{cccc}
\Psi_* & \rightarrow & H_n(M, M \setminus \{\Upsilon(x)\}) & \xrightarrow{\cong} & H_n(M) \\
\downarrow & & \downarrow & & \downarrow \\
\Upsilon_* & \rightarrow & H_n(\Delta^n, \Delta^n \setminus \{x\}) & \xrightarrow{\cong} & H_n(\bar{B}^n, \bar{B}^n \setminus \{0\}) \\
\downarrow & & \downarrow & & \downarrow \\
\Psi_* & \rightarrow & H_n(M, M \setminus \{\Psi(x)\}) & \xrightarrow{\cong} & H_n(M) \\
\end{array}
$$

We make the following observations and clarifications:

(a) It follows from (i) and from Proposition 42.5 that the map $f_\ast: H_n(M) \to H_n(M)$ is the identity.

(b) Note that by Theorem 68.1 we know that the maps $\omega_{\Upsilon(x)}$ and $\omega_{\Psi(x)}$ are isomorphisms.

(c) Note that it follows immediately from the Excision Theorem 43.20 that the map $\theta_\ast: H_n(\bar{B}^n, \bar{B}^n \setminus \{0\}) \to H_n(\Delta^n, \Delta^n \setminus \{x\})$ is an isomorphism.

(d) By (c) we can now set $\sigma := \theta_\ast^{-1}(\{id_{\Delta^n}\}) \in H_n(\bar{B}^n, \bar{B}^n \setminus \{0\})$.

We make the following observations:

\[
\begin{align*}
\omega_{\Upsilon(x)}([M]) &= \text{sign}(\Upsilon, x) \cdot [\Upsilon: \Delta^n \to M] & \text{by the above special case} \\
\omega_{\Psi(x)}([M]) &= \text{sign}(\Psi, x) \cdot \tilde{\Psi}_\ast(\sigma) & \text{by (d), since } \tilde{\Upsilon}_\ast = \Upsilon_\ast \circ \theta_\ast \\
\omega_{\Psi(x)}([M]) &= \text{sign}(\Psi, x) \cdot \tilde{\Psi}_\ast(\sigma) & \text{by (d), since } \tilde{\Psi}_\ast = \Psi_\ast \circ \theta_\ast.
\end{align*}
\]

\footnote{Since $\Psi$ is admissible we know that $\Psi^{-1}(\Psi(x)) = \{x\}$. This implies that $\Psi$ does indeed induce a map $\Psi_\ast: H_n(\Delta^n, \Delta^n \setminus \{x\}) \to H_n(M, M \setminus \{\Psi(x)\})$.}
Finally we suppose that (*) does not hold. Let
\[ \rho: \Delta^n \to \Delta^n \]
\[ (t_0, t_1, t_2, \ldots, t_n) \mapsto (t_1, t_0, t_2, \ldots, t_n) \]
be the map that swaps the first two coordinates. Since \( \rho \) is orientation-preserving we now see that \( \bar{\Upsilon} \) and \( \bar{\Psi} \circ \rho \) satisfy (*). Now we see that
\[ \omega_{(\bar{\Psi} \circ \rho)(\rho(x))}(M) = \text{sign}(\bar{\Psi} \circ \rho(x)) \cdot [\bar{\Psi} \circ \rho: \Delta^n \to M] \]
\[ = \Psi_*([\rho_*([\text{id}_{\Delta^n}])] \]
since \( \bar{\Upsilon} \) and \( \bar{\Psi} \circ \rho \) satisfy (*)
we can apply the above
\[ \Rightarrow \omega_{\Psi(x)}(M) = \text{sign}(\bar{\Psi} \circ \rho(x)) \cdot \Psi_*([\text{id}_{\Delta^n}]) \]
by Exercise [45.2]
\[ \Rightarrow \omega_{\Psi(x)}(M) = (-\text{sign}(\bar{\Psi}, x)) \cdot \Psi_*([\text{id}_{\Delta^n}]) \]
since \( \rho \) is orientation-reversing
\[ \Rightarrow \omega_{\Psi(x)}(M) = \text{sign}(\bar{\Psi}, x) \cdot [\Psi: \Delta^n \to M]. \]

We have now proved Theorem [68.1] for all closed smooth manifolds. It remains to prove Theorem [68.1] for smooth manifold with non-empty boundary.

**Proof of Theorem [68.1] for manifolds with non-empty boundary (***). Let \( M \) be a compact oriented connected \( n \)-dimensional smooth manifold with non-empty boundary. Let \( M' \) be another copy of \( M \). We consider the double \( \partial M = M \cup_{\partial M = \partial M'} M' \) of \( M \), as defined on page [1163]. Since \( \partial M \neq \emptyset \) we obtain from Lemma [44.12] that \( \partial M \) is a closed oriented \( n \)-dimensional smooth manifold such that the map \( M \to \partial M \) is an orientation-preserving embedding.

1. Let \( x \in M \setminus \partial M \). We consider the following commutative diagram:
   \[ \begin{array}{ccc}
   H_n(M, \partial M) & \cong & H_n(D M, M') \\
   \downarrow & & \downarrow \cong \\
   H_n(M, M \setminus \{x\}) & \cong & H_n(D M, D M \setminus \{x\}).
   \end{array} \]

As we saw in Lemma [44.12] (6), it follows from the Excision Theorem [44.10] that the top left horizontal map is an isomorphism. Basically the same argument shows that the bottom horizontal map is an isomorphism. Furthermore note that in the proof of Theorem [66.8] we saw that the top right horizontal map is an isomorphism. By
the above discussion of closed smooth manifolds we know that the right vertical map is an isomorphism. It now follows, as desired, that the left vertical map is also an isomorphism.

(2) By the discussion of the closed case we can consider the class \([D \ M] \in H_n(D \ M)\). We define \([M] \in H_n(M, \partial M)\) to be the preimage of \([D \ M]\) under the composition of the above two horizontal isomorphisms. A slight variation on the argument provided in (1) now shows that \([M]\) has all the desired properties. We leave it to the reader to fill in the details. ■

Theorem \[68.1\] leads us to the following definition.

**Definition.** Let \(n \in \mathbb{N}\) and let \(M\) be a compact oriented \(n\)-dimensional smooth manifold.

1. We denote by \(N_1, \ldots, N_k\) the components of \(M\). Furthermore for \(i = 1, \ldots, k\) we now denote by \([N_i] \in H_n(N_i, \partial N_i)\) the homology class from Theorem \[68.1\]. We refer to
   \[ [M] := \sum_{i=1}^{k} [N_i] \in H_n(M, \partial M) = \bigoplus_{i=1}^{k} H_n(N_i, \partial N_i). \]
   isomorphism given by Lemma \[41.14\]
   as the **fundamental class** of \(M\).

2. We refer to any cycle in \(C_n(M, \partial M)\) that represents the fundamental class \([M]\) as a **fundamental cycle**.

**Remark.** In Chapter \[86\] we will introduce the notion of an orientation on a topological manifold and on page \[2120\] we will introduce fundamental classes for oriented topological manifolds. After a few reinterpretations one sees that Proposition \[86.11\] together with Theorem \[87.1\] provide in particular an alternative proof of Theorem \[68.1\].

Conveniently enough, the proof of Theorem \[68.1\] actually gives an algorithm for determining explicit fundamental cycles.

**Algorithm 68.2.** Let \(n \in \mathbb{N}\) and let \(M\) be a compact oriented non-empty \(n\)-dimensional smooth manifold.

1. By Theorem \[64.2\] we can pick a smooth simplicial structure \((K = (V, S), |K| \xrightarrow{\lambda} M)\).
   Since \(V\) is finite we can pick a total order “\(\leq\)” on \(V\).
2. We denote by \(s_1, \ldots, s_k\) the \(n\)-simplices of \(K\).
3. For \(i \in \{1, \ldots, k\}\) we consider the characteristic map
   \[ \Phi_{s_i}^\leq: \Delta^n \to |K| \]
   \[ (t_0, \ldots, t_n) \mapsto \sum_{j=0}^{n} t_j \cdot j\text{-th vertex of } s_i \]
   we use the total order on \(V\) to order the vertices of \(s_i\)
   and we set
   \[ \epsilon_i := \begin{cases} +1, & \text{if } \lambda \circ \Phi_{s_i}^\leq: \Delta^n \to M \text{ is orientation-preserving}, \\ -1, & \text{if } \lambda \circ \Phi_{s_i}^\leq: \Delta^n \to M \text{ is orientation-reversing}. \end{cases} \]
(4) The cycle \( \epsilon_1 \cdot \lambda \circ \Phi_{s_1}^\leq + \cdots + \epsilon_k \cdot \lambda \circ \Phi_{s_k}^\leq \in C_n(M) \) is a fundamental cycle of \( M \).

**Proof.** It is basically clear that it suffices to prove the validity of the algorithm for the connected case. Next note that if \( M \) is closed, then it follows immediately from the proof of Theorem 68.1(1) that \( \epsilon_1 \cdot \lambda \circ \Phi_{s_1}^\leq + \cdots + \epsilon_k \cdot \lambda \circ \Phi_{s_k}^\leq \in C_n(M) \) is a cycle. Furthermore, in the proof of Theorem 68.1(2) we saw that this cycle represents the fundamental class \([M] \in H_n(M)\) of \( M \). If \( M \) has non-empty boundary, then we equip the double \( DM \) with the simplicial structure given by “doubling” the simplicial structure of \( M \). It is now straightforward to verify that the above algorithm also works in that case. We leave it to the reader to fill in the details. ■

**Example.** In Figure 1049 we consider the annulus \( M = ([0,3] \times [0,1])/(0,y) \sim (3,y) \) equipped with an orientation and equipped with a smooth simplicial structure. In Figure 1049 we use two different ways to name the vertices, namely once the vertex set is \( V = \{a,\ldots,f\} \) and once it is \( V = \{A,\ldots,F\} \). In both cases we equip these sets with the obvious total order. We now see that the singular chains

\[
\begin{align*}
\mu &= +\Phi_{\{a,d,f\}}^\leq - \Phi_{\{d,e,f\}}^\leq + \Phi_{\{c,e,f\}}^\leq - \Phi_{\{b,c,e\}}^\leq + \Phi_{\{a,b,c\}}^\leq - \Phi_{\{a,b,d\}}^\leq \in C_n(M, \partial M) \\
\nu &= +\Phi_{\{A,B,C\}}^\leq - \Phi_{\{B,C,D\}}^\leq + \Phi_{\{C,D,E\}}^\leq - \Phi_{\{D,E,F\}}^\leq + \Phi_{\{A,E,F\}}^\leq - \Phi_{\{A,B,F\}}^\leq \in C_n(M, \partial M)
\end{align*}
\]

are both fundamental cycles of \( M \).

![Diagram](image)

**Figure 1049**

Even though Algorithm 68.2 is very explicit, it also has some drawbacks. For example simplicial structures tend to have many simplices, which in the above algorithm leads to cycles with many summands. In a minute we will state a result that addresses this issue. But first let us prove a lemma which in particular says that, in order to show that we are given the fundamental class of a compact oriented connected smooth manifold, we only have to verify the defining property for a single choice of a map \( \Psi : \Delta^n \to M \) and an admissible point \( x \in \Delta^n \).
Lemma 68.3. Let $M$ be a compact oriented non-empty $n$-dimensional smooth manifold and let $\varphi \in H_n(M, \partial M)$. We denote by $N_1, \ldots, N_k$ the components of $M$. The following statements are equivalent:

1. $\varphi$ is the fundamental class of $M$.
2. For each $i \in \{1, \ldots, k\}$ there exists a map $\Psi: \Delta^n \to N_i$ and an admissible point $x \in \Delta^n$ such that the following equality holds in $H_n(M, M \setminus \{\Psi(x)\})$:
   \[
   \omega_{\Psi(x)}(\varphi) = \text{sign}(\Psi, x) \cdot \left[ \Psi: \Delta^n \to N_i \to M \right].
   \]
   
   the map $H_n(M, \partial M) \to H_n(M, M \setminus \{\Psi(x)\})$

3. For each $i \in \{1, \ldots, k\}$ there exists a point $y \in N_i \setminus \partial_i N$ such that
   \[
   \omega_y(\varphi) = \omega_y([M]).
   \]

Proof (\(*\)). A short moment of reflection shows that it suffices to prove the lemma in the case that $M$ is connected. Next we note that the $(1) \Rightarrow (2)$-direction and $(1) \Rightarrow (3)$-direction are of course tautologies. We turn to the proof of the $(2) \Rightarrow (1)$-direction. We have the following two equalities in $H_n(M, M \setminus \{x\})$:

\[
\omega_{\Psi(x)}(\varphi) = \text{sign}(\Psi, x) \cdot \left[ \Psi: \Delta^n \to M \right] = \omega_{\Psi(x)}([M]).
\]

by hypothesis

Since we assume that $M$ is connected we know by Theorem 68.1 that $\omega_{\Psi(x)}$ is an isomorphism. Thus it follows from the above that $\varphi = [M]$.

Finally we consider the $(3) \Rightarrow (1)$-direction. This statement follows again from the fact that $\omega_y$ is an isomorphism. \[\blacksquare\]

The following proposition now gives us a practical criterion for showing that a given cycle represents the fundamental class.

Proposition 68.4. Let $M$ be a compact oriented connected $n$-dimensional smooth manifold. Let $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \in C_n(M, \partial M)$ be a cycle. Suppose there exists a $j \in \{1, \ldots, m\}$ such that the following three conditions are satisfied:

1. The map $\sigma_j: \Delta^n \to M$ is an orientation-preserving smooth embedding.\[1031\]
2. There exists an $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n)$ which is not contained in the image of any other $\sigma_i: \Delta^n \to M$.
3. $r_j = 1$.

Then the cycle $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m$ represents the fundamental class of the oriented smooth manifold, i.e. we have

\[
[r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m] = [M] \in H_n(M, \partial M).
\]

Example. It follows easily from Proposition 68.4 and our orientation convention, see page 299, that the singular 1-simplex $\mu: \Delta^1 \to S^1$ given by $\mu(1 - t, t) = e^{2\pi it}$ represents the fundamental class of the oriented smooth manifold $S^1$.

\[1031\] Note that we do not place any conditions on the restriction of $\sigma_j$ to $\partial \Delta^n$. 

Proof of Proposition 68.4 (*). Let $M$ be a compact oriented connected $n$-dimensional smooth manifold, let $\sum_{i=1}^{m} r_i \cdot \sigma_i \in C_n(M, \partial M)$ be a cycle and let $j \in \{1, \ldots, m\}$ such that conditions (1)-(3) above are satisfied. We pick $x \in \sigma_j(\hat{\Delta}^n)$ as in (2). Now we see that we have the following equalities in $H_n(M, M \setminus \{x\})$:

$$
\omega_x([r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m]) = \left[\underbrace{r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m}_{\in C_n(M, M \setminus \{x\})}\right] = [r_j \cdot \sigma_j] = [\sigma_j: \Delta^n \to M].
$$

since (2) implies that for $i \neq j$ we have $\sigma_i(\Delta^n) \subset M \setminus \{x\}$.

By hypothesis $\sigma_j: \Delta^n \to M$ restricts to an orientation-preserving embedding $\sigma_j: \hat{\Delta}^n \to M$. Since $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n)$ we see that $x$ is an admissible point for $\sigma_j$. Thus all the hypotheses of Lemma 68.3 hold, and therefore we conclude from Lemma 68.3 that the cycle $r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \in C_n(M, \partial M)$ is indeed a fundamental cycle of $M$. 

68.2. Examples of fundamental classes. In this section we will give explicit cycles representing the fundamental classes of $\overline{B}^n$, of $S^n$ and of surfaces of genus $\geq 1$. At this stage it is convenient to recall the following notation.

Notation.

(1) We consider the projection

$$p: \Delta^n \to \triangle^n := \left\{ (t_1, \ldots, t_n) \in [0, 1]^n \ \big| \ \sum_{j=1}^{n} t_j \in [0, 1] \right\}$$

$$(t_0, \ldots, t_n) \mapsto (t_0, \ldots, t_{n-1}).$$

One can easily verify that the restriction $p: \triangle^n \to \Delta^n$ is orientation-preserving if and only if $n$ is even.

(2) (a) Let $\mu: \triangle^n \to \overline{B}^n$ be the explicit homeomorphism with $\mu\left(\frac{1}{n+1}, \ldots, \frac{1}{n+1}\right) = 0$ that is given by Proposition 2.53 (2). Note that the restriction of $\mu$ to a map $\Delta^n \to B^n$ is not smooth. But it is easily seen to be an orientation-preserving smooth embedding on an open dense subset of $\triangle^n$.

(b) Let $\nu: \triangle^n \to \overline{B}^n$ be the explicit homeomorphism with $\nu\left(\frac{1}{n+1}, \ldots, \frac{1}{n+1}\right) = 0$ given in Exercise 41.1. This map has the very neat feature that the restriction $\Delta^n \to B^n$ is actually an orientation-preserving diffeomorphism.

The following lemma is an immediate consequence of the above and Lemma 68.3.

Lemma 68.5. Let $n \in \mathbb{N}$. The cycles $(-1)^n \cdot (\mu \circ p: \Delta^n \to \overline{B}^n) \in C_n(\overline{B}^n, S^{n-1})$ and $(-1)^n \cdot (\nu \circ p: \Delta^n \to \overline{B}^n) \in C_n(\overline{B}^n, S^{n-1})$ are both representatives of the fundamental class $[\overline{B}^n] \in H_n(\overline{B}^n, S^{n-1})$. 

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1050.png}
\caption{Figure 1050}
\end{figure}
Let \( n \in \mathbb{N} \). The eagle-eyed reader will have noticed that by now we have introduced the symbol \([S^n] \in H_n(S^n)\) twice:

1. On page 1174 we introduced the “standard generator” \([S^n] = [\alpha - \beta] \in H_n(S^n)\). Here \( \alpha \) is given by

\[
\Delta^n \xrightarrow{\mu \circ p} \overset{\circ}{B}^n \rightarrow S^n \subset \mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R}
\]

and \( \beta: \Delta^n \rightarrow S^n \) is the composition of \( \alpha \) with reflection in the hyperplane defined by \( x_{n+1} = 0 \).

2. We endow \( S^n \) with the orientation introduced on page 299 namely given \( P \in S^n \) we say a basis \( v_1, \ldots, v_n \) of \( T_PM = V_PM \) is positive if \( P, v_1, \ldots, v_n \) is a positive basis for \( \mathbb{R}^{n+1} \). With this orientation of \( S^n \) we now also have the corresponding fundamental class \([S^n] \in H_n(S^n)\).

Fortunately the next lemma says that our various sign conventions work out in such a way that the two definitions of \([S^n]\) agree.

**Lemma 68.6.** Let \( n \in \mathbb{N} \). The standard generator \([S^n] \in H_n(S^n)\) that we introduced on page 1174 agrees with the fundamental class of the oriented smooth manifold \( S^n \).

**Proof.** It follows from the above discussion, and some elementary arguments that the map \( \alpha: \Delta^n \rightarrow S^n \) is an embedding and that it is an orientation-preserving embedding on an open subset of \( \overset{\circ}{\Delta}^n \). The desired equality now follows almost immediately from Proposition 68.4 applied to the cycle \( \alpha - \beta \).

We move on to giving explicit representatives of fundamental classes for surfaces. This will require the introduction of more notation.

**Notation.** We will give many examples of fundamental classes of 2-dimensional smooth manifolds. Since we want to be very careful what singular simplex we mean by a given picture we adopt the following convention:

A triangle \( T \) with a dot in a corner and a directional arrow in the center means the unique affine linear map \( \Delta^2 \rightarrow T \) which sends \((1,0,0)\) to the vertex decorated with the dot and which respects the orientation of the vertices. We illustrate this notation in Figure 1052.

We also take some artistic liberties and allow triangles where the boundary is not given by segments and where the boundary consists of curves. In this case we expect that the boundary curves are parametrized with constant speed. Since the precise definition of the boundary of a singular 2-simplex is often a source of confusion we recall the definition in Figure 1053.
Example. In Figure 1054 we show the torus $T = ([0, 1] \times [0, 1]) / \sim$. We equip $T$ with the orientation coming from the standard orientation on $(0, 1) \times (0, 1) \subset T$, which we can also view as an open subset of $\mathbb{R}^2$. In Figure 1054 we also show two singular 2-simplices $\sigma_1$ and $\sigma_2$. It is straightforward to verify that $-\sigma_1 + \sigma_2$ is a cycle. (In the verification it is very helpful to keep Figure 1053 in mind.) The summand $\sigma_2$ satisfies the conditions imposed in Proposition 68.4, thus we see that $-\sigma_1 + \sigma_2$ represents a fundamental class of $T$, in particular it represents a generator of $H_2(T)$. This is of course the same cycle that we had already initially encountered on page 1083. We already saw in Lemma 46.12 (2) in a somewhat ad hoc argument that it represents a generator of $H_2(T)$.

Examples. In Figure 1055 we show the surface of genus 2 with eight singular 2-simplices $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ and $\tau_1, \tau_2, \tau_3, \tau_4$. The interior of the octagon is an open subset of $\mathbb{R}^2$ and we equip the surface of genus 2 with the orientation coming from the standard orientation of $\mathbb{R}^2$. It is a fun exercise to verify that the singular 2-chain

$$\sigma_1 + \sigma_2 - \sigma_3 - \sigma_4 + \tau_1 + \tau_2 - \tau_3 - \tau_4$$

is indeed a cycle. It follows easily from Proposition 68.4 that the singular 2-chain is a fundamental cycle, i.e. it represents a fundamental class of the surface of genus 2.

We will discuss more examples and properties of the fundamental class shortly. But for coherence it is best to first quickly discuss the slightly annoying case of 0-dimensional manifolds.
68.3. **Orientations of 0-dimensional manifolds.** The following definition might initially feel rather artificial.

**Definition.**

1. An orientation for a 0-dimensional smooth manifold \( M \) is a map \( \epsilon: M \to \{ \pm 1 \} \).
2. Let \( W \) be an oriented 1-dimensional smooth manifold. We define
   \[
   \epsilon: \partial W \to \{ \pm 1 \},
   \]
   \[
   P \mapsto \begin{cases} 
   -1, & \text{if for every smooth map } f: W \to \mathbb{R}_{\geq 0} \text{ with } f(P) = 0 \\
   +1, & \text{and for every positive vector } v \in T_P W \text{ we have } v(f) \geq 0, \\
   \end{cases}
   \]
   Loosely speaking \( \partial W \) is the oriented 0-dimensional smooth manifold given by the set \( \partial W \) and the sign \( +1 \) respectively \( -1 \) assigned to the points depending on whether or not the orientation of \( W \) sticks “out of” respectively “into” \( W \).
3. Let \( (M = \{ P_1, \ldots, P_k \}, \epsilon: M \to \{ \pm 1 \}) \) be a compact oriented 0-dimensional smooth manifold. The corresponding fundamental class \([M]\) is defined as the homology class
   \[
   [M] := \sum_{i=1}^k \epsilon(P_i) \cdot [P_i] \in H_0(M).
   \]
4. Let \( k \in \mathbb{N} \), let \( N \) be an oriented \( k \)-dimensional topological manifold and let \( \{ P \} \) be the 0-dimensional smooth manifold consisting of a single point \( P \) that is equipped with an orientation \( \epsilon \in \{-1, 1\} \). If \( \epsilon = 1 \), then we equip the product manifold \( \{ P \} \times N \) with the unique orientation that turns the obvious map \( N \to \{ P \} \times N \) into an orientation-preserving diffeomorphism. Furthermore, if \( \epsilon = -1 \), then we equip the product manifold \( \{ P \} \times N \) with the unique orientation that turns the map \( N \to \{ P \} \times N \) into an orientation-reversing diffeomorphism. The same way we define the orientation on \( N \times \{ P \} \).

**Examples.**

1. The definition of the orientation of the boundary of an oriented 1-dimensional smooth manifold is illustrated in Figure 1056.

---

1032 Recall that on page 291 we defined the tangent space \( T_P W \) as the set of derivations at \( P \).
1033 We leave it to the reader to verify that the definition and the intuition agree.
“graph” of a function \( f : M \to \mathbb{R}_{\geq 0} \) with \( f(P) = 0 \) and \( f(Q) = 0 \)

\[
\begin{array}{c}
P \\
\uparrow \\
M \\
\downarrow \\
Q
\end{array}
\quad \begin{array}{c}
\partial M \\
\uparrow \\
- P
\end{array}
\}
\]

**Figure 1056**

(2) The boundary of the 1-dimensional smooth manifold \([0, 1], \) which we equip with the usual orientation coming from \( \mathbb{R}, \) is easily seen to be given by \((-\{0\}) \cup \{1\}.\)

(3) One can easily verify that the statement regarding product orientations from Proposition 6.51 (5a) also holds in this context, i.e., given a 1-dimensional smooth manifold \( M \) with boundary and a smooth manifold \( N \) without boundary we have the equality \( \partial(M \times N) = (\partial M) \times N \) as oriented smooth manifolds. In particular we have

\[
\partial([0, 1] \times N) = (-\{0\} \times N) \cup (\{1\} \times N).
\]

This now gives a prettier description of the boundary orientations, than the ad hoc description in Proposition 6.51 (5b).

(4) We equip the 0-dimensional sphere \( S^0 = \{\pm 1\} \) with the orientation given by \( \pm 1 \mapsto \pm 1.\) Note that this implies that for any oriented smooth manifold \( M \) we have a natural orientation-preserving diffeomorphism \( M \times S^0 \cong (-M) \sqcup M. \)

**Convention.** Unless we say anything we will equip any given 0-dimensional manifold \( M \) with the orientation given by assigning \(+1\) to every point in \( M.\)

68.4. **Properties of the fundamental class.** Before we continue with the discussion of the fundamental class, let us consider the one case that we had not dealt with, namely the empty manifold. As we mentioned on page 264 basically by definition the empty set is a topological and smooth manifold of any dimension. Note that for the empty manifold \( \emptyset \) we have the equality \( H_0(\emptyset) = H_1(\emptyset) = H_2(\emptyset) = \cdots = \{0\}. \) We define the fundamental class \([\emptyset]\) of the empty manifold to be 0. Note that by the above the fundamental class \([\emptyset]\) is an element in every homology group of \( \emptyset. \)

Now let us continue with serious mathematics. The following lemma tells us the behavior of the fundamental class under diffeomorphisms.

**Lemma 68.7.** Let \( n \in \mathbb{N}_0, \) let \( M \) and \( N \) be compact oriented connected \( n \)-dimensional smooth manifolds and let \( f : M \to N \) be a diffeomorphism. We have

\[
f_*([M]) = \begin{cases} [N], & \text{if } f \text{ is orientation-preserving,} \\ -[N], & \text{if } f \text{ is orientation-reversing.} \end{cases}
\]

**Proof (\( \ast \)).** If \( n = 0, \) then the statement follows immediately from the definitions. As we will see, for \( n \in \mathbb{N} \) the statement follows basically immediately from the definition property of the fundamental class. Indeed, we set \( \epsilon := +1 \) if \( f \) is orientation-preserving, otherwise \( 1034 \)Note that this statement now also makes sense for the empty manifold.
we set $\epsilon := -1$. Let $\Psi: \Delta^n \to M$ be an embedding such that the map $\Psi: \hat{\Delta}^n \to M$ is orientation-preserving. We pick some $x \in \hat{\Delta}^n$. We consider the following commutative diagram:

\[
\begin{array}{ccc}
H_n(M, \partial M) & \xrightarrow{\omega_{\Psi(x)}} & H_n(M \setminus \{\Psi(x)\}) \\
\downarrow f_* & & \downarrow f_* \\
H_n(N, \partial N) & \xrightarrow{\omega_{(f \circ \Psi)(x)}} & H_n(N \setminus \{(f \circ \Psi)(x)\}).
\end{array}
\]

Now we see that

\[
\omega_{\Psi(x)}([M]) = \text{sign}(\Psi, x) \cdot [\Psi], \quad \text{by definition of } [M]
\]

\[
\Rightarrow \omega_{(f \circ \Psi)(x)}(f_*(M)) = \text{sign}(\Psi, x) \cdot [f \circ \Psi], \quad \text{by definition of diagram commutes}
\]

\[
\Rightarrow \omega_{(f \circ \Psi)(x)}(f_*(M)) = \epsilon \cdot \text{sign}(f \circ \Psi, x) \cdot [f \circ \Psi], \quad \text{by definition of } \epsilon
\]

\[
\Rightarrow f_*(M) = \epsilon \cdot [N], \quad \text{by Lemma 68.3}
\]

Given an oriented smooth manifold $M$ we denote, as usual, by $-M$ the same smooth manifold but with the opposite orientation. Now we can formulate the following lemma.

**Lemma 68.8.** For every compact oriented $n$-dimensional smooth manifold $M$ we have

\[[-M] = -[M] \in H_n(M, \partial M).\]

**Proof.** This statement follows basically immediately from Lemma 68.7 since the identity map $M \to -M$ is orientation-reversing. □

On page 303 we saw that the boundary of an oriented smooth manifold inherits a natural orientation. For compact smooth manifolds the following proposition gives the relationship between the fundamental class of the smooth manifold and of its boundary.

**Proposition 68.9.** Let $M$ be a compact oriented $n$-dimensional smooth manifold with boundary. The connecting homomorphism

\[\partial: H_n(M, \partial M) \to H_{n-1}(\partial M)\]

of the long exact sequence in homology of the pair $(M, \partial M)$ has the property that

\[[M] \mapsto [\partial M].\]

**Remark.** In Proposition 67.27 we will prove the analogue of Proposition 68.9 for topological manifolds.

**Proof (\#).** Let $M$ be a compact oriented $n$-dimensional smooth manifold with boundary components $N_1, \ldots, N_k$. By Theorem 64.2 the smooth manifold $M$ admits a smooth simplicial structure $(K = (V, S), \lambda: |K| \to M)$. By Proposition 66.1 (3) we know that there exists a subcomplex $J = (U, R)$ of $= (V, S)$ such that $(J = (U, R), \lambda: |J| \to \partial M)$
is a smooth simplicial structure for $\partial M$. We pick some total order "≤" on $V$. Next we introduce the following notation for $K$:

1. We denote by $S_n$ the set of $n$-simplices of $K$.

2. For each $s \in S_n$ we denote by $\Phi^<_s \colon \Delta^n \to |K|$ the corresponding characteristic map.

3. For each $s \in S_n$ we set

$$\varepsilon_s := \begin{cases} +1, & \text{if } \lambda \circ \Phi^<_s \colon \Delta^n \to M \text{ is orientation-preserving,} \\ -1, & \text{if } \lambda \circ \Phi^<_s \colon \Delta^n \to M \text{ is orientation-reversing.} \end{cases}$$

Next we introduce the analogous notions for the subcomplex $J$:

4. We denote by $R_{n-1}$ the set of $(n-1)$-simplices of $R$.

5. For each $r \in R_{n-1}$ we denote by $\Psi^<_r \colon \Delta^{n-1} \to |J|$ the corresponding characteristic map.

6. For each $r \in R_{n-1}$ we set

$$\mu_r := \begin{cases} +1, & \text{if } \lambda \circ \Psi^<_r \colon \Delta^{n-1} \to \partial M \text{ is orientation-preserving,} \\ -1, & \text{if } \lambda \circ \Psi^<_r \colon \Delta^{n-1} \to \partial M \text{ is orientation-reversing.} \end{cases}$$

Now we see that

$$\partial [M] = \partial \left[ \sum_{s \in S_n} \varepsilon_s \cdot \lambda \circ \Phi^<_s \right] = \partial \left[ \sum_{s \in S_n} \varepsilon_s \cdot \lambda \circ \partial_n (\Phi^<_s) \right] = \partial \left[ \sum_{s \in S_n} \varepsilon_s \cdot \lambda \cdot \sum_{j=0}^{n} (-1)^j \cdot \Phi^<_s \circ \imath^<_j \right]$$

since we are given a cycle in $C_n(M, \partial M)$ the contributions of singular simplices for which the image does not lie in $\partial M$ cancel

$$= \partial \left[ \sum_{s \in S_n \text{ and } j \in \{0, \ldots, n\} \text{ such that } (\Phi^<_s \circ \imath^<_j)(\Delta^{n-1}) \subset \partial M} (-1)^j \cdot \varepsilon_s \cdot \lambda \circ \Phi^<_s \circ \imath^<_j \right]$$

by Proposition 66.1 (4) we have a bijection Algorithm 68.2 of singular simplices that appear in the sums, furthermore the corresponding signs match by the discussion on page 1664.

Algorithm 68.2

Proposition 63.15

definition of $\partial_n \colon C_n(M) \to C_{n-1}(M)$

Figure 1058. Illustration for the proof of Proposition 68.9

The following straightforward corollary says that we can “extend” fundamental cycles from the boundary to the total manifold.
Corollary 68.10. (*) Let $M$ be a compact oriented $n$-dimensional smooth manifold. Let $A$ be a union of components of $\partial M$. We write $B := \partial M \setminus A$. We consider the map

$$
C_n(M, \partial M) \xrightarrow{\partial_n} C_{n-1}(\partial M) \xrightarrow{id} C_{n-1}(A \sqcup B) \xrightarrow{\cong} C_{n-1}(A) \oplus C_{n-1}(B) \xrightarrow{\cong} C_{n-1}(A).
$$

Given any fundamental cycle $\mu \in C_{n-1}(A)$ there exists a chain $\nu \in C_n(M)$ such that $\nu$ represents a fundamental cycle in $C_n(M, \partial M)$ and such that $\Theta_A(\nu) = \mu$.

**Proof (†).** First note that it is basically clear that it suffices to prove the statement for the case $A = \partial M$. Next, pick a singular chain $\tilde{\nu} \in C_n(M)$ that represents a fundamental cycle in $C_n(M, \partial M)$. By Propositions 68.9 and 13.15 we know that the cycles $\partial_n(\tilde{\nu})$ and $\mu$ are homologous in $C_{n-1}(\partial M)$. This means that there exists a $\sigma \in C_n(\partial M)$ with $\partial \sigma = \partial_n(\tilde{\nu}) - \mu$. Now we set $\nu := \tilde{\nu} - \sigma \in C_n(M)$. Since $\nu$ and $\tilde{\nu}$ represent the same element in $C_n(M, \partial M)$ we see that $\nu$ is also a fundamental cycle. Finally we note that by construction we have $\partial_n(\nu) = \partial_n(\tilde{\nu}) - \partial_n(\sigma) = \mu$.

**Figure 1059.** Illustration of Corollary 68.10.

Next we record the following useful corollary to Proposition 68.9.

Corollary 68.11. Let $M$ be a compact oriented connected $n$-dimensional smooth manifold. We denote by $i: \partial M \to M$ the inclusion map and we denote by $N_1, \ldots, N_k$ the components of $\partial M$.

1. We have

$$
\ker\left( i_*: H_{n-1}(\partial M) \to H_{n-1}(M) \right) = \mathbb{Z} \cdot [\partial M] \subseteq H_{n-1}(\partial M).
$$

2. Let $j \in \{1, \ldots, k\}$. We consider the following maps:

$$
0 \to H_{n-1}(\partial M)/\mathbb{Z} \cdot [\partial M] \xrightarrow{i_*} H_{n-1}(M) \to \operatorname{coker}(H_{n-1}(\partial M) \xrightarrow{i_*} H_{n-1}(M)) \to 0.
$$

The following two statements hold:

a. The horizontal sequence is exact and it splits.

b. The vertical map is an isomorphism.

3. If $M$ has precisely one boundary component, then $i_*: H_{n-1}(\partial M) \to H_{n-1}(M)$ is the zero map.

4. The boundary $\partial M$ is not a retract of $M$.  

Remark.

(1) The special case that $M$ is a 2-dimensional smooth manifold is foreshadowed by Exercise 48.14.

(2) In Proposition 43.7 we showed that the sphere $S^{n-1} = \partial B^n$ is not a retract of the closed ball $B^n$. Corollary 68.11 (3) can thus be viewed as a generalization of Proposition 43.7 from $B^n$ to the case of compact oriented connected smooth manifolds with non-empty boundary.

Example. In Figure 1060 we show a compact oriented $n$-dimensional smooth manifold with three boundary components $N_1, N_2$ and $N_3$. Corollary 68.11 says that any two boundary components generate a subsummand of $H_{n-1}(M)$. Furthermore in $H_{n-1}(M)$ we have the equality $[N_1] + [N_2] + [N_3] = 0$.

![Figure 1060](image)

**Proof.** Let $M$ be a compact oriented $n$-dimensional smooth manifold. We denote by $i: \partial M \to M$ the inclusion map.

(1) Using Proposition 68.9 and the long exact sequence in homology of the pair $(M, \partial M)$ we obtain that the following sequence is exact:

$$
\begin{array}{c}
H_n(M, \partial M) \\
\xrightarrow{[M] \mapsto [\partial M]} H_{n-1}(\partial M) \\
\xrightarrow{i_*} H_{n-1}(M)
\end{array}
$$

Statement (1) is now an immediate consequence.

(2) (a) It follows from (1) that the horizontal sequence is exact. By Theorem 66.6 (2) the group $H_{n-1}(M)$ is free abelian. It follows from Lemma 19.8 that the group $\text{coker}(i_*): H_{n-1}(\partial M) \to H_{n-1}(M) \cong \ker(H_{n-1}(M) \to H_{n-1}(M, \partial M))$ is also free abelian. It now follows from Lemma 16.1 that the short exact sequence splits.

(b) It follows immediately from $[\partial M] = [N_1] + \cdots + [N_k]$ that the vertical map is an isomorphism.

(3) Now we assume that $\partial M$ has precisely one component. By Theorem 68.1 we now have $H_{n-1}(\partial M) = \mathbb{Z} \cdot [\partial M]$. Thus this statement is now an immediate consequence of (1).

(4) Suppose there exists a retraction $r: M \to \partial M$, i.e. a map with $r \circ i = \text{id}_{\partial M}$. We consider the following commutative diagram

$$
\begin{array}{ccc}
H_{n-1}(M) & \xrightarrow{i_*} & H_{n-1}(\partial M) \\
\xrightarrow{(r \circ i)_* = \text{id}} & (r_*):= & H_{n-1}(\partial M)
\end{array}
$$
We just saw in (1) that $i_*$ is not injective. But this leads immediately to a contradiction. ■

In the next lemma we study the fundamental classes of codimension-zero submanifolds.

**Lemma 68.12.** Let $M$ be a compact oriented $n$-dimensional smooth manifold. Furthermore let $W \subset M$ be a compact $n$-dimensional submanifold. We write $\hat{W} = W \setminus \partial W$ and we equip $W$ with the orientation given by Lemma 6.46 (5). The following two statements hold:

1. The inclusion induced map $H_n(W, \partial W) \to H_n(M, M \setminus \hat{W})$ is an isomorphism.
2. The images of the fundamental classes $[M] \in H_n(M, \partial M)$ and $[W] \in H_n(W, \partial W)$ under the maps

$$H_n(M, \partial M) \to H_n(M, M \setminus \hat{W}) \cong H_n(W, \partial W)$$

agree.

**Figure 1061.** Illustration for the proof of Lemma 68.12.

**Proof (**) .

(1) The first statement is an immediate consequence of the Excision Theorem 44.10.

(2) We denote by $\Phi : H_n(M, \partial M) \to H_n(W, \partial W)$ the map given in statement (2). We have to show that $\Phi([M])$ is the fundamental class for $W$. So let $\Psi : \Delta^n \to W$ be a map and let $x \in \Delta^n$ be an admissible point. We consider the following commutative diagram

$$\begin{array}{ccc}
H_n(M, \partial M) & \xrightarrow{\Phi} & H_n(M, M \setminus \hat{W}) \\
\omega_{\Psi(x)} \downarrow & & \cong \downarrow \omega_{\Psi(x)} \\
H_n(M, M \setminus \{\Psi(x)\}) & \xleftarrow{\Psi_*} & H_n(W, W \setminus \{\Psi(x)\}) \\
\cong & & \cong \\
H_n(\Delta^n, \Delta^n \setminus \{x\}). & \xleftarrow{\Psi_*} & H_n(\Delta^n, \Delta^n \setminus \{x\}).
\end{array}$$

The desired statement now follows easily from the defining properties of fundamental classes and the above discussions. We leave the few remaining details to the reader. ■
One of the most popular approaches to computing the homology groups of some topological space $X$ is to write $X$ as the union $X = A \cup B$ of "simpler topological spaces $A$ and $B$" in a suitable way and to use the Mayer–Vietoris Theorem \[46.5\] The catch of the Mayer–Vietoris Theorem \[46.5\] is that not only does one need to understand the homology groups of $A$, $B$ and $A \cap B$, one also needs to understand the inclusion induced maps on homology groups, which can be quite difficult. Fortunately Corollary \[68.11\] (2) now gives an interesting calculation of an inclusion induced map of homology groups. In the following two sections we will use Corollary \[68.11\] (2) to study the homology groups of the connected sum of two smooth manifolds and to study the homology groups of knot complements.

68.5. The homology groups of the connected sum of two smooth manifolds (*). Let $M$ and $N$ be two compact oriented connected non-empty $n$-dimensional smooth manifolds. We recall the definition of the connected sum $M \# N$ that we gave on page \[377\]. First we pick an orientation-preserving smooth embedding $\varphi: \overline{B^n} \to M \setminus \partial M$ and we pick an orientation-reversing smooth embedding $\psi: \overline{B^n} \to N \setminus \partial N$. Then we defined the connected sum of $M$ and $N$ as follows:

$$M \# N := (M \setminus \varphi(B^n)) \sqcup (N \setminus \psi(B^n)) / \{ \varphi(P) = \psi(P) \mid P \in S^{n-1} \}.$$

We refer to Proposition \[8.35\] for some key properties of $M \# N$. Recall that in Proposition \[20.12\] we showed that $\pi_1(M \# N)$ is isomorphic to the free product of $\pi_1(M)$ and $\pi_1(N)$. The following proposition says that a very similar result holds for the homology groups of $M \# N$.

**Proposition 68.13.** Let $M$ and $N$ be two closed oriented connected non-empty $n$-dimensional smooth manifolds. For any $k \in \mathbb{N}_0$ we have

$$H_k(M \# N) \cong \begin{cases} H_k(M) \oplus H_k(N), & \text{if } k \neq 0, n, \\ \mathbb{Z}, & \text{if } k = 0, n. \end{cases}$$

Moreover, for $k \neq 0, n$ the inclusion maps induce isomorphisms

$$H_k(M) \oplus H_k(N) \xrightarrow{\cong} H_k(M \setminus B^n) \oplus H_k(N \setminus B^n) \xrightarrow{\cong} H_k(M \# N)$$

where $B^n \subset M$ and $B^n \subset N$ denote the open balls used in the definition of the connected sum of $M$ and $N$.

**Remark.** In Exercise \[68.8\] we will consider the homology groups of $M \# N$ if we drop the condition that the smooth manifolds are closed.

The key to the proof of Proposition \[68.13\] is the following lemma.

**Lemma 68.14.** Let $X$ and $Y$ be two compact orientable connected $n$-dimensional smooth manifolds such that $\partial X \cong S^{n-1}$ and $\partial Y \cong S^{n-1}$. We pick a diffeomorphism $\varphi: \partial X \to \partial Y$.

1. There exists an isomorphism

$$H_n(X \cup_{\varphi} Y) \cong \mathbb{Z}.$$
Furthermore for every $k < n$ the inclusion maps $X \to X \cup \varphi Y$ and $Y \to X \cup \varphi Y$ induce an isomorphism

$$\tilde{H}_k(X) \oplus \tilde{H}_k(Y) \xrightarrow{\cong} \tilde{H}_k(X \cup \varphi Y).$$

(2) In particular for the case that $Y = \overline{B}^n$ we obtain that for any $k < n$ the inclusion map $X \to X \cup \varphi \overline{B}^n$ induces an isomorphism

$$\tilde{H}_k(X) \xrightarrow{\cong} \tilde{H}_k(X \cup \varphi \overline{B}^n).$$

**Figure 1062. Illustration for Lemma 68.14.**

**Proof of Lemma 68.14.** The second statement is an immediate consequence of the first statement and the fact that for every $k < n$ we have $\tilde{H}_k(\overline{B}^n) = 0$. Thus it suffices to prove the first statement. To simplify the notation we write $S^{n-1} = \partial X = \partial Y$. We also write $Z = X \cup \varphi Y$. It follows from the Mayer-Vietoris Theorem 46.10 for Manifolds\(^{1035}\) that there exists a long exact sequence

$$\to \tilde{H}_k(S^{n-1}) \xrightarrow{i_\ast + i^\ast} \tilde{H}_k(X) \oplus \tilde{H}_k(Y) \xrightarrow{i_\ast + i^\ast} \tilde{H}_k(Z) \xrightarrow{\partial_k} \tilde{H}_{k-1}(S^{n-1}) \to \ldots$$

where $i$ always stands for the corresponding inclusion map. By Proposition 43.4 we have $\tilde{H}_n(S^n) \cong \mathbb{Z}$ and $\tilde{H}_k(S^n) = 0$ for $k \neq n$. We see immediately that for any $k < n$ the inclusion maps induce an isomorphism $\tilde{H}_k(X) \oplus \tilde{H}_k(Y) \to \tilde{H}_k(Z)$.

Now we turn to the $n$-th homology of $Z$. First note that by Theorem 66.8 we have $\tilde{H}_n(X) = \tilde{H}_n(Y) = 0$. Therefore the above long exact sequence gives rise to an exact sequence

since $S^{n-1}$ is the unique boundary component of $X$ we deduce from Corollary 68.11 that the map $i_\ast : \tilde{H}_{n-1}(S^{n-1}) \to \tilde{H}_{n-1}(X)$ is the zero map, the same way we also see that the map $i_\ast : \tilde{H}_{n-1}(S^{n-1}) \to \tilde{H}_{n-1}(Y)$ is the zero map

$$\underbrace{\tilde{H}_n(X) \oplus \tilde{H}_n(Y)} \to \tilde{H}_n(Z) \xrightarrow{\partial_n} \underbrace{\tilde{H}_{n-1}(S^{n-1})} \xrightarrow{i_\ast + i^\ast} \underbrace{\tilde{H}_{n-1}(X) \oplus \tilde{H}_{n-1}(Y)} \to \tilde{H}_{n-1}(Z) \to 0.$$

All the desired statements follow from the above data. \hfill \blacksquare

**Proof of Proposition 68.13.** Let $M$ and $N$ be two closed oriented connected nonempty $n$-dimensional smooth manifolds. As required in the definition of the connected sum of $M$ and $N$ we pick an orientation-preserving smooth embedding $\varphi : \overline{B}^n \to M$ and we pick an orientation-reversing smooth embedding $\psi : \overline{B}^n \to N$. Recall that

$$M \# N = \left( M \setminus \varphi(B^n) \right) \sqcup \left( N \setminus \psi(B^n) \right) / \left\{ \varphi(P) = \psi(P) \mid P \in S^{n-1} \right\}.$$

\(^{1035}\)Note that here secretly we also used Proposition 8.1.
We write $X = M \backslash \varphi(B^n)$ and $Y = N \backslash \psi(B^n)$. Note that it follows immediately from Lemma 68.14 (1) that $H_n(M \# N) = H_n(X \cup_S Y) \cong \mathbb{Z}$. Now let $k < n$. Note that in this case we have

$$H_k(M) \oplus H_k(N) \cong H_k(M \backslash \varphi(B^n)) \oplus H_k(N \backslash \psi(B^n)) \cong H_k(M \# N)$$

Lemma 68.14 (1) applied to $M = X \cup_S B^n$ and $N = Y \cup_S B^n$

**Examples.**

1. Let $T = S^1 \times S^1$ be the torus. In Figure 220 we saw that the connected sum $T \# T$ is diffeomorphic to the surface $\Sigma_2$ of genus 2. More generally, the same argument shows that the connected sum of $g$ copies of the torus $T$ is diffeomorphic to the surface $\Sigma_g$ of genus $g$. Together with the calculation of the homology groups of the torus in Lemma 46.12 we now see that

$$H_k(\Sigma_g) \cong H_k(T \# \ldots \# T) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, \\ \mathbb{Z}^{2g}, & \text{if } k = 1, \\ 0, & \text{if } k > 2. \end{cases}$$

This agrees of course with the result obtained in Proposition 48.9.

2. We consider the complex manifold $\mathbb{C}P^2$. On page 1262 we showed that

$$H_k(\mathbb{C}P^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \\ 0, & \text{otherwise.} \end{cases}$$

As always we equip $\mathbb{C}P^2$ with the natural orientation coming from Proposition 12.7. We can now form the connected sum $\mathbb{C}P^2 \# \mathbb{C}P^2$. It follows from Proposition 68.13 that

$$H_k(\mathbb{C}P^2 \# \mathbb{C}P^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

For the complex projective space $\mathbb{C}P^2$ we use the common notation that we write $\mathbb{C}P^2$ instead of $-\mathbb{C}P^2$. Since the homology groups do not depend on the orientation we have the same homology groups for $\mathbb{C}P^2$ and the calculation shows that the homology groups of $\mathbb{C}P^2 \# \mathbb{C}P^2$ and $\mathbb{C}P^2 \# -\mathbb{C}P^2$ agree.

Recall that on page 1442 we showed, using the Künneth Theorem 58.8 that

$$H_k(S^2 \times S^2) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

This fact, and our above calculations shows, that the homology groups of the connected sums $\mathbb{C}P^2 \# \mathbb{C}P^2$, $\mathbb{C}P^2 \# -\mathbb{C}P^2$ and of $S^2 \times S^2$ are all isomorphic. Furthermore, note that by Propositions 14.14, 16.20, 20.12 and the discussion on page 997 we know that all of these topological spaces are simply connected. So this raises the following intriguing question.
Remark. In Lemma 46.14 we already showed that \( H_0(X_K) = \mathbb{Z} \) and that \( H_1(X_K) = \mathbb{Z} \cdot [\mu_K] \). In fact in the proof of Lemma 68.16 (4) below we will follow the same approach as in Lemma 46.14 except that now can overcome the hurdle which prevented us back then from computing all homology groups.

\( \text{We will give an alternative approach to calculating these homology groups in Exercise 68.5.} \)
Proof. Let $K \subset S^3$ be an oriented knot and let $P \in K$. We pick a tubular neighborhood $B^2 \times K$ for $K$ and we pick $Q \in S^1$. We write $\mu_K = S^1 \times \{P\}$ and $\gamma = \{Q\} \times K$.

(1) This statement is basically a consequence of Proposition 8.2.

(2) This statement is an immediate consequence of Proposition 8.26.

(3) A deformation retraction from $S^3 \setminus K$ to $X_K$ is given by the map

$$ (S^3 \setminus K) \times [0, 1] \to X_K = S^3 \setminus (B^2 \times K) $$

$$ (x, t) \mapsto \begin{cases} x, & \text{if } x \in Y = S^3 \setminus (\overline{B^2} \times K), \\ ((1-t)r + t)e^{i\alpha}, & \text{if } x = (re^{i\alpha}, z) \in \overline{B^2} \times K. \end{cases} $$

It follows easily from Lemma 3.10 and Proposition 8.2 that this map is indeed continuous.

(4) First note that by Corollary 42.8, Lemma 18.14 and by (3) we know that the inclusion $X_K \to S^3 \setminus K$ induces an isomorphism on all homology groups.

Now we proceed with almost the same argument as in the proof of Lemma 46.14. Namely, we consider the decomposition

$$ S^3 = (S^3 \setminus (B^2 \times K)) \cup_{S^1 \times K} (\overline{B^2} \times K) $$

and we apply the Mayer-Vietoris Theorem 46.10 with reduced homology groups. We obtain the following long exact sequence:

$$ \to H_3(\partial X_K) \xrightarrow{i_*-i_*} H_3(X_K) \oplus H_3(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_3(S^3) \xrightarrow{\partial_3} $$

$$ \to H_2(\partial X_K) \xrightarrow{i_*-i_*} H_2(X_K) \oplus H_2(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_2(S^3) \xrightarrow{\partial_2} $$

$$ \to H_1(\partial X_K) \xrightarrow{i_*-i_*} H_1(X_K) \oplus H_1(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_1(S^3) \xrightarrow{\partial_1} 0. $$

Now we throw in everything we know about the above setting:

$$ \to H_3(\partial X_K) \xrightarrow{i_*-i_*} H_3(X_K) \oplus H_3(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_3(S^3) \xrightarrow{\partial_3} $$

$$ \to H_2(\partial X_K) \xrightarrow{i_*-i_*} H_2(X_K) \oplus H_2(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_2(S^3) \xrightarrow{\partial_2} $$

by Corollary 68.11 (2) this is the zero map

$$ \to H_1(\partial X_K) \xrightarrow{i_*-i_*} H_1(X_K) \oplus H_1(\overline{B^2} \times K) \xrightarrow{i_*+i_*} H_1(S^3) \xrightarrow{\partial_1} 0. $$

Note that we obtain from the above discussion that the connecting homomorphism $\partial_3 : \mathbb{Z} \cdot [S^3] = H_3(S^3) \to H_2(\partial X_K) = \mathbb{Z} \cdot [\partial X_K]$ is an epimorphism. Since every epimorphism $\mathbb{Z} \to \mathbb{Z}$ is necessarily an isomorphism we see that the connecting homomorphism is in fact an isomorphism. Thus we obtain that $H_3(X_K) = H_2(X_K) = 0$. At the lower end we obtain easily, as we explained in the proof of Lemma 46.14 that $H_1(X_K) = \mathbb{Z} \cdot [\mu_K]$. ■
68.7. The $\mathbb{F}_2$-fundamental class ($\ast$). In this final section we introduce the $\mathbb{F}_2$-fundamental class for any compact (not necessarily orientable) smooth manifold. Truth be told, this notion will only play a fairly minor role in the subsequent chapters.

Now let $M$ be a compact connected $n$-dimensional smooth manifold. Recall that by Theorem 66.8 (3) we know that, regardless of whether or not $M$ is orientable, we have $H_n(M,\partial M;\mathbb{F}_2) \cong \mathbb{F}_2$. This leads us to the following definition.

**Definition.** Let $M$ be a compact $n$-dimensional smooth manifold. We denote by $N_1,\ldots,N_k$ the components of $M$. We refer to

$$[M]_{\mathbb{F}_2} := \sum_{i=1}^k \text{the unique non-zero element of } H_n(N_i,\partial N_i;\mathbb{F}_2) \in H_n(M,\partial M;\mathbb{F}_2) \cong \bigoplus_{i=1}^k H_n(N_i,\partial N_i;\mathbb{F}_2)$$

as the $\mathbb{F}_2$-fundamental class of $M$.

**Remark.** In Corollary 87.5 we will generalize this notion to compact *topological* manifolds.

The following proposition is the “$\mathbb{F}_2$”-analogue of some of the results from Section 68.1.

**Proposition 68.17.** Let $M$ be a compact $n$-dimensional smooth manifold.

1. Let $(K = (V,S),\lambda: |K| \to M)$ be a smooth simplicial structure for $M$. We pick a total order “$\leq$” on $V$. We denote by $s_1,\ldots,s_k$ the $n$-simplices of $K$. Furthermore for $i \in \{1,\ldots,k\}$ we consider the characteristic map $\Phi_{s_i}^\leq: |K| \to \Delta^n$. With this notation the singular chain

$$\lambda \circ \Phi_{s_1}^\leq \otimes 1 + \cdots + \lambda \circ \Phi_{s_k}^\leq \otimes 1 \in C_n(M) \otimes \mathbb{F}_2 = C_n(M;\mathbb{F}_2)$$

is a cycle which represents the $\mathbb{F}_2$-fundamental class of $M$.

2. Let $x \in M \setminus \partial M$.

(a) The image of the $\mathbb{F}_2$-fundamental class $[M]_{\mathbb{F}_2} \in H_n(M,\partial M;\mathbb{F}_2)$ under the natural map $H_n(M,\partial M;\mathbb{F}_2) \to H_n(M,M \setminus \{x\};\mathbb{F}_2)$ is the unique non-trivial element.

(b) If $M$ is connected, then the natural map $H_n(M,\partial M;\mathbb{F}_2) \to H_n(M,M \setminus \{x\};\mathbb{F}_2)$ is an isomorphism.

**Sketch of proof.** It is straightforward to see that it suffices to consider the case that $M$ is connected. Furthermore, using a doubling argument one can fairly easily reduce the proof of the statement to the case of a closed $n$-dimensional smooth manifold $M$. Next note that a slight variation on the argument of Theorem 66.4 shows that

$$\sigma := \lambda \circ \Phi_{s_1}^\leq \otimes 1 + \cdots + \lambda \circ \Phi_{s_k}^\leq \otimes 1 \in C_n(M;\mathbb{F}_2)$$

is indeed a cycle in the chain complex $C_*(M;\mathbb{F}_2) = C_*(M) \otimes \mathbb{F}_2$. Next note that the argument of the proof of Theorem 68.1 (1) shows that for every $x \in M$ the natural map $H_n(M;\mathbb{F}_2) \to H_n(M,M \setminus \{x\};\mathbb{F}_2)$ sends $[\sigma]$ to the unique non-zero element. Furthermore note that by Theorem 66.8 (3) we know that $H_n(M;\mathbb{F}_2) \cong \mathbb{F}_2$. Finally note that this implies that the natural map $H_n(M;\mathbb{F}_2) \to H_n(M,M \setminus \{x\};\mathbb{F}_2)$ is indeed an isomorphism and that $[\sigma]$ is indeed a generator of $H_n(M;\mathbb{F}_2)$.

The following proposition is the $\mathbb{F}_2$-analogue of Proposition 68.4.
Proposition 68.18. Let $M$ be a compact connected $n$-dimensional smooth manifold. Let $(\sigma_1 + \cdots + \sigma_m) \otimes 1 \in C_n(M, \partial M; \mathbb{F}_2) = C_n(M, \partial M) \otimes \mathbb{F}_2$ be a cycle. Suppose there exists an $j \in \{1, \ldots, m\}$ such that the following two conditions are satisfied:

1. The map $\sigma_j: \Delta^n \to M$ is a smooth embedding.
2. There exists an $x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n)$ which is not contained in the image of any other $\sigma_i: \Delta^n \to M$.

Then the cycle $(\sigma_1 + \cdots + \sigma_m) \otimes 1$ represents the $\mathbb{F}_2$-fundamental class of $M$.

Proof. The proof of this proposition is almost the same as the proof of Proposition 68.4. We leave it to the reader to make the necessary modifications.

Examples.

1. Now we will give a representative for the $\mathbb{F}_2$-fundamental class for the real projective plane $\mathbb{R}P^2$. More precisely, we consider the four singular simplices $\sigma_1, \sigma_2, \tau_1$ and $\tau_2$ of $\mathbb{R}P^2$ shown in Figure 1064, where we use a hopefully obvious variation on the notation introduced in Figure 1052. It is straightforward to see that the singular 2-chain $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in C_2(\mathbb{R}P^2; \mathbb{F}_2)$ is a cycle. Using Proposition 68.18 we see that it represents the $\mathbb{F}_2$-fundamental class of the real projective plane.

![Figure 1064](image)

The cycle $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in C_2(\mathbb{R}P^2; \mathbb{F}_2)$ represents the $\mathbb{F}_2$-fundamental class of the real projective plane.

2. In Exercise 68.13 we will write down a representative for the $\mathbb{F}_2$-fundamental class of the Klein bottle.

The following proposition is the analogue of Proposition 68.9.

Proposition 68.19. Let $M$ be a compact $n$-dimensional smooth manifold. The connecting homomorphism

$$
\partial: H_n(M, \partial M; \mathbb{F}_2) \to H_{n-1}(\partial M; \mathbb{F}_2)
$$

of the long exact sequence in homology with $\mathbb{F}_2$-coefficients of the pair $(M, \partial M)$ has the property that

$$
[M]_{\mathbb{F}_2} \mapsto [\partial M]_{\mathbb{F}_2}.
$$

Proof. The proof is the obvious modification of the previous proof.

Finally we have the following analogue of Corollary 68.11.
**Corollary 68.20.** Let $M$ be a compact $n$-dimensional smooth manifold. We denote by $i: \partial M \to M$ the inclusion map.

1. We have

$$\ker (i_*: \text{H}_n(M) \to \text{H}_n(M)) = \mathbb{Z} \cdot [\partial M] \in \text{H}_n(\partial M; \mathbb{F}_2).$$

2. If $M$ has precisely one boundary component, then $i_*: \text{H}_n(\partial M; \mathbb{F}_2) \to \text{H}_n(M; \mathbb{F}_2)$ is the zero map.

3. The boundary $\partial M$ is not a retract of $M$.

**Proof.** Once again the proof is basically the same as the proof of the analogous statement for ordinary homology groups.

**Remark.** It is perhaps instructive to consider the good old Möbius band $M$. We denote by $i: \partial M \to M$ the inclusion map. Furthermore let $[b] \in \text{H}_1(M)$ and $[c] \in \text{H}_1(\partial M)$ be the generators shown in Figure 1065. We end up with the following situation:

$$
\begin{array}{c}
\text{H}_1(\partial M) \\
\cong [\sigma] \to [\sigma \otimes 1] \\
\end{array}
\xymatrix{
\ar[r]^-{[b] \to 2[c]} & \text{H}_1(M) \\
\ar[u]^-{\cong [\sigma] \to [\sigma \otimes 1]} & \ar[u]^-{\cong [\sigma] \to [\sigma \otimes 1]} \\
\text{H}_1(\partial M; \mathbb{F}_2) \\
\ar[r]^-{[b \otimes 1] \to [2c \otimes 1] = [c \otimes 2] = 0} & \text{H}_1(M; \mathbb{F}_2).
}
$$

Note that the vertical maps are isomorphisms by the Universal Coefficient Theorem. We see that the top horizontal map is an injective map, in fact it is basically given by multiplication by 2. On the other hand we see that the bottom horizontal map is the zero map.

**Figure 1065**

---

**Exercises for Chapter 68**

**Exercise 68.1.** We consider the surface $\Sigma = E_8/\sim$ of genus two as shown in Figure 1066. Show that there exists a cycle of the form $\epsilon_1 \cdot \sigma_1 + \cdots + \epsilon_6 \cdot \sigma_6 \in C_2(E_8/\sim)$ such that the images of the six singular simplices $\sigma_1, \ldots, \sigma_6$ are precisely the six triangles shown in Figure 1066.

![Surface](image)

**Figure 1066.** Illustration of Exercise 68.1
Exercise 68.2. Let $M$ be a compact oriented connected $n$-dimensional smooth manifold with at least two boundary components. Let $C$ be one of the boundary components. By Corollary 68.11 we know that the inclusion induced map $i_*: H_{n-1}(C) \to H_{n-1}(M)$ admits a left-inverse, i.e. there exists a homomorphism $\varphi: H_{n-1}(M) \to H_{n-1}(C)$ such that $\varphi \circ i_* = \text{id}_{H_{n-1}(C)}$. Also note that in Lemma 23.13 we showed that in the case $n = 2$ a stronger statement holds, namely $C$ is a retract of $M$. Is it true in general that $C$ is necessarily a retract of $M$?

Exercise 68.3. Let $M$ be a closed oriented connected $n$-dimensional smooth manifold and let $C \subset M$ be a closed oriented connected $(n-1)$-dimensional submanifold of $M$. We assume that $C$ is non-separating. Recall that according to the definition on page 682 this means that $M \setminus C$ is connected. By the Tubular Neighborhood Theorem 8.24 we can pick a tubular neighborhood $[-1, 1] \times C$. We write $W := M \setminus ((-1, 1) \times C)$.

(a) Show that there exists an exact sequence of the form

$$0 \to H_{n-1}(M \setminus ((-1, 1) \times C)) \to H_{n-1}(M) \to H_{n-2}(C) \to \cdots$$

Hint. Consider a Meyer–Vietoris sequence.

(b) Use (a) and Exercise 68.2 to show that the map $i_*: H_{n-1}(C) \to H_{n-1}(M)$ admits a left-inverse.

Remark. This implies in particular that $i_*([C])$ is a non-trivial element of $H_{n-1}(M)$.

(c) Does the conclusion of (b) also hold if we replace the hypothesis that $M$ is closed by the hypothesis that $M$ is compact?

![Figure 1067](image)

Exercise 68.4. Let $K = \gamma(S^1) \subset S^3$ be a knot and let $\Phi: \overline{B}^2 \times K \to S^3$ be a tubular map for $K$. As on page 1728 we refer to $X_K = S^3 \setminus \Phi(\overline{B}^2 \times K)$ as the exterior of the knot $K$ and we refer to $\mu_K = \Phi(S^1 \times \{P\})$ as a meridian of $K$. In Lemma 46.14 or alternatively in Lemma 68.16 we saw that $[\mu_K]$, viewed as an element in $H_1(X_K)$, is a generator of $H_1(X_K)$.

(a) Show that there exists an $n \in \mathbb{Z}$ such that the curve

$$S^1 \to \partial X_K = \Phi(S^1 \times K),
\quad z \mapsto \Phi(z^n, \gamma(z))$$

represents a generator of $\ker(H_1(\partial X_K) \to H_1(X_K))$. We refer to the image of this curve as a longitude $\lambda_K$ of $K$.

(b) Sketch longitudies for the three knots that are shown in Figure 1068.

(c) Now suppose that we are given two knots $K$ and $J$. We define $\overline{X}_K, \overline{X}_J, \mu_K, \mu_J$ and $\lambda_K$ and $\lambda_J$ as above. We pick a diffeomorphism $\varphi: \partial X_K \to \partial X_J$ with $\varphi_*(\mu_K) = \lambda_J$.
and \( \varphi_*(\lambda_K) = \mu_K \). We denote \( Y = X_K \cup_{\varphi} X_J \) the result of gluing \( X_K \) to \( X_J \) along the boundary. Show that \( Y \) is a homology sphere, i.e. show that \( H_1(Y) = H_2(Y) = 0 \) and \( H_3(Y) \cong \mathbb{Z} \).

**Remark.** If \( K \) and \( J \) are two non-trivial knots, then it follows from Proposition ?? (which in turn is a consequence of the famous Loop Theorem ??) together with Proposition 21.24 that the fundamental group of \( Y \) is always non-trivial. This shows that \( Y \) is a homology sphere with non-trivial fundamental group. In other words we have now found an alternative proof of Proposition 66.11.

![Figure 1068](image)

**Exercise 68.5.** In this exercise we will consider an alternative approach to computing the homology groups of a knot complement. Let \( K \subset S^3 \) be a knot. We pick a tubular neighborhood \( B^2 \times K \) and we consider the exterior \( X_K = S^3 \setminus (B^2 \times K) \). Now do the following:

(a) Show that the inclusion induced maps

\[ H_*(S^3, K) \xrightarrow{\cong} H_*(S^3, B^2 \times K) \xleftarrow{\cong} H_*(X_K, \partial X_K) \]

are both isomorphisms.

(b) Compute the homology groups of the pair \( (X_K, \partial X_K) \).

(c) Determine, using (b), the homology groups of \( X_K \).

**Exercise 68.6.** We define an \( m \)-component link to be a 1-dimensional submanifold of \( S^3 \) that is diffeomorphic to the disjoint union of \( m \) copies of \( S^1 \). We pick a tubular neighborhood \( B^2 \times L \) and we define the exterior of \( L \) as \( X_L := S^3 \setminus (B^2 \times L) \). We denote the components of \( L \) by \( L_1, \ldots, L_m \). For each \( i \in \{1, \ldots, m\} \) we pick a point \( P_i \in L_i \) and we define \( \mu_i := S^1 \times \{P_i\} \).

(a) Show that \( H_1(X_L) = \mathbb{Z} \cdot [\mu_1] \oplus \cdots \oplus \mathbb{Z} \cdot [\mu_m] \).

(b) Determine \( H_2(X_L) \).

**Remark.** There are basically two ways to go about doing this exercise, you can modify the proof of Lemma 68.16 or you could generalize the approach taken in Exercise 68.5.

**Exercise 68.7.**

(a) In Figure 1069 we see two 2-component links, namely the unlink and the Hopf link. Are these two links isotopic?

(b) Let \( L \subset S^3 \) be an \( m \)-component link. Show that the weight of the group \( \pi_1(S^3 \setminus L) \), as defined in Exercise 27.13 equals \( m \).
Exercise 68.8. Let $M$ and $N$ be two oriented, connected $n$-dimensional smooth manifolds. We suppose that $M$ is closed and that $N$ has non-empty boundary. Express the homology groups of $M \# N$ in terms of the homology groups of $M$ and $N$.

Exercise 68.9. Let $f : M \to N$ be a map between two compact orientable connected $n$-dimensional smooth manifolds with non-empty boundary. We assume that $f : \partial M \to \partial N$ is a homeomorphism. Show that $f$ is a surjection.

Exercise 68.10. Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $p : \tilde{M} \to M$ be a finite covering. By Proposition 17.1 we can equip $\tilde{M}$ with the structure of a compact oriented smooth manifold such that $p : \tilde{M} \to M$ is an orientation-preserving map. Let $p^* : H_n(M) \to H_n(\tilde{M})$ be the transfer map that we introduced on page 1445. Show that $p^*([M]) = [\tilde{M}] \in H_n(\tilde{M}, \partial \tilde{M})$.

Exercise 68.11. Let $\Sigma$ be a closed orientable connected 2-dimensional smooth manifold and let $f : \Sigma \to \Sigma$ be a diffeomorphism. We consider the corresponding mapping torus $M := \text{Tor}(\Sigma, f)$. Note that we know by Lemma 24.22 that $M$ is a closed connected 3-dimensional smooth manifold.

(a) Suppose that if $f$ is orientation-preserving, then $\text{rank}(H_2(M)) = \text{rank}(H_1(M))$.

(b) Suppose that if $f$ is orientation-reversing, then $\text{rank}(H_2(M)) = \text{rank}(H_1(M)) - 1$.

Remark. You might want to use Proposition 46.21.

Exercise 68.12. Give examples of closed oriented connected non-empty smooth manifolds $M$ and $N$ of the same dimension such that $\pi_2(M \# N)$ is not isomorphic to $\pi_2(M) \oplus \pi_2(N)$.

Exercise 68.13. Give an example of a representative for the $\mathbb{F}_2$-fundamental class for the Klein bottle.

Exercise 68.14. Can you find a representative for the $\mathbb{F}_2$-fundamental class of $\mathbb{R}P^2$ with two or three summands?

Exercise 68.15. Let $n \in \mathbb{N}$ and let $M$ be a compact oriented $n$-dimensional smooth manifold. The image of the fundamental class $[M] \in H_n(M, \partial M)$ under the natural map $H_n(M, \partial M) \to H_n(M, \partial M; \mathbb{R})$ is called the real fundamental class, denoted by $[M]_\mathbb{R}$. Let $(K = (V, S), \Theta : |K| \to M)$ be a smooth simplicial structure. Given an ordered $n$-simplex $s = (v_0, \ldots, v_n)$ of $K$ we denote by $\Phi_s : \Delta^n \to |K|$ the corresponding characteristic map given by $(t_0, \ldots, t_n) \mapsto t_0 \cdot v_0 + \cdots + t_n \cdot v_n$. 
(a) Show that

\[ \sigma := \sum_{s = (v_0, \ldots, v_n)} (\Theta \circ \Phi_s \circ \Delta^n \to M) \in C_n(M) \]

represents a cycle in \( C_n(M, \partial M) \).  

(b) Show that \([\sigma] \otimes \frac{2}{n!} \in C_n(M, \partial M; \mathbb{R}) = C_n(M, \partial M) \otimes \mathbb{R}\) represents \([M]_\mathbb{R}\).

**Exercise 68.16.** Let \( X \) be a topological space. Given a homology class \( \varphi \in H_k(X; \mathbb{R}) \) we define

\[ \| \varphi \|_\mathbb{R} := \inf \left\{ \sum_{i=1}^n |r_i| \mid \sigma = \sum_{i=1}^n \sigma_i \otimes r_i \text{ is a cycle with } [\sigma] = \varphi \in H_k(X; \mathbb{R}) \right\} \]

with \( \sigma_i \neq \sigma_j \) for \( i \neq j \).

In the following let \( M \) be a closed oriented connected non-empty \( n \)-dimensional smooth manifold. Let \([M] \in H_n(M)\) be the fundamental class and let \( i : H_1(S^1) \to H_1(S^1; \mathbb{R})\) be the homomorphism from Lemma \[57.7\] (1). We define the *simplicial volume of \( M \) as*

\[ \| M \|_\mathbb{R} := \| i_*([M]) \| \in \mathbb{R}_{\geq 0} \]

(a) Show that \( \| S^1 \|_\mathbb{R} = 0 \).

(b) Show that \( \|(S^1)^2\|_\mathbb{R} = 0 \).

(c) Let \( n \in \mathbb{N}_{\geq 2} \). What is \( \| S^n \|_\mathbb{R} \)?

(d) Let \( f : M \to N \) be a map between closed oriented connected non-empty \( n \)-dimensional smooth manifold. Show that

\[ \| N \|_\mathbb{R} \leq \frac{1}{\text{deg}(f)} \cdot \| M \|_\mathbb{R} \]

where \( \text{deg}(f) \) denotes the degree of \( f \) as defined on page \[1737\].

(e) Let \( M \) and \( N \) be two closed oriented connected non-empty \( n \)-dimensional smooth manifolds. We suppose that \( M \) and \( N \) are in fact homotopy equivalent. Show that \( \| M \|_\mathbb{R} = \| N \|_\mathbb{R} \).

(f) Let \( N \) be a closed oriented non-empty \( n \)-dimensional smooth manifold and let \( p : M \to N \) be a \( d \)-fold covering. Show that \( \| M \|_\mathbb{R} = d \cdot \| N \|_\mathbb{R} \).

(g) Let \( g \in \mathbb{N}_0 \). As usual we denote by \( \Sigma_g \) the surface of genus \( g \geq 1 \). Show that \( \| \Sigma_g \|_\mathbb{R} \leq 2g - 2 \).

**Hint.** Make use of (f).

**Remark.** In \[Frig17\] Corollary 7.5 or alternatively \[Thu78\] Theorem 6.2 it is shown that we also have the reverse inequality, i.e. we have \( \| \Sigma_g \|_\mathbb{R} = 2g - 2 \).

**Remark.** The invariant \( \| \varphi \|_\mathbb{R} \) is the “real analogue” of the invariant \( \| \varphi \|_\mathbb{Z} \) introduced in Exercise \[45.14\].
Let \( n \in \mathbb{N} \) and let \( M \) be a compact oriented connected non-empty \( n \)-dimensional smooth manifold. Recall that in Theorem 68.1 and Lemma 68.3 we proved that there exists a unique class \([M] \in H_n(M, \partial M)\) such that the following holds:

1. We have \( H_n(M, \partial M) = \mathbb{Z} \cdot [M] \).
2. For every smooth embedding \( \Psi: \Delta^n \to M \) and for every point \( x \in \Delta^n \) with \( \Psi^{-1}(\Psi(x)) = \{x\} \) we have the following equality in \( H_n(M, M \setminus \{\Psi(x)\}) \):

\[
\omega_{\Psi(x)}([M]) = \text{sign}(\Psi, x) \cdot [\Psi: \Delta^n \to M].
\]

This is the natural map \( H_n(M, \partial M) \to H_n(M, M \setminus \{\Psi(x)\}) \), which is in fact an isomorphism by Theorem 68.1(1).

In this short chapter we will explore the following definition.

**Definition.** Let \( f: M \to N \) be a map between two compact oriented connected non-empty \( n \)-dimensional smooth manifolds. We assume that \( f(\partial M) \subset \partial N \). We denote by \( \deg(f) \in \mathbb{Z} \) the unique integer with

\[
f_*(\partial M) = \deg(f) \cdot [N] \in H_n(N, \partial N) = \mathbb{Z} \cdot [N].
\]

since \( f(\partial M) \subset \partial N \) we have an induced map \( f_*: H_n(M, \partial M) \to H_n(N, \partial N) \).

We refer to \( \deg(f) \) as the degree of \( f \).

**Remark.** For a map \( f: S^n \to S^n \) the above degree is, by definition, exactly the same as the degree that we defined on page 1181.

The following simple lemma generalizes several statements of Lemma 45.11.

**Lemma 69.1.** Let \( n \in \mathbb{N} \) and let \( L, M \) and \( N \) be compact oriented connected non-empty \( n \)-dimensional smooth manifolds.

1. \( \deg(\text{id}_M) = 1. \)
2. For every map \( f: M \to N \) such that \( f(\partial M) \subset \partial N \) we have the following equality:

\[
f_*(\partial M) = \deg(f: M \to N) \cdot [\partial N] \in H_{n-1}(\partial N).
\]
3. Let \( f: M \to N \) be a map with \( f(\partial M) \subset \partial N \). If \( f \) is not surjective, then \( \deg(f) = 0. \)
4. Let \( f, g: M \to N \) be two maps with \( f(\partial M) \subset \partial N \) and \( g(\partial M) \subset \partial N \). If \( f \) is homotopic to \( g \), then \( \deg(f) = \deg(g) \).
5. For any two maps \( f: L \to M \) and \( g: M \to N \) with \( f(\partial L) \subset \partial M \) and \( g(\partial M) \subset \partial N \) we have \( \deg(f \circ g) = \deg(f) \cdot \deg(g) \).

**Proof.**

1. This statement is trivial.

---

\(^{1037}\)Recall that on page 1589 we defined what it means for a map \( \Delta^n \to M \) to be a smooth embedding.
(2) We consider the following diagram:

$$
\begin{array}{c}
H_n(M, \partial M) \\
\downarrow \ f_* \\
H_n(N, \partial N)
\end{array}
\xrightarrow{\partial_n} \begin{array}{c}
H_{n-1}(\partial M) \\
\downarrow \ f_* \\
H_{n-1}(\partial N)
\end{array}
$$

where the horizontal maps are given by the connecting homomorphisms of the pairs 
\((M, \partial M)\) and \((N, \partial N)\). By Proposition [43.15] we know that the connecting homomorphism are natural, in other words, the diagram commutes. The statement now follows from Proposition [68.9].

(3) So let \(f: M \to N\) be a non-surjective map with \(f(\partial M) \subset \partial N\). We pick a point \(P\) in \(N\) that is not in the image of \(f\). Note that \(N \setminus \{P\}\) is an open subset of \(N\). Thus, by the discussion on page 281, we can view it as an \(n\)-dimensional smooth manifold with \(\partial(N \setminus \{P\}) = \partial N \cap (N \setminus \{P\}) = \partial N \setminus \{P\}\). Also note that it follows easily from \(n \geq 1\) that \(N \setminus \{P\}\) is non-compact.

Now we consider the following very simple commutative diagram:

$$
\begin{array}{c}
H_n(M, \partial M) \\
\downarrow \ f_* \\
H_n(N \setminus \{P\}, \partial(N \setminus \{P\}))
\end{array}
\xrightarrow{=0} \begin{array}{c}
H_n(N, \partial N)
\end{array}
$$

It follows immediately that \(f_*: H_n(M, \partial M) \to H_n(N, \partial N)\) is the zero map.

(4) This statement follows immediately from Proposition [42.5].

(5) Exactly as in the proof of Lemma [45.11] (4) we have

\[
(g \circ f)_*[L] = g_*(f_*[L]) = g_*(\deg(f) \cdot [M]) = \deg(g) \cdot \deg(f) \cdot [N].
\]

This shows that \(\deg(g \circ f) = \deg(g) \cdot \deg(f)\). ■

We move on to the following definition.

**Definition.** Let \(f: M \to N\) be a smooth map between two smooth manifolds of the same dimension. Let \(P \in M \setminus \partial M\). We say \(f\) is a local diffeomorphism at \(P\) if there exists an open neighborhood \(U\) of \(P\) such that \(f|_U\) is an embedding.

The following proposition is much more interesting than the previous lemma. It gives in particular a practical criterion for a map to have degree \(\pm 1\).

**Proposition 69.2.** Let \(n \in \mathbb{N}\) and let \(f: M \to N\) be a map between two compact oriented connected non-empty \(n\)-dimensional smooth manifolds such that \(f^{-1}(\partial N) = \partial M\). We suppose that there exists an \(x \in M \setminus \partial M\) such that \(f^{-1}(f(x)) = \{x\}\) and we suppose that

\[\tag{1038}
\text{Note that it follows from the Smooth Invariance of Domain, i.e. from Theorem [6.19] that this definition of a “local diffeomorphism at a point” is consistent with the definition given on page 295.} \]

Proof. Let $U$ be an open connected neighborhood of $x$ such that $f: U \to N$ is an embedding. We set
\[
\epsilon := \begin{cases} 
+1, & \text{if } f: U \to N \text{ is orientation-preserving} \\
-1, & \text{if } f: U \to N \text{ is orientation-reversing.}
\end{cases}
\]
Note that we need to show that $\deg(f) = \epsilon$. Since $f^{-1}(\partial N) = \partial M$ we can pick a smooth embedding $\Psi: \Delta^n \to U$ such that $x \in \Psi(\Delta^n)$. Note that $\Psi^{-1}(x)$ is an admissible point for $\Psi$ and note that it follows from our hypothesis $f^{-1}(x) = \{x\}$ that $\Psi^{-1}(x)$ is also an admissible point for $f \circ \Psi$. We consider the following commutative diagram:
\[
\begin{array}{ccc}
H_n(M, \partial M) & \xrightarrow{\omega_x} & H_n(M, M \setminus \{x\}) \\
\downarrow f_* & & \downarrow f_* \\
H_n(N, \partial N) & \xrightarrow{\omega_{f(x)}} & H_n(N, N \setminus \{f(x)\}).
\end{array}
\]
After these preparations we can now turn to the actual proof:

since $x \in \Psi(\Delta^n)$ and $\Psi$ is an embedding we see that $\Psi: \Delta^n \to M$ defines an element of $H_n(M, M \setminus \{x\})$
\[
\omega_x([M]) = \text{sign}(\Psi, x) \cdot [\Psi: \Delta^n \to M] \quad \text{by definition of } [M]
\]
\[
\Rightarrow \quad f_* (\omega_x([M])) = \text{sign}(\Psi, x) \cdot f_*([\Psi]) \quad \text{applying } f_*
\]
\[
\Rightarrow \quad \omega_{f(x)}(f_*([M])) = \text{sign}(\Psi, x) \cdot [f \circ \Psi] \quad \text{since the diagram commutes}
\]
\[
\Rightarrow \quad \omega_{f(x)}(f_*([M])) = \epsilon \cdot \text{sign}(f \circ \Psi, x) \cdot [f \circ \Psi] \quad \text{since } \text{sign}(f \circ \Psi, x) = \epsilon \cdot \text{sign}(\Psi, x)
\]
\[
\Rightarrow \quad \omega_{f(x)}(\deg(f) \cdot [N]) = \epsilon \cdot \omega_{f(x)}([N]) \quad \text{by definition of } \deg(f) \text{ and } [N]
\]
\[
\Rightarrow \quad \deg(f) \cdot [N] = \epsilon \cdot [N] \quad \text{by Theorem 68.1} \quad (1)
\]
\[
\Rightarrow \quad \deg(f) = \epsilon \quad \text{since } H_n(N) = \mathbb{Z} \cdot [N].
\]

\[\text{Figure 1070. Illustration for the proof of Proposition 69.2}\]

Proposition 69.3. Let $n \in \mathbb{N}$ and let $M$ be a closed oriented connected non-empty $n$-dimensional smooth manifold. For every $k \in \mathbb{Z}$ there exists a map $f: M \to S^n$ of degree $k$.

Proof. Let $M$ be a closed oriented connected non-empty $n$-dimensional smooth manifold and let $k \in \mathbb{Z}$. As we mentioned on page 1184, by Lemmas 45.10 and 45.12 there exists a

\[\text{Note that our hypothesis that } f^{-1}(f(x)) = \{x\} \text{ implies that } f(M \setminus \{x\}) \subset N \setminus \{f(x)\}. \text{ Also note that } x \in M \setminus \partial M \text{ and } f(x) \in N \setminus \partial N. \text{ In particular this implies that the various inclusion induced maps actually make sense.}\]
map $g: S^n \to S^n$ of degree $k$. It follows from this fact and Lemma 69.1 (4) that it suffices to prove the following claim.

**Claim.** There exists a map $f: M \to S^n$ of degree $+1$.

First we pick an orientation-preserving smooth embedding $\Phi: \overline{B}^n \to M$. It follows fairly easily from Lemma 3.28 (2), and Proposition 2.43 (3) together with Lemma 2.40 and Lemma 3.26 that the induced map $\bar{\Phi}: \overline{B}^n/S^{n-1} \to M/(M \setminus \Phi(B^n))$ is a homeomorphism. We denote by $\Omega: \overline{B}^n/S^{n-1} \to S^n$ the explicit homeomorphism from page 182. As we mentioned on page 182 this homeomorphism has the property that the restriction of $\Omega$ to $B^n$ is in fact an orientation-preserving embedding. We consider the map $f: M \to S^n$ that is given by

$$M \xrightarrow{\Phi} M/(M \setminus \Phi(B^n)) \xrightarrow{\bar{\Phi}^{-1}} \overline{B}/S^{n-1} \xrightarrow{\Omega} S^n.$$  

It follows almost immediately from Proposition 69.2 that $f$ is a map of degree $+1$.

![Figure 1071](image)

**Figure 1071.** Illustration for the proof of Proposition 69.3

To put the previous proposition into context we state the following theorem from a later chapter. It says that for maps to $S^n$ the converse to Lemma 69.1 (3) holds.

**Theorem 69.6. (Hopf Theorem)** Let $M$ be a closed oriented connected non-empty $n$-dimensional smooth manifold and let $f, g: M \to S^n$ be two maps. If $\deg(f) = \deg(g)$, then the maps $f$ and $g$ are actually homotopic.

For the record we also state the following open question, see [Kir97, Problem 5.26], which was initially posed by Heinz Hopf.

**Question 69.4. (Hopf)** Let $M$ be a closed orientable smooth manifold $M$. Is every map $f: M \to M$ of degree $\pm 1$ a homotopy equivalence?

In the following discussion, given $g \in \mathbb{N}_0$, we denote as usual by $\Sigma_g$ the surface of genus $g$. We move on to our next list of interesting examples of maps of no-zero degree.

**Lemma 69.5.** Let $k \in \mathbb{N}_0$. For every $g \geq k$ there exists a degree-one map from $\Sigma_g$ to $\Sigma_k$.

**Proof.** We prove the lemma for $g = 2$ and $k = 1$. It should be clear how to modify the discussion for other values of $g \geq k$. Let us consider the map from the surface $\Sigma_2$ of genus two to the torus $\Sigma_1$ that is shown in Figure 1072. In fact in Figure 1072 we show the map twice, on top we show a slightly informal description of the map, at the bottom we give a more formal description. Note that the hypotheses of Proposition 69.2 are satisfied. Thus we see that $\deg(f) = 1$.

The following question arises naturally.
**Question 69.6.** Suppose that $g < k$. Does there exist a degree-one map from $\Sigma_g$ to $\Sigma_k$?

We will be able to give an answer to this question later on in Corollary 69.10.

But first let us move on to the next proposition, which is a generalization of Proposition 69.2.

**Proposition 69.7.** Let $f : M \to N$ be a map between two compact oriented connected non-empty $n$-dimensional smooth manifolds such that $f^{-1}(\partial N) = \partial N$.

1. Let $y \in N \setminus \partial N$ such that the following condition is satisfied:
   
   (*) The preimage $f^{-1}(\{y\})$ consists of finitely many points $x_1, \ldots, x_m$ and $f$ is a local diffeomorphism around each $x_i$.

   Then
   
   $$\deg(f) = \sum_{i=1}^{m} \left\{ \begin{array}{ll} +1, & \text{if } f \text{ is orientation-preserving at } x_i \\ -1, & \text{if } f \text{ is orientation-reversing at } x_i. \end{array} \right.$$  

2. If $f$ is smooth, then every regular value in $N \setminus \partial N$ satisfies (*).

3. If $f$ is smooth, then the set of regular values in $N \setminus \partial N$ has full measure in $N$.

**Remark.** In Proposition 87.32 we state a result that generalizes Proposition 69.7 (1) in the sense that we no longer demand that $f$ is a local diffeomorphism around each $x_i$.

**Example.** Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $W$ be the union of some components of $\partial M$. As on page 1163 we consider the double

$$D_W M = (M \times \{1\}) \cup_{W \times \{1\}=W \times \{2\}} (M \times \{2\})$$

of $M$ along $W$. By Lemma 44.12 we know that $D_W M$ is naturally a compact oriented $n$-dimensional smooth manifold. We consider the folding map

$$f : D_W M \to M$$

$$[(P, i)] \mapsto P.$$ 

If we take any $x \in M \setminus \partial M$, then we see that $f^{-1}(P)$ consists of precisely two points, namely $x_1 = [(x, 1)]$ and $x_2 = [(x, 2)]$. The folding map is an orientation-preserving local

---

1040 We refer to page 316 for the definition of a subset of full measure in $N$ and, more usefully, we refer to Proposition 6.62 for the main properties of subsets of full measure.
diffeomorphism around $x_1$ and it is an orientation-reversing local diffeomorphism around $x_2$. Thus we obtain from Proposition 69.7 that the degree of the folding map is zero.

\[
\begin{array}{c}
x_1 \quad \text{folding map} \quad x_2
\end{array}
\]

**Figure 1073**

Since the two parts of Proposition 69.7 are of very different nature we break the proof of Proposition 69.7 into two parts.

**Proof of Proposition 69.7 (1) (\textast).** Let $f: M \to N$ be a map between two compact oriented connected non-empty $n$-dimensional smooth manifolds such that $f^{-1}(\partial N) = \partial M$.

Let $y \in N \setminus \partial N$ such that $f^{-1}\{y\}$ consists of finitely many points $x_1, \ldots, x_m$ and such that $f$ is a local diffeomorphism around each $x_i$.

For $i = 1, \ldots, m$ we pick an open connected neighborhood $U_i$ of $x_i$ such that $f: U_i \to N$ is an embedding. Note that we can arrange that for any $i \neq j$ we have $x_j \notin U_i$. For $i = 1, \ldots, m$ we set

\[
\epsilon_i := \begin{cases} 
+1, & \text{if } f: U_i \to N \text{ is orientation-preserving} \\
-1, & \text{if } f: U_i \to N \text{ is orientation-reversing.}
\end{cases}
\]

Note that we need to show that $\deg(f) = \epsilon_1 + \cdots + \epsilon_m$.

Let $i \in \{1, \ldots, m\}$. Since $y \in N \setminus \partial N$ and since by hypothesis we have $f^{-1}(\partial N) = \partial M$ we know that $x_i \in M \setminus \partial M$. Thus we can pick a smooth embedding $\Psi_i: \Delta^i \to U_i$ such that $x_i \in \Psi_i(\Delta^i)$. We consider the following commutative diagram

\[
\begin{array}{cccc}
H_n(M, \partial M) & \overset{=\!\nu_i}{\longrightarrow} & H_n(M, M \setminus \{x_1, \ldots, x_m\}) & \overset{=\!\nu_i}{\longrightarrow} \\
\downarrow f_* & & \downarrow f_* & \\
H_n(N, \partial N) & \overset{=\!\omega_f(y)}{\longrightarrow} & H_n(N, N \setminus \{y\}). & \\
\end{array}
\]

We make the following clarifications and observations:

1. The map $\mu: H_n(M, \partial M) \to H_n(M, M \setminus \{x_1, \ldots, x_m\})$ and furthermore all the maps $\nu_i: H_n(M, M \setminus \{x_1, \ldots, x_m\}) \to H_n(M, M \setminus \{x_i\})$ are induced by the natural maps on the pairs of topological spaces. Note that here we use that $x_1, \ldots, x_m \in M \setminus \partial M$, that $y \in N \setminus \partial N$ and that $f(\partial M) \subset \partial N$.

2. It follows easily from the Excision Theorem 43.20 (see also Exercise 44.1) that the diagonal map $\bigoplus_{i=1}^m \nu_i: H_n(M, M \setminus \{x_1, \ldots, x_m\}) \to \bigoplus_{i=1}^m H_n(M, M \setminus \{x_i\})$ is an isomorphism.

3. Let $i \in \{1, \ldots, m\}$. Note that we arranged that $\Psi_i(\partial \Delta^i) \subset M \setminus \{x_1, \ldots, x_m\}$. In particular $\Psi_i: \Delta^i \to M$ defines an element in $H_n(M, M \setminus \{x_1, \ldots, x_m\})$.\]
Now we see that
\[
\sum_{i=1}^{m} \omega_{x_i}([M]) = \sum_{i=1}^{m} \text{sign}(\Psi_i, x_i) \cdot [\Psi_i]
\]
by definition of $[M]$.
\[
\Rightarrow \left( \sum_{i=1}^{m} \omega_{x_i} \right)([M]) = \left( \sum_{i=1}^{m} \nu_i \right) \left( \sum_{j=1}^{\mu} \text{sign}(\Psi_j, x_j) \cdot [\Psi_j] \right)
\]
since $\nu_i([\Psi_j]) = \delta_{ij} \cdot [\Psi_i]$.
\[
\Rightarrow \mu([M]) = \sum_{j=1}^{\mu} \text{sign}(\Psi_j, x_j) \cdot [\Psi_j]
\]
since $\sum \nu_i$ is an isomorphism and since the triangle commutes.
\[
\Rightarrow f_*(\mu([M])) = \sum_{j=1}^{\mu} \text{sign}(\Psi_j, x_j) \cdot f_*(\Psi_j)
\]
applying $f_*$.
\[
\Rightarrow \omega_{f(x)}(f_*(\Psi_j)) = \sum_{j=1}^{\mu} \text{sign}(\Psi_j, x_j) \cdot [f \circ \Psi_j]
\]
since the diagram commutes.
\[
\Rightarrow \omega_{f(x)}(f_*(\Psi_j)) = \sum_{j=1}^{\mu} \epsilon_j \cdot \text{sign}(f \circ \Psi_j, x_j)
\]
since $\text{sign}(f \circ \Psi_j, x_j) = \epsilon_j \cdot \text{sign}(\Psi_j, x_j)$.
\[
\Rightarrow \omega_{f(x)}(\deg(f) \cdot [N]) = \sum_{j=1}^{\mu} \epsilon_j \cdot \omega_{f(x)}([N])
\]
by definition of $\deg(f)$ and $[N]$.
\[
\Rightarrow \deg(f) \cdot [N] = \sum_{j=1}^{\mu} \epsilon_j \cdot [N]
\]
by Theorem 68.1 (1).
\[
\Rightarrow \deg(f) = \sum_{j=1}^{\mu} \epsilon_j
\]
since $H_n(N, \partial N) = \mathbb{Z} \cdot [N]$.

**Figure 1074.** Illustration for the proof of Proposition 69.7 (1).

**Proof of Proposition 69.7** (2) and (3)(*). Let $f : M \to N$ be a smooth map between two compact oriented connected non-empty $n$-dimensional smooth manifolds $M$ and $N$ such that $f^{-1}(\partial N) = \partial M$.

(2) Let $y \in N \setminus \partial N$ be a regular value. It follows from Lemma 65.4 (2) that $f^{-1}(\{y\})$ consists of finitely many points $x_1, \ldots, x_m$. Let $i \in \{1, \ldots, m\}.$ Note that it follows from $f^{-1}(\partial N) = \partial M$ that $x_i \in M \setminus \partial M$. Since $x_i$ is a regular point we obtain from Lemma 65.4 (1) that $f$ is a local diffeomorphism around $x_i$.

(3) By Sard’s Theorem 6.63 together with Proposition 6.62 we know that the set of regular values of $f$ that are contained in $N \setminus \partial N$ has full measure in $N$.

The following proposition gives us many examples of degrees of maps between smooth manifolds.

**Proposition 69.8.** Let $p : \tilde{M} \to M$ be a finite covering of compact oriented connected non-empty smooth manifolds. If $p$ is orientation-preserving, then
\[
\deg(p) = [\tilde{M} : M].
\]

**Proof.** It turns out that there are two quick proofs for the proposition. In fact the desired statement follows immediately from Proposition 69.7. Alternatively, if we denote
by \( p^*: H_n(M, \partial M) \to H_n(\tilde{M}, \partial \tilde{M}) \) the transfer map that we introduced on page 1445, then we also see that
\[
p_*([\tilde{M}]) = p_*(p^*([M])) = [\tilde{M}: M] \cdot [M].
\]

The following proposition is the key to answering Question 69.6.

**Proposition 69.9.** Let \( f: M \to N \) be a map between compact oriented connected non-empty \( n \)-dimensional smooth manifolds such that \( f(\partial M) \subset \partial N \). If \( \deg(f) = \pm 1 \), then \( f_*: \pi_1(M) \to \pi_1(N) \) is an epimorphism.

The statement of Proposition 69.9 is somewhat surprising, in so far as it takes as input fairly simple information, namely the induced map on \( n \)-th homology, which is an abelian group, and gives as output information about fundamental groups, which are usually much harder to deal with. Also it is a priori not clear why the homology in the maximal dimension should have any impact on fundamental groups.

**Proof.** Let \( f: M \to N \) be a map between compact oriented connected non-empty \( n \)-dimensional smooth manifolds such that \( f(\partial M) \subset \partial N \). We fix a base point \( P \in M \) and we write \( Q = f(P) \). Furthermore we write \( \pi = \pi_1(N, Q) \) and \( \Gamma = f_*(\pi_1(M, P)) \).

By Proposition 29.10 there exists a path-connected covering \( p: (\tilde{N}, \tilde{Q}) \to (N, Q) \) such that \( p_*(\pi_1(\tilde{N}, \tilde{Q})) = \Gamma \) and such that \( [\tilde{N} : N] = [\pi : \Gamma] \). By Proposition 17.1 we can equip the covering space \( \tilde{N} \) with the structure of a compact oriented smooth manifold such that the projection \( p: \tilde{N} \to N \) is an orientation-preserving map and such that we have \( \partial \tilde{N} = p^{-1}(\partial N) \). Since by design we know that \( p_*(\pi_1(\tilde{N}, \tilde{Q})) = \Gamma = f_*(\pi_1(M, P)) \) we obtain from Proposition 29.2 that the map \( f: (M, P) \to (N, Q) \) lifts to a map \( \tilde{f}: (M, P) \to (\tilde{N}, \tilde{Q}) \).

We can summarize the situation in the following simple commutative diagram

\[
\begin{array}{ccc}
\tilde{N} & \xrightarrow{\tilde{f}} & N \\
p \downarrow & & \downarrow \\
M & \xrightarrow{f} & N.
\end{array}
\]

First suppose that \( \Gamma \) is a subgroup of \( \pi \) of infinite index. It follows immediately from \( [\tilde{N} : N] = [\pi : \Gamma] \) and Lemma 16.3 (5) that \( \tilde{N} \) is non-compact. Therefore we obtain from Theorem 66.6 that \( H_n(\tilde{N}) = 0 \). But this shows that \( f_* = p_* \circ \tilde{f}_*: H_n(M) \to H_n(N) \) factors through the trivial group. Hence \( \deg(f) = 0 \). But this is a contradiction to our hypothesis that \( \deg(f) = \pm 1 \).

So now we know that \( \Gamma \) is necessarily a finite-index subgroup of \( \pi \). It follows from \( [\tilde{N} : N] = [\pi : \Gamma] \) and Lemma 16.3 (4) that \( \tilde{N} \) is compact. Therefore, by the above we now know that \( \tilde{N} \) is a compact oriented connected \( n \)-dimensional smooth manifold. We deduce

\[\text{Exercise 68.10 Proposition 59.1 \[\blacksquare\]}\]

The following proposition is the key to answering Question 69.6.

**Proposition 69.9.** Let \( f: M \to N \) be a map between compact oriented connected non-empty \( n \)-dimensional smooth manifolds such that \( f(\partial M) \subset \partial N \). If \( \deg(f) = \pm 1 \), then \( f_*: \pi_1(M) \to \pi_1(N) \) is an epimorphism.

The statement of Proposition 69.9 is somewhat surprising, in so far as it takes as input fairly simple information, namely the induced map on \( n \)-th homology, which is an abelian group, and gives as output information about fundamental groups, which are usually much harder to deal with. Also it is a priori not clear why the homology in the maximal dimension should have any impact on fundamental groups.

**Proof.** Let \( f: M \to N \) be a map between compact oriented connected non-empty \( n \)-dimensional smooth manifolds such that \( f(\partial M) \subset \partial N \). We fix a base point \( P \in M \) and we write \( Q = f(P) \). Furthermore we write \( \pi = \pi_1(N, Q) \) and \( \Gamma = f_*(\pi_1(M, P)) \).

By Proposition 29.10 there exists a path-connected covering \( p: (\tilde{N}, \tilde{Q}) \to (N, Q) \) such that \( p_*(\pi_1(\tilde{N}, \tilde{Q})) = \Gamma \) and such that \( [\tilde{N} : N] = [\pi : \Gamma] \). By Proposition 17.1 we can equip the covering space \( \tilde{N} \) with the structure of a compact oriented smooth manifold such that the projection \( p: \tilde{N} \to N \) is an orientation-preserving map and such that we have \( \partial \tilde{N} = p^{-1}(\partial N) \). Since by design we know that \( p_*(\pi_1(\tilde{N}, \tilde{Q})) = \Gamma = f_*(\pi_1(M, P)) \) we obtain from Proposition 29.2 that the map \( f: (M, P) \to (N, Q) \) lifts to a map \( \tilde{f}: (M, P) \to (\tilde{N}, \tilde{Q}) \).

We can summarize the situation in the following simple commutative diagram

\[
\begin{array}{ccc}
\tilde{N} & \xrightarrow{\tilde{f}} & N \\
p \downarrow & & \downarrow \\
M & \xrightarrow{f} & N.
\end{array}
\]

First suppose that \( \Gamma \) is a subgroup of \( \pi \) of infinite index. It follows immediately from \( [\tilde{N} : N] = [\pi : \Gamma] \) and Lemma 16.3 (5) that \( \tilde{N} \) is non-compact. Therefore we obtain from Theorem 66.6 that \( H_n(\tilde{N}) = 0 \). But this shows that \( f_* = p_* \circ \tilde{f}_*: H_n(M) \to H_n(N) \) factors through the trivial group. Hence \( \deg(f) = 0 \). But this is a contradiction to our hypothesis that \( \deg(f) = \pm 1 \).

So now we know that \( \Gamma \) is necessarily a finite-index subgroup of \( \pi \). It follows from \( [\tilde{N} : N] = [\pi : \Gamma] \) and Lemma 16.3 (4) that \( \tilde{N} \) is compact. Therefore, by the above we now know that \( \tilde{N} \) is a compact oriented connected \( n \)-dimensional smooth manifold. We deduce

\[\text{Exercise 68.10 Proposition 59.1 \[\blacksquare\]}\]

Here we use that according to the discussion on pages 816 any smooth manifold is locally simply connected.
that
\[ \pm 1 = \deg(f) = \deg(\tilde{f}) \cdot \deg(p) = \deg(\tilde{f}) \cdot [\tilde{N} : N] = \deg(\tilde{f}) \cdot [\Gamma : \pi]. \]

Lemma 69.1 Proposition 69.8

This shows that \([\Gamma : \pi] = 1\), i.e. \(\Gamma = \pi\). ■

Now we can give a negative answer to Question 69.6.

**Corollary 69.10.** Let \(g, k \in \mathbb{N}_0\). If there exists a degree-one map from \(\Sigma_g\) to \(\Sigma_k\), then \(g \geq k\).

**Proof.** Suppose that there exists a degree-one map from \(\Sigma_g\) to \(\Sigma_k\). By Proposition 69.9 we obtain an epimorphism \(\pi_1(\Sigma_g) \rightarrow \pi_1(\Sigma_k)\). In particular we obtain an epimorphism from the abelianization \(\pi_1(\Sigma_g)\) onto the abelianization of \(\pi_1(\Sigma_k)\). By Proposition 22.3 the former is isomorphic to \(\mathbb{Z}^{2g}\) and the latter is isomorphic to \(\mathbb{Z}^{2k}\). It follows from Lemma 19.6 that \(g \geq k\). ■

We conclude this chapter with several questions. Recall that it follows from Lemma 69.5 that there exists a degree-one map \(S^2 \times S^2 \rightarrow S^4\). It is natural to ask whether the converse holds. This leads us to the following question which we will answer in Lemma 84.5.

**Question 69.11.** Does there exist a degree-one map from the 4-dimensional sphere \(S^4\) to \(S^2 \times S^2\)?

Later, in Corollary 88.15 we will also address the following question.

**Question 69.12.** Does there exist a degree-one map from \(S^1 \times S^2\) to \(\mathbb{R}P^3\)?

It is also interesting to study degrees of self-maps of smooth manifolds. For example note that it follows from Lemmas 45.10 and 45.12 that given any \(k \in \mathbb{Z}\) and given any \(n \in \mathbb{N}\) there exists a map \(f : S^n \rightarrow S^n\) of degree \(k\). Also note that it follows easily from Proposition 69.8 that the torus \(T = S^1 \times S^1\) admits a self-map of any degree. This naturally leads us to the question whether similar phenomena hold for surfaces of higher genus.

**Question 69.13.**

(1) Let \(g \geq 2\). Does there exist a self-map \(f : \Sigma_g \rightarrow \Sigma_g\) of degree \(-1\)?

(2) Let \(g \geq 2\) and let \(k \geq 2\). Does there exist a self-map \(f : \Sigma_g \rightarrow \Sigma_g\) of degree \(k\)?

(3) Does there exist a self-map \(f : \mathbb{C}P^2 \rightarrow \mathbb{C}P^2\) of degree \(-1\)?

We will address the first question in Exercise 69.3 and we will address the last two questions later on in Proposition 81.17 and Corollary 90.10.

Finally we conclude this chapter with two conjectures that were formulated by Heinz Hopf in 1931. We refer to [Hau87, Neum53] for some more information and partial results.

**Conjecture 69.14. (Hopf Conjecture)** Let \(M\) be a closed oriented connected smooth manifold and let \(f : M \rightarrow M\) be a map.

(1) If \(\deg(f) = \pm 1\), then \(f_* : \pi_1(M) \rightarrow \pi_1(M)\) is an isomorphism.

(2) If \(\deg(f) = \pm 1\), then \(f\) is a homotopy equivalence.
Remark. Let $M$ be a closed oriented connected smooth manifold and let $f : M \to M$ be a map with $\deg(f) = \pm 1$.

(1) By Proposition 69.9 we know that $f_*$ is an epimorphism. Thus the Hopf Conjecture 69.14 (2) leads to the group-theoretic question, under what circumstances is a surjective automorphism of a group also injective. In particular this leads to the definition of a Hopfian group that we gave on page 862.

(2) In Proposition ?? we will see that in general $f$ is not homotopic to a homeomorphism. Thus in general “homotopy equivalence” is the best we can hope for. Note though that if $M$ is in fact aspherical, see page 1344 for the definition, then the Borel Conjecture ?? predicts that $f$ is actually homotopic to a homeomorphism.

Exercises for Chapter 69.

Exercise 69.1. Let $M$ be a compact oriented $n$-dimensional smooth manifold with non-empty boundary. Show that there exists a map $f : M \to \overline{B^n}$ with $f(\partial M) \subset S^{n-1}$ of degree $+1$.

Remark. For $n \geq 2$ one can combine this result with Exercise 45.5 to get maps of arbitrary degree.

Exercise 69.2. Given an example of a map $f : M \to N$ between closed oriented connected non-empty $n$-dimensional smooth manifolds such that $f_* : \pi_1(M) \to \pi_1(N)$ is an epimorphism, but such that the degree of $f$ is zero.

Exercise 69.3. Given $g \in \mathbb{N}$ we denote by $\Sigma_g$ the surface of genus $g$.

(a) Let $g \geq 2$. Does there exist a self-map $f : \Sigma_g \to \Sigma_g$ of degree $-1$?

(b) Let $g \geq 1$ and let $k \geq 2$. Does there exist a self-map $f : \Sigma_g \to \Sigma_g$ of degree $k$?

Exercise 69.4. Given $g \in \mathbb{N}$ we denote by $\Sigma_g$ the surface of genus $g$. Show that if there exists a map $f : \Sigma_g \to \Sigma_k$ of non-zero degree, then $g \geq k$.

Exercise 69.5. Let $f : M \to N$ be a map between two closed connected non-empty $n$-dimensional smooth manifolds. Furthermore let $p : \widetilde{N} \to N$ be a finite covering. As in Lemma 25.16 we consider the pullback

$$\widetilde{M} := f^* \widetilde{N} = \{(x, y) \in M \times \widetilde{N} \mid f(x) = p(y)\}$$

together with the following commutative diagram:

$$\begin{array}{ccc}
\widetilde{M} & \xrightarrow{(x,y) \mapsto y} & \widetilde{N} \\
\downarrow_{\text{=} \; q} & \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \q
(b) Suppose that the induced map \( f_* : H_n(M; \mathbb{F}_2) \to H_n(N; \mathbb{F}_2) \) is an isomorphism. Show that \( F_* : H_n(\tilde{M}; \mathbb{F}_2) \to H_n(\tilde{N}; \mathbb{F}_2) \) is also an isomorphism.

**Exercise 69.6.** Let \( M \) be the torus minus one open disk and let \( N \) be \( S^2 \) minus three open disks.

(a) Show that there is no degree one map \( f : M \to N \).

(b) Show that there is no degree one map \( g : N \to M \).

\[ \text{Figure 1075. Illustration for Exercise 69.6} \]

**Exercise 69.7.** Given \( m \in \mathbb{N} \) we denote by \( N_m \) the non-orientable surface of genus \( m \), as defined on page 206. Let \( k \in \mathbb{N} \).

(a) Let \( g \geq k \). Show that there exists a map \( f : N_g \to N_k \) such that the induced map \( H_2(N_g; \mathbb{F}_2) \to H_2(N_k; \mathbb{F}_2) \) is an isomorphism.

(b) Let \( g < k \). Show that there does not exist a map \( f : N_g \to N_k \) such that the induced map \( H_2(N_g; \mathbb{F}_2) \to H_2(N_k; \mathbb{F}_2) \) is an isomorphism.

*Remark.* Recall that in Exercise 57.14 we saw that \( H_1(N_m; \mathbb{F}_2) \cong \mathbb{F}_2^m \).
70. Homology classes and smooth (sub-)manifolds

In Chapter 68 we saw that every compact oriented n-dimensional smooth manifold \( N \) comes naturally with a fundamental class \([N]\in H_n(N,\partial N)\). In Chapters 68 and 69 we already saw several interesting applications of the fundamental class and we now feel like we have a good understanding of fundamental classes.

In this chapter we want to study to which degree homology classes can be understood in terms of fundamental classes. More precisely, we want to study the following two questions:

1. Given a topological space \( X \) and a homology class \( \varphi\in H_n(X) \), can we always find a closed oriented \( n \)-dimensional smooth manifold \( N \) and a map \( f\colon N\to X \) such that \( f_*([N]) = \varphi \)?

2. If \( X \) is in fact a smooth manifold, can we find an \( f\colon N\to X \) as in (1) that is actually a smooth embedding?

70.1. Realizing homology classes by smooth manifolds. Let us start out with the following friendly definition.

**Definition.** Let \( X \) be a topological space, let \( A\subset X \) be a subset and let \( \varphi\in H_n(X,A) \) be a homology class. We say \( \varphi \) can be realized by a smooth manifold if there exists a compact oriented \( n \)-dimensional smooth manifold \( N \) and a map \( f\colon (N,\partial N)\to (X,A) \) such that \( f_*([N]) = \varphi \).

**Examples.** Let \((X,x_0)\) be a path-connected pointed topological space and let \( n\in\mathbb{N} \). Recall that the Hurewicz homomorphism is defined as the map

\[
\Phi_{(X,x_0)}\colon \pi_n(X,x_0) \to H_n(X) \quad [f\colon S^n\to X] \mapsto f_*([S^n]).
\]

Thus we see that every homology class that lies in the image of the Hurewicz homomorphism is realized by a smooth manifold. But as we remarked on page 1326, in general the Hurewicz homomorphism is certainly not an epimorphism.

In this and the subsequent section we want to study the following question.

**Question 70.1.** Let \( X \) be a topological space and let \( A\subset X \) be a subset. For which \( n\in\mathbb{N}_0 \) can homology classes in \( H_n(X,A) \) be realized by smooth manifolds?

The case \( n = 0 \) is evidently trivial. So let us continue with the case \( n = 1 \).

**Proposition 70.2.** Let \( X \) be a topological space. Every class in \( H_1(X) \) is realized by a smooth manifold.
Finally we see that for each 1-dimensional smooth manifold and that we can equip \( N \) with an orientation such that for each \( j \in \{1, \ldots, k\} \) the map \( p \circ \Psi_j: \Delta^1 \to N \) is an orientation-preserving embedding. Finally we see that
\[
f_*([N]) = f_*([p \circ \Psi_1 + \cdots + p \circ \Psi_k]) = [\sigma_1 + \cdots + \sigma_k] = c.
\]
follows from Proposition 58.4 by definition of \( f \) and \( p \circ \Psi_j \)

Evidently the idea now is to work our way up to higher dimensions. In fact we have the following proposition.

**Proposition 70.3.** Let \( X \) be a topological space. Every class in \( H_2(X) \) is realized by a smooth manifold.
In Lemma 70.9 we will see that any naive attempt of generalizing the ideas behind the proofs of Propositions 70.2 and 70.3 to higher dimensions runs into serious problems.

We move on to the following proposition that summarizes a few generalities on realizing homology classes by smooth manifolds.

**Proposition 70.4.** Let \( k \in \mathbb{N} \).

1. Let \( X \) be a topological space and let \( A \subset X \) be a subset. We suppose that \( X \) is path-connected. If \( A = \emptyset \) or if \( k \geq 2 \), then every homology class in \( H_k(X, A) \) that can be realized by a smooth manifold can also be realized by a connected smooth manifold.
2. Suppose that for every topological space \( X \) every homology class in \( H_k(X) \) can be realized by a smooth manifold. Then also for every pair \((X, A)\) of topological spaces every relative homology class in \( H_k(X, A) \) can be realized by a smooth manifold.

**Proof.** In order not to disrupt the flow of the conversation too much we postpone the somewhat technical proof of Proposition 70.4 to Section 70.3.

Note that Propositions 70.2 and 70.3 together with Proposition 70.4 give us a complete, and affirmative, answer to Question 70.1 for the dimensions \( k = 1 \) and \( k = 2 \).

We move on to the following much more fancy theorem which was first proved by René Thom [Thom54b, Thom07] in 1954.\(^{1042}\) The proof of the theorem uses methods that go well beyond our present abilities. We will not make use of the theorem.

**Theorem 70.5.** (Thom’s Theorem I)

1. If \( X \) is a topological space, then every homology class of dimension \( \leq 6 \) can be realized by a smooth manifold.
2. Given any \( n \geq 7 \) there exists a topological space \( X \) and a homology class in \( H_n(X) \) that is not realized by a smooth manifold.
3. Given any \( n \in \mathbb{N}_0 \) there exists a \( k \in \mathbb{N} \) such that for any topological space \( X \) and any homology class \( \sigma \in H_n(X) \) the class \( k \cdot \sigma \) can be realized by a smooth manifold.

---

\(^{1042}\)René Thom (1923-2002) was a French mathematician who received the Fields Medal in 1958.
Proof. As mentioned before, the theorem is proved in [Tho54b, Theorem III.3, III.4 and III.9]. A more modern account of the proof is given in Theorems IV.7.35, IV.7.36, IV.7.37 and IV.7.38 together with Remark IV.7.40 of [Rudy98]. In fact the topological space $X$ in (2) is given by the $(n-7)$-fold suspension of the Eilenberg-Maclane space $K(\mathbb{Z}_3, 2)$, which we will introduce later in Chapter 120.

For completeness we also mention $\mathbb{F}_2$-coefficients.

**Theorem 70.6. (Thom’s Theorem II)** Let $X$ be a path-connected topological space and let $A \subset X$ be a subset. Given any $\varphi \in H_n(X, A; \mathbb{F}_2)$ there exists a compact connected $n$-dimensional smooth manifold $N$ and a map $f : N \to X$ with $f(\partial N) \subset A$ such that $f_*([N]_{\mathbb{F}_2}) = \varphi$.

**Proof.** First let us consider the case $A = \emptyset$ and for the time being let us allow possibly disconnected smooth manifolds. In this setting, for $n = 1$ and $n = 2$ the statement follows from straightforward modifications of the proofs of Propositions 70.2 and 70.3. In fact, much more interestingly, the statement now holds in all dimensions by the above work of René Thom [Tho54b, Theorem III.2], see also [Rudy98, Theorem IV.7.33]. The statements about relative homology and connectedness follow from the obvious variations on Proposition 70.4.

We conclude this section with the following remark.

**Remark.** In Chapter 86 we will introduce the notion of an orientation of a topological manifold. Furthermore in Chapter 87 we will introduce the notion of the fundamental class $[N] \in H_n(N, \partial N)$ of a compact oriented $n$-dimensional topological manifold $N$. It now makes sense to ask whether a homology class can be realized by a topological manifold. By [Rudy98, Theorem IV.7.35 and Remark IV.3.740] there exist homology classes in any dimension $\geq 7$ that cannot be realized by topological manifolds. But by [Rudy98, Theorem IV.7.38] there do exist homology classes that can be realized by topological manifolds but which cannot be realized by smooth manifolds.

### 70.2. Proof of Proposition 70.3

In this section we prove the following proposition from the last section.

**Proposition 70.3.** Let $X$ be a topological space. Every class in $H_2(X)$ is realized by a smooth manifold.

The proof of Proposition 70.3 is modeled on the proof of Proposition 70.2. But, as we will see, the proof is technically more difficult.

We start out our proof with the more general setting of some $n$-dimensional class. Later on we will specialize to the case that $n = 2$. It is even worthwhile keeping the case $n = 1$ in mind, since even for $n = 1$ the argument below differs slightly from the argument provided in the proof of Proposition 70.2.

Thus let $X$ be a topological space, let $n \in \mathbb{N}$ and let $c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k$ be an $n$-dimensional singular chain in $X$. We do not necessarily demand that the $\sigma_j$ are different.
In fact note that by “taking multiple copies of the singular simplices \( \sigma_j \)” we can and will arrange that \( a_j \in \{-1, 1\}, j = 1, \ldots, k \). We set \( T := \{1, \ldots, k\} \times \{0, \ldots, n\} \).

Now assume that \( c \) is a cycle. We see that we have the following equality in the free abelian group \( C_{n-1}(X) \):

\[
0 = \partial_1(c) = \partial_1 \left( \sum_{j=1}^{k} a_j \cdot \sigma_j \right) = \sum_{j=1}^{k} \sum_{r=0}^{n} (-1)^r \cdot a_j \cdot \sigma_j \circ i_r^n \uparrow \text{since } c \text{ is a cycle}
\]

Here \( i_r^n \colon \Delta^{n-1} \to \Delta^n \) is the \( r \)-th face map.

It follows from Lemma 52.4 that there exists a decomposition \( T = T_1 \sqcup T_2 \) into two disjoint subsets together with a bijection

\[
\Theta = (\theta_1, \theta_2) \colon T_1 \to T_2
\]

such that the following condition is satisfied: For every \((j, r) \in T_1\) we have

\[
\sigma_j \circ i_r^n = \sigma_{\theta_1(j, r)} \circ i_{\theta_2(j, r)}^n
\]

and

\[
(-1)^r \cdot a_j = (-1)^{\theta_2(j, r)} \cdot a_{\theta_1(j, r)}.
\]

Next we introduce some notation:

1. We consider the topological space

\[
Y(\Theta) := (\{1, \ldots, k\} \times \Delta^n) / \sim \quad \text{where for each } (j, r) \in T_1 \text{ and each } P \in \Delta^{n-1}
\]

we have \((j, i_r^n(P)) \sim (\theta_1(j, r), i_{\theta_2(j, r)}^n(P))\).

Informally speaking \( Y(\Theta) \) is given by taking one \( n \)-simplex for each singular simplex \( \sigma_j \) and gluing these simplices along \((n - 1)\)-dimensional faces.

2. For \( j = 1, \ldots, k \) we denote by \( \Psi_j \colon \Delta^n \ni (j, x) \mapsto 1, \ldots, k \times \Delta^n \) the \( j \)-th inclusion map.

3. We denote by \( p \colon \{1, \ldots, k\} \times \Delta^n \to Y(\Theta) \) the projection map.

4. It follows immediately from the definitions and Lemma 3.22 that the map

\[
f \colon Y(\Theta) = (\{1, \ldots, k\} \times \Delta^n) / \sim \to X
\]

\[
[(j, P)] \mapsto \sigma_j(P)
\]

is well-defined and continuous.

5. We set

\[
\mu := \sum_{j=1}^{k} a_j \cdot p \circ \Psi_j \in C_n(Y(\Theta)).
\]

We can now formulate the following lemma.

**Lemma 70.7.**

1. \( \mu \in C_n(Y(\Theta)) \) is a cycle.

Note that if \( n \) is even, then it follows from Exercise 41.10 that we cannot arrange that all \( a_j \) are of the same sign. This is one, but not the main, reason why the proof of Proposition 70.3 is more difficult than the proof of Proposition 70.2.

It might seem that \( Y(\Theta) \) has an “obvious simplicial structure”, but that is not necessarily the case, for example after gluing there might be two \( n \)-dimensional simplices that intersect in more than just one \((n - 1)\)-dimensional face.
The proof of Proposition 70.3. Note that, as a bonus, we also obtain a new proof of Proposition 70.2.

**Proof.** First we show that $\mu$ is a cycle. This follows from the following straightforward calculation:

$$\partial \mu = \partial \left( \sum_{j=1}^{k} a_j \cdot p \circ \Psi_j \right) = \sum_{j=1}^{k} \sum_{r=0}^{n} (-1)^r \cdot a_j \cdot p \circ \Psi_j \circ i^n_r = \sum_{(j,r) \in T} (-1)^r \cdot a_j \cdot p \circ \Psi_j \circ i^n_r$$

$$= \sum_{(j,r) \in T_1} (-1)^r \cdot a_j \cdot p \circ \Psi_j \circ i^n_r + \sum_{(j,r) \in T_2} (-1)^{\theta_2(j,r)} \cdot a_{\theta_1(j,r)} \cdot p \circ \Psi_{\theta_1(j,r)} \circ i^n_{\theta_2(j,r)}$$

Since $T = T_1 \cup T_2$ and since $\Theta = (\theta_1, \theta_2) : T_1 \to T_2$ is a bijection

$$= \sum_{(j,r) \in T_1} (-1)^r \cdot a_j \cdot p \circ \Psi_j \circ i^n_r + (-1)^{\theta_2(j,r)} \cdot a_{\theta_1(j,r)} \cdot p \circ \Psi_{\theta_1(j,r)} \circ i^n_{\theta_2(j,r)} = 0.$$  

It follows immediately from the definitions that $f_*(\mu) = c \in C_n(X)$. In particular we have $f_*(\mu) = c \in H_n(X)$.  

We move on to the next lemma, which together with Lemma 70.7 provides the long-desired proof of Proposition 70.3. Note that, as a bonus, we also obtain a new proof of Proposition 70.2.

**Lemma 70.8.** We continue with the above notation. If $n = 1$ or if $n = 2$, then the topological space $Y(\Theta)$ admits the structure of a closed oriented 2-dimensional smooth manifold such that $[\mu] \in H_2(Y(\Theta))$ is the corresponding fundamental class.

**Remark.** In Lemma 70.9 below we will see that for $n = 3$ the topological space $Y(\Theta)$ is in general not a topological manifold.

**Sketch of a proof of Lemma 70.8.** The proof of Lemma 70.8 for the case $n = 1$ is very elementary and thus left to the reader.

In the following we sketch a proof of Lemma 70.8 for the case $n = 2$. As we will see, the proof is quite similar to the proof, given in Propositions 6.8 and 6.21 that the surface $\Sigma_g$ of genus $g$ is indeed a closed orientable 2-dimensional smooth manifold.

First note that it follows easily from Lemma 3.21 (4) that $Y(\Theta)$ is compact. We leave it to the reader to verify, say using Lemma 3.26 that $Y(\Theta)$ is Hausdorff.
Next we construct a finite atlas for $Y(\Theta)$. To do so we introduce the following notation:

- Let $\pi: \Delta^2 \to \Delta_2$ be the projection map. Note that in Lemma 41.1 we saw that $\pi$ is a homeomorphism.
- We denote by $v_0 = (1, 0, 0)$, $v_1 = (0, 1, 0)$ and $v_2 = (0, 0, 1)$ the three vertices of $\Delta^2$.
- Let $j \in \{0, 1, 2\}$. In the following will define two open subsets $X_j$ and $Y_j$ of $\Delta^2$. In the subsequent definition we denote by $w, w'$ the two vertices that are not equal to $v_j$.

Now we introduce the following notation:

- $\triangleright$ We denote by $X_j$ the union of the open interval from $w$ to $w'$ and the open triangle in $\Delta^2$ spanned by $w, w'$ and the barycenter $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ of $\Delta^2$.

- We denote by $Y_j$ the intersection of $\Delta^2 \subset \mathbb{R}^3$ with the open ball in $\mathbb{R}^3$ of radius $\frac{1}{2}$ around the $j$-th vertex $v_j$.

We refer to Figures 1079 and 1080 for an illustration of the above definitions.

Next we sketch the construction of three types of charts for the topological space $Y(\Theta)$. We leave it to the reader to fill in the details in the discussions below.

1. For each $j \in \{1, \ldots, k\}$ we let $\alpha_j := \pi \circ \Psi^{-1}_j \circ p^{-1}: U_j := p(\Delta_j) \to V_j := \Delta_2 \subset \mathbb{R}^2$ be the “obvious” chart.

2. Let $(j, r) \in T$. We write $\Theta(j, r) =: (j', r')$. Similar to the proof of Proposition 6.8 one can easily write down an explicit chart

$$
\beta_{j, r}: U_{j, r} := p(\Psi_i(X_r)) \cup p(\Psi_{j'}(X_r)) \to V_{j, r} \subset \mathbb{R}^2
$$

such that the maps $\beta_{j, r} \circ p \circ \Psi_j^{-1} \circ \pi^{-1}: \Delta_2 \to \mathbb{R}^2$ and $\beta_{j, r} \circ p \circ \Psi_{j'}^{-1} \circ \pi^{-1}: \Delta_2 \to \mathbb{R}^2$ are both affine linear and such that they are both orientation-preserving if and only if $(-1)^r \cdot a_j = 1$ and such that they are both orientation-reversing if and only if $(-1)^r \cdot a_j = -1$. 

![Figure 1079](image1.png)

![Figure 1080](image2.png)
Let \( j \in \{1, \ldots, k\} \) and let \( r \in \{0, 1, 2\} \). An open neighborhood of \( p(\Psi_j(v_r)) \) is given by

\[
\tilde{U}_{j,r} := \bigcup_{(j', r') \in T \text{ such that } p(\Psi_j'(v_{r'})) = p(\Psi_j(v_r))} p(\Psi_j'(Y_{r'})).
\]

Again similar to the proof of Propositions 6.8, one can now write down an explicit chart \( \gamma_{j,r} : \tilde{U}_{j,r} \to B^2_\varepsilon \) such that on each \( p(\Psi_r(Y, s)) \) the map is a concatenation of \( \pi \), \((p \circ \Psi_r)^{-1}\), translation, rotation and a map of the form \( e^{it} \mapsto e^{iw t} \) for some \( w \in \mathbb{R}_{\geq 0} \). In fact we can take \( w = \frac{2\pi}{m} \) where \( m \in \mathbb{N} \) is the number of terms \( (j', r') \) that appear in the above definition of \( \tilde{U}_{j,r} \).

We leave it to the reader to verify that all of these maps are homeomorphisms and that they form an atlas for \( Y(\Theta) \). Note that by Lemma 6.4 (2) we now also know that \( Y(\Theta) \) is second-countable. We have thus verified that \( Y(\Theta) \) is a closed 2-dimensional topological manifold.

Next note that, as in the proof of Proposition 6.21, one can now verify easily that the transition maps between the given charts are indeed smooth and that they are orientation-preserving. Not surprisingly, once again we leave the details to the reader. Thus in summary we obtain from the above discussion, together with Lemmas 6.4 and 6.45, that \( Y(\Theta) \) is a smooth manifold that is endowed with an orientation such that all charts are orientation-preserving.

Recall that in Lemma 70.7 we showed that \( \mu = a_1 \cdot \Psi_1 + \cdots + a_k \cdot p \circ \Psi_k \in C_2(Y(\Theta)) \) is a cycle. It follows almost immediately from Proposition 68.4 that \( \mu \) represents the fundamental class of the closed oriented smooth manifold \( Y(\Theta) \).

We conclude this section with the following lemma which shows that the above approach will not work in higher dimensions.

**Lemma 70.9.** Given any \( n \in \mathbb{N}_{\geq 3} \) there exists a topological space \( X \) together with a cycle \( c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k \in C_n(X) \) such that for any choice of \( \Theta \) the topological space \( Y(\Theta) \) is not a closed topological manifold, let alone a closed smooth manifold.
Sketch of proof. Let \( n \in \mathbb{N}_{\geq 3} \) and let \( M \) be the \((n-1)\)-dimensional torus. Furthermore, let \((K, \Xi: |K| \to M)\) be a smooth simplicial structure for \( M \), which we know exists by Theorem 64.2 or by some more down-to-earth argument.

By Propositions 66.1 and 66.7 we know that \( K \) is a closed orientable \((n-1)\)-dimensional pseudomanifold. Next we consider the suspension \( \Sigma(K) \), as defined on page 1506. Note that by Corollary 61.21 we know that \( X := |\Sigma(K)| \) is homeomorphic to \( |\Sigma(M)| \).

Next recall that by the fairly straightforward Exercise 66.1 we know that \( \Sigma(K) \) is a closed \( n \)-dimensional pseudomanifold that admits an orientation \( \{ (\epsilon_1, Y_1), \ldots, (\epsilon_k, Y_k) \} \).

Now let \( \varphi = \epsilon_1 \cdot Y_1 + \cdots + \epsilon_k \cdot Y_k \in C_n^{\simp}(\Sigma(K)) \) be the cycle from Theorem 66.4. Next note that after picking some total order on the vertex set of \( \Sigma(K) \) we obtain from Lemmas 63.8 and Theorem 63.25 a corresponding singular cycle \( c = a_1 \cdot \sigma_1 + \cdots + a_k \cdot \sigma_k \in C_n(X) = C_n(|\Sigma(K)|) \). We set \( T := \{1, \ldots, k\} \times \{0, \ldots, n\} \). We leave it to the dedicated reader to verify that for every \((j, r)\in T_1\) we have

\[
\sigma_j \circ i^n_r = \sigma_{\theta_1(j, r)} \circ i^n_{\theta_2(j, r)} \quad \text{and} \quad (-1)^r \cdot a_j = -(-1)^{\theta_2(j, r)} \cdot a_{\theta_1(j, r)}. 
\]

Furthermore we leave it to the reader to verify that \( Y(\Theta) \) is actually homeomorphic to \(|\Sigma(K)| \cong |\Sigma(M)| \).

Finally we point out that it follows from Exercise 45.8, together with the fact that \( H_1(M) = H_1((S^1)^n) \neq 0 \) and together with our hypothesis \( n \geq 3 \) that \( X = |\Sigma(K)| \cong |\Sigma(M)| \) is not a closed topological manifold.

70.3. Proof of Proposition 70.4. The sole goal of this section is to prove Proposition 70.4. For convenience we prove the two parts of the proposition separately.

Proposition 70.4.

1. Let \( k \in \mathbb{N} \), let \( X \) be a topological space and let \( A \subset X \) be a subset. We suppose that \( X \) is path-connected. If \( A = \emptyset \) or if \( k \geq 2 \), then every homology class in \( H_k(X, A) \) that can be realized by a smooth manifold can also be realized by a connected smooth manifold.

Proof of Proposition 70.4 (1). To simplify the discussion we only consider the case that \( A = \emptyset \). The case \( A \neq \emptyset \) is proved in a completely analogous fashion, the only difference is that the notation becomes even more messy. We will point out though explicitly where we need that \( k \geq 2 \) for \( A \neq \emptyset \).

Let \( X \) be a path-connected topological space and let \( \theta \in H_k(X) \) be a homology class. Suppose there exists a closed oriented \( k \)-dimensional smooth manifold \( W \) and a map \( f: W \to X \) with \( f_*([W]) = \theta \). If \( W \) is connected, then there is nothing to show. In the following we will deal with the case that \( W \) has precisely two components \( M \) and \( N \). The general case is dealt with the same way.
We make the following preparations.

(1) As usual we denote by $\overline{B}^k_3 \subset \mathbb{R}^k$ the closed ball of radius 3 around the origin. We pick an orientation-preserving smooth embedding $\varphi: \overline{B}^k_3 \to M$ and we pick an orientation-reversing smooth embedding $\psi: \overline{B}^k_3 \to N$. We write $P := \varphi(0)$ and $Q := \psi(0)$.

(2) We use the restrictions of $\varphi$ and $\psi$ to $\overline{B}^k_3$ to form, following the definition on page 377 the connected sum $M \# N$, i.e. we consider

$$M \# N = ((M \setminus \varphi(B^k)) \sqcup (N \setminus \psi(B^k))/\sim$$

where $\varphi(z) \sim \psi(z)$ for $z \in S^{k-1}$.

(3) We recall a few statements from Proposition 8.35

(a) The connected sum $M \# N$ is a closed $k$-dimensional smooth manifold which can be oriented in such a way that the two natural inclusions $M \setminus \varphi(B^k) \to M \# N$ and $N \setminus \psi(B^k) \to M \# N$ are both orientation-preserving smooth embeddings.

(b) If $k \geq 2$ or if at least one of $M$ or $N$ is closed, then $M \# N$ is connected.

Next we denote by $p: Z \to M$ the map that is given by the identity on $M$ and which sends all other points to $P$. Similarly we define $q: Z \to N$.

(4) We consider the topological space $Z := (M \sqcup [-1, 1] \sqcup N)/\sim$ where we make the identifications $P \sim -1$ and $1 \sim Q$.

(5) We denote by $i: M \to Z$ and $j: N \to Z$ the obvious maps. It is easy to see that they are in fact embeddings. Next we denote by $p: Z \to M$ the map that is given by the identity on $M$ and which sends all other points to $P$. Similarly we define $q: Z \to N$.

(6) We consider the following maps:

$$H_k((M \sqcup [-1, 1])/\sim) \oplus H_k((N \sqcup [-1, 1])/\sim) \xrightarrow{i_* \oplus j_*} H_k(M) \oplus H_k(N) \xrightarrow{i_* \oplus j_*} H_k(M) \oplus H_k(N)$$

is an isomorphism since inclusions are homotopy equivalences.

Mayer–Vietoris Theorem 46.5. It follows that the right diagonal map $i_* \oplus j_*: H_k(M) \oplus H_k(N) \to H_k(Z)$ is an isomorphism. It is now straightforward to see that the inverse of $i_* \oplus j_*$ is given by $p_* + q_*: H_k(Z) \to H_k(M) \oplus H_k(N)$.

(7) We consider the map

$$\Theta: M \# N \to Z$$

$$x \mapsto \begin{cases} [x], & \text{if } x \in M \setminus \varphi(B^k_3), \\ [\varphi(3(r - 2) \cdot y)], & \text{if } x = \varphi(r \cdot y) \text{ with } r \in [2, 3] \text{ and } y \in S^{k-1}, \\ [-r + 1], & \text{if } x = \varphi(r \cdot y) \text{ with } r \in [1, 2] \text{ and } y \in S^{k-1}, \\ [r - 1], & \text{if } x = \psi(r \cdot y) \text{ with } r \in [1, 2] \text{ and } y \in S^{k-1}, \\ [\psi(3(r - 2) \cdot y)], & \text{if } x = \psi(r \cdot y) \text{ with } r \in [2, 3] \text{ and } y \in S^{k-1}, \\ [x], & \text{if } x \in N \setminus \psi(B^k_3). \end{cases}$$

It follows easily from Lemma 2.35 (2) that $\Theta: M \# N \to Z$ is actually continuous.
(8) It follows almost immediately from Proposition 69.2 together with (3a) that the maps \( p \circ \Theta : M \# N \to M \) and \( q \circ \Theta : M \# N \to N \) both have degree one. In other words, we have the equality

\[
(p_* \oplus q_*)(\Theta_*([M \# N])) = [M] + [N] \in H_k(M) \oplus H_k(N) = H_k(M \sqcup N) = H_k(W).
\]

(9) By hypothesis the topological space \( X \) is path-connected. This implies that there exists a path \( \gamma : [-1, 1] \to X \) with \( \gamma(-1) = P \) and \( \gamma(1) = Q \). Using \( \gamma \) we can extend the map \( f : W = M \sqcup N \to X \) to a map \( g : Z \to X \) in the obvious way.

By (3) the connected sum \( M \# N \) is a closed oriented connected smooth manifold. Thus it remains to prove the following claim.

**Claim.** We have \((g \circ \Theta)_*([M \# N]) = \theta \in H_k(X)\).

It follows from the above that we have the following diagram:

\[
\begin{array}{ccc}
H_k(M) \oplus H_k(N) & \cong & H_k(M \sqcup N) = H_k(W) \\
\uparrow p_* \oplus q_* & & \downarrow f_* \\
H_k(M \# N) & \xrightarrow{\Theta_*} & H_k(Z) \xrightarrow{g_*} H_k(X).
\end{array}
\]

It follows from the definition of \( g \) together with (6) that the diagram commutes. Now we see that we have the following equalities in \( H_k(X)\):

\[
(g \circ \Theta)_*([M \# N]) = g_* (i_*([M]) + j_*([N])) = f_*([M]) + f_*([N]) = f_*([M \sqcup N]) = \theta.
\]

by (8) and (6) \hspace{1cm} since the diagram commutes

\[\blacksquare\]

**Figure 1082.** Illustration for the proof of Proposition 70.4(1).

We move on to the second statement of Proposition 70.4.

**Proposition 70.4.**

(2) Let \( k \in \mathbb{N} \). Suppose that for every topological space \( X \) every homology class in \( H_k(X) \) can be realized by a smooth manifold. Then also for every pair \((X, A)\) of
topological spaces every relative homology class in $H_k(X,A)$ can be realized by a smooth manifold.

**Proof.** Let $k \in \mathbb{N}$. We make the following hypothesis:

(*) For every topological space $Y$ every homology class in $H_k(Y)$ can be realized by a smooth manifold.

Now let $(X,A)$ be a pair of topological spaces and let $\varphi \in H_k(X,A)$ be a relative homology class. We denote by $i: A \to X$ the inclusion map. We consider the mapping cone

$$\text{Cone}(i: A \to X) = \left( \text{Cone}(A) \sqcup X \right) / \sim$$

where $[(a,1)] \sim i(a) = a$ for $a \in A$.

We denote by $[*A \times \{0\}] \in \text{Cone}(i: A \to X)$ the cone point. We consider the following diagram:

$$
\begin{array}{cccc}
H_k(M,\partial M) & \cong & H_k(W, N) & \cong \leftarrow H_k(W) \\
\downarrow (r \circ g)_* & & \downarrow g_* & \downarrow g_* \\
H_k(X, A) & \cong & H_k(\text{Cone}(i: A \to X) \setminus \{\ast\}, \text{Cone}(A) \setminus \{\ast\}) & \cong H_k(\text{Cone}(i: A \to X)).
\end{array}
$$

We make the following explanations, clarifications and observations:

1. By Lemma 24.9 (2) and (3) we can and will view $\text{Cone}(A)$ and $X$ as subsets of $\text{Cone}(i: A \to X)$.
2. All maps that are not specified explicitly are inclusion induced maps.
3. The maps $\ast$ are the natural maps from absolute to relative homology.
4. Note that by Lemma 24.9 (6) there exists a natural deformation retraction from $\text{Cone}(i: A \to X) \setminus \{\ast\}$ to $X$. We denote by $r: \text{Cone}(i: A \to X) \setminus \{\ast\} \to X$ the corresponding retraction. Note that it restricts to a retraction from $\text{Cone}(A) \setminus \{\ast\}$ to $A$.
5. By the proof of Lemma 46.16 we know that the four maps at the bottom, shown in blue, are isomorphisms.
6. By (5) together with our hypothesis (*) we know that there exists a closed oriented $k$-dimensional smooth manifold $W$ and a map $g: W \to \text{Cone}(i: A \to X)$ such that $\ast(g_*(\left[ W \right]))$ equals the image of our given class $\varphi$ in the central red group $H_k(\text{Cone}(i: A \to X), \text{Cone}(A))$.
7. Since $\text{Cone}(i: A \to X) \setminus \{\ast\}$ and $\text{Cone}(A) \setminus A$ are open subsets that cover $\text{Cone}(i)$ we obtain from Exercise 6.36 that there exist two compact codimension-zero submanifolds $M$ and $N$ of $W$ such that $M \cup N = W$, $M \cap N = \partial M = \partial N$, such that $M \subset g^{-1}(\text{Cone}(i: A \to X) \setminus \{\ast\})$ and such that $N \subset g^{-1}(\text{Cone}(A) \setminus A)$. 
(8) By (7) we have \( g(N) \subseteq \text{Cone}(A) \) and \( g(\partial M) \subseteq \text{Cone}(A) \). This implies that the two maps in relative homology denoted by \( g_* \), namely the diagonal map to the left and the vertical map in the middle, actually do exist.

(9) By Lemma 68.12 (2) we know that the images of \([M]\) and \([W]\) in \(H_k(W,N)\) agree.

It is clear that the diagram commutes. It is now straightforward to verify that the compact oriented \( n \)-dimensional smooth manifold \( M \) together with the map \( r \circ g \colon (M, \partial M) \to (X, A) \) has all the desired properties.

![Figure 1084](image)

**Figure 1084.** Illustration for the proof of Proposition 70.4 (2).

### 70.4. Representing homology classes by submanifolds I.

In the previous sections we studied the following definition.

**Definition.** Let \( X \) be a topological space, let \( A \subset X \) be a subset and let \( \varphi \in H_k(X, A) \) be a homology class. We say \( \varphi \) can be realized by a smooth manifold if there exists a compact oriented \( k \)-dimensional smooth manifold \( N \) and a map \( f \colon (N, \partial N) \to (X, A) \) such that \( f_*(|[N]|) = \varphi \).

If the topological space \( X \) we are interested in is in fact a smooth manifold it is natural to ask whether one can actually find maps \( f \) that are smooth embeddings. This leads us to the following definition.

**Definition.** Let \( M \) be a smooth manifold and let \( A \) be a union of components of \( \partial M \).

1. Let \( N \) be a compact oriented proper \( k \)-dimensional submanifold of \( M \) with \( \partial N \subset A \). By a slight abuse of notation, we denote by \( [N] \) the image of the fundamental class \( [N] \) under the inclusion induced map \( H_k(N, \partial N) \to H_k(M, A) \).

2. We say that a homology class \( \varphi \in H_k(M, A) \) is represented by a submanifold if there exists a compact oriented proper \( k \)-dimensional submanifold \( N \) with \( \partial N \subset A \) such that \([N] = \varphi\).

### Examples.

1. We first consider the 2-dimensional torus \( T = S^1 \times S^1 \). Under the usual isomorphism \( H_1(S^1 \times S^1) \cong \mathbb{Z}^2 \) the basis element \((1,0)\) is represented by the oriented submanifold \( S^1 \times \{1\} \) and the basis element \((0,1)\) is represented by the oriented submanifold \( \{1\} \times S^1 \). This situation is illustrated in Figure 1086 on the left.

2. We consider the surface \( \Sigma_2 \) of genus 2. As in Figure 220 we view \( \Sigma_2 \) as the connected sum \( T \# T \) of two tori. If we use the calculation on page 1727 to determine an isomorphism \( H_1(\Sigma_2) \cong \mathbb{Z}^4 \), then it follows from (1) that the basis elements are
represented by the submanifolds $a_1, b_1, a_2, b_2$ that are illustrated in Figure 1086.

(3) Let $L = L_1 \cup \cdots \cup L_m$ be an $m$-component link in $S^3$. Those readers who solved Exercise 68.6 will see that the $m$ meridians represent a basis for $H_1(S^3 \setminus L) \cong \mathbb{Z}^m$ and that any choice of $m - 1$ tori $S^1 \times L_i$ represent a basis for $H_2(S^3 \setminus L) \cong \mathbb{Z}^{m-1}$.

(4) Any zero class $0 \in H_k(M)$ is represented by the empty submanifold.

(5) We consider the complex projective space $\mathbb{C}P^n$. We saw on page 935 that for $k \leq n$ the map

$$\mathbb{C}P^k \to \mathbb{C}P^n \quad [v_0 : \ldots : v_k] \mapsto [v_0 : \ldots : v_k : 0 : \ldots : 0]$$

is a smooth embedding. We use this map to view $\mathbb{C}P^k$ as a submanifold of $\mathbb{C}P^n$. It follows from the discussion on page 1262 and the natural isomorphism of Proposition 48.4 that

$$H_k(\mathbb{C}P^n) \cong \left\{ \begin{array}{ll} \mathbb{Z} \cdot [\mathbb{C}P^i], & \text{if } k = 2i \text{ for some } i \in \{0, \ldots, n\}, \\ 0, & \text{otherwise.} \end{array} \right.$$
Put differently, the generators of the non-trivial homology groups of the complex projective space $\mathbb{C}P^n$ are represented by the complex projective spaces $\mathbb{C}P^i$ with $i = 0, \ldots, n$.

(6) Let $M$ be a compact oriented connected $k$-dimensional smooth manifold. By Theorem 66.8 we have $H_n(M, \partial M) = \mathbb{Z} \cdot [M]$. It follows from Lemma 68.8 that the classes $\pm [M]$ are represented by $M$, viewed as its own submanifold, equipped with the two possible orientations. Since $M$ is connected we know by Exercise 6.24 that $M$ admits no other non-empty $n$-dimensional proper submanifold. Thus we see that the classes $k \cdot [M]$ with $k \not\in \{\pm 1\}$ are not represented by submanifolds.

For completeness’ sake we state the following lemma.

**Lemma 70.10.** Let $M$ be a smooth manifold, let $A$ be a union of components of $\partial M$ and let $\varphi \in H_k(M, A)$. If $N$ is a proper submanifold that represents $\varphi$, then $\partial N$ represents the class $\partial_k(\varphi) \in H_{k-1}(A)$ where $\partial_k : H_k(M, A) \to H_{k-1}(A)$ is the connecting homomorphism of the long exact sequence of the pair $(M, A)$.

**Proof (⋆).** We consider the following diagram:

$$
\begin{array}{ccc}
H_k(M, A) & \xrightarrow{\partial_k} & H_{k-1}(A) \\
\varphi \mapsto \partial_k(\varphi) & & \downarrow \psi \\
H_k(N, \partial N) & \xrightarrow{\partial_k} & H_{k-1}(\partial N)
\end{array}
$$

where the horizontal maps are given by the connecting homomorphisms and where the vertical maps are induced by the inclusion maps. By Proposition 43.15 we know that the connecting homomorphism are natural, in other words, the diagram commutes. The statement now follows from Proposition 68.9.

We are naturally lead to the following question which can be viewed as a refinement of Question 70.1 in the context of smooth manifolds.

**Question 70.11.** Let $M$ be a smooth manifold and let $A$ be a union of components of $\partial M$. For which $k \in \mathbb{N}_0$ can homology classes in $H_k(M, A)$ be represented by submanifolds?

The following proposition, which can be viewed as analogue of Proposition 70.4 (2) says that the relative problem is equivalent to the absolute problem.

**Proposition 70.12.** Let $k \in \mathbb{N}$. Suppose that for every (orientable) $n$-dimensional smooth manifold every homology class in $H_k(M)$ can be represented by a submanifold. Then also for every (orientable) $n$-dimensional smooth manifold $M$ and every union $A$ of components of $\partial M$ every relative homology class in $H_k(M, A)$ can be represented by a submanifold.

**Proof (⋆).** Let $A$ be the union of some components of $\partial M$ and let $\sigma \in H_k(M, A)$. Let $M'$ be a second copy of $M$. As on page 1163 we consider the double of $M$ along $A$, i.e. we consider $D_A M = M \cup_{A=M'} M'$. Note that by Lemma 44.12 we know that $D_A M$ is an (orientable) $n$-dimensional smooth manifold which contains $A$ as a submanifold. Next let $D : H_k(M, A) \to H_k(D_A M)$ be the doubling homomorphism given by Lemma 44.16.
By our hypothesis there exists a closed oriented submanifold $W$ of $D_A M$ such that $[W] = D(\sigma)$. It follows from the Transversality Theorem 9.10 and Proposition 42.5 that we can arrange that $W$ is transverse to $A$. Now we set $N := W \cap M$. It follows from Lemma 6.5 that $N$ is a proper submanifold of $W$. It remains to prove the following claim.

Claim. We have $[N] = \sigma \in H_k(M, A)$.

We denote by $i: W \to D_A M$ the inclusion map. Now we consider the following diagram

$$
\begin{array}{ccc}
H_k(N, \partial N) & \xrightarrow{\alpha} & H_k(W, W \setminus \hat{N}) \\
\downarrow{i_*} & & \downarrow{i_*} \\
H_k(M, A) & \xrightarrow{\gamma} & H_k(D_A M, M')
\end{array}
$$

Here $\alpha, \beta, \gamma$ and $\delta$ are the obvious maps. Now we make the following observations:

- $i_*(\alpha([W])) = D(\sigma)$ by choice of $W$
- $i_*(\beta([W])) = \delta(D(\sigma))$ since the diagram commutes
- $i_*(\gamma([N])) = \gamma(\sigma)$ by Lemmas 68.12 and 44.16 (3)
- $\gamma(i_*(\gamma([N]))) = \gamma(\sigma)$ since the diagram commutes
- $i_*(\gamma([N])) = \sigma$ since $\gamma$ is an isomorphism by the Excision Theorem 44.10.

![Figure 1088. Illustration for the proof of Proposition 70.12](image)

One obvious approach to Question 70.11 is as follows: in Section 70.1 we already saw that in many cases, given a class $\varphi \in H_k(M, A)$, there exists a compact oriented $k$-dimensional smooth manifold $N$ together with a map $f: (N, \partial N) \to (X, A)$ such that $f_*(\gamma([N])) = \varphi$. The question now is the following: can we replace $f$ by some proper embedding? The following proposition, which we will prove in Section 70.6 addresses this issue:

**Proposition 70.13.** Let $n \in \mathbb{N}$, let $M$ be an $n$-dimensional smooth manifold and let $A$ be a union of components of $\partial M$. Furthermore let $N$ be a compact oriented $k$-dimensional smooth manifold and let $\varphi: (N, \partial N) \to (M, A)$ be a map.

1. If $n > 2k$, then $\varphi: (N, \partial N) \to (M, A)$ is homotopic, as a map of pairs of topological spaces, to a proper embedding $\psi: (N, \partial N) \to (M, A)$. In particular by Proposition 8.1, (2) $\psi(N)$ is a proper submanifold of $M$ and by Proposition 43.17 we have $\varphi_*(\gamma([N])) = [\psi(N)] \in H_k(M, A)$.

2. If $n = 2k$, then there exists a compact oriented proper $k$-dimensional submanifold $W$ of $N$ with $\partial W \subset A$ such that $\varphi_*(\gamma([N])) = [W] \in H_k(M, A)$. 

It is worth stating the following immediate corollary to Propositions 70.2 and 70.13.

**Corollary 70.14.** Let $M$ be an $m$-dimensional smooth manifold with $m \geq 2$ and let $A$ be the union of some components of $\partial M$. Given any homology class in $\sigma \in H_1(M, A)$ there exists a compact oriented proper 1-dimensional submanifold $P$ with $\partial P \subset A$ such that $[P] = \sigma$.

**Example.** Let $M$ be a 2-dimensional smooth manifold and let $\sigma \in H_1(M)$ be a homology class. For fun we illustrate in Figure 1089 the three main steps in the proof of Proposition 70.13 in this special case.

![Figure 1089](image)

Next we want to consider the question whether we can represent a homology class by a connected submanifold. For tori we have the following ambiguous answer.

**Lemma 70.15.** Let $T = S^1 \times S^1$ be the torus. We denote by $x = [S^1 \times \{1\}]$ and $y = \{1\} \times S^1$ the obvious basis for $H_1(T)$. A non-zero class $r \cdot x + s \cdot y$ can be represented by a connected submanifold if and only if $\gcd(r, s) = 1$.

![Figure 1090](image)

**Proof.** We, i.e. you, will provide the proof in Exercise 70.4. For fun we will deal with the analogous problem for surfaces of higher genus in Exercise 70.5.

The following proposition, which can be viewed as an analogue of Proposition 70.4 (1), shows that in most settings we will not have troubles finding connected submanifolds. As for the previous proposition we postpone the proof to Section 70.7.

**Proposition 70.16.** Let $n \in \mathbb{N}$, let $M$ be a connected $n$-dimensional smooth manifold and let $A$ be a union of components of $\partial M$. Furthermore let $N$ be a compact oriented
**Corollary 70.17.** Let \( M \) be an \( n \)-dimensional smooth manifold with \( n \geq 4 \) and let \( A \subset \partial M \) be a union of boundary components. Every class in \( H_2(M, A) \) is represented by a connected submanifold.

**Remark.** Let \( M \) be a compact 4-dimensional smooth manifold and let \( \sigma \in H_2(M) \). By Corollary 70.17 it makes sense to define the *genus* of \( \sigma \):

\[
\text{genus}(\sigma) := \text{minimal genus of a closed oriented connected smooth submanifold } \Sigma \text{ of } M \text{ with } [\Sigma] = \sigma.
\]

As an example let us consider the 4-dimensional smooth manifold \( \mathbb{C}P^2 \). By the discussion on page 1761 we know that \( H_2(\mathbb{C}P^2) = \mathbb{Z} \cdot [\mathbb{C}P^1] \). Let \( n \in \mathbb{Z} \). We consider

\[
W_n := \{ [x : y : z] \in \mathbb{C}P^2 \mid x^n + y^n + z^n = 0 \}.
\]

In Exercise 12.3 we showed that \( W_n \) is a closed 1-dimensional complex submanifold of the 2-dimensional complex manifold \( \mathbb{C}P^2 \). In particular this shows that \( W_n \) is a closed 2-dimensional submanifold of \( \mathbb{C}P^2 \). In Exercise 94.6 we will show that \( [W_n] = n \cdot [\mathbb{C}P^1] \). As is pointed out in [GoS99, p. 38], it is a consequence of the "adjunction formula", that \( W_n \) is diffeomorphic to the surface of genus \( \frac{1}{2}(n-1)(n-2) \). In particular we have the inequality

\[
\text{genus}(n \cdot [\mathbb{C}P^1]) \leq \frac{1}{2}(n-1)(n-2).
\]

The Thom Conjecture predicted that equality holds. This conjecture was proved in 1994 by Peter Kronheimer and Tom Mrowka [KrM94] using "Seiberg-Witten Theory". In general though it is still a very difficult problem to determine the genus of the homology class of a given smooth manifold.

Corollary 70.17 suffers from the rather annoying defect that it does not apply to the case of 3-dimensional smooth manifolds. Perhaps rather surprisingly this gets taken care of by coming "from the other direction", namely this case gets taken care of by the following proposition.

**Proposition 98.4.** Let \( M \) be a compact orientable \( n \)-dimensional smooth manifold and let \( A \subset \partial M \) be a union of boundary components. Every class in \( H_{n-1}(M, A) \) can be represented by a submanifold.

**Sketch of proof.** As the number already suggests, we will not prove this statement in this chapter. In the following we will just provide the flavor of the argument which is meant to serve as an amuse-bouche. For simplicity we assume that \( M \) is closed. Now suppose we are given a homology class \( \sigma \in H_{n-1}(M) = H_{n-1}(M; \mathbb{Z}) \). By the Poincaré Duality Theorem 88.1 we have an isomorphism \( \text{PD}_M : H_{n-1}(M; \mathbb{Z}) \to H^1(M; \mathbb{Z}) \). Thus
we obtain the Poincaré dual $\text{PD}_M(\sigma) \in H^1(M; \mathbb{Z})$. We will see that cohomology classes in $H^1(M; \mathbb{Z})$ give rise to smooth maps $f: M \to K(\mathbb{Z}, 1) = S^1$. (Here $K(G, n)$ stands for an Eilenberg-Maclane space of type $K(G, n)$, the precise definition is irrelevant right now, except that in the discussion below it indicates some similarities between initially quite different looking arguments.) The desired submanifold is then given by the preimage of a regular value of $f$.

The analogue for codimension-two homology classes also holds:

**Proposition 70.17.** Let $M$ be a compact orientable $n$-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components. Every class in $H_{n-2}(M, A)$ can be represented by a submanifold.

**Sketch of proof.** The logic of the proof is somewhat similar to the idea behind the proof of Proposition 98.4. This time the Poincaré Duality Theorem 88.1 gives us an isomorphism $\text{PD}_M: H_{n-2}(M; \mathbb{Z}) \to H^2(M; \mathbb{Z})$. Thus the given homology class in $H_{n-2}(M; \mathbb{Z})$ corresponds to a cohomology class in $H^2(M; \mathbb{Z})$. We will see that such cohomology classes give rise to maps $f: M \to K(\mathbb{Z}, 2) = \mathbb{C}P^\infty$. Since $M$ is compact we obtain a map $f: M \to \mathbb{C}P^m$ for sufficiently large $m$. In this occasion the desired submanifold of $M$ is given by the preimage of $\mathbb{C}P^{m-1} \subset \mathbb{C}P^m$.

Optimistically one might hope that the pattern of the previous two propositions extends to codimension-three homology classes. But Statement (2) of the following theorem shows that this is not the case.

**Theorem 70.18. (Thom’s Theorem III)**

1. Let $M$ be a compact orientable $n$-dimensional smooth manifold and let $A$ be a union of boundary components. Given $k \leq 6$ with $k < n$ every class in $H_k(M, A)$ can be represented by a submanifold.

2. There exists a 10-dimensional closed smooth manifold$^{1048}$ and a class in $H_7(M)$ that cannot be represented by a submanifold.

**Proof.**

1. First let us deal with the case that $A = \emptyset$. In this case, for $k \leq 5$ the statement can be found in [Tho54a, Théorème 6] and also in [Tho54b, Théorème II.27]. The statement for $k = 6$ can be found in the footnote on page 173 of [Tho07]. The relative case now follows from the above together with Proposition 70.12.

2. This statement was proved by Christian Bohr, Bernhard Hanke and Dieter Kotschick, see [BHK02, Theorem 1]. Their work builds on earlier work of René Thom [Tho54b, p. 62f].

For completeness’ sake we now also discuss homology with $\mathbb{F}_2$-coefficients. Given a compact (possibly non-orientable) proper $k$-dimensional submanifold $N$ of a manifold $M$.

---

$^{1048}$It follows from Statement (1) together with Propositions 98.4 and ?? that for a compact orientable $n$-dimensional smooth manifold of dimension $n \leq 9$ any homology class of dimension $< n$ can be represented by a submanifold. Thus the example in Statement (2) is “dimensionally minimal”.
we denote by \([N]_{\mathbb{F}_2}\) the image of the \(\mathbb{F}_2\)-fundamental class \(N\) under the inclusion induced map \(H_k(N, \partial N; \mathbb{F}_2) \to H_k(M, \partial M; \mathbb{F}_2)\). We say \(N\) represents the homology class \([N]_{\mathbb{F}_2}\).

Surely it does not come as a surprise that we have the following analogue of Corollaries 70.14 and 70.17 for \(\mathbb{F}_2\)-coefficients. We will skip the proof since it is essentially the same.

**Proposition 70.19.** Let \(M\) be an \(n\)-dimensional smooth manifold and let \(A \subset \partial M\) be a union of boundary components.

1. If \(n \geq 2\), then every class in \(H_1(M, A; \mathbb{F}_2)\) can be represented by a submanifold.
2. If \(n \geq 4\), then every class in \(H_2(M, A; \mathbb{F}_2)\) can be represented by a connected submanifold.

The following proposition is an analogue of Proposition 98.4

**Proposition ??:** Let \(M\) be a compact \(n\)-dimensional smooth manifold and let \(A\) be a union of boundary components. Every class in \(H_{n-1}(M, A; \mathbb{F}_2)\) can be represented by a submanifold.

**Remark.** This result will have its moment of glory when we will employ it in our proof, provided in Section 117.5, that \(\pi_{n+2}(S^n) \cong \mathbb{Z}_2\) for \(n \geq 3\).

**Sketch of proof.** The proof of this proposition is quite similar to the proof of Proposition 98.4. The Poincaré Duality Theorem [88,6] with \(\mathbb{F}_2\)-coefficients gives us an isomorphism \(PD_M: H_{n-1}(M; \mathbb{F}_2) \to H^1(M; \mathbb{F}_2)\). Thus given the homology class in \(H_{n-1}(M; \mathbb{F}_2)\) corresponds to a cohomology class in \(H^1(M; \mathbb{F}_2)\). We will see that such cohomology classes give rise to maps \(f: M \to K(\mathbb{F}_2, 1) = \mathbb{R}P^\infty\). Since \(M\) is compact we obtain a map \(M \to \mathbb{R}P^m\) for sufficiently large \(m\). Now the desired submanifold is given by the preimage of \(\mathbb{R}P^{m-1} \subset \mathbb{R}P^m\). \(\blacksquare\)

**Remark.** Note that this author is not aware of an analogue of Proposition 98.4.

Finally let us see once again what René Thom has to say:

**Theorem 70.20. (Thom’s Theorem IV)** Let \(M\) be a compact \(n\)-dimensional smooth manifold and let \(A\) be a union of boundary components.

1. If \(n \leq 5\), then any class in \(H_{n-2}(X, A; \mathbb{F}_2)\) can be represented by a submanifold.
2. If \(n \leq 7\), then any class in \(H_{n-3}(X, A; \mathbb{F}_2)\) can be represented by a submanifold.
3. For \(k \leq \lfloor \frac{n}{2} \rfloor\) any class in \(H_k(X, A; \mathbb{F}_2)\) can be represented by a submanifold.

**Proof.** In the case \(A = \emptyset\) the three statements are precisely the content of [Tho07, Théorème II.26]. The relative case follows from the \(\mathbb{F}_2\)-analogue of Proposition 70.12.

Finally note that Statement (3) also follows from Theorem 70.5 together with the \(\mathbb{F}_2\)-analogue of Proposition 70.13 (2). \(\blacksquare\)

We conclude this section with the following remark.

**Remark.** As we already mentioned on page 1751, later in Chapter 86 we will introduce the notion of an orientation of a topological manifold and in Chapter 87 we will introduce the notion of the fundamental class \([N] \in H_n(N, \partial N)\) of a compact oriented \(n\)-dimensional topological manifold \(N\). Thus it makes sense to ask which homology classes of a given
topological manifold can be represented by submanifolds. This question is discussed in [FNOP19].

In the remainder of this chapter we will provide the proofs of Proposition 70.13 and 70.16.

70.5. **Rearranging maps from smooth manifolds**. Let \((X, A)\) be a pair of topological spaces. In this section we will state and prove a proposition which allows us to replace certain compact oriented smooth manifolds \(M\) and maps \(f: (M, \partial M) \to (X, A)\) by a different compact oriented smooth manifold \(N\) together with a map \(g: (N, \partial N) \to (X, A)\) such that \(f_*([M]) = g_*([N])\). This procedure will come in handy in the proofs of Proposition 70.13 and 70.16.

The following definition is a special case of a more general concept introduced on page 284.

**Definition.** Let \(M\) be a compact \(n\)-dimensional smooth manifold. We say \(M\) is decomposed into submanifolds \(A\) and \(B\) if the following conditions hold:

1. \(M = A \cup B\).
2. \(A\) and \(B\) are both compact \(n\)-dimensional submanifolds of \(M\).
3. We have \(A \cap B = \partial_0 A = \partial_0 B\).

![Figure 1091](image)

Now we can state the one result of this section.

**Proposition 70.21.** Let \(M\) and \(\tilde{M}\) be two compact oriented \(n\)-dimensional smooth manifolds. Suppose that \(M\) is decomposed into two submanifolds \(A\) and \(B\) and that \(\tilde{M}\) is decomposed into two submanifolds \(\tilde{A}\) and \(\tilde{B}\). We equip \(A \cap B\) and \(\tilde{A} \cap \tilde{B}\) with the orientation coming from \(A\) respectively \(\tilde{A}\). Suppose that we are given an orientation-preserving diffeomorphism \(\Theta: A \cap B \to \tilde{A} \cap \tilde{B}\). Next we set

\[N := (A \cup \tilde{B})/x \sim \Theta(x) \text{ for } x \in A \cap B\]

and \(\tilde{N} := (\tilde{A} \cup B)/y \sim y \text{ for } y \in A \cap B\).

Note that it follows from Proposition 8.15 that \(N\) and \(\tilde{N}\) are both compact oriented \(n\)-dimensional smooth manifolds such that the obvious maps \(A \to N\) and \(\tilde{A} \to \tilde{N}\) are orientation-preserving embeddings. Next let \((X, S)\) be a pair of topological space and furthermore let \(f: (M, \partial M) \to (X, S)\) and \(\tilde{f}: (\tilde{M}, \partial \tilde{M}) \to (X, S)\) be two maps such that we have \(\tilde{f} \circ \Theta = f: A \cap B \to X\). We define

\[g: N = (A \cup \tilde{B})/\sim \to X \quad \text{and} \quad \tilde{g}: \tilde{N} = (\tilde{A} \cup B)/\sim \to X\]

\[ [P] \mapsto \begin{cases} f(P), & \text{if } P \in A, \\ \tilde{f}(P), & \text{if } P \in \tilde{B} \end{cases} \quad \text{and} \quad [P] \mapsto \begin{cases} \tilde{f}(P), & \text{if } P \in \tilde{A}, \\ f(P), & \text{if } P \in B. \end{cases} \]

With this notation we have

\[f_*([M]) + \tilde{f}_*([\tilde{M}]) = g_*([N]) + \tilde{g}_*([\tilde{N}]) \in H_n(X, S).\]
We pick a fundamental cycle $\mu \in C_{n-1}(A \cap B)$ for the closed oriented $(n-1)$-dimensional smooth manifold $A \cap B$. We consider the map

$$C_n(A, \partial A) \xrightarrow{\partial_n} C_{n-1}(\partial_0 A \sqcup \partial_1 A) \xrightarrow{\approx} C_{n-1}(A \cap B) \oplus C_{n-1}(\partial_1 A) \xrightarrow{=} C_{n-1}(A \cap B).$$

By Corollary [68.10](#corollary) we know that there exists a singular chain $\nu_A \in C_n(A)$ such that $\nu_A$ represents a fundamental cycle in $C_n(A, \partial A)$ and such that $\omega_A(\nu_A) = \mu$. With the same notation we also obtain some $\nu_B \in C_n(B)$ with $\omega_B(\nu_B) = \mu$.

Next we consider $\tilde{\mu} := \Theta_*(\mu) \in C_{n-1}(\tilde{A} \cap \tilde{B})$. As above we pick corresponding singular chains $\tilde{\nu}_A \in C_n(\tilde{A})$ and $\tilde{\nu}_B \in C_n(\tilde{B})$. Now we see that we have the following equalities in $H_n(X, S)$:

$$f_*([M]) + \tilde{f}_*([\tilde{M}]) = f_*(\nu_A - \nu_B) + \tilde{f}_*(\tilde{\nu}_A - \tilde{\nu}_B) = [f_*(\nu_A) - \tilde{f}_*(\tilde{\nu}_A)] + \tilde{f}_*(\tilde{\nu}_B) - f_*(\nu_B)$$

By definition of $g$ and $\tilde{g}$

$$= g_*(\nu_A) - g_*(\tilde{\nu}_B) + \tilde{g}_*(\tilde{\nu}_A) - g_*(\nu_B) = \tilde{g}_{\star}(\tilde{\nu}_A - \tilde{\nu}_B) = [\tilde{N}] = [N].$$

Figure 1092. Illustration for Proposition [70.21](#proposition)

---

1049 It follows from $\tilde{f} \circ \Theta = f$ that both maps are continuous.
70.6. **Proofs of Proposition 70.13** For the reader’s convenience we recall the statement of Proposition 70.13.

**Proposition 70.13** Let \( n \in \mathbb{N} \), let \( M \) be an \( n \)-dimensional smooth manifold and let \( A \) be a union of components of \( \partial M \). Furthermore let \( N \) be a compact oriented \( k \)-dimensional smooth manifold and let \( \varphi : (N, \partial N) \to (M, A) \) be a map.

1. If \( n > 2k \), then \( \varphi : (N, \partial N) \to (M, A) \) is homotopic, as a map of pairs of topological spaces, to a proper embedding \( \psi : (N, \partial N) \to (M, A) \). In particular \( \psi(N) \) is a proper submanifold of \( M \) and we have \( \varphi_*(\pi_1[N]) = [\psi(N)] \in H_k(M, A) \).
2. If \( n = 2k \), then there exists a compact oriented proper \( k \)-dimensional submanifold \( W \) of \( N \) with \( \partial W \subset A \) such that \( \varphi_*([N]) = [W] \in H_k(M, A) \).

![Figure 1094. Illustration for the proof of Proposition 70.13](image)

**Proof.** Let \( n \in \mathbb{N} \), let \( M \) be an \( n \)-dimensional smooth manifold and let \( A \) be a union of components of \( \partial M \). Furthermore let \( N \) be a compact oriented \( k \)-dimensional smooth manifold and let \( \varphi : (N, \partial N) \to (M, A) \) be a map.

First let us consider the case \( n > 2k \). In this case it follows from Theorem 9.15 (3) that \( \varphi : (N, \partial N) \to (M, A) \) is homotopic, as a map of pairs of topological spaces, to a proper embedding \( \psi : (N, \partial N) \to (M, A) \). It follows from Proposition 8.1 (2) that \( \psi(N) \) is a proper submanifold of \( M \) and that \( \psi : N \to \psi(N) \) is a diffeomorphism. Thus we see that

\[
\varphi_*([N]) = \psi_*([N]) = [\psi(N)] \in H_k(M, A).
\]

Proposition 43.17 since \( \psi \) is a diffeomorphism

Now let us deal with the much more subtle case \( n = 2k \). From Theorem 9.15 (2) we now obtain that the map \( \varphi \) is homotopic, as a map of pairs of topological spaces, to a proper immersion \( \psi : N \to M \) which has furthermore the property that there exist points \( P_1, \ldots, P_m \) in \( M \setminus \partial M \) with the following properties:

1. For each \( i \in \{1, \ldots, m\} \) the preimage \( \psi^{-1}(P_i) \) consists of precisely two points \( Q_i^\pm \) which furthermore satisfy that \( \psi_*(T_{Q_i^+} N) + \psi_*(T_{Q_i^-} N) = T_{P_i}(M) \).

2. The restriction of \( \psi \) to \( N \setminus \{Q_i^+, \ldots, Q_m^+\} \) is injective.

In the following we write

\[
X := \{(x, 0) \in B^{2k} \mid x \in B^k\} \quad \text{and} \quad Y := \{(0, y) \in B^{2k} \mid y \in B^k\}.
\]
We view $X$ and $Y$ as submanifolds of $\overline{B}^{2k}$. We equip $X$ and $Y$ with the obvious orientation. It follows easily from Proposition 8.1 (2) together with Lemma 6.52 (1) that we can find the following:

1. Disjoint $k$-dimensional submanifolds $C^{\pm}_{1}, \ldots, C^{\pm}_{m}$ of $N$ such that for each $i \in \{1, \ldots, m\}$ we have $Q_{i}^{\pm} \in \hat{C}_{i}^{\pm} = C_{i}^{\pm}$. Note that the restriction of $\psi$ to any $\hat{C}_{i}^{\pm}$ is in fact a smooth embedding.

2. Disjoint embeddings $f_{1}, \ldots, f_{m}: \overline{B}^{2k} \to M \setminus \partial M$ such that for each $i \in \{1, \ldots, m\}$ we have
   \[
   \psi(C_{i}^{+}) = f_{i}(X), \quad \psi(C_{i}^{-}) = f_{i}(Y), \quad \text{and} \quad f_{i}(\overline{B}^{2k}) \cap \psi(N) = f_{i}(X) \cup f_{i}(Y).
   \]
Furthermore, after possibly precomposing the maps $f_{i}$ with reflections in hyperplanes we can assume that the maps $X \to f_{i}(X) \leftarrow C_{i}^{+}$ and $Y \to f_{i}(Y) \leftarrow C_{i}^{-}$ are orientation-preserving.

**Claim.** There exists a proper smooth embedding $\Theta: [0, 1] \times S^{k-1} \to \overline{B}^{2k}$ with the following three properties:

1. For $t \in [0, \frac{1}{4}]$ and $z \in S^{k-1}$ we have $\Theta(t, z) = ((1 - t)z, 0) \in \mathbb{R}^{k} \times \mathbb{R}^{k}$. Furthermore the map $\Theta_{0}: \{0\} \times S^{k-1} \to S^{k-1} \times \{0\}$ is orientation-preserving.

2. For $t \in [\frac{1}{4}, 1]$ and $z \in S^{k-1}$ we have $\Theta(t, z) = (0, t \cdot z) \in \mathbb{R}^{k} \times \mathbb{R}^{k}$. Furthermore the map $\Theta_{0}: \{1\} \times S^{k-1} \to \{0\} \times S^{k-1}$ is orientation-reversing.

To prove the claim first note that, using Lemma 6.13 one can easily find a smooth function $\mu: [0, 1] \to [0, 1]$ such that $\mu(t) = t$ for $t \in [0, \frac{1}{4}]$, and such that $\mu(t) = 1$ for $t \in [\frac{1}{4}, 1]$ and such that $\mu'(t) > 0$ for any $t \in (0, \frac{1}{4})$. We leave it to the reader to verify that the following map has all the desired properties:

\[
\Theta: [0, 1] \times S^{k-1} \to \overline{B}^{2k} \subset \mathbb{R}^{k} \times \mathbb{R}^{k}
\]

\[
(t, z) \mapsto ((1 - \mu(t)) \cdot z, (1 - \mu(1 - t)) \cdot z).
\]

**Figure 1095**

Next we set $Z := \Theta([0, 1] \times S^{k-1})$ and we set

\[
W := \psi\left(\bigcup_{i=1}^{m} (C_{i}^{+} \cup \hat{C}_{i}^{-})\bigcup \bigcup_{i=1}^{m} f_{i}(Z)\right) \subset \mathbb{N}.
\]

We leave it to the reader to verify that $W$ is in fact a compact proper $k$-dimensional submanifold of $M$ with $\partial W \subset A$ which can be oriented in such a way that the embedding $\psi: \mathbb{N} \to W$ is orientation-preserving. It remains to prove the following claim.

**Claim.** We have $\varphi_{*}([N]) = [W] \in H_{k}(X, A)$. 

As usual we denote by \([-W]\) the same smooth manifold but with the opposite orientation. By Lemma \[68.8\] we have \([-W]=-[W]\). Thus it suffices to show that \(\varphi_*([N])+[-W]=0\). Now we perform the following calculation:

by Proposition \[43.17\] since \(\psi\) is homotopic to \(\varphi\)

\[
\varphi_*([N])+[-W] = \psi_*([N])+[-W] = \psi_*\left(\left(\hat{N} \cup \bigcup_{i=1}^{m} (C^+_i \cup C^-_i)\right)\right) + \left[-\psi(\hat{N}) \cup \bigcup_{i=1}^{m} f_i(Z)\right] \\
= \left(\psi \cup \psi\right)_*\left(\left(\hat{N} \cup \partial_0 \hat{N} = \partial_0 \hat{N} - \hat{N}\right)\right) + \sum_{i=1}^{m} \left(\psi \cup f_i\right)_*\left((Q^+_i \cup Q^-_i) \cup Z\right) = 0.
\]

by Corollary \[9.14\] that it follows from our hypothesis \(n-k \geq 2\) that such \(\gamma\) always exists.

Next we write \(D := \{(x,0) \in \mathbb{R}^k \times \mathbb{R}^{n-1-k} | x \in \overline{B}^k\} \subset \overline{B}^{n-1}\). Once again we challenge the courageous reader to show, by using a suitable variation on the Tubular Neighborhood Theorem \[8.24\] that there exists an embedding \(\Phi: \overline{B}^{n-1} \times C \to M\) such that \(\Phi(\overline{B}^{n-1} \times C) \cap N_0 = \Phi(D \times \{P_0\})\) and such that \(\Phi(\overline{B}^{n-1} \times C) \cap N_1 = \Phi(D \times \{P_1\})\).

Using Exercise \[6.9\] one can easily find a smooth embedding \(\Theta: S^{k-1} \times [0,1] \to \overline{B}^{k-1} \times C\) with the following two properties:

(a) For \(z \in S^{k-1}\) and \(t \in [0, \frac{1}{2}]\) we have \(\Theta(z,t) = ((1-t) \cdot z, P_0)\).
(b) For \(z \in S^{k-1}\) and \(t \in [\frac{3}{4}, 1]\) we have \(\Theta(z,t) = (t \cdot z, P_1)\).

We set \(Z := \Theta(S^{k-1} \times [0,1])\).

There are now two cases to consider.
Case (1) Among the two maps $\Phi: D \times \{P_0\} \to N_0$ and $\Phi: D \times \{P_1\} \to N_1$ one is orientation-preserving and one is orientation-reversing. In this case we set

$$N_0 \#_{\gamma} N_1 := (N_0 \setminus \Phi(D \times \{P_0\})) \cup (N_1 \setminus \Phi(D \times \{P_1\})) \cup \Phi(D \times C).$$

Case (2) If both maps $\Phi: D \times \{P_0\} \to N_0$ and $\Phi: D \times \{P_1\} \to N_1$ are orientation-preserving or if both are orientation-reversing then we add a “half-twist” to get us back into the game. More precisely, we consider the map

$$\Omega: D \times C \to \mathbb{B}^{n-1} \times C,$$

$$(x_1, x_2, \ldots, x_k, (0, 0), \gamma(t)) \mapsto ((\cos(t) \cdot x_1, x_2, \ldots, x_k), (\sin(t) \cdot x_1, 0), \gamma(t)).$$

Note that $\Omega$ is the identity on $D \times \{P_0\}$ and that $\Omega$ restricts to an orientation-reversing self-diffeomorphism of $D \times \{P_1\}$. Now we set

$$N_0 \#_{\gamma} N_1 := (N_0 \setminus \Phi(D \times \{P_0\})) \cup (N_1 \setminus \Phi(D \times \{P_1\})) \cup (\Phi \circ \Omega)(D \times C).$$

It is straightforward to verify that in both cases $N_0 \#_{\gamma} N_1$ is a $k$-dimensional submanifold of $M$. Furthermore one sees easily that in both cases we can equip the smooth manifold $N_0 \#_{\gamma} N_1$ with an orientation in such a way that the inclusions $N_0 \setminus \Phi(D \times \{P_0\}) \to N_0 \#_{\gamma} N_1$ and $N_1 \setminus \Phi(D \times \{P_1\}) \to N_0 \#_{\gamma} N_1$ are both orientation-preserving. We refer to $N_0 \#_{\gamma} N_1$ as the internal connected sum of $N_0$ and $N_1$ along $\gamma$ or as a tubing of $N_0$ and $N_1$ along $\gamma$.\[1050\]

![Figure 1096. Illustration of Construction 70.22.](image)

The following lemma justifies the name “internal connected sum”.

**Lemma 70.23.** We continue with the above notation. The internal connected sum $N_0 \#_{\gamma} N_1$, viewed as a smooth manifold in its own right, is diffeomorphic to the connected sum $N_0 \# N_1$.

**Proof.** The lemma can be proved fairly easily using the Collar Neighborhood Theorem [8.12](page) applied to $N_0 \setminus \Phi(D \times \{P_0\})$ and $N_1 \setminus \Phi(D \times \{P_1\})$. We leave it to the reader to fill in the details. \[1051\]

**Example.** In Figure 1097 we show two disjoint oriented knots $J$ and $J$. By definition both are submanifolds of $S^3$. We also show a path $\gamma$ that connects $K$ to $J$ and we show a corresponding internal connected sum $K \#_{\gamma} J$. On page [784](page) we introduced the connected

\[1050\]Note that here we use again, in a most subtle way, our hypothesis $n - k \geq 2$.

\[1051\]The construction also depends on the choice of $\Phi$ and $\Theta$. We do not claim that the isotopy type of $N_0 \#_{\gamma} N_1$ is well-defined.
The resulting image, see e.g. Figure 1097, looks quite similar to what we see in Figure 1097. With some effort one can show that given any two oriented knots the corresponding connected sum \( K \# J \) is smoothly isotopic to any internal connected sum \( K \#_\gamma J \). In fact sometimes this approach is used as the definition of the connected sum of two oriented knots.

![Figure 1097](image)

We recall the statement of proposition that we are actually supposed to prove.

**Proposition 70.16.** Let \( n \in \mathbb{N} \), let \( M \) be a connected \( n \)-dimensional smooth manifold and let \( A \) be a union of components of \( \partial M \). Furthermore let \( N \) be a compact oriented \( k \)-dimensional submanifold with \( \partial N \subset N \). We suppose that \( n-k \geq 2 \). If \( n \geq 2 \) or if \( A = \emptyset \), then there exists a compact oriented connected submanifold \( W \) of \( M \) with \( \partial W \subset A \) such that \([W] = [N] \in H_k(M, A)\).

**Sketch of proof.** To simplify the notation we assume that \( N \) has precisely two components \( N_0 \) and \( N_1 \). As explained in Construction 70.22 since \( n-k \geq 2 \) we can perform an internal connected sum \( N_0 \#_\gamma N_1 \). As in the proof of Proposition 70.13 one can deduce, using Proposition 70.21, that \([N_0 \#_\gamma N_1] = [N_0] + [N_1] \in H_k(M, A)\).

Next, as we pointed out in Lemma 70.23, the internal connected sum \( N_0 \#_\gamma N_1 \) is diffeomorphic to the connected sum \( N_0 \# N_1 \). If \( n \geq 2 \), then it follows immediately from Proposition 8.35 that the connected sum \( N_0 \# N_1 \) is connected. Finally, if \( A = \emptyset \), then we know that both \( N_0 \) and \( N_1 \) are closed. Thus it follows again from Proposition 8.35 that \( N_0 \# N_1 \) is connected. ■

**Exercises for Chapter 70.**

**Exercise 70.1.** Let \( M \) be a closed 3-dimensional smooth manifold and let \( \sigma \in H_2(M) \) be a homology class. By Proposition 70.3 there exists a closed oriented 2-dimensional smooth manifold \( F \) and a map \( \varphi : F \to M \) such that \( \varphi_*([F]) = \varphi \). Can you modify the proof of Proposition 70.13 to show that there exists a closed oriented 2-dimensional smooth manifold \( G \) and an embedding \( \psi : G \to M \) such that \( \psi_*([G]) = \sigma \)? Identify the issues you run into and try to resolve them.

**Exercise 70.2.** Let \( n \in \mathbb{N} \). As on page 194 we consider the complex projective space \( \mathbb{C}P^n = (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}) \). By the discussion on page 1262 we know that

\[
H_k(\mathbb{C}P^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k \in \{0, 2, \ldots, 2n\}; \\ 0, & \text{otherwise}. \end{cases}
\]

We consider the map \( f : \mathbb{C}P^n \to \mathbb{C}P^n \) given by \( f([z_0 : \cdots : z_n]) = [z_0 : \cdots : z_n] \). For each \( k \in \{0, 2, \ldots, 2n\} \) determine the degree of the induced map \( f_* : H_k(\mathbb{C}P^n) \to H_k(\mathbb{C}P^n) \).
Exercise 70.3. Let \( g \in \mathbb{N}_0 \). As usual we denote by \( \Sigma_g \) the surface of genus \( g \). Let \( M \) be a smooth manifold and let \( P \in M \). Now let \( k \in \mathbb{N}_0 \). Show that if there exists a map \( f: \Sigma_k \to M \times \Sigma_g \) with \( f_*(\{\Sigma_k\}) = \{P\} \times \Sigma_g \) \( \in H_2(M \times \Sigma_g) \), then \( k \geq g \).

Exercise 70.4. Let \( T = S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2 \) be the torus. We denote by \( x = [S^1 \times \{1\}] \) and \( y = \{1\} \times S^1 \) the obvious basis for \( H_1(T) \). Let \( (r, s) \neq (0, 0) \in \mathbb{Z}^2 \). Show that the following two statements are equivalent:

(a) The homology class \( r \cdot x + s \cdot y \) can be represented by a connected submanifold of \( T \).

(b) \( \gcd(r, s) = 1 \).

Hint. For the “(a) \( \Rightarrow \) (b)”-direction you might want to use the classification of 2-dimensional smooth manifolds.

Exercise 70.5. Let \( g \in \mathbb{N} \). We consider the surface \( \Sigma \) of genus \( g \). Let \( \varphi \neq 0 \in H_1(\Sigma) \). Show that the following two statements are equivalent:

(a) \( \varphi \) can be represented by a connected submanifold of \( \Sigma \).

(b) \( \varphi \) is a primitive class in \( H_1(\Sigma) \).

Remark. The case \( g = 1 \) is evidently just the content of Exercise 70.4.
71. THE SIMPLICIAL POINCARÉ DUALITY THEOREM

In this chapter we will prove one of the most beautiful and powerful theorems in the theory of abstract simplicial complexes, namely the Simplicial Poincaré Duality Theorem 71.4. This theorem has many applications, arguably the most interesting ones concern the singular (co-)homology groups of smooth manifolds.

71.1. Simplicial Homology Manifolds. To state the Simplicial Poincaré Duality Theorem we will need the following notion.

Definition.

1. We say that an abstract simplicial complex \( L \) is an simplicial homology \( m \)-sphere if for every \( i \in \mathbb{N}_0 \) we have

\[
\tilde{H}_i^{\text{simp}}(L) \cong \begin{cases} 
\mathbb{Z}, & \text{if } i = m, \\
0, & \text{else.} 
\end{cases}
\]

Furthermore we say that \( L \) is a simplicial homology ball if \( \tilde{H}_i^{\text{simp}}(L) = 0 \) for all \( i \in \mathbb{N}_0 \).

2. We say that an abstract simplicial complex \( K \) is an \( n \)-dimensional simplicial homology manifold if for every \( k \in \mathbb{N}_0 \) and every \( k \)-simplex \( s \) of \( K \) the link \( Lk(K, s) \) is a simplicial homology \((n - 1 - k)\)-sphere or if it is a simplicial homology ball.

3. We say a simplicial homology manifold \( K \) is closed, if \( K \) is finite and if for every \( k \)-simplex \( s \) of \( K \) the link \( Lk(K, s) \) is a simplicial homology \((n - 1 - k)\)-sphere.

Remark. Note that by the discussion on page 1549 the empty abstract simplicial complex is a simplicial homology \((-1)\)-sphere. It follows in particular that every simplex in a closed \( n \)-dimensional simplicial homology manifold has dimension at most \( n \).

The following lemma gives a reformulation of the definition of a simplicial homology manifold.

Lemma 71.1. Let \( K \) be an abstract simplicial complex. As always we denote by \( \text{sd}(K) \) its barycentric subdivision. The following two statements are equivalent:

1. \( K \) is a closed \( n \)-dimensional simplicial homology manifold.

2. For every vertex \( v \) of the barycentric subdivision \( \text{sd}(K) \) the link \( Lk(\text{sd}(K), v) \) is a simplicial homology \((n - 1)\)-sphere.

Proof. The lemma follows immediately from the second part of the following claim.

Claim. Let \( K \) be an abstract simplicial complex and let \( s \) be a \( k \)-simplex of \( K \).

\(^{1052}\) It is worth remembering that by definition the vertices of \( \text{sd}(K) \) are precisely the barycenters of the simplices of \( K \).
(a) There is a simplicial isomorphism $\text{Lk}(K, s) \ast \partial s \cong \text{Lk}(\text{sd}(K), s)$.

(b) For each $i \in \mathbb{N}_0$ we have $\widetilde{H}^i_{\text{simp}}(\text{Lk}(K, s)) \cong \widetilde{H}^i_{\text{simp}}(\text{Lk}(\text{sd}(K), s))$.

Let us prove the two statements.

(a) This statement is actually the content of Exercise 62.2. For the reader’s convenience we sketch the proof. So let us consider the map

$$\text{Lk}(K, s) \ast \partial s \rightarrow \text{Lk}(\text{sd}(K), s)$$

$$v \mapsto \begin{cases} s \setminus \{v\}, & \text{if } v \in \partial s, \\ s \sqcup \{v\}, & \text{if } v \in \text{Lk}(K, s). \end{cases}$$

It is elementary to verify that this map on the level of vertices induces an isomorphism of abstract simplicial complexes.

(b) For any $i \in \mathbb{N}_0$ we have

$$\widetilde{H}^i_{\text{simp}}(\text{Lk}(K, s)) \cong \widetilde{H}^i_{\text{simp}}(\text{Lk}(\text{sd}(K), s)) \cong \widetilde{H}^i_{\text{simp}}(\text{Lk}(\text{sd}(K), s)).$$

Lemma 63.13 (1) by (a) \hfill \blacksquare

Figure 1099. Illustration of the proof of Lemma 71.1

Slightly annoyingly the notion of a “simplicial homology manifold” is now the third definition of a “manifold-like” structure on an abstract simplicial complex. Namely on page 1650 we introduced the notion of a pseudomanifold and on page 1599 we introduced the notion of a PL-manifold. For the reader’s and also the author’s convenience we now recall these two earlier notions. Thus let $K$ be a finite non-empty abstract simplicial complex.

(1) $K$ is a closed $n$-dimensional pseudomanifold if the following conditions are satisfied:

(a) Every simplex of $K$ is a face of an $n$-simplex of $K$.

(b) Every $(n - 1)$-simplex has order two, i.e. it is the face of precisely two $n$-dimensional faces.

(c) Given any two $n$-simplices $t$ and $t'$ there exists a sequence $t = s_0, s_1, \ldots, s_k = t'$ of $n$-simplices such that any two consecutive simplices have a common $(n - 1)$-dimensional face.

(2) By Proposition 64.11 we know that $K$ is a closed $n$-dimensional PL-manifold if and only if for every $k$-simplex $s \in S$ the link $\text{Lk}(K, s)$ is a PL $(n - k - 1)$-sphere, i.e. $|\text{Lk}(K, s)|$ is PL-homeomorphic to the simplicial complex $\partial \Delta^{n-k}$.

---

\textsuperscript{1053} By the Alexander-Newman Theorem 64.21 the notion of a PL-manifold is basically equivalent to the notion of a combinatorial manifold that we introduced on page 1611. Since the notion of a PL-manifold is more commonly used we stick in the discussion to PL-manifold even though the notion of a combinatorial manifold would be slightly more appropriate.
The following proposition summarizes everything anybody ever wanted to know about the relationship between this new concept and our two earlier concepts.

**Proposition 71.2.**

1. A closed connected non-empty \( n \)-dimensional simplicial homology manifold \( K \) is a closed \( n \)-dimensional pseudomanifold with \( \partial K = \emptyset \).
2. There exists a closed pseudomanifold that is not a simplicial homology manifold.
3. Every closed non-empty \( n \)-dimensional PL-manifold is a closed \( n \)-dimensional simplicial homology manifold.
4. There exists a closed simplicial homology manifold that is not a PL-manifold.

**Remark.** Slightly more informally Proposition 71.2 can be summarized as follows:

\[
\text{PL-manifold} \iff \text{simplicial homology manifold} \iff \text{pseudomanifold}.
\]

**Proof.**

1. Let \( K \) be a closed connected non-empty \( n \)-dimensional simplicial homology manifold. We want to show that \( K \) is a closed \( n \)-dimensional pseudomanifold. The well-versed reader will easily spot that arguments below are at times almost identical to the arguments provided in the proof of Proposition 66.1.

Let us prove that the three conditions of a pseudomanifold, which we recalled above, are satisfied.

(a) Let \( s \) be a \( k \)-simplex of \( K \). By hypothesis \( \tilde{H}_{n-k-1}^{\text{simp}}(\text{Lk}(K, s)) \neq 0 \). This implies immediately that \( s \) is the face of an \( n \)-simplex.

(b) Let \( s \) be an \((n-1)\)-simplex of \( K \). By hypothesis \( \tilde{H}_0^{\text{simp}}(\text{Lk}(K, s)) \cong \mathbb{Z} \), which implies by Lemma 63.10 that \( H_0^{\text{simp}}(\text{Lk}(K, s)) \cong \mathbb{Z}^2 \). Recall that on page 1776 we pointed out that the maximal dimension of a simplex of \( K \) is \( n \). Since \( s \) is \((n-1)\)-dimensional we see that \( \text{Lk}(K, s) \) is a 0-dimensional simplicial complex. Now we see that it consists of precisely two vertices, which implies that there are precisely two \( n \)-simplices which contain \( s \) as a face.

(c) We say that two \( n \)-simplices \( t \) and \( t' \) of \( K \) are equivalent if there exists a sequence \( t = s_0, s_1, \ldots, s_k = t' \) of \( n \)-simplices such that any two consecutive simplices have a common \((n-1)\)-dimensional face. Recall that our task is to show that any two \( n \)-simplices are equivalent in the above sense.

The key to doing so is the following claim:

**Claim.** Let \( t \) and \( t' \) be two \( n \)-simplices. If \( t \cap t' \neq \emptyset \), then \( t \) and \( t' \) are actually equivalent in the above sense.

Given \( m \in \{0, \ldots, n-1\} \) we say that two \( n \)-simplices \( x \) and \( x' \) are \( m \)-equivalent if there exists a sequence \( x = s_0, s_1, \ldots, s_k = x' \) of \( n \)-simplices such that any two consecutive simplices have a common face of dimension \( \geq m \). It suffices to show that if we are given \( m \in \{0, \ldots, n-2\} \) such that any two \( n \)-simplices in \( K \) are \( m \)-equivalent, then any two \( n \)-simplices in \( K \) are also \((m+1)\)-equivalent. In fact evidently it suffices to show that if we are given two \( n \)-simplices \( x \) and \( x' \) which
have an $m$-simplex $s$ in common, then $x$ and $x'$ are $(m+1)$-equivalent. To do so we first note that since $\dim(x) > \dim(s)$ we can pick a vertex $w$ of $x \cap \text{Lk}(K, s)$ and similarly we can pick a vertex $w'$ of $x' \cap \text{Lk}(K, s)$.

By hypothesis we know that $\widetilde{H}_0^{\text{simp}}(\text{Lk}(K, s)) = 0$. It follows from this fact together with Lemma 43.1 and Exercise 61.11 that the abstract simplicial complex $\text{Lk}(K, s)$ is in fact connected. This means in our setting that there exist 1-simplices $e_1, \ldots, e_k \in S$ of $\text{Lk}(K, s)$ such that the following holds:

(*) We have $w \in e_1$, for every $i \in \{1, \ldots, k-1\}$ we have $e_i \cap e_{i+1} \neq \emptyset$ and we have $w' \in e_k$.

Let $i \in \{1, \ldots, k\}$. Since $e_i$ is a simplex in $\text{Lk}(K, s)$ there exists a simplex $f_i$ of $K$ with $e_i \cup s \subset f_i$. By (a) we can in fact find an $n$-simplex $\widetilde{f}_i$ of $K$ with $e_i \cup s \subset f_i \subset \widetilde{f}_i$. We set $\widetilde{f}_0 := x$ and $\widetilde{f}_{k+1} := x'$. Note that it follows from (§) that any two consecutive $\widetilde{f}_i$ and $\widetilde{f}_{i+1}$ have $s$ and a vertex of $\text{Lk}(K, s)$ in common, i.e. they have an $(m+1)$-simplex in common. This shows that $x$ and $x'$ are in fact $(m+1)$-connected.}

\[ \text{Lk}(K, s) \text{ is connected} \]

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1100}
\caption{Illustration for the proof of Proposition 71.2.}
\end{figure}

Now let $t$ and $t'$ be any two $n$-simplices of $K$. By hypothesis $K$ is connected. Together with (a) this implies easily that there exists a sequence of $n$-simplices $t = u_0, u_1, \ldots, u_k = t'$ such that any two consecutive $n$-simplices share at least one vertex. By the claim any two consecutive $n$-simplices are equivalent. Hence $t$ and $t'$ are equivalent.

(2) Let $K$ be a closed $n$-dimensional pseudomanifold. It follows from the discussion on page 1651 that the suspension $\Sigma(K) = K \ast \{\pm 1\}$ is a closed $(n+1)$-dimensional pseudomanifold. By the discussion on page 1523 we know that $\text{Lk}(\Sigma(K), \{-1\}) = K$.

Thus if $\widetilde{H}_i^{\text{simp}}(K) \neq 0$ for two different dimensions, e.g. if $K = S_1 \times S_1$ is the simplicial torus, then $\Sigma(K)$ is not a simplicial homology manifold.

(3) Let $K$ be a closed $n$-dimensional PL-manifold and let $s$ be a $k$-simplex. We see that

\[ \widetilde{H}_i^{\text{simp}}(\text{Lk}(K, s)) \cong \widetilde{H}_i(|\text{Lk}(K, s)|) \cong \widetilde{H}_i(S^{n-k-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } i = n-k-1, \\ 0, & \text{else.} \end{cases} \]

by Theorem 63.23 since $\text{Lk}(K, s)$ is a PL $(n-k-1)$-sphere we know that $|\text{Lk}(K, s)|$ is homeomorphic to $\partial \Delta^{n-k}$ in particular $|\text{Lk}(K, s)|$ is homeomorphic to $S^{n-k-1}$.

(4) By Proposition 66.11 we know that there exists a closed orientable 3-dimensional smooth manifold $Y$ that is a homology 3-sphere, but such that $\pi_1(Y)$ is a non-trivial
As a parenthetical remark we point out that alternatively we could have proved the lemma using Lemma 71.1 instead of using Proposition 66.2.
71.2. The statement of the Simplicial Poincaré Duality Theorem. Let $K$ be a closed connected $n$-dimensional simplicial homology manifold. By Proposition 71.2 (1) we know that $K$ is in particular a closed $n$-dimensional pseudomanifold. In particular it makes sense to talk of orientations of $K$. We recall the notion of a fundamental class.

(1) If $K$ is oriented, then by the definition on page 1653 we have a fundamental class $[K] \in H_n^\text{simp}(K)$. In the following, given a commutative ring $R$ we denote by $[K]$ also the image of $[K]$ under the natural map $H_n^\text{simp}(K) \xrightarrow{[\sigma] \mapsto [\sigma \otimes 1_R]} H_n^\text{simp}(K; R)$.

(2) Regardless of whether or not $K$ is orientable we defined on page 1653 the $\mathbb{F}_2$-fundamental class $[K]_{\mathbb{F}_2} \in H_n^\text{simp}(K; \mathbb{F}_2)$.

The following theorem is the main theorem on simplicial (co-) homology groups of simplicial homology manifolds.

**Theorem 71.4. (Simplicial Poincaré Duality Theorem)** Let $K$ be a closed $n$-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$. If $K$ is orientable, then for every choice of orientation and every commutative ring $R$ the map

$$H^k(K; R) \rightarrow H^{n-k}_\text{simp}(K; R)$$

$$\varphi \mapsto \varphi \cap [K]$$

is an isomorphism. Regardless of whether or not $K$ is orientable the map

$$H^k(K; \mathbb{F}_2) \rightarrow H^{n-k}_\text{simp}(K; \mathbb{F}_2)$$

$$\varphi \mapsto \varphi \cap [K]_{\mathbb{F}_2}$$

is an isomorphism.

**Remark.** One might think or hope that the Simplicial Poincaré Duality Theorem 71.4 also holds for closed (orientable) pseudomanifolds, but as we will see in Exercise 71.1 this is not the case. Nonetheless, it turns out that on pseudomanifolds one can introduce more refined (co-) homology groups, namely intersection homology, that do satisfy an analogue of the Poincaré Duality Theorem. We refer to [Ban07] for details.

The proof of the Simplicial Poincaré Duality Theorem 71.4 is evidently non-trivial and somewhat lengthy. Thus we will first draw several interesting conclusions before we head to the proof.

**Example.** Let $K$ be a closed orientable $n$-dimensional simplicial homology manifold. Let us see what the Simplicial Poincaré Duality Theorem 71.4 tells us for $k = 1$. We have the following isomorphisms:

$$H^1_\text{simp}(K) \cong H^1_\text{simp}(K; \mathbb{Z}) \cong \text{Hom}(H^1_\text{simp}(K), \mathbb{Z}) \oplus \text{Ext}(H^0_\text{simp}(K), \mathbb{Z})$$

Poincaré Duality Theorem 71.4

Universal Coefficient Theorem 67.8

$$\cong \text{Hom}(H^1_\text{simp}(K), \mathbb{Z}) \cong \text{Hom}(\mathbb{Z}^k \oplus T, \mathbb{Z}) \cong \mathbb{Z}^k.$$
We have thus shown that $H_{n-1}^\text{simp}(K)$ is a free abelian group. In the more general setting of closed orientable pseudomanifolds we had obtained the same result in Theorem 66.4 but using a rather different argument.

Our richest source of simplicial homology manifolds are smooth manifolds. We obtain the following corollary to the Simplicial Poincaré Duality Theorem 71.4.

**Theorem 71.5. (Poincaré Duality Theorem)** Let $M$ be a closed $n$-dimensional smooth manifold and let $k \in \mathbb{N}_0$. If $M$ is orientable, then for every choice of orientation and every commutative ring $R$ the map

$$H^k(M; R) \rightarrow H_{n-k}(M; R)$$

$$\varphi \mapsto \varphi \cap [M]$$

is an isomorphism. Regardless of whether or not $M$ is orientable the map

$$H^k(M; \mathbb{F}_2) \rightarrow H_{n-k}(M; \mathbb{F}_2)$$

$$\varphi \mapsto \varphi \cap [M]_{\mathbb{F}_2}$$

is an isomorphism.

**Proof.** It follows easily from Lemma 83.3 that we can assume that $M$ is actually connected. Recall that by Theorem 64.2 we know that $M$ admits a smooth simplicial structure $(K = (V, S), f: |K| \rightarrow M)$. Without loss of generality we can assume that $|K| = M$. We denote by $\Xi_*: H^\text{simp}_k(K; R) \rightarrow H_k(M; R)$ and $\Xi^*: H_k(M; R) \rightarrow H^\text{simp}_k(K; R)$ the natural isomorphisms provided by Proposition 67.1 (1) and 67.6 (3). By Lemma 71.3 we know that $K$ is a closed $n$-dimensional simplicial homology manifold.

Let us first deal with the case that $M$ is equipped with a natural orientation. By Proposition 66.7 we know that the simplicial homology manifold $K$ inherits an orientation. Next we consider the following diagram:

$$H^k(M; R) \xrightarrow{\cap [M]} H^\text{simp}_k(M; R)$$

$$\Xi_* \downarrow \cong$$

$$H^k(M; R) \xrightarrow{\cap [K]} H^\text{simp}_{n-k}(M; R)$$

We make the following observations:

1. By Algorithm 68.2 we know that $\Xi_*([K]) = [M]$.
2. It follows from (1) and Proposition 67.1 (3) that the diagram commutes.
3. The top horizontal map is an isomorphism by the Simplicial Poincaré Duality Theorem 71.4.

Since the vertical maps are isomorphisms we obtain from the above that the bottom horizontal map is, as promised, an isomorphism.

The proof for the statement regarding $\mathbb{F}_2$-coefficients is almost identical. We leave it to the reader to make the necessary straightforward modifications to the above argument.

There are many applications of the Poincaré Duality Theorem 71.5. In the following we will state two results. Since we have a predilection for smooth manifolds we state them...
in the context of smooth manifolds, but the statements also hold in the admittedly more general setting of simplicial homology manifolds.

**Theorem 88.6.** Let \( M \) be a closed \( n \)-dimensional smooth manifold and let \( k \in \mathbb{N}_0 \).

1. We have \( \dim_F (H_k(\mathbb{F}_2)) = \dim_F (H_{n-k}(\mathbb{F}_2)) \).
2. If \( M \) is orientable, then for any field \( F \) we have \( \dim_F (H_k(M; F)) = \dim_F (H_{n-k}(M; F)) \).

**Proposition 88.7.** The Euler characteristic of any closed odd-dimensional smooth manifold is zero.

As the reader will have noticed, the numbers of these results correspond to Chapter 88. In fact, in Chapter 88 we will prove a more general Poincaré Duality Theorem that applies also to topological manifolds, possibly with boundary. In Section 88.2 we discuss many consequences of the Poincaré Duality Theorem. For closed smooth manifolds all statements in Section 88.2 can also be deduced from the above Poincaré Duality Theorem 71.5. In particular this way we obtain the above results. To avoid repetition, and for the sake of brevity, we do not spell out the proofs twice.

There are many other applications of the Poincaré Duality Theorem 71.5. Arguably one of the most interesting applications is that the Poincaré Duality Theorem 71.5 allows us to compute the cup product of the real and complex projective spaces. This will be done in Chapter 90.

**Remark.** The Poincaré Duality Theorem 71.5 has two significant limitations and one aesthetic issue.

1. The theorem only deals with closed smooth manifolds. In fact the approach taken in the proof of Poincaré Duality Theorem 71.4 can be generalized, with some effort, to deal with compact (oriented) smooth manifolds with boundary. We refer to [SZ94, Satz 14.8.8] for details.
2. The Poincaré Duality Theorem 71.5 applies only to smooth manifolds. There is though some room for improvement. More precisely, the Simplicial Poincaré Duality Theorem 71.4 together with Lemma 71.3 shows that we have Poincaré Duality for any closed oriented topological manifold that admits a simplicial structure. But by Manolescu’s Theorem 85.33 we know that for every \( n \geq 5 \) there exists a closed orientable \( n \)-dimensional topological manifold that does not admit a simplicial structure. Thus the Poincaré Duality Theorem 71.4 does not imply that Poincaré Duality holds for all closed topological manifolds.
3. Even for smooth manifolds the proof of the Poincaré Duality Theorem 71.5 is aesthetically problematic since it makes use of the somewhat artificial choice of a simplicial structure.

All three issues will be addressed by the Poincaré Duality Theorem 88.1 that we will state and prove in Chapter 88. Nonetheless, the (proof) of the Poincaré Duality Theorems 71.4 and 71.5 also have two advantages over the Poincaré Duality Theorem 88.1:

1. The proofs in this chapter are much more visual, whereas the proof of the Poincaré Duality Theorem 88.1 is rather formal and it is difficult to get an intuition for “why” and “how” it works.
71.3. The barycentric subdivision. The proof of the Simplicial Poincaré Duality Theorem \[71.4\] relies on a clever use of the barycentric subdivision of the simplicial homology manifold. In this section we will recall the main definitions and statements on barycentric subdivisions which we will need later on in this chapter.

We recall the following definitions from pages 1518 and 1580:

Definition. Let \( K = (V, S) \) be an abstract simplicial complex.

1. For each \( k \)-simplex \( s = \{v_0, \ldots, v_k\} \in S \) we define the barycenter of \( s \) to be the point
   \[
   \bar{s} := \sum_{v \in s} \frac{1}{\dim(s)+1} \cdot v = \frac{1}{k+1} \cdot v_0 + \cdots + \frac{1}{k+1} \cdot v_k \in \mathbb{R}^{|V|}.
   \]

2. The barycentric subdivision of \( K \) is defined to be the following abstract simplicial complex:
   \[
   \text{sd}(K) = \left( \{ \bar{s} \}_{s \in S}, \left\{ \{ s_0, \ldots, s_k \} \mid s_0 \subseteq \cdots \subseteq s_k \right\} \right).
   \]

3. Given an ordered \( k \)-simplex \( (v_0, \ldots, v_k) \) of \( K \) we consider the following ordered \( k \)-simplex of \( \text{sd}(K) \):
   \[
   F(v_0, \ldots, v_k) := \left( \{ v_0 \}, \{ v_0, v_1 \}, \ldots, \{ v_0, v_1, \ldots, v_k \} \right).
   \]

4. Given an ordered \( k \)-simplex \( s = (v_0, \ldots, v_k) \) of \( K \) we set
   \[
   u_k(s) := \sum_{\sigma \in \text{Bij}\{0, \ldots, k\}} (-1)^{\text{sign}(\sigma)} \cdot [F(v_{\sigma(0)}, \ldots, v_{\sigma(k)})] \in C_k^{\text{simp}}(\text{sd}(K)).
   \]

We refer to the resulting map
\[
C_k^{\text{simp}}(K) \rightarrow C_k^{\text{simp}}(\text{sd}(K)) \quad [s] \mapsto u_k(s)
\]

as the simplicial subdivision map. By Lemma 63.41 (1) we know that these subdivision maps are actually well-defined and that they form a chain map.

Remark. Let \( K = (V, S) \) be an abstract simplicial complex. Note that it follows easily from the definitions that given any \( n \)-simplex \( t \) of \( \text{sd}(K) \) there exists a unique ordered \( n \)-simplex \( (v_0, \ldots, v_n) \) of \( K \) with \( [F(v_0, \ldots, v_n)] = t \).
The following lemma shows that subdivision maps induce isomorphisms on simplicial (co-) homology groups.

Lemma 63.38. Let \((K, \leq)\) be an ordered abstract simplicial complex.

1. There exists a unique simplicial map \(\sigma : \text{sd}(K) \to K\), called the stretching map, with the following property: given an \(n\)-simplex \(s = \{v_0 < \cdots < v_n\}\) of \(K\) the map \(\sigma\) sends the corresponding vertex \(s\) of \(\text{sd}(K)\) to the vertex \(v_n\) of \(K\).

![Illustration of Lemma 63.38](image)

Figure 1103. Illustration of Lemma 63.38

The following lemma is an excerpt of Lemma 63.41 together with a little dose of Lemma 73.8 (4).

Lemma 63.41. Let \(K\) be an abstract simplicial complex. We pick an order on \(K\) and we consider the corresponding stretching map \(\sigma : \text{sd}(K) \to K\).

5. For every choice of some \(k \in \mathbb{N}_0\) and of some abelian group \(G\) the two induced maps \(u_* : H^k_{\text{simp}}(K; G) \to H^k_{\text{simp}}(\text{sd}(K); G)\) and \(u^* : H^k_{\text{simp}}(\text{sd}(K); G) \to H^k_{\text{simp}}(K; G)\) are isomorphisms and the inverses are given by \(\sigma_*\) and \(\sigma^*\).

Next we turn to barycentric subdivisions of pseudomanifolds. At this point it is convenient to introduce the following definition.

Definition. Let \(K = (V, S)\) be a closed oriented \(n\)-dimensional pseudomanifold. Given an ordered \(n\)-simplex \(t\) of \(K\) we write

\[
\text{sign}(t) := \begin{cases} 
+1, & \text{if the oriented } n\text{-simplex } [(+1, t)] \text{ corresponds to the orientation,} \\
-1, & \text{otherwise.}
\end{cases}
\]

The following lemma contains everything anybody ever wanted to know about barycentric subdivisions of closed pseudomanifolds.

Lemma 71.6. Let \(K = (V, S)\) be a closed \(n\)-dimensional pseudomanifold.

1. The barycentric subdivision \(\text{sd}(K)\) is a closed \(n\)-dimensional pseudomanifold.

2. Suppose that \(K\) is equipped with an orientation. Let \(t\) be an \(n\)-simplex of \(\text{sd}(K)\). As we pointed out on page 1784 there exists a unique ordered \(n\)-simplex \(\langle v_0, \ldots, v_n \rangle\) of \(K\) with \(F(v_0, \ldots, v_n) = t\). We equip the \(n\)-simplex \(t\) of \(\text{sd}(K)\) with the orientation given by \((\text{sign}(t), F(v_0, \ldots, v_n))\).

(a) The above orientations of the \(n\)-simplices define an orientation for \(\text{sd}(K)\).

(b) We have \(u_*([K]) = [\text{sd}(K)] \in H^k_{\text{simp}}(\text{sd}(K))\).
(3) If $K$ is oriented, then given any $k \in \mathbb{N}_0$ and given any commutative ring $R$ the following diagram commutes:

\[
\begin{array}{ccc}
\text{H}^k_{\text{simp}}(K; R) & \xrightarrow{\cap [K]} & \text{H}^n_{\text{simp}}(K; R) \\
\approx & & \approx \\
\text{H}^k_{\text{simp}}(\text{sd}(K); R) & \xrightarrow{\cap [\text{sd}(K)]} & \text{H}^n_{\text{simp}}(\text{sd}(K); R).
\end{array}
\]

The analogues of (2) and (3) hold for arbitrary closed $n$-dimensional pseudomanifolds if we work with $\mathbb{F}_2$-coefficients and the simplicial $\mathbb{F}_2$-fundamental classes $[K]_{\mathbb{F}_2}$ and $[\text{sd}(K)]_{\mathbb{F}_2}$.

**Sketch of proof.** Statements (1) and (2a) follow almost immediately from the definitions, the proof is outsourced to Exercise 66.3. Furthermore Statement (2b) can be deduced easily from the definition of the fundamental class on page 1653 and the definition of the subdivision map $u_n: C^\text{simp}_n(K) \to C^\text{simp}_n(\text{sd}(K))$. We leave it to the reader to fill in the details.

Next we turn to the proof of (3). We pick an order “$\leq$” on $K$ and we denote by $\sigma: \text{sd}(K) \to K$ the corresponding stretching map. Note that by the above Lemma 63.41 (5) we know that $u_* = \sigma^{-1}$ and $u^* = (\sigma^*)^{-1}$. It follows that it suffices to show that the following diagram commutes:

\[
\begin{array}{ccc}
\text{H}^k_{\text{simp}}(K; R) & \xrightarrow{\cap [K]} & \text{H}^n_{\text{simp}}(K; R) \\
\sigma^* \approx & & \approx \\
\text{H}^k_{\text{simp}}(\text{sd}(K); R) & \xrightarrow{\cap [\text{sd}(K)]} & \text{H}^n_{\text{simp}}(\text{sd}(K); R).
\end{array}
\]

Now let $\varphi \in \text{H}^k_{\text{simp}}(K; R)$. We see that we have the following equalities:

- $\sigma_*(\sigma^*(\varphi) \cap [\text{sd}(K)]) = \varphi \cap \sigma_*([\text{sd}(K)]) = \varphi \cap [K]$.
  - by Lemma 67.20 here we use that $\sigma: \text{sd}(K) \to K$ is a simplicial map.

Finally we leave it to the reader to verify that the $\mathbb{F}_2$-analogues also hold. ■

### 71.4. The dual chain complex I

In this section, given a pseudomanifold $K$, we will introduce the dual chain complex $D^\text{simp}_*(K)$. This is the main new concept needed for the proof of the Simplicial Poincaré Duality Theorem 71.4.

**Definition.** Let $K = (V, S)$, let $s \in S$ be a $k$-simplex and let $v_1, \ldots, v_l \in V$ such that $s \cup \{v_1, \ldots, v_l\}$ is a $(k + l)$-simplex of $K$. We set

\[
G(s \mid v_1, \ldots, v_l) = \left(\left(s, s \cup \{v_1\}\right), \ldots, s \cup \{v_1, \ldots, v_l\}\right).
\]

**Remark.** Note that for an ordered $k$-simplex $s = (v_0, \ldots, v_k)$ of $K$ we have by definition $G(\{v_0\} \mid v_1, \ldots, v_k) = F(v_0, \ldots, v_k)$. 

**Definition.** Let $K = (V, S)$ be a closed oriented $n$-dimensional pseudomanifold.

1. Let $s = (v_0, \ldots, v_k)$ be an ordered $k$-simplex of $K$. We define the dual chain of $s$ to be the following simplicial chain in $C_{n-k}^{\text{simp}}(\text{sd}(K))$:
   \[ s^\dagger := \sum_{\{v_{k+1}, \ldots, v_n\} \in V^{n-k} \text{ such that } \{v_0, \ldots, v_k, v_{k+1}, \ldots, v_n\} \in S_n} \text{sign}((v_0, \ldots, v_k, v_{k+1}, \ldots, v_n)) \cdot [G(s | v_{k+1}, \ldots, v_n)]. \]

2. We define
   \[ D_{n-k}^{\text{simp}}(K) = \text{subgroup of } C_{n-k}^{\text{simp}}(\text{sd}(K)) \text{ generated by the } s^\dagger, \]
   where $s$ runs over all $k$-simplices of $K$.

**Figure 1104.** The dual chains of a 0-simplex and a 1-simplex.

**Lemma 71.7.** Let $K = (V, S)$ be a closed oriented $n$-dimensional pseudomanifold and let $k \in \mathbb{N}_0$.

1. Given two ordered $k$-simplices $s$ and $\tilde{s}$ with $[s] = [\tilde{s}] \in C_k^{\text{simp}}(K)$ we have $s^\dagger = \tilde{s}^\dagger$.

2. Let “$\leq$” be an order on $K = (V, S)$. The dual chains
   \[ \{s^\dagger | s = (v_0, \ldots, v_k) \text{ an ordered } k\text{-simplex of } K \text{ with } v_0 < \cdots < v_k \} \]
   form a basis for $D_{n-k}^{\text{simp}}(K)$.

**Proof (威胁).** The first statement of the lemma follows easily from the definitions. Thus let us turn to the proof of the second statement. We pick an order “$\leq$” on $K = (V, S)$. We set
   \[ Y := \{(v_0, \ldots, v_k) \in V^{k+1} | \{v_0, \ldots, v_k\} \in S_k \text{ and } v_0 < \cdots < v_k \}. \]

Recall that by Proposition [66.1] we know that in a closed $n$-dimensional pseudomanifold any simplex is the face of an $n$-simplex. It follows that given any $y = (v_0, \ldots, v_k) \in Y$ we can pick an ordered $(n-k)$-simplex $\tilde{y} = (w_0, \ldots, w_{n-k})$ of $K$ such that $v_k = w_0$, such that...
\{v_0, \ldots, v_k = w_0, \ldots, w_{n-k}\} \in S_n \text{ and such that } w_1 < \cdots < w_{n-k}. \text{ We make the following observation:}

\((\ast)\) \text{ It follows easily from the definition of an order that for } y_1 \neq y_2 \in Y \text{ we have } \bar{y}_1 \neq \bar{y}_2. \text{ Now we consider the following maps:}

\[
\begin{array}{ccc}
\bigoplus_{y \in Y} \mathbb{Z} \cdot y & \xrightarrow{y \mapsto y^\dagger} & D^\text{simp}_{n-k}(K) \\
\uparrow y & & \downarrow \Phi^{-1}\\
\{\bar{y} | y \in Y\} & \xleftarrow{\text{projection}} & Z \cdot (w_0, \ldots, w_{n-k})
\end{array}
\]

\[
\begin{array}{ccc}
D^\text{simp}_{n-k}(K) & \xrightarrow{\Phi} & C^\text{simp}_{n-k}(\text{sd}(K)) \\
\uparrow \Phi^{-1} & & \uparrow (w_0, \ldots, w_{n-k})\\
\bigoplus \mathbb{Z} \cdot (w_0, \ldots, w_{n-k}) & \bigoplus & Z \cdot (w_0, \ldots, w_{n-k})
\end{array}
\]

We make the following observations:

(a) The right vertical map is an isomorphism. This follows from the observation, which we basically already mentioned on page 1784, that given any ordered \((n-k)\)-simplex \((s_0, s_1, \ldots, s_{n-k})\) of \(\text{sd}(K)\) with \(s_0 \subseteq s_1 \subseteq \cdots \subseteq s_{n-k}\) there exists a unique ordered \(n\)-simplex \((w_0, \ldots, w_{n-k})\) of \(K\) with \(\Phi(w_0, \ldots, w_{n-k}) = (s_0, s_1, \ldots, s_{n-k})\).

(b) It follows immediately from the definitions of the various maps that the diagram commutes.

Now we turn to the actual proof of the second statement of the lemma. First note that it follows from (1) that \(\{y^\dagger\}_{y \in Y}\) form a generating set for \(D^\text{simp}_{n-k}(K)\). Secondly note that it follows from (a) and (b) that the map \(p \circ \Phi^{-1} : D^\text{simp}_{n-k}(K) \to \bigoplus \mathbb{Z} \cdot \bar{y}\) sends \(y^\dagger\) to \(\bar{y}\). It follows from \((\ast)\) that the \(\{y^\dagger\}_{y \in Y}\) are linearly independent. Thus we have shown that the given dual chains \(\{y^\dagger\}_{y \in Y}\) are a basis for \(D^\text{simp}_{n-k}(K)\).

To fully appreciate our next lemma it is worth recalling the following lemma.

**Lemma 67.4** \textit{Let } \(K = (V, S)\text{ be an abstract simplicial complex. Given any ordered } k\text{-simplex } s = (v_0, \ldots, v_k) \text{ we have the following equality:}

\[
\delta_k([v_0, \ldots, v_k]^*) = (-1)^{k+1} \sum_{w \in V \text{ such that } \{v_0, \ldots, v_k, w\} \text{ is a } (k+1)\text{-simplex}} [v_0, \ldots, v_k, w]^* \in C^k_{\text{simp}}(K; \mathbb{Z}).
\]

Now we can state the promised lemma. Its statement perfectly matches the statement of Lemma 67.4.
Lemma 71.8. Let $K = (V, S)$ be an abstract simplicial complex that is an orientable $n$-dimensional pseudomanifold.

1. Given any ordered $k$-simplex $s = (v_0, \ldots, v_k)$ we have the following equality:
   \[
   \partial_{n-k}([v_0, \ldots, v_k]^\dagger) = \sum_{w \in V \text{ such that } \{v_0, \ldots, v_k, w\} \in S_{k+1}} [v_0, \ldots, v_k, w]^\dagger \in C^n_{n-k-1}(\text{sd}(K)).
   \]

2. The groups $D^\text{simp}_*(K)$ form a subcomplex of $C^\text{simp}_*(\text{sd}(K))$.

**Proof.** The second statement is an immediate consequence of the first statement. Thus we just need to prove the first statement. We start out with the following elementary observation.

**Observation.** Let $s = (v_0, \ldots, v_k)$ be some ordered $k$-simplex of $K$ and furthermore let $(v_{k+1}, \ldots, v_n) \in V^{n-k}$ such that $s \cup \{v_{k+1}, \ldots, v_n\} = \{v_0, \ldots, v_k, v_{k+1}, \ldots, v_n\} \in S_n$. Given any $i \in \{1, \ldots, n - k - 1\}$ we have by definition

\[
G(s \mid v_{k+1}, \ldots, v_n) \text{ with } i\text{-th vertex removed} = (s, \ldots, s \cup \{v_{k+1}, \ldots, v_{k+i-1}\}, s \cup \{v_{k+1}, \ldots, v_{k+i+1}\}, \ldots, s \cup \{v_{k+1}, \ldots, v_n\}).
\]

Furthermore it follows immediately from the definitions that we have

\[
G(s \mid v_{k+1}, \ldots, v_n) \text{ with } 0\text{-th vertex removed} = G(s \cup \{v_{k+1}\} \mid v_{k+2}, \ldots, v_n)
\]
\[
G(s \mid v_{k+1}, \ldots, v_n) \text{ with } (n - k)\text{-th vertex removed} = G(s \mid v_{k+1}, v_{k+2}, \ldots, v_{n-1}).
\]
Now we turn to the actual proof of the first statement. Thus let \( s = (v_0, \ldots, v_k) \) be an ordered \( k \)-simplex of \( K \). We see that

\[
\partial s^\dagger = \sum_{(v_0, \ldots, v_n) \in V^{n-k}} (-1)^i \cdot \text{sign}(v_0, \ldots, v_n) \cdot [G(s \mid v_{k+1}, \ldots, v_n) \text{ with } i\text{-th vertex removed}]
\]

\[
= \sum_{(v_0, \ldots, v_n) \in V^{n-k}} (-1)^i \cdot \text{sign}(v_0, \ldots, v_n) \cdot [G(s \mid v_{k+1}, \ldots, v_n) \text{ with } i\text{-th vertex removed}]
\]

given a fixed \( (v_{k+1}, \ldots, v_n) \in V^{n-k} \) with \( \{v_0, \ldots, v_k, v_{k+1}, \ldots, v_n\} \in S_n \) and given \( i \in \{1, \ldots, n-k-1\} \) it follows almost immediately from the above observation that the contributions by \((v_{k+1}, \ldots, v_{k+i}, \ldots, v_n), i\) and \((v_{k+1}, \ldots, v_{k+i+1}, \ldots, v_n), i+1\) cancel, in other words, for \( i = 1, \ldots, n-k-1 \) all terms cancel

\[
= \sum_{(v_0, \ldots, v_n) \in V^{n-k}} \text{sign}(v_0, \ldots, v_n) \cdot [G(s \mid v_{k+1}, \ldots, v_n) \text{ with } 0\text{-th vertex removed}]
\]

by definition of a closed pseudomanifold every \((n-1)\)-simplex has order 2, since the pseudomanifold is oriented we obtain from the above observation that all contributions for \( i = n-k \) cancel

\[
= \sum_{v_{k+1} \in V} \sum_{(v_0, \ldots, v_{k+1}) \in S_{k+1}} \text{sign}(v_0, \ldots, v_n) \cdot [G(s \cup \{v_{k+1}\} \mid v_{k+2}, \ldots, v_n)]
\]

follows from fact that any subset of a simplex is again a simplex, we also use the above observation to rewrite the summand

\[
= \sum_{w \in V} [v_0, \ldots, v_k, w]^\dagger.
\]

**Figure 1107.** Illustration for the proof of Lemma 71.8

Using Lemma 71.8 we can now easily prove the following proposition which is one of the key steps in the proof of the Simplicial Poincaré Duality Theorem 71.4.

**Proposition 71.9.** Let \( K = (V, S) \) be a closed oriented \( n \)-dimensional pseudomanifold.

1. For each \( k \in \mathbb{N}_0 \) the map

\[
\Lambda : \text{Hom}(C^\text{simp}_k(K), \mathbb{Z}) \to D^\text{simp}_{n-k}(K)
\]

\[
\sum_{i=1}^m a_i \cdot s_i^* \mapsto \sum_{i=1}^m a_i \cdot s_i^\dagger
\]

here \( s_i \) is a \( k \)-simplex of \( K \) and we define \( s_i^\dagger : C^\text{simp}_k(K) \to \mathbb{Z} \) as on page 1686.
is a natural isomorphism of abelian groups.

(2) For each $k \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
\text{Hom}(C_k^\text{simp}(K), \mathbb{Z}) & \xrightarrow{s^* \mapsto s^!} & D_{n-k}^\text{simp}(K) \\
\downarrow (-1)^k \cdot \partial_k = (-1)^k \cdot \partial_{k+1} & & \downarrow \partial_{n-k} \\
\text{Hom}(C_{k+1}^\text{simp}(K), \mathbb{Z}) & \xrightarrow{s^* \mapsto s^!} & D_{n-k-1}^\text{simp}(K).
\end{array}
$$

(3) The maps

$$
\Lambda_* : H^k_\text{simp}(K; \mathbb{Z}) \to H_{n-k}(D_n^\text{simp}(K))
$$

are well-defined and they are natural isomorphisms.

**Proof.**

(1) First note that $K$ is by definition a finite abstract simplicial complex. Thus it follows immediately from Lemma 67.2 and Lemma 71.7 (2) that the maps $\Lambda$ are isomorphisms. Basically by definition the maps $\Lambda$ are natural.

(2) Let $k \in \mathbb{N}_0$ and let $s = (v_0, \ldots, v_k)$ be an ordered $k$-simplex of $K$. We calculate that

$$
\partial_{n-k}(\Lambda(s)) = \partial_{n-k}([v_0, \ldots, v_k]) \mapsto \sum_{w \in V \text{ such that } \{v_0, \ldots, v_k, w\} \in S_{k+1}} [v_0, \ldots, v_k, w] = (-1)^k \cdot \Lambda(\delta_k([v_0, \ldots, v_k])).
$$

(3) In (2) we showed that the maps $\Lambda$ are cochain maps “up to sign”, i.e. they are generalized cochain maps in the sense of the discussion on page 1819. As we pointed out on page 1819 this sign issue is completely irrelevant and we still get a well-defined map on cohomology groups. Furthermore, by (1) we know that the maps on each cochain level are isomorphisms, thus we get in fact an isomorphism of cohomology groups.

It is a good moment to keep stock of where we are in the proof of the Simplicial Poincaré Duality Theorem 71.4. Let $K$ be a closed oriented $n$-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$. Let us consider the following diagram:
Our main goal is to show that the top horizontal map is an isomorphism. By now we already know the following:

1. By Proposition 71.9 we now know that the left vertical map is an isomorphism.
2. By Lemma 63.41 we know that the subdivision maps $u_\ast$ and $u^\ast$ are isomorphisms.
3. By Lemma 71.6 (3) we know that the upper quadrilateral commutes.

Thus to prove the core of the Simplicial Poincaré Duality Theorem 71.4 it remains to carry out the following steps:

4. We need to show that the lower left part of the diagram commutes.
5. We need to show that the bottom horizontal map is an isomorphism.

As we will see in a second, Step (4) follows from a fairly straightforward calculation. Step (5) is much more difficult and we postpone Step (5) to the next section. Note though that Step (5) is particularly interesting since so far we have only used that $K$ is a closed $n$-dimensional pseudomanifold. We did not yet use the hypothesis that we are dealing with a simplicial homology manifold.

As promised, here is the lemma that takes care of Step (4).

**Lemma 71.10.** Given any closed oriented $n$-dimensional pseudomanifold $K$ the following diagram commutes:

$$
\begin{array}{c}
\text{H}_{n-k}(\text{D}^*_{\text{simp}}(K)) \\
\downarrow \sim \\
\text{H}_{n-k}(\text{sd}(K); \mathbb{Z})
\end{array}
\begin{array}{c}
\sim \\
\downarrow \\
\text{H}_k(\text{sd}(K); \mathbb{Z})
\end{array}
\begin{array}{c}
\mu := \sum_{(u_0, \ldots, u_n)} \text{sign}(u_0, \ldots, u_n) \cdot [(u_0), (u_0, u_1), \ldots, (u_0, \ldots, u_n)] \\
\in C_{n}^{\text{simp}}(\text{sd}(K)).
\end{array}
$$

**Proof.** Let $K = (V, S)$ be a closed oriented $n$-dimensional pseudomanifold. Given two $k$-simplices $s$ and $t$ of $K$ we write $s \leq t$ if $s \subset t$. As we pointed out in Lemma 62.2, this order on the vertex set of $\text{sd}(K)$ turns $\text{sd}(K)$ naturally into an ordered abstract simplicial complex. In the following we use the natural isomorphisms $C_{\text{simp}}^{\leq}(\text{sd}(K)) \to C_{\text{simp}}(\text{sd}(K))$ and $C_{\text{simp}}(\text{sd}(K); \mathbb{Z}) \to C_{\text{simp}}^{\leq}(\text{sd}(K); \mathbb{Z})$ to identify these two (co-)chain complexes and throughout the proof we will work with $C_{k}^{\text{simp}}(\text{sd}(K))$ and $C_{\text{simp}}^{k}(\text{sd}(K))$.

We set

$$
\mu := \sum_{(u_0, \ldots, u_n)} \text{sign}(u_0, \ldots, u_n) \cdot [(u_0), (u_0, u_1), \ldots, (u_0, \ldots, u_n)] \\
\in C_{n}^{\text{simp}}(\text{sd}(K)).
$$

It follows immediately from Lemma 71.6 and Theorem 66.4 that $\mu$ is a simplicial cycle that represents the simplicial fundamental class $[\text{sd}(K)] \in \text{H}_{n}^{\text{simp}}(\text{sd}(K))$.

Next we pick an order “$\leq$” on $K$ and we denote by $\sigma : \text{sd}(K) \to K$ the corresponding stretching map, as defined on page 1785. Recall that by Lemma 63.41 we know that
\( \sigma^* : H^k_{\text{simp}}(K; \mathbb{Z}) \to H^k_{\text{simp}}(\text{sd}(K); \mathbb{Z}) \) and \( u^* : H^k_{\text{simp}}(\text{sd}(K); \mathbb{Z}) \to H^k_{\text{simp}}(K; \mathbb{Z}) \) are inverses of one another. Thus it remains to prove the following claim.

**Claim.** The following diagram commutes:

\[
\begin{array}{ccc}
C^k_{\text{simp}}(K; \mathbb{Z}) & \xrightarrow{\sigma^*} & C^k_{\text{simp}}(\text{sd}(K); \mathbb{Z}) \\
\Sigma a_i s^* & \cong & \cap \mu \\
\Sigma a_i s^* & \xrightarrow{\rightarrow} & C^k_{n-k}(\text{sd}(K)).
\end{array}
\]

The verification of the claim consists of a careful, but at the end of the day elementary, calculation. Note that by Lemma 67.2 (2) it suffices to show that for every ordered \( k \)-simplex \( s = (v_0, \ldots, v_k) \) of \( K \) with \( v_0 < \cdots < v_k \) we have the following equality:

\[
\sigma^*(s^*) \cap \mu = s^+ \in C^k_{n-k}(\text{sd}(K)).
\]

To verify this equality it is helpful to first do one specific calculation separately. Namely let \( (z_0, \ldots, z_k) \) be some other ordered \( k \)-simplex of \( S \). We perform the following little calculation:

\[
\sigma^*(s^*) \cap \mu = \sigma^*(s^*) \cap \left( \sum_{(z_0, \ldots, z_n) \text{ ordered } n \text{-simplex of } K} \text{sign}(z_0, \ldots, z_n) \cdot [z_0, \{z_0, z_1 \}, \ldots, \{z_0, \ldots, z_n \}] \right)
\]

by the definition of the cap product, here we use that \( \{z_0 \} < \{z_0, z_1 \} < \cdots < \{z_0, \ldots, z_n \} \)

\[
= \sum_{(z_0, \ldots, z_n) \text{ ordered } n \text{-simplex of } K} \text{sign}(z_0, \ldots, z_n) \cdot \sigma^*(s^*) \cdot [z_0, \{z_0, z_1 \}, \ldots, \{z_0, \ldots, z_n \}] = G([z_0, \ldots, z_k | z_{k+1}, \ldots, z_n]) = s^+.
\]

Here, as on many other occasions we will use the remark on page 1552 to make the identification \( C^*_{\text{simp}}(\text{sd}(K)) = C^*_{\text{simp}}(\text{sd}(K); \mathbb{Z}) \).

It follows from Proposition 71.9 and the formula in the proof of Lemma 67.16 that the two vertical maps are (co-) chain maps “up to the sign \((-1)^k\)."
71.5. **The dual chain complex II.** As mentioned in the last section, the following proposition is the last major puzzle-piece in the proof of the Simplicial Poincaré Duality Theorem 71.4.

**Proposition 71.11.** Let $K$ be a closed $n$-dimensional simplicial homology manifold.

1. The inclusion map $D^\mathrm{simp}_*(K) \to C^\mathrm{simp}_*(\mathrm{sd}(K))$ is a chain homotopy equivalence.
2. For every abelian group $G$ the induced maps $H_k(D^\mathrm{simp}_*(K) \otimes G) \to H^\mathrm{simp}_k(\mathrm{sd}(K); G)$ are isomorphisms.

**Remark.**

1. Note that in Proposition 71.11 we finally work with simplicial homology manifolds and not just with pseudomanifolds.
2. Note that in Proposition 71.11 we do not demand that $K$ is orientable.
3. In Section 71.7 we will see that the dual chain complex $D^\mathrm{simp}_*(K)$ can be viewed as the cellular chain complex of a “dual CW-structure” on $|K|$. The proof of Proposition 71.11 is in fact similar in spirit to the proof, given in Proposition 48.4 and Corollary 49.9, that the cellular chain complex of a CW-complex $X$ is chain homotopy equivalent to the singular chain complex of $X$.

**Definition.** Let $K = (V, S)$ be an $n$-dimensional abstract simplicial complex.

1. Given $k \in \mathbb{N}_0$ we define

$$X^k := \text{all simplices of } \mathrm{sd}(K) \text{ of the form } G(s \mid v_1, \ldots, v_l)$$

where $s$ is a simplex of $S$ of dimension at least $n - k$.

It follows immediately from the definitions that $X^k$ can be viewed as a $k$-dimensional subcomplex of $\mathrm{sd}(K)$ and that $X^n = \mathrm{sd}(K)$.

2. Let $k \in \mathbb{N}_0$. Similar to the discussion on page 1259 we consider the map

$$d_k: H_k^\mathrm{simp}(X^k, X^{k-1}) \to H_k^\mathrm{simp}(X^{k-1}, X^{k-2})$$

$$[\sigma] \mapsto [\partial_k(\sigma)].$$

where $\sigma \in C^\mathrm{simp}_k(X^k)$

![Figure 1108](image_url)

**Figure 1108**

The following lemma can be viewed as a partial analogue of Lemma 48.1

**Lemma 71.12.** Let $K = (V, S)$ be a closed $n$-dimensional simplicial homology manifold and let $k \in \mathbb{N}_0$.

1. For $i \neq k$ we have $H_i^\mathrm{simp}(X^k, X^{k-1}) = 0$. 

(2) The map
\[ \Theta : D_k^{\text{simp}}(K) \rightarrow \tilde{H}_k^{\text{simp}}(X^k, X^{k-1}) \]
is well-defined, i.e. every chain \( \sigma \in D_k^{\text{simp}}(K) \) does indeed represent a cycle in \( C_k^{\text{simp}}(X^k, X^{k-1}) \). Furthermore the map \( \Theta \) is an isomorphism.

(3) The maps \( \Theta \) introduced in (2) define an isomorphism of chain complexes
\[ (D_k^{\text{simp}}(K), \partial_k) \rightarrow (\tilde{H}_k^{\text{simp}}(X^k, X^{k-1}), d_k). \]

**Proof.** Let \( K = (V, S) \) be a closed \( n \)-dimensional simplicial homology manifold. Given \( l \in \mathbb{N}_0 \) we denote by \( S_l \) the set of \( l \)-simplices of \( K \). Given an \((n-k)\)-simplex \( s \in S_{n-k} \) we define the following:

\[
\begin{align*}
Z(s) &= \{ \text{all simplices of } \text{sd}(K) \text{ of the form } G(t | v_1, \ldots, v_l) \text{ with } s \subset t \} \subset X^k \\
\partial Z(s) &= \{ \text{all simplices of } \text{sd}(K) \text{ of the form } G(t | v_1, \ldots, v_l) \text{ with } s \subsetneq t \} \subset X^{k-1}.
\end{align*}
\]

**Figure 1109**

**Claim 1.** Let \( s \) be an \((n-k)\)-simplex of \( K \). Given any \( l \in \mathbb{N} \) we have
\[
\tilde{H}_l^{\text{simp}}(Z(s)) = 0 \quad \text{and} \quad \tilde{H}_l^{\text{simp}}(\partial Z(s)) \cong \begin{cases} \mathbb{Z}, & \text{if } l = k-1, \\ 0, & \text{otherwise.} \end{cases}
\]

In particular \( \partial Z(s) \) is a simplicial homology \((k-1)\)-sphere.

Let \( s \) be an \((n-k)\)-simplex of \( K \). We start out with the following little observation:

(*) Note that \( Z(s) \) and \( \text{sd}(\partial s) \) are subcomplexes of \( \text{St}(\text{sd}(K), s) \) and that \( \partial Z(s) \) and \( \text{sd}(\partial s) \) are subcomplexes of \( \text{Lk}(\text{sd}(K), s) \). It is now elementary to verify that the natural maps on the vertex sets induce simplicial isomorphisms
\[
Z(s) \ast \text{sd}(\partial s) \xrightarrow{\cong} \text{St}(\text{sd}(K), s) \quad \text{and} \quad \partial Z(s) \ast \text{sd}(\partial s) \xrightarrow{\cong} \text{Lk}(\text{sd}(K), s).
\]

We leave it to the reader to go over the details. It might be helpful to have a look at Figure [1109] to do a reality check.

---

Note that it follows immediately from the definitions that \( Z(s) \) are precisely the simplices that appear as summands in \( s^! \in C_k^{\text{simp}}(K) \) and that \( \partial Z(s) \) are precisely the simplices that appear as summands in \( \partial s^! \in C_k^{-1}(K) \).
Now let us turn to the actual calculation of the simplicial homology groups of $Z(s)$ and $\partial Z(s)$. Thus let $l \in \mathbb{N}_0$. We perform the following two calculations:

$$\tilde{H}_l^{\text{simp}}(Z(s)) = \tilde{H}_{l+n-k}^{\text{simp}}(Z(s) * sd(\partial s)) = \tilde{H}_{l+n-k}^{\text{simp}}(\text{St}(sd(K), s)) = 0,$$

since $s$ is an $(n-k)$-simplex we obtain from Lemma 63.41 that $\tilde{H}_{n-k-1}^{\text{simp}}(sd(\partial s)) \cong \mathbb{Z}$ and that $\tilde{H}_i^{\text{simp}}(sd(\partial s)) = 0$ for $i \neq n - k - 1$, the statement now follows from Exercise 63.14 by (*)

Claim 2. Let $k \in \mathbb{N}_0$. The map

$$\bigoplus_{s \in S_{n-k}} j_s : \bigoplus_{s \in S_{n-k}} C_s^{\text{simp}}(Z(s), \partial Z(s)) \to C_k^{\text{simp}}(X^k, X^{k-1}),$$

induced by the inclusions, is an isomorphism of chain complexes.

Since each of the inclusion induced maps $C_s^{\text{simp}}(Z(s), \partial Z(s)) \to C_s^{\text{simp}}(X^k, X^{k-1})$ is a chain map we see that the given map is indeed a chain map. Thus it suffices to show that the map is an isomorphism in each degree. Now let $l \in \mathbb{N}_0$. We consider the following diagram:

$$\begin{array}{cccccc}
0 & \longrightarrow & \bigoplus_{s \in S_{n-k}} C_l^{\text{simp}}(\partial Z(s)) & \overset{\alpha}{\longrightarrow} & \bigoplus_{s \in S_{n-k}} C_l^{\text{simp}}(Z(s)) & \longrightarrow & \bigoplus_{s \in S_{n-k}} C_l^{\text{simp}}(Z(s), \partial Z(s)) & \longrightarrow & 0 \\
& & \downarrow \cong \varphi & & \downarrow \cong \psi & & \downarrow & & \\
0 & \longrightarrow & C_l^{\text{simp}}(X^{k-1}) & \longrightarrow & C_l^{\text{simp}}(X^k) & \longrightarrow & C_l^{\text{simp}}(X^k, X^{k-1}) & \longrightarrow & 0.
\end{array}$$

We make the following clarifications and observations:

(a) The horizontal sequences are evidently exact.

(b) The vertical maps between the first and second row are induced by the inclusions $\partial Z(s) \to X^{k-1}$ and $Z(s) \to X^k$.

(c) It is basically clear that the middle vertical map $\psi$ is an epimorphism.

(d) Let $G(t | v_0, \ldots, v_l)$ be an $l$-simplex in $X^{k-1}$. By definition of $X^{k-1}$ this means that $t$ is a simplex of $K$ of dimension $\geq n - (k - 1)$. For any $(n-k)$-simplex $s$ with $s \subset t$ we have by definition that $G(t | v_0, \ldots, v_l)$ is a simplex of $\partial Z(s)$. This shows that the left vertical map $\varphi$ is also an epimorphism.

(e) The vertical map $\rho$ is the natural projection given by the fact that the bottom group is generated by a subset of the set of $l$-simplices of $X^k$. 

By our hypothesis that $K$ is an $n$-dimensional simplicial homology manifold together with Lemma 71.1 we know that $\text{Lk}(sd(K), s)$ is an $(n-1)$-dimensional simplicial homology sphere.
(f) It follows easily from the definitions that \( \ker(p \circ \psi) \subset \im(\alpha) \).

(g) It follows from (f) that \( \ker(\psi) \subset \im(\alpha) \).

It now follows from (a), (b), (c) and (g) together with an elementary diagram chase, see Exercise [13.11] that the right vertical map is indeed an isomorphism.

\[ \text{Claim 3. For every ordered \((n-k)\)-simplex } s \text{ of } K \text{ we have } Z \cdot [s^1] = H^\text{simp}_{k-1}(Z(s), \partial Z(s)). \]

Let \( s = (v_0, \ldots, v_{n-k}) \) be an ordered \((n-k)\)-simplex of \( K \). By Proposition [71.2] we know that \( K \) is a closed \( n \)-dimensional pseudomanifold. By definition this implies that \( s \) is the face of an \( n \)-simplex. We pick vertices \( w_1, \ldots, w_k \) of \( K \) such that \((v_0, \ldots, v_{n-k}, w_1, \ldots, w_k)\) is an \( n \)-simplex of \( K \). Next we consider the following diagram:

\[
\begin{array}{cccc}
\tilde{H}^\text{simp}_k(Z(s)) & \xrightarrow{=0 \text{ by Claim 1}} & H^\text{simp}_k(Z(s), \partial Z(s)) & \xrightarrow{\partial_k} \tilde{H}^\text{simp}_{k-1}(\partial Z(s))
\end{array}
\]

We make the following clarifications and observations:

(a) It follows from Claim 1 that the connecting homomorphism \( \partial_k \) on the top is an isomorphism.

(b) Note that \( \partial Z(s) \) is a \((k-1)\)-dimensional simplicial complex. Therefore we have the inclusion \( \iota: \tilde{H}^\text{simp}_{k-1}(\partial Z(s)) \to \tilde{C}^\text{simp}_{k-1}(\partial Z(s)) \).

(c) It follows immediately from the definitions that \( \partial s^1 \) lies in \( \tilde{C}^\text{simp}_{k-1}(\partial Z(s)) \). In particular \( s^1 \) defines an element \( H^\text{simp}_k(Z(s), \partial Z(s)) \). In other words, the vertical map \( \phi \) is defined.

(d) We denote by \( p: C^\text{simp}_{k-1}(\partial Z(s)) \to Z \) the projection from the free abelian group \( C^\text{simp}_{k-1}(\partial Z(s)) \) onto the \( G(s \cup \{w_{k+1}\}) \to Z \) coefficient.

(e) It follows easily from Lemma [71.8] (1) together with the various definitions that the map \( p \circ \iota \circ \partial_k \circ \phi: Z \to Z \) is multiplication by \( \pm 1 \).

(f) By Claim 1 we have \( \tilde{H}^\text{simp}_{k-1}(\partial Z(s)) \cong Z \).

(g) It follows easily from (d) and (e) that \( \partial_k \circ \phi \) is an isomorphism. Together with (1) we see that \( \phi \) is an isomorphism.

As the reader will have noticed, the above claims basically take care of the three statements of the proposition:

1. It follows from Claim 1 and 2 that for \( i \neq k \) we have \( H^\text{simp}_i(X^k, X^{k-1}) = 0 \).

2, 3. We consider the following diagram:

\[
\begin{array}{c}
D^\text{simp}_k(K) \xrightarrow{\partial_k} D^\text{simp}_{k-1}(K) \\
\xrightarrow{\partial_k} \bigoplus_{s \in S_{n-k}} H^\text{simp}_k(Z(s), \partial Z(s)) \xrightarrow{=0} \bigoplus_{s \in S_{n-k+1}} H^\text{simp}_{k-1}(Z(s), \partial Z(s)) \xrightarrow{=0} \bigoplus_{s \in S_{n-k}} H^\text{simp}_k(X^k, X^{k-1}) \\
\end{array}
\]
We make the following clarifications and observations:

(a) By Lemma 71.7 we know that the \( \{ s^l \}_{s \in S_{n-l}} \) form a basis for each \( D^\ast_{\text{simp}}(K) \).

(b) The composition of the horizontal maps equals the map \( \Theta \) that is induced by the maps \( D^\ast_{\text{simp}}(K) \to C^\ast_{k}(X^k) \to C^\ast_{k}(X^k, X^{k-1}) \).

(c) It follows immediately from the definitions that the diagram commutes.

(d) By Claim 3 we know that the left horizontal maps are isomorphisms and by Claim 2 we know the right horizontal maps are isomorphisms.

This discussion shows that the maps

\[
\Theta: D^\ast_{\text{simp}}(K) \to H^\ast_{\text{simp}}(X^k, X^{k-1})
\]

define an isomorphism \( (D^\ast_{\text{simp}}(K), \partial) \to (H^\ast_{\text{simp}}(X^k, X^{k-1}), d_k)_{k \in \mathbb{N}_0} \) of chain complexes.

The following lemma is also a partial analogue of Lemma 48.1.

**Lemma 71.13.** Let \( K = (V, S) \) be a closed \( n \)-dimensional simplicial homology manifold and let \( k \in \mathbb{N}_0 \).

1. For every \( i > k \) we have \( H^i_{\text{simp}}(X^k) = 0 \).
2. For every \( i < k \) the inclusion induced map \( H^i_{\text{simp}}(X^k) \to H^i_{\text{simp}}(\text{sd}(K)) \) is an isomorphism.

**Proof.**

(1) Note that \( X^k \) is an abstract simplicial complex of dimension \( k \). It follows immediately from the definition of simplicial homology that \( H^i_{\text{simp}}(K) = 0 \) for \( i > k \).

(2) We fix \( i \in \mathbb{N}_0 \). Let \( m > i \). We consider the following excerpt from the long exact sequence in simplicial homology of the pair \( (X^{m+1}, X^m) \):

\[
\ldots \to H^i_{\text{simp}}(X^{m+1}) \xrightarrow{\partial_{m+1}} H^i_{\text{simp}}(X^m) \xrightarrow{\partial_i} H^i_{\text{simp}}(X^{m+1}) \to \ldots
\]

\[= 0 \text{ by Lemma 71.12 (1) since } i < m \]

Now let \( k > i \). The above discussion immediately implies that the following inclusion induced maps are isomorphisms: \( H^i_{\text{simp}}(X^k) \xrightarrow{\partial_{k}} H^i_{\text{simp}}(X^{k+1}) \xrightarrow{\partial_{k+1}} \ldots \xrightarrow{\partial_{n}} H^i_{\text{simp}}(X^n) \). The desired statement follows from the fact that \( X^n = \text{sd}(K) \).

Now we are finally in a position to provide the long overdue proof of Proposition 71.11.

**Proof of Proposition 71.11.** Let \( K \) be a closed \( n \)-dimensional simplicial homology manifold and let \( G \) be an abelian group. Recall that we need to prove the following two statements:

1. The inclusion map \( D^\ast_{\text{simp}}(K) \to C^\ast_{k}(\text{sd}(K)) \) is a chain homotopy equivalence.
2. The induced maps \( H_k(D^\ast_{\text{simp}}(K) \otimes G) \to H^\ast_{\text{simp}}(\text{sd}(K); G) \) are isomorphisms.
Similarly to the proof of Proposition 48.4, we consider the following diagram:

\[
\begin{array}{c}
0 \\
\downarrow \\
\partial_{k+1} \\
\downarrow \\
H^{\text{simp}}_{k+1} (X^{k+1}, X^k) \\
\downarrow \\
\rightarrow \\
H^{\text{simp}}_k (X^{k+1}) \\
\downarrow \\
\rightarrow \\
H^{\text{simp}}_k (X^k, X^{k-1}) \\
\downarrow \\
\rightarrow \\
H^{\text{simp}}_k (X^{k-1}, X^{k-2}) \\
\downarrow \\
\rightarrow \\
\rightarrow \\
H^{\text{simp}}_k (X^{k-1}) \\
\rightarrow \\
0
\end{array}
\]

We make the following observations:

1. It follows from Lemma 63.29, i.e. from the long exact sequence in simplicial homology, together with Lemma 71.12 (1) and Lemma 71.13 (1) that all diagonal sequences are exact.

2. It follows from the definition of \(d_k\) that the map \(H^{\text{simp}}_k (X^k) \rightarrow H^{\text{simp}}_k (X^k, X^{k-1})\) takes values in \(\ker (d_k : H^{\text{simp}}_k (X^k, X^{k-1}) \rightarrow H^{\text{simp}}_{k-1} (X^{k-1}, X^{k-2}))\).

We move on to the main diagram of this proof:

\[
\begin{array}{c}
D^{\text{simp}}_{k+1} (K) \\
\downarrow \\
\rightarrow \\
\partial_{k+1} \\
\downarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
H^{\text{simp}}_{k+1} (X^{k+1}, X^k) \\
\downarrow \\
\rightarrow \\
d_{k+1} \\
\downarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
\rightarrow \\
H^{\text{simp}}_k (X^k) \\
\rightarrow \\
\rightarrow \\
\ker (H^{\text{simp}}_k (X^k, X^{k-1}) \rightarrow H^{\text{simp}}_{k-1} (X^{k-1}, X^{k-2})).
\end{array}
\]

We make the following clarification and observations:

3. All the maps called \(j_*\) are induced by inclusions on the level of chain groups. In fact note that every map in the diagram is either induced by taking boundaries or it is induced by an inclusion. It follows almost immediately from this observation that the diagram commutes.

4. The vertical maps are isomorphisms by Lemma 71.12.

5. By (1) the map \(H^{\text{simp}}_k (X^k) \rightarrow \ker (d_k : H^{\text{simp}}_k (X^k, X^{k-1}) \rightarrow H^{\text{simp}}_{k-1} (X^{k-1}, X^{k-2}))\) is a monomorphism.
(6) It follows from (1), together with Lemma 71.13, that the diagonal blue sequence
\[ H^\text{simp}_{k+1}(X^{k+1}, X^k) \xrightarrow{\partial_{k+1}} H^\text{simp}_k(X^k) \xrightarrow{j_*} H^\text{simp}_k(\text{sd}(K)) \to 0 \]
is exact.

An amusing little diagram chase now shows that the sequence
\[ D^\text{simp}_{k+1}(K) \xrightarrow{\partial_{k+1}} \ker(\partial_k : D^\text{simp}_k(K) \to D^\text{simp}_{k-1}(K)) \xrightarrow{j_*} H^\text{simp}_k(\text{sd}(K)) \to 0 \]
is also exact. In other words we have proved the following statement:

(0) The inclusion map \( D^\text{simp}_* (K) \to C^\text{simp}_* (\text{sd}(K)) \) induces for each \( k \in \mathbb{N}_0 \) an isomorphism \( H_k(D^\text{simp}_* (K)) \to H_k^\text{simp}(\text{sd}(K)) \).

Now let us turn to the two statements we actually need to prove.

(1) It follows from (0) and Proposition 49.2 that the chain map \( D^\text{simp}_* (K) \to C^\text{simp}_* (\text{sd}(K)) \) is in fact a chain homotopy equivalence.

(2) Finally note that it follows either from (1), or from (0) together with the Algebraic Universal Coefficient Theorem 57.18 and the Five Lemma 43.12, that the maps \( H_k(D^\text{simp}_* (K); G) \to H^\text{simp}_k(\text{sd}(K); G) \) are also isomorphisms. Alternatively we could have carried through the above arguments with \( G \)-coefficients without any hiccup.

71.6. **The proof of the Simplicial Poincaré Duality Theorem** 71.4. In this section we combine the results from the previous sections to finally provide the proof of the Simplicial Poincaré Duality Theorem 71.4. For the most part we are now just saying that the program, set out on page 1791 has been completed successfully.

Let \( K \) be a closed \( n \)-dimensional pseudomanifold. First we assume that \( K \) is orientable and that we are given an orientation for \( K \). In the following we will only work with the commutative ring \( R = \mathbb{Z} \). The proof for the general case is basically the same, except that one has to carry slightly more notation around. As on page 1791 we consider the following diagram:

\[
\begin{array}{ccc}
H^k_k(K; \mathbb{Z}) & \xrightarrow{\wedge [K]} & H^\text{simp}_{n-k}(K; \mathbb{Z}) \\
[\Sigma a_is_i^*] & \cong & [\Sigma a_is_i^+]
\end{array}
\]

\[
\begin{array}{ccc}
H^k\text{simp}(\text{sd}(K); \mathbb{Z}) & \xrightarrow{\wedge [\text{sd}(K)]} & H^\text{simp}_{n-k}(\text{sd}(K); \mathbb{Z}) \\
\text{id} & \cong & u_*
\end{array}
\]

In the last sections we have shown the following:

(1) By Proposition 71.9 we now know that the left vertical map is an isomorphism.
(2) By Lemma 63.41 we know that the subdivision maps \( u_* \) and \( u^* \) are isomorphisms.
(3) By Lemma 71.6 (3) we know that the upper quadrilateral commutes.
(4) By Lemma 71.10 we know that the lower left part of the diagram commutes.
(5) Finally we now know by Proposition 71.11 that the bottom horizontal map is an isomorphism.
The combination of the above five statements implies that the map

\[ H^k_{\text{simp}}(K; \mathbb{Z}) \rightarrow H_{n-k}^{\text{simp}}(K; \mathbb{Z}) \]

\[ \varphi \mapsto \varphi \cap [K] \]

is, as promised and desired, an isomorphism.

Finally suppose that we are dealing with any closed \( n \)-dimensional pseudomanifold, in other words we drop the hypothesis that \( K \) is orientable. We need to show that the map

\[ H^k_{\text{simp}}(K; \mathbb{F}_2) \rightarrow H_{n-k}^{\text{simp}}(K; \mathbb{F}_2) \]

\[ \varphi \mapsto \varphi \cap [K]_{\mathbb{F}_2} \]

is an isomorphism. The argument is almost identical to the previous argument. In fact the only place where we ever really used the orientation was in the definition of \( s^! \) on page 1787 and the resulting map \( C^k_{\text{simp}}(K; \mathbb{Z}) \rightarrow D^k_{\text{simp}}(K) \) that is given by \( s^* \mapsto s^! \). A little bit of thought shows that the same recipe defines a map \( C^k_{\text{simp}}(K; \mathbb{F}_2) \rightarrow D^k_{\text{simp}}(K) \otimes \mathbb{F}_2 \) and the argument of Proposition 71.9 shows that this map is actually an isomorphism of cochain complexes. In the remainder of the argument we did not really use the orientation, so these parts stay virtually untouched. For example Proposition 71.11 says that the maps \( H_{n-k}(D^*_{\text{simp}}(K) \otimes \mathbb{F}_2) \rightarrow H_{n-k}^{\text{simp}}(\text{sd}(K); \mathbb{F}_2) \) are isomorphisms. We leave it to the reader to turn this sketch of a proof into a proper argument.

71.7. **The dual CW-structure of a smooth manifold \( \ast \).** Let \( M \) be a closed smooth manifold that is equipped with a smooth simplicial structure \( (K = (V, S), \Theta: |K| \rightarrow M) \).

Some of the figures above, e.g. Figures \ref{fig:1105} and \ref{fig:1109}, suggest that the dual chains correspond to an alternative decomposition of \( M \) into cells. As we will see shortly, that is indeed the case.

First we recall some of the notation that we introduced earlier.

**Notation.** Let \( K = (V, S) \) be an \( n \)-dimensional pseudomanifold.

1. Given \( m \in \mathbb{N}_0 \) we denote by \( S_m \) the set of \( m \)-simplices of \( K \).
2. Let \( s \in S_m \) be an \( m \)-simplex and let \( v_1, \ldots, v_l \in V \) such that \( s \cup \{v_1, \ldots, v_l\} \in S_{m+l} \).
   - As on page 1786 we consider the following ordered \( l \)-simplex of \( \text{sd}(K) \):
     \[ G(s \mid v_1, \ldots, v_l) := (s, s \cup \{v_1\}, \ldots, s \cup \{v_1, \ldots, v_l\}) \]
   - (3) Let \( k \in \mathbb{N}_0 \) and let \( s \in S_{n-k} \) be an \((n-k)\)-simplex. As on page 1795 we consider
     \[ Z(s) := \{ \text{all simplices of } \text{sd}(K) \text{ of the form } G(t \mid v_1, \ldots, v_l) \text{ with } s \subset t \} \]
     Furthermore, as on page 1794 we consider the following:
     \[ X^k := \text{the subcomplex of } \text{sd}(K) \text{ given by all } Z(s) \text{ with } s \in S_{n-k} \]

Now we can formulate the main result of this section.

**Proposition 71.14.** Let \( M \) be a closed \( n \)-dimensional smooth manifold. Furthermore let \((K = (V, S), \Theta: |K| \rightarrow M)\) be a smooth simplicial structure.

1. For each \((n-k)\)-simplex \( s \) we have a homeomorphism \(|Z(s)| \cong B^k\).
(2) There exists a CW-structure on $M$ such that for each $k \in \mathbb{N}_0$ the following holds:
   (a) The $k$-cells are given by the $|Z(s)|$ with $s \in S_{n-k}$.
   (b) The $k$-skeleton is given by $|X^k|$.
(3) If we equip $M$ with the CW-structure from (2), then there exists a natural isomorphism $D_k^{\text{simp}}(K) \to C_k^{CW}(M)$ of chain complexes.

We refer to the CW-structure described in Proposition 11.4 as the dual CW-structure of the smooth manifold. We refer to Figure 1110 for an illustration.

**Sketch of proof.** Let $M$ be a closed $n$-dimensional smooth manifold. Furthermore let $(K = (V, S), \Theta: |K| \to M)$ be a smooth simplicial structure. Note that we know by Theorem 61.14 that $(K = (V, S), \Theta: |K| \to M)$ is a closed $n$-dimensional PL-manifold. This implies that we might as well prove the statement under the hypothesis that we are dealing with a closed $n$-dimensional PL-manifold. Furthermore note that it follows immediately from the definition of a PL-manifold, see page 1599, together with Lemma 62.3 that the barycentric subdivision $\text{sd}(K)$ is also a closed $n$-dimensional PL-manifold.

Now let us turn to the proof of the three statement.

(1) One could prove this statement in one go, but it seems didactically opportune to first consider the two simplest cases.

   (a) Let $s = \{v_0\}$ be a 0-simplex of $K$. We have the following homeomorphisms:

   $$|Z(\{v_0\})| \uparrow \uparrow = |\text{St}(\text{sd}(K), \{v_0\})| \uparrow \uparrow = |\text{PL } n\text{-ball}| \cong \overline{B}^n.$$ 

   follows immediately by Proposition 61.11 since $\text{sd}(K)$ is an $n$-dimensional PL-manifold implies homeomorphic

   (b) Next let $s = \{v_0, v_1\}$ be a 1-simplex of $K$. Note that

   $$|Z(\{v_0, v_1\})| \uparrow \uparrow = |\text{St}(\text{Lk}(\text{sd}(K), \{v_0\}), \{v_0, v_1\})| \uparrow \uparrow = |\text{St}(\text{PL } (n-1)\text{-sphere}, \{v_0, v_1\})|
   = |\text{St}(\text{closed } (n-1)\text{-dimensional PL-manifold}, \{v_0, v_1\})|$$

   as we pointed out on page 1600 it follows from Proposition 61.10 that a PL $(n-1)$-sphere is a closed $(n-1)$-dimensional PL-manifold

   $$\cong |\text{PL } (n-1)\text{-ball}| \cong \overline{B}^{n-1}.$$ 

   Proposition 61.11 since PL-homeomorphic implies homeomorphic
(c) Finally let \( s = \{v_0, \ldots, v_k\} \) be any \( k \)-simplex of \( K \). Similar to (b) we see that \( Z(s) \) is the star of an iterated sequence of \( k \) links. Applying Proposition 64.11 multiple times we see that \( Z(s) \) is homeomorphic to \( B^{n-k} \). We leave it to the reader to write down this notationally messy argument.

**Figure 11.11.** Illustration for the proof of Proposition 71.14 (b).

(2) This statement follows fairly immediately from (1). We leave it to the reader to fill in the details.

(3) Given each \( k \in \mathbb{N}_0 \) we consider the map

\[
\text{D}_k^{\text{simp}}(K) \to \text{H}_k^{\text{simp}}(X^k, X^{k-1}) \xrightarrow{\xi} \text{H}_k(\partial X^k, \partial X^{k-1}) = C_k^{CW}(M).
\]

Note that by Lemma 63.30 we know that the left maps are well-defined and that they form an isomorphism of chain complexes. We obtain immediately from Lemma 63.30 (3) that the right maps also form an isomorphism of chain complexes. The composition of the two chain isomorphisms thus gives us the promised natural isomorphism of chain complexes.

**Exercises for Chapter 71**

**Exercise 71.1.** Let \( T \) be the simplicial 2-dimensional torus. By Exercise 66.1 we know that the suspension \( \Sigma(T) \) is a closed orientable 3-dimensional pseudomanifold. Show that the conclusion of the Simplicial Poincaré Duality Theorem 71.4 does not hold for \( \Sigma(T) \).

**Exercise 71.2.** Let \( K \) be a simplicial complex. Show that \( K \) is an \( n \)-dimensional simplicial homology manifold if and only if the topological realization \( |K| \) is an \( n \)-dimensional homology manifold. Recall by the definition on page 1168 a topological space \( X \) is called an \( n \)-dimensional homology manifold if for each \( x \in X \) we have

\[
\text{H}_k(X, X \setminus \{x\}; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = n, \\
0, & \text{otherwise}. 
\end{cases}
\]

**Exercise 71.3.**

(a) Let \( M \) be a connected closed 3-dimensional smooth manifold. Show that if \( M \) is non-orientable, then \( \text{H}_1(M; \mathbb{Z}) \) is infinite.

(b) Is the hypothesis in (a) that \( M \) is closed necessary?
Exercise 71.4. Let $M$ and $N$ be two closed orientable connected non-empty 3-dimensional smooth manifolds such that $\pi_1(M)$ is isomorphic to $\pi_1(N)$. Show that for all $i \in \mathbb{N}_0$ there exists an isomorphism $H_i(M;\mathbb{Z}) \cong H_i(N;\mathbb{Z})$.

Exercise 71.5. Let $W$ be a closed orientable connected 4-dimensional smooth manifold with Euler characteristic $\chi(W) = -3$.

(a) Show that $W$ admits a finite connected covering $\tilde{W}$ with $\chi(\tilde{W}) < -27$.

(b) Is the hypothesis in (a) that $W$ is orientable necessary?

Exercise 71.6. Let $M$ be a closed orientable connected odd-dimensional smooth manifold and let $f: M \to M$ be a map such that the induced map $f_*: H_n(M) \to H_n(M)$ is the identity. Show that the Lefschetz number

$$\Lambda(\varphi) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\varphi_*: H_n(M) \to H_n(M)),$$

equals zero.

Exercise 71.7. Let $n \in \mathbb{N}$ and let $M$ be a closed oriented connected non-empty $n$-dimensional smooth manifold. Suppose that there exists a map $f: S^n \to M$ of degree $\pm 1$, i.e. such that $f_*([S^n]) = [M] \in H_n(M)$. Show that $H_i(M) = 0$ for $i = 1, \ldots, n - 1$.

Remark. In Proposition 69.9 we showed under the same hypotheses that we also have $\pi_1(M) = 0$.

Exercise 71.8.

(1) Give a suitable definition of an $n$-dimensional simplicial homology manifold with boundary.

(2) Let $K$ be a connected orientable $n$-dimensional simplicial homology manifold with non-empty boundary $\partial K$. We consider $M := K \cup_{\partial K} \text{Cone}(\partial K)$, i.e. we consider the simplicial mapping cone of the inclusion $L \to K$.

(a) Show that $M = K \cup_{\partial K} \text{Cone}(\partial K)$ is a closed orientable $n$-dimensional pseudo-manifold.

(b) Show that

$$H_i(D_k(M)) \cong \begin{cases} 0, & \text{if } k = n, \\ H^\text{simp}_i(\text{sd}(K)), & \text{otherwise}. \end{cases}$$

Remark. This is a non-trivial variation on Proposition 71.11.

(c) Use the above together with Proposition 71.9 and Exercise 67.3 to show that for every $i \in \mathbb{N}_0$ there exists a natural isomorphism $H^\text{simp}_i(K,\partial K;\mathbb{Z}) \to H^\text{simp}_{n-i}(K;\mathbb{Z})$. 
Part VIII

Singular Cohomology
In this section we will take a short break from overly abstract concepts and we study chirality of objects in $\mathbb{R}^3$, knots and topological manifolds. We will run into several questions which will motivate us to develop new tools in the study of topological spaces.

72.1. Chiral objects. In physics or chemistry an object $X$ in $\mathbb{R}^3$ is called amphichiral (or often short achiral) if it agrees with its mirror image, otherwise it is called chiral. To make this definition more precise we have to explain what we mean by “mirror image” and what we mean by “agree”.

First of all, given a hyperplane $H \subset \mathbb{R}^3$ through the origin we denote by $\rho_H : \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the hyperplane $H$. Sometimes in this chapter we will extend $\rho_H$ to a map from $S^3 = \mathbb{R}^3 \cup \{\infty\}$ to itself by setting $\rho_H(\infty) = \infty$.

The following lemma says that any two reflections in a hyperplane through the origin differ by multiplication by a matrix in $\text{SO}(3)$.

**Lemma 72.1.** If $H$ and $G$ are two hyperplanes in $\mathbb{R}^3$ through the origin, then there exists a matrix $A \in \text{SO}(3)$ such that for all $v \in \mathbb{R}^3$ we have

$$\rho_G(v) = A \cdot \rho_H(v).$$

**Sketch of proof.** With respect to the standard basis of $\mathbb{R}^3$ the maps $\rho_G$ and $\rho_H$ are represented by orthogonal matrices $P$ and $Q$ with determinant $-1$. The matrix $A = PQ^{-1}$ then lies in $\text{SO}(3)$ and for any $v \in \mathbb{R}^3$ we have $\rho_G(v) = Pv = A \cdot Qv = A \cdot \rho_H(v)$. ■

The above discussion leads us to the following definitions.

**Definition.** Let $X$ be a subset of $\mathbb{R}^3$.

1. We say another subset $Y$ of $\mathbb{R}^3$ agrees with $X$ if there exists a matrix $A \in \text{SO}(3)$ and a point $P \in \mathbb{R}^3$ such that $X = A \cdot Y + P = \{A \cdot y + P \mid y \in Y\}$.
2. For every hyperplane $H \subset \mathbb{R}^3$ we refer to $\rho_H(X)$ as the mirror image of $X$.
3. We say $X$ is amphichiral if its mirror image agrees with $X$, otherwise we say $X$ is chiral.

**Examples.**

1. Human hands are chiral, indeed, the left-hand does not agree with the right-hand. In fact the term chirality is derived from the Greek word for hand, χειρ.
2. Many molecules are chiral, see e.g. Figure 112 for an example of a chiral molecule.

---

1057 How is the reflection in a hyperplane defined?
1058 To be precise, the definition of the mirror image depends on the choice of the hyperplane. By Lemma 72.1 reflections in two different hyperplanes differ by multiplication by a matrix in $\text{SO}(3)$, i.e. the mirror images with respect to different hyperplanes agree in the above sense.
1059 The same word is also the etymological root for the German word “Chirurg”.
1060 In fact, how can you show that the molecule is chiral?
72.2. **Chiral knots.** Now we turn our focus to knots. We recall some of the relevant definitions from pages 385 and 780.

**Definition.**

1. A *knot* is a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to $S^1$.
2. Given a knot $K \subset S^3$ the reflection of $K$ in any hyperplane of $\mathbb{R}^4$ is called *mirror* of $K$ and denoted by $K^{\text{mir}}$. Note that in Exercise 27.1 we showed that, up to a smooth isotopy, the definition of $K^{\text{mir}}$ does not depend on the choice of the hyperplane.

**Example.** In Figure 1113 we show the trefoil and its mirror and we also show the figure-8 knot and its mirror. In both cases the question arises whether the original knot and its mirror are smoothly isotopic.

Next we recall the following definition from page 781.

**Definition.** We say that a knot $K$ in $\mathbb{R}^3$ is *amphichiral* if it is smoothly isotopic to its mirror image, otherwise we call the knot $K$ *chiral.*

**Example.** In Figure 504 we showed that the figure-8 knot $J$ is smoothly isotopic to its mirror image $J^*$, i.e. the figure-8 knot is amphichiral.

We recall the following question on which so far we have made zero progress.

**Question 27.9.** Is the trefoil chiral?
The question that naturally arises is, what does this discussion have to do with homology groups? How can we address this question using the tools of algebraic topology? In the following section we will turn Question 27.9 into a question about homology groups.

72.3. Chiral topological manifolds.

Definition. Let $M$ be a compact oriented topological manifold. We say that $M$ is amphichiral if $M$ admits an orientation-reversing self-homeomorphism, otherwise we say that $M$ is chiral.

In the next proposition, which is a variation on Lemma 68.7, we will give several criteria for a self-homeomorphism to be orientation-preserving.

Proposition 72.2. Let $M$ be a compact oriented connected $n$-dimensional topological manifold and let $f: M \to M$ be a homeomorphism. Then the following three statements are equivalent:

1. The map $f$ is orientation-preserving in the sense of the definition on page 2105.
2. There exists a point $x \in M \setminus \partial M$ and an open neighborhood $U$ of $x$, e.g. $U = M$, such that
   \[ f_*(\text{orientation at } x) = \text{orientation at } f(x). \]

3. We have $f_*(\lbrack M \rbrack) = \lbrack M \rbrack$.

Suppose $M$ is in fact a smooth manifold and that $f$ is a diffeomorphism. We equip $M$ with the orientation in the sense of Section 6.11 coming from Proposition 86.11. Then the above are equivalent to the following statement:

4. The map $f$ is orientation-preserving in the sense of Section 6.11.

Analogously the above statements also hold if in (1) and (4) we replace “orientation-preserving” by “orientation-reversing” and if in (2) and (3) we add a minus sign.

For the most part the proof of Proposition 72.2 boils down to the following lemma which is also useful in its own right.

Lemma 72.3. Let $f: M \to N$ be a map between compact oriented connected $n$-dimensional topological manifolds such that $f(\partial M) \subset \partial N$. Let $x \in M \setminus \partial M$ and let $U$ be an open neighborhood of $x$ with the property that $f$ restricts to a homeomorphism $f: U \to f(U)$ and such that $f^{-1}(f(x)) = \{x\}$. Then

\[
\deg(f: M \to N) = \deg(f_*: H_n(M, M \setminus \{x\}; \mathbb{Z}) \to H_n(N, N \setminus \{f(x)\}; \mathbb{Z})) = \deg(f_*: H_n(U, U \setminus \{x\}; \mathbb{Z}) \to H_n(f(U), f(U) \setminus \{f(x)\}; \mathbb{Z})).
\]

Proof. Let $M$ and $N$ be compact connected $n$-dimensional topological manifolds that are equipped with orientations $\{\mu_x\}_{x \in M \setminus \partial M}$ and $\{\nu_x\}_{x \in N \setminus \partial N}$. Furthermore let $f, x \in M \setminus \partial M$.

---

\textsuperscript{106} Recall that by the construction of Lemma 86.17 the orientation on $M$ induces an orientation on any open subset.
and $U$ as above. We consider the following commutative diagram

$$
\begin{array}{ccc}
H_n(M, \partial M; \mathbb{Z}) & \xrightarrow{f^*} & H_n(N, \partial N; \mathbb{Z}) \\
\downarrow & & \downarrow \\
H_n(M, M \setminus \{x\}; \mathbb{Z}) & \xrightarrow{f^*} & H_n(N, N \setminus \{f(x)\}; \mathbb{Z}) \\
\uparrow & & \uparrow \\
H_n(U, U \setminus \{x\}; \mathbb{Z}) & \xrightarrow{f^*} & H_n(f(U), f(U) \setminus \{f(x)\}; \mathbb{Z}).
\end{array}
$$

We make the following observations:

1. the top vertical maps are isomorphisms by Theorem 87.1,
2. the bottom vertical maps are isomorphisms by the Excision Theorem 43.20,
3. it follows from Corollary 87.4 that the vertical maps send the fundamental classes $[M]$ and $[N]$ to the orientations $\mu_x$ respectively $\nu_{f(x)}$.

The desired equalities follow easily from these observations.\addcontentsline{toc}{chapter}{Examples.}

**Examples.** Let $n \in \mathbb{N}_0$.

1. It follows from Lemma 45.11 (6) that the map

$$
\rho: S^n \rightarrow S^n
$$

$$(x_0, \ldots, x_{n-1}, x_n) \mapsto (x_0, \ldots, x_{n-1}, -x_n),$$

i.e. the map that is given by reflection in the $x_n = 0$ hyperplane, is orientation-reversing. This shows that the sphere $S^n$ is amphichiral.

2. Let $M$ be a closed, oriented topological manifold. It follows from (1) and the naturality of the Künneth Theorem 58.8 for topological spaces that the map

$$
S^n \times M \rightarrow S^n \times M
$$

$$(x, P) \mapsto (\rho(x), P),$$

is orientation-reversing. This shows that the product of the sphere $S^n$ with any closed, oriented topological manifold is amphichiral.

Now we want to relate the notion of amphichiral knots to the notion of amphichiral smooth manifolds. Before we can do so we recall the following definition.

**Definition.** Let $K \subset \mathbb{R}^3$ be a knot. We pick a tubular neighborhood $B^2 \times K$ as provided by the Tubular Neighborhood Theorem 8.24. We refer to $X_K := S^3 \setminus (B^2 \times K)$ as the **exterior of $K$**.
**Proposition 72.4.** Let $K \subset \mathbb{R}^3$ be a knot. If $K$ is amphichiral, then the knot exterior $X_K$ is also amphichiral.

**Remark.** We had just seen in Proposition 72.4 that the exterior of an amphichiral knot is amphichiral. The converse to that statement is also true, i.e. if the exterior of a knot is amphichiral, then the knot is also amphichiral. But this direction is much harder to prove. To the best of my knowledge it follows from a very difficult theorem by Cameron Gordon and John Luecke [GL89] p. 371 from 1989.

**Proof.** Let $K \subset \mathbb{R}^3$ be an amphichiral knot. By the Tubular Neighborhood Theorem 8.24 we can pick a tubular neighborhood $\nu K = B^2 \times K$. As on page 1728 we consider the knot exterior $X_K := S^3 \setminus (B^2 \times K)$. By Proposition 72.2 it suffices to show that there exists a homeomorphism $f: X_K \to X_K$ with $f_*([X_K]) = -[X_K]$.

We denote by $\rho$ the reflection in a hyperplane of $\mathbb{R}^3$. As usual we extend $\rho$ to a self-homeomorphism of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ by setting $\rho(\infty) = \infty$. We write $K^{\text{mir}} = \rho(K)$ and $\nu K^{\text{mir}} = \rho(\nu K)$. By hypothesis there exists a smooth isotopy from $K^{\text{mir}}$ to $K$. By the Isotopy Extension Theorem 8.27 this smooth isotopy extends to a smooth diffeotopy of $S^3$. This means that we have a smooth map

$$F: S^3 \times [0,1] \to S^3$$

such that $F_0 = \text{id}$, such that each $F_t$ is a diffeomorphism and such that $F_1(K^{\text{mir}}) = K$. We write $\Phi := F_1: S^3 \to S^3$. Then $\Phi(\nu K^{\text{mir}})$ is also a tubular neighborhood for $K$ and by Proposition 8.26 there exists an orientation-preserving diffeomorphism $\Psi: S^3 \to S^3$ with $\Psi(\Phi(\nu K^{\text{mir}})) = \nu K$. We write $f := \Psi \circ \Phi \circ \rho$.

\[\text{Figure 1114}\]

The following proposition together with Proposition 72.2 now turns Question 27.9 into a question about topological spaces.

As we pointed out in Lemma 68.16 the exterior $X_K$ is a compact orientable smooth manifold and the diffeomorphism type of $X_K$ as an oriented smooth manifold is well-defined, i.e. it is independent of the choice of the tubular neighborhood.
Now we consider the following commutative diagram

\[
\begin{array}{cccccc}
H_3(S^3) & \xrightarrow{\rho_*} & H_3(S^3) & \xrightarrow{\Phi_*} & H_3(S^3) & \xrightarrow{\Psi_*} & H_3(S^3) \\
\downarrow{\cong} & & \downarrow{\cong} & & \downarrow{\cong} & & \downarrow{\cong} \\
H_3(S^3, \nu K) & \xrightarrow{\rho_*} & H_3(S^3, \nu K^{\text{mir}}) & \xrightarrow{\Phi_*} & H_3(S^3, \Phi(\nu K^{\text{mir}})) & \xrightarrow{\Psi_*} & H_3(S^3, \nu K) \\
\downarrow{\cong} & & \downarrow{\cong} & & \downarrow{\cong} & & \downarrow{\cong} \\
H_3(X_K, \partial X_K) & \xrightarrow{\rho_*} & H_3(X_K^{\text{mir}}, \partial X_K^{\text{mir}}) & \xrightarrow{\Phi_*} & H_3(\Phi(X_K^{\text{mir}}), \Phi(\partial X_K^{\text{mir}})) & \xrightarrow{\Psi_*} & H_3(X_K, \partial X_K). \\
\end{array}
\]

Here the upper left vertical map is an isomorphism by the long exact sequence of the pair \((S^3, \nu K)\) and the fact that \(H_i(\nu K) = 0\) for \(i = 2, 3\) since \(\nu K = K \times B^2\) is homotopy equivalent to \(S^1\). Exactly the same argument shows that in fact all upper vertical maps are isomorphisms. The lower vertical maps are induced by the inclusion of pairs of topological spaces. All of them are isomorphisms by the Excision Theorem for Smooth Manifolds [44.10].

By Proposition [72.2], we are done once we have shown that the composition of three bottom horizontal maps is given by multiplication by \(-1\). By the commutative diagram it suffices to prove the analogous statement for the composition of the top three horizontal maps. It follows from Lemma [45.11] (6) that the top-left horizontal map is given by multiplication by \(-1\). It is a consequence of Proposition [42.5] that the top-middle horizontal map is the identity, since \(\Phi\) is homotopic to the identity. Finally using Proposition [72.2], we see that the top-right horizontal map is the identity since \(\Psi\) is orientation-preserving.

Now we continue with our discussion of examples of amphichiral smooth manifolds.

Examples.

1. We had just seen on page [1809] that topological manifolds of the type \(S^n \times M\) are amphichiral. It follows that the torus \(S^1 \times S^1\) is amphichiral.

2. The surface of genus 2 is amphichiral. Pictorially an orientation-reversing self-homeomorphism is given by “reflection in the \(yz\)-plane”, see Figure [1113] on the left. In the “octagon-picture” an orientation-reversing self-homeomorphism is given by the reflection \(f\) in the line illustrated in Figure [1115] on the left. It follows easily from Proposition [72.2] applied to the point \(x = 0\) and \(U\) an open disk around \(x\) together with Lemma [86.2] that the map \(f\) is indeed orientation-reversing.

![Figure 1115](image-url)
(3) All other compact oriented 2-dimensional smooth manifolds are also amphichiral. We show some of the orientation-reversing maps in Figure 1116. In Exercise 72.2 we will discuss how these maps can be described rigorously.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1116.png}
\caption{Reflection in the \(yz\)-hyperplane is orientation reversing}
\end{figure}

(4) Example (2) can also be generalized as follows: if \(M\) is a compact oriented topological manifold, then its double \(D M = (M \cup M')/ \sim\) is amphichiral. Indeed, the map \(f: D M \to D M\) that swaps the two copies of \(M\) is orientation-reversing. This follows immediately from the definition of the orientation of \(D M\) that we gave in Lemma 86.18.

The long list of examples of amphichiral smooth manifolds raises the following question.

\textbf{Question 72.5. Are there compact oriented topological manifolds that are chiral?}

We end this chapter with a short discussion of lens spaces. Let \(p \in \mathbb{N}\) and let \(q \in \mathbb{N}\) be coprime to \(p\). On page 502 we defined the lens space

\[ L(p, q) = S^3 / \mathbb{Z}_p = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\}/(z_1, z_2) \sim (e^{2\pi i/p} z_1, e^{2\pi i q/p} z_2). \]

Furthermore, on page 502 we had equipped \(L(p, q)\) with the orientation which turns the obvious projection map \(S^3 \to L(p, q)\) into an orientation-preserving map.

Now let \(q, r \in \mathbb{Z}\) with \(\gcd(p, q) = \gcd(p, r) = 1\). In Lemma 16.6 we showed that if \(q \equiv \pm r \mod p\), then \(L(p, q)\) and \(L(p, r)\) are diffeomorphic.\footnote{We still don’t know whether the converse holds.} The following lemma is now a slight refinement of Lemma 16.6.

\textbf{Lemma 72.6.} Let \(p \in \mathbb{N}\) and let \(q, r \in \mathbb{Z}\) with \(\gcd(p, q) = \gcd(p, r) = 1\).

1. In the case that \(q \equiv r \mod p\) there exists an orientation-preserving diffeomorphism \(L(p, q) \to L(p, r)\).

2. On the other hand, if \(q \equiv -r \mod p\), then there exists an orientation-reversing diffeomorphism \(L(p, q) \to L(p, r)\).
Proof. Let \( p \in \mathbb{N} \) and let \( q, r \in \mathbb{Z} \) with \( \gcd(p, q) = \gcd(p, r) = 1 \). We suppose that \( q \equiv \pm r \pm 1 \mod p \). As in the proof of Lemma \[16.6\] we define a diffeomorphism

\[ \Phi : S^3 \to S^3 \]

as follows:

- Case 1: \( q \equiv r \mod p \). \((z_1, z_2) \mapsto (z_1, z_2)\)
- Case 2: \( q \equiv -r \mod p \). \((z_1, z_2) \mapsto (z_1, z_2)\)
- Case 3: \( q \equiv r^{-1} \mod p \). \((z_1, z_2) \mapsto (z_2, z_1)\)
- Case 4: \( q \equiv -r^{-1} \mod p \). \((z_1, z_2) \mapsto (z_2, z_1)\)

In all four cases it is straightforward to verify that the map descends to a diffeomorphism \( L(p, q) \to L(p, r) \). It follows fairly easily from Lemma \[45.11\] and Proposition \[72.2\] that the diffeomorphism \( \Phi \) is orientation-preserving in cases 1 and 3 and that it is orientation-reversing in cases 2 and 4.\footnote{For example in case 3 the map is given by \((x_1, x_2, x_3, x_4) \mapsto (x_3, x_4, x_1, x_2)\) which is the composition of two reflections in hyperplanes, namely in the \( x_1 = x_3 \) and the \( x_2 = x_4 \) hyperplane.}

The lemma now follows from the fact that the projection maps \( S^3 \to L(p, q) \) and \( S^3 \to L(p, r) \) are orientation-preserving.

Example. Note that \(-2^{-1} \equiv -3 \equiv 2 \mod 5\). Thus we obtain from Lemma \[72.6\] that there exists an orientation-reversing diffeomorphism \( L(5, 2) \to L(5, 2) \), i.e. the lens space \( L(5, 2) \) is amphichiral.

The argument of the previous example does not work for the lens space \( L(3, 1) \). So the following question arises:

**Question 72.7.** Is the lens space \( L(3, 1) \) chiral?

With our present knowledge we are not able to answer Questions \[27.9\], \[72.5\] and \[72.7\]. The key to answering these three questions will be the cohomology groups that we introduce in Chapter \[73\].

---

**Exercises for Chapter 72**

**Exercise 72.1.** Why is the molecule shown in Figure \[117\] chiral? How can you show rigorously that the two molecules left and right cannot be turned into one another using a translation and a matrix in SO(3)?

**Exercise 72.2.**

(a) Give a rigorous proof for the statement that the surface of genus 3 is amphichiral. More precisely, give a precise description of the surface of genus 3 (e.g. as a dodecagon with appropriate identifications) and indicate carefully an orientation-reversing self-homeomorphism.

(b) Do the same exercise for the genus 2 surface with two open disks removed.
Figure 1117
73. THE COHOMOLOGY GROUPS OF A TOPOLOGICAL SPACE

In this chapter we will introduce the cohomology groups $H^k(X; G)$ of a topological space together with a choice of an abelian group $G$. These study of the cohomology will keep us busy for a very long time. For many mathematicians it takes a long time till they feel fully comfortable with cohomology group since elements of cohomology groups are much less visual than elements of homology groups. Perhaps, before we embark on our new adventure it is good quote John von Neumann who said

“In mathematics you don’t understand things. You just get used to them.”

73.1. The Hom-functor. We start out with the following obvious notation.

Notation. Given a group $A$ and an abelian group $G$ we write

$$\text{Hom}(A, G) = \{\text{all group homomorphisms } A \to G\}.$$  

The set of homomorphisms $\text{Hom}(A, G)$ has the structure of an abelian group with the sum of two homomorphisms $\varphi, \psi: A \to G$ given by the group homomorphism that is defined by $(\varphi + \psi)(a) := \varphi(a) + \psi(a)$.

Example. We leave it to the reader to provide a proof for the statement that for any $n \in \mathbb{N}$ and any abelian group $G$ we have a natural isomorphism $\text{Hom}(\mathbb{Z}_n, G) \cong \ker(G \xrightarrow{n} G)$. Note that this implies in particular that for any $m \in \mathbb{N}$ we have $\text{Hom}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n, m)}$.

On several occasions we will implicitly and explicitly use the following lemma which is an immediate consequence of Lemma 19.1.

Lemma 73.1. (⋆) Let $G$ be an abelian group. If $S$ is a non-empty set, then the homomorphism

$$\text{Hom}(\mathbb{Z}^S(G), G) \to \{\text{all maps from the set } S \text{ to } G\}$$

$$(\varphi: \mathbb{Z}^S \to G) \mapsto \left( S \to G \quad s \mapsto \varphi(s) \right)$$

is an isomorphism. In particular the map

$$\text{Hom}(\mathbb{Z}, G) \to G$$

$$\varphi \mapsto \varphi(1)$$

is an isomorphism.

Recall that on page 580 given a non-empty set $S$ we defined

$$\mathbb{Z}^S := \text{ all maps from } S \text{ to } \mathbb{Z},$$

and we defined the free abelian group generated by $S$ to be the subgroup

$$\mathbb{Z}^S := \text{ all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S.$$ 

Following the notation introduced on page 580 we view each $s \in S$ as an element in $\mathbb{Z}^S$.

Why do we write $\mathbb{Z}^S$ in the lemma? Should it not be $\mathbb{Z}^S$?

Note that the group structure on $G$ turns both sides of the lemma into a group, so the given map clearly respects this group structure, i.e. the given map is a homomorphism.
Let $G$ be an abelian group and let $f: A \to B$ be a group homomorphism. Then $f$ induces a homomorphism
\[ f^*: \text{Hom}(B, G) \to \text{Hom}(A, G) \]
\[ (\varphi: B \to G) \mapsto \left( A \to G, a \mapsto \varphi(f(a)) \right). \]

**Example.** Let $G$ be an abelian group.

1. If $A$ is a subgroup of a group $B$ and if $i: A \to B$ is the inclusion map, then for each homomorphism $\varphi: B \to G$ the homomorphism $i^* \varphi: A \to G$ is just the restriction of $\varphi$ to $A \subset B$.

2. If $S$ is a subset of a set $T$, then we have a natural inclusion $i: \mathbb{Z}(S) \to \mathbb{Z}(T)$ and it follows from Lemma 73.1 that the map $i^*: \text{Hom}(\mathbb{Z}(T), G) \to \text{Hom}(\mathbb{Z}(S), G)$ is an epimorphism. Indeed, we just extend the map $S \to G$ to a map $T \to G$ by assigning the trivial element in $G$ to all elements in $T \setminus S$.

It follows immediately from the definitions that
\[ (\text{id}_A)_* = \text{id}_{\text{Hom}(A, G)}, \quad \text{for all groups } A \]
and
\[ (g \circ f)^* = f^* \circ g^* \quad \text{for all homomorphisms } f: A \to B \text{ and } g: B \to C. \]

Put differently, given an abelian group $G$ the maps
\[ A \mapsto \text{Hom}(A, G) \]
\[ (f: A \to B) \mapsto (f^*: \text{Hom}(B, G) \to \text{Hom}(A, G)) \]
define a contravariant functor from the category of groups to the category of abelian groups.

**Remark.** If $R$ is a commutative ring, for example if $R = \mathbb{Z}_n, R = \mathbb{Z}, R = \mathbb{Q}$ or $R = \mathbb{R}$, then for any group $C$ the set of homomorphisms $\text{Hom}(C, R)$ forms an $R$-module in an obvious way. More precisely, given a homomorphism $\varphi: C \to R$ and $r \in R$ we define $r \varphi$ to be the homomorphism given by $c \mapsto r \cdot \varphi(c)$. Now we see easily that the above maps $A \mapsto \text{Hom}(A, R)$ and $f \mapsto f^*$ define a contravariant functor from the category of groups to the category of $R$-modules.

The following lemma might be familiar from linear algebra. We refer to [Rot09, Theorem 2.32(i)] for more details.

**Lemma 73.2.** Let $\{A_i\}_{i \in I}$ be a family of groups and let $G$ be an abelian group. Then the map
\[ \text{Hom} \left( \bigoplus_{i \in I} A_i, G \right) \to \prod_{i \in I} \text{Hom}(A_i, G) \]
\[ f \mapsto \prod_{i \in I} f|_{A_i} \]
is an isomorphism.

The following rather technical lemma will be used later on.
Lemma 73.3. Let \( \{ A_i \}_{i \in \mathbb{N}}, \{ \varphi_{ij} : A_i \to A_j \}_{i \leq j} \) be a direct system of groups and let \( G \) be an abelian group. Then

\[
\{ \text{Hom}(A_i, G) \}_{i \in \mathbb{N}}, \{ \varphi^*_{ij} : \text{Hom}(A_j, G) \to \text{Hom}(A_i, G) \}_{i \leq j}
\]
is an inverse system of abelian groups (or modules if \( G \) is a commutative ring), and we have a natural isomorphism

\[
\text{Hom} \left( \lim_{\longrightarrow} A_i, G \right) \cong \lim_{\longleftarrow} \text{Hom}(A_i, G)
\]
of abelian groups (or modules if \( G \) is a commutative ring).

Proof. As so often for arguments regarding limits, the proof follows mostly from unraveling the definitions. We refer to [Rot09, Proposition 5.26] for more details. ■

We continue with the following lemma which we will use on many occasions.

Lemma 73.4. Let

\[
0 \to A \overset{i}{\to} B \overset{\varphi}{\to} C \to 0
\]

be a short exact sequence of abelian groups and let \( G \) be an abelian group. If \( C \) is free abelian, then the dual sequence

\[
0 \to \text{Hom}(C, G) \overset{\varphi^*}{\to} \text{Hom}(B, G) \overset{i^*}{\to} \text{Hom}(A, G) \to 0
\]
is also exact.

Proof. It follows from the hypothesis that \( C \) is a free abelian and from Lemma 46.1 that the initial short exact sequence splits. But this means that, according to Splitting Lemma 46.2, that there exists an isomorphism \( \Phi : B \to A \oplus C \) such that the following diagram commutes:

\[
\begin{array}{c}
0 \to A \overset{i}{\to} B \overset{\varphi}{\to} C \to 0 \\
\downarrow^{=} \quad \quad \quad \quad \quad \quad \quad \quad \downarrow^{=} \\
0 \to A \overset{\Phi}{\to} A \oplus C \overset{(a,c)\to c}{\to} C \to 0.
\end{array}
\]

By applying the contravariant \( \text{Hom}(-, G) \) functor we obtain the upper half of the following commutative diagram:

\[
\begin{array}{c}
0 \leftarrow \text{Hom}(A, G) \leftarrow \varphi^* \leftarrow \text{Hom}(B, G) \leftarrow \varphi^* \leftarrow \text{Hom}(C, G) \leftarrow 0 \\
\uparrow^{=} \quad \quad \quad \quad \quad \quad \quad \quad \uparrow^{=} \\
0 \leftarrow \text{Hom}(A, G) \leftarrow (a \to (a,0))^* \leftarrow \text{Hom}(A \oplus C, G) \leftarrow ((a,c)\to c)^* \leftarrow \text{Hom}(C, G) \leftarrow 0 \\
\uparrow^{=} \quad \quad \quad \quad \quad \quad \quad \quad \uparrow^{=} \\
0 \leftarrow \text{Hom}(A, G) \leftarrow f \oplus g \to f \leftarrow \text{Hom}(A \oplus C, G) \leftarrow g \oplus 0 \leftarrow \text{Hom}(C, G) \leftarrow 0.
\end{array}
\]

One can easily verify that the lower half of the diagram commutes. Furthermore it is evident that the bottom sequence is exact. Finally it is straightforward to see that the vertical maps are isomorphisms we obtain that the upper sequence is also exact. But that is exactly what we wanted to prove. ■
73.2. Cochain complexes. Now we introduce the notion of a cochain complex and of its cohomology groups. A cochain complex is exactly the same as a chain complex except that the boundary map now increases the degree by one instead of lowering it by one.

**Definition.**

1. A cochain complex is a sequence

\[ \cdots \leftarrow D^n \xleftarrow{\delta_{n-1}} D^{n-1} \xleftarrow{\delta_{n-2}} \cdots \xleftarrow{\delta_2} D^1 \xleftarrow{\delta_1} D^0 \leftarrow 0 \]

of maps between abelian groups such that for all \( i \in \mathbb{N}_0 \) we have \( \delta_{i+1} \circ \delta_i = 0 \). We refer to the maps \( \delta_i \) as coboundary maps.

2. We define the \( n \)-th cohomology group of a cochain complex \((D^*, \delta_*)\) to be

\[ H^n(D) := \frac{\ker(\delta_n : D^n \to D^{n+1})}{\text{im}(\delta_{n-1} : D^{n-1} \to D^n)}. \]

**Example.** It follows from [Lee02, Theorem 14.24] that the groups

\[ \Omega_n(M) := \{\text{all smooth } n\text{-forms on } M\}, \quad n \in \mathbb{N}_0 \]

together with the differentials \( d_n : \Omega_n(M) \to \Omega_{n+1}(M) \) define a cochain complex. The corresponding cohomology groups are called the de Rham cohomology groups of \( M \). We will return to this example in more detail in Chapter 78.

Now we will see that most of the definitions and algebraic results for chain complexes can be generalized almost verbatim to cochain complexes.

**Definition.**

1. A cochain map \( f : C^* \to D^* \) between two cochain complexes consists of a family \( \{f_n : C^n \to D^n\}_{n \in \mathbb{N}_0} \) of maps that commute with the coboundary maps, i.e. such that for all \( n \in \mathbb{N}_0 \) we have

\[ \delta_n \circ f_n = f_{n+1} \circ \delta_n : C^n \to D^{n+1}. \]

2. Let \( f, g : C^* \to D^* \) be two cochain maps between two cochain complexes \( C^* \) and \( D^* \). A cochain homotopy \( P = \{P_n\}_{n \in \mathbb{N}_0} \) between the cochain maps \( f \) and \( g \) consists of a family \( \{P_n : C^n \to D^{n-1}\}_{n \in \mathbb{N}_0} \) of maps such that for each \( n \in \mathbb{N}_0 \) we have

\[ \delta_{n-1} \circ P_n + P_{n+1} \circ \delta_n = f_n - g_n. \]

If there exists a cochain homotopy between cochain maps \( f \) and \( g \), then we say that \( f \) and \( g \) are cochain homotopic.
**Remark.** For orientation we summarize in the following diagram all objects arising in the definition of a cochain homotopy:

![Diagram of cochain homotopy](image)

The statements of the next lemma surely do not come as much of a surprise.

**Lemma 73.5.**

1. If \( f: C^* \to D^* \) is a cochain map between cochain complexes \( C^* \) and \( D^* \), then the map
   \[
   f_*: H^n(C) \to H^n(D)
   \]
   is well-defined.
2. Two cochain maps that are cochain homotopic induce the same map on cohomology groups.
3. Cochain complexes together with the cochain maps form a category, called the category of cochain complexes.

**Proof.** The first statement is proved the same way as Lemma 41.7 and the second statement is proved the same way as Lemma 42.1. The last statement follows immediately from the definitions. 

**Remark.** Let \( C^* \) and \( D^* \) be cochain complexes. On a few rare occasions we will need to deal with the following slight generalization of a cochain map. A *generalized cochain maps* is a family \( \{f_n: C^n \to D^n\}_{n \in \mathbb{N}_0} \) of maps that commute with the coboundary maps up to sign, i.e. such that for every \( n \in \mathbb{N}_0 \) there exists an \( \epsilon \in \{-1, 1\} \) such that \( \delta_n \circ f_n = f_{n+1} \circ \delta_n \). One can easily verify that the conclusion of Lemma 73.5 (1) also holds for generalized cochain maps.

One of the most important algebraic constructions in Algebraic Topology II was that we could associate to a short exact sequence of chain complexes a long exact sequence of homology groups. We have an almost identical construction for short exact sequences of cochain complexes and their cohomology groups. We will discuss this construction in detail. So let

\[
0 \to C^* \to B^* \to A^* \to 0
\]

be a short exact sequence of cochain complexes. In particular for each \( n \in \mathbb{N}_0 \) we have a commutative diagram

![Diagram of cochain complex sequence](image)
where the horizontal sequences are exact. Now we will define a connecting homomorphism

\[ \delta : H^n(A) \to H^{n+1}(C). \]

The definition is almost verbatim the same as the definition on page \[1115\] of the connecting homomorphism in homology. More precisely, we perform the following steps:

1. Let \( z \in H^n(A) \).
2. We pick \( \alpha \in A^n \) with \( z = [\alpha] \).
3. By the surjectivity of \( g_n \) we have \( \alpha = g_n(\beta) \) for some \( \beta \in B^n \).
4. From the commutativity of the diagram and the exactness of the horizontal sequences we see that \( \delta_n(\beta) = f_{n+1}(\gamma) \) for some uniquely determined \( \gamma \in C^{n+1} \).
5. We put \( \delta_n(z) := [\gamma] \in H^{n+1}(C) \).

The following proposition is now the obvious analogue of Lemma \[43.10\] and Proposition \[43.11\]. We leave it to the reader to make the necessary changes to the proof.

**Proposition 73.6.**

1. The connecting homomorphisms are well-defined and they are indeed homomorphisms.\[1069\]
2. The connecting homomorphisms are natural in the sense that commuting diagrams of short exact sequences of cochain complexes give rise to commuting diagrams of cohomology groups involving the connecting homomorphisms.
3. If

\[ 0 \to C^* \xrightarrow{f} B^* \xrightarrow{g} A^* \to 0 \]

is a short exact sequence of cochain complexes, then

\[ \cdots \to H^n(C) \xrightarrow{f} H^n(B) \xrightarrow{g} H^n(A) \xrightarrow{\delta} H^{n+1}(C) \xrightarrow{f} H_{n+1}(B) \xrightarrow{g} \cdots \]

forms an exact sequence.

Finally the following lemma says that cohomology commutes with direct sums and direct products. The proof of the lemma is identical to the proof of Lemma \[41.13\] that we did not give.

**Lemma 73.7.** If \( \{C_a\}_{a \in A} \) is a family of cochain complexes, then the family of inclusion maps \( C_a \to \bigoplus_{a \in A} C_a, a \in A, \) and \( C_a \to \prod_{a \in A} C_a, a \in A, \) induce isomorphisms

\[ \bigoplus_{a \in A} H^n(C_a) \xrightarrow{\cong} H^n \left( \bigoplus_{a \in A} C_a \right) \text{ and } \prod_{a \in A} H^n(C_a) \xrightarrow{\cong} H^n \left( \prod_{a \in A} C_a \right). \]

73.3. **Dual cochain complexes.** Now we will present the arguably most important source of cochain complex.

**Definition.** Let

\[ (C_*, \partial_*) : \to C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} \cdots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0 \]

Furthermore, if the cochain complexes are cochain complexes over a commutative ring \( R \), then the connecting homomorphism is in fact an \( R \)-module homomorphism.
be a chain complex and let $G$ be an abelian group. For each $n \in \mathbb{N}_0$ we write
\[ \delta_n := \partial_{n+1}^*: \text{Hom}(C_n, G) \to \text{Hom}(C_{n+1}, G). \]
We obtain the following cochain complex\(^{1070}\)
\[
\begin{array}{c}
\text{Hom}(C_{n+1}, G) \xleftarrow{\delta_n} \text{Hom}(C_n, G) \xleftarrow{\delta_{n-1}} \cdots \xleftarrow{\delta_1} \text{Hom}(C_1, G) \xleftarrow{\delta_0} \text{Hom}(C_0, G) \xleftarrow{0}.
\end{array}
\]
We refer to it as cochain complex dual to $(C_*, \partial_*)$ and we denote it by $\text{Hom}(C_*, G)$. We define the $n$-th cohomology group of the chain complex $(C_*, \partial_*)$ with $G$-coefficients as the cohomology of the cochain complex $(\text{Hom}(C_*, G), \delta^*)$, i.e. we define
\[ H^n(C; G) := \frac{\ker(\delta_n: \text{Hom}(C_n, G) \to \text{Hom}(C_{n+1}, G))}{\text{im}(\delta_{n-1}: \text{Hom}(C_{n-1}, G) \to \text{Hom}(C_n, G))}. \]

**Remark.**

(1) We had just defined $\delta_n := \partial_{n+1}^*$, i.e. the coboundary map in the cochain complex is the dual of the boundary map in the chain complex. This is the same definition that is used in most books on algebraic topology, see e.g. [Mun84, p. 251] or [Hat02, p. 189]. In the book by Bredon [Bre93, p. 321] the coboundary is defined as $\delta_n := (-1)^{n+1} \partial_{n+1}^*$. The different conventions do not affect the definition of the cohomology groups, but they will affect the sign conventions in some formulas later on. In particular if one cites results from other books one needs to be careful about the sign conventions used.

(2) If $R$ is a commutative ring and if $(C_*, \partial_*)$ is a chain complex, then it follows immediately from the remark on page 1816 that the corresponding cohomology groups $H^n(C; R)$ come naturally with the structure of $R$-modules.

Many of the statements about chain complexes and their homology groups hold in a slightly modified version also for cohomology groups. For example we have the following purely algebraic lemma.

**Lemma 73.8.** Let $G$ be an abelian group.

1. Let $f = \{f_n: C_n \to D_n\}_{n \in \mathbb{N}_0}$ be a chain map between chain complexes $C_*$ and $D_*$, then for each $n \in \mathbb{N}_0$ the map
\[ f^*: \text{Hom}(D_n, G) \to \text{Hom}(C_n, G) \]
\[ (\varphi: D_n \to G) \mapsto (C_n \xrightarrow{f_n} D_n \xrightarrow{\varphi} G) \]
is a cochain map, in particular it induces a well-defined map
\[ f^*: H^n(D; G) \to H^n(C; G). \]

2. For each $n \in \mathbb{N}_0$ the maps
\[ C_* \mapsto H^n(C; G) \quad \text{and} \quad f \mapsto f^* \]

\(^{1070}\)It follows the functoriality property of $\text{Hom}(\cdot, G)$ that $\delta_n \circ \delta_{n-1} = \partial_{n+1}^* \circ \partial_n^* = (\partial_n \circ \partial_{n+1})^* = 0$, i.e. this is indeed a cochain complex.
define a contravariant functor from the category ChPfC of chain complexes to the category AbGr of abelian groups. (If G is a commutative ring, then this is in fact a functor to the category of G-modules.)

(3) Let \( f, g: C_* \to D_* \) be two chain maps. If they are chain homotopic, then the induced cochain maps \( f^*, g^*: \text{Hom}(D_*, G) \to \text{Hom}(C_*, G) \) are cochain homotopic and therefore the induced maps \( f^*, g^*: \text{H}^n(D; G) \to \text{H}^n(C; G) \) are identical.

(4) If \( f_*: C_* \to D_* \) is a chain homotopy equivalence, then for every \( n \in \mathbb{N}_0 \) the induced maps \( f^*: \text{H}^n(D; G) \to \text{H}^n(C; G) \) are isomorphisms.

**Proof.**

(1) Let \( f = \{f_n: C_n \to D_n\}_{n \in \mathbb{N}_0} \) be a chain map. This means that for each \( n \in \mathbb{N}_0 \) we have

\[
f_{n-1} \circ \partial_n = \partial_n \circ f_n
\]

which implies by the fact that \( A \mapsto \text{Hom}(A, G) \) is a contravariant functor that

\[
\partial^*_{n} \circ f^*_{n-1} = f^*_{n} \circ \partial^*_n.
\]

We have thus shown that \( f^* \) is a cochain map. The second statement follows immediately from Lemma 73.5.

(2) This statement follows easily from the definitions.

(3) Let \( \{P_n: C_n \to D_{n+1}\}_{n \in \mathbb{N}_0} \) be a chain homotopy \( P = \{P_n\}_{n \in \mathbb{N}_0} \) between \( f \) and \( g \). Recall that this means that for each \( n \in \mathbb{N}_0 \) we have

\[
\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n = f_n - g_n.
\]

We set \( Q_n := P^*_{n-1}: \text{Hom}(D_n, G) \to \text{Hom}(C_{n-1}, G) \). It follows again from the fact that \( A \mapsto \text{Hom}(A, G) \) is a contravariant functor that

\[
P^*_{n-1} \circ \partial^*_n + \partial^*_n \circ P^*_{n-1} = f^*_n - g^*_n.
\]

This shows that the maps \( Q_n, n \in \mathbb{N}_0 \) form a cochain homotopy. It follows from Lemma 73.5 that the induced maps on cohomology groups agree.

(4) The last statement follows immediately from (2) and (3).

In Lemma 57.7 (2) we basically saw that for any chain complex \( C_* \) and any homomorphism \( f: A \to B \) of abelian groups the maps

\[
f_*: C_* \otimes A \to C_* \otimes B
\]

\[
\left[ \sum_{i=1}^{k} \sigma_i \otimes a_i \right] \mapsto \left[ \sum_{i=1}^{k} \sigma_i \otimes f(a_i) \right]
\]

form a chain map, in particular for each \( n \in \mathbb{N}_0 \) we obtain an induced map

\[
f_*: \text{H}_n(C_* \otimes A) \to \text{H}_n(C_* \otimes B).
\]
Similarly, it is straightforward to check that the maps
\[ f_* : \text{Hom}(C_n, A) \to \text{Hom}(C_n, B) \]
\[ \varphi \mapsto f \circ \varphi \]
define a cochain map, in particular we get for each \( n \in \mathbb{N}_0 \) an induced map
\[ f_* : \mathbb{H}^n(C_*; A) \to \mathbb{H}^n(C_*; B) \]
The following lemma basically says that these maps have all the properties one could possibly hope for. The lemma can be viewed as a cohomological analogue of Lemma 57.7.

**Lemma 73.9.** (*)

1. Given a chain complex \( C_* \) and \( n \in \mathbb{N}_0 \) the maps
\[ A \mapsto \mathbb{H}^n(C_*; A) \]
\[ (f : A \to B) \mapsto (f_* : \mathbb{H}^n(C_*; A) \to \mathbb{H}^n(C_*; B)) \]
form a covariant functor from the category of abelian groups to the category of abelian groups. In other words, “cohomology is covariant in the coefficients”.

2. Given a group homomorphism \( f : A \to B \) the induced maps \( f_* \) define a natural transformation from the contravariant functor \( C_* \mapsto \mathbb{H}^n(C_*; A) \) to the contravariant functor \( C_* \mapsto \mathbb{H}^n(C_*; B) \).

**Proof.** The two statements follow basically immediately from the definitions. \( \blacksquare \)

### 73.4. The singular cohomology groups of topological spaces

Now we apply the somewhat dry algebra from the last section to our favorite chain complex, namely the singular complex of a pair of topological spaces.

**Definition.** Let \((X, A)\) be a pair of topological spaces and let \(G\) be an abelian group.

1. For each \( n \in \mathbb{N}_0 \) we write
\[ C^n(X, A; G) := \text{Hom}(C_n(X, A), G) \]
and \( \delta_n := \partial_{n+1}^* : C^n(X, A; G) \to C^{n+1}(X, A; G) \).

We use the following notation:

(a) We refer to the elements of \( C^n(X, A; G) \) as *singular n-cochains,*

(b) we refer to the elements in the kernel of \( \delta_n : C^n(X, A; G) \to C^{n+1}(X, A; G) \) as *singular n-cocycles* and

(c) we refer to the elements in the image of \( \delta_{n-1} : C^{n-1}(X, A; G) \to C^n(X, A; G) \) as *singular n-coboundaries.*

When \( n \in \mathbb{N}_0 \) is understood then sometimes we just write \( \delta \) instead of \( \delta_n \).

2. We refer to the cochain complex
\[ \ldots \leftarrow C^{n+1}(X, A; G) \overset{\delta_n}{\leftarrow} C^n(X, A; G) \overset{\delta_{n-1}}{\leftarrow} C^{n-1}(X, A; G) \leftarrow \ldots \overset{\delta_1}{\leftarrow} C^0(X, A; G) \leftarrow 0 \]
as the *singular cochain complex of \((X, A)\) with \(G\)-coefficients.* We define the \( n \)-th *singular cohomology group of \((X, A)\) with \(G\)-coefficients* \(^{[07]} \) as follows
\[ \mathbb{H}^n(X, A; G) := \mathbb{H}^n(C_*(X, A); G) = \frac{\ker(\delta_n : C^n(X, A; G) \to C^{n+1}(X, A; G))}{\text{im}(\delta_{n-1} : C^{n-1}(X, A; G) \to C^n(X, A; G))}. \]
(3) If \( A = \emptyset \) then we just write \( C^n(X; G) = C^n(X, \emptyset; G) \) and similar for cohomology groups.

(4) If \( G = \mathbb{Z} \) then often we drop the coefficients from the notation, e.g. often we write \( H^n(X, A) = H^n(X, A; \mathbb{Z}) \).

**Remark.** As we had already pointed out on page 1821 if \( R \) is a commutative ring, e.g. if \( R = \mathbb{Z}_n, \mathbb{Z}, \mathbb{Q}, \mathbb{R} \) or \( R = \mathbb{C} \), then the cohomology groups \( H^n(X, A; R) \) can in fact be viewed as \( R \)-modules and the coboundary maps are \( R \)-module homomorphisms.

In the following we first discuss the definition and examples of the absolute cohomology groups \( H^*(X; G) \). A little later we will discuss the arguably even more confusing relative cohomology groups \( H^*(X, A; G) \). We start this discussion of absolute cohomology groups with the following remark.

**Remark.** Let \( G \) be an abelian group.

1. Let \( X \) be a topological space and let \( n \in \mathbb{N}_0 \). We denote by \( S_n(X) \) the set of singular \( n \)-simplices. We then have natural identifications

\[
C^n(X; G) = \text{Hom}(C_n(X), G) = \text{Hom}(\mathbb{Z}^{S_n(X)}), G) = \text{maps from } S_n(X) \text{ to } G.
\]

by definition \( C_n(X) = \mathbb{Z}^{S_n(X)} \)
identification given by Lemma 73.1

Put differently, a singular \( n \)-cochain is precisely the same as assigning to each singular \( n \)-simplex an element in \( G \). We will use this bijection throughout the course without explicitly referring to it.

2. Let \( X \) be a topological space. We recall that, following the discussion on page 1078, we can identify the singular 0-simplices in \( X \) with the points in \( X \). According to the discussion in (1) we can now make the identification

\[
C^0(X; G) = \{ \text{all maps from } X \text{ to } G \}.
\]

Before we develop the theory of cohomology groups in detail we first want to consider some explicit examples. As a starter we consider cochains and cocycles on the topological spaces \( \mathbb{R} \) and \( S^1 \).

**Examples.**

1. We start out with the topological space \( X = \mathbb{R} \). We consider the two functions

\[
\alpha_\mathbb{R} : \mathbb{R} \to \mathbb{R} \quad \text{and} \quad \alpha_\mathbb{Z} : \mathbb{R} \to \mathbb{Z} \quad \text{where} \quad x \mapsto x \quad \text{and} \quad x \mapsto \lfloor x \rfloor := \max\{ n \in \mathbb{Z} \mid n \leq x \}.
\]

As pointed out above, these two functions define singular 0-cochains. We denote these 0-cochains again by \( \alpha_\mathbb{R} \) and \( \alpha_\mathbb{Z} \). For any singular 1-simplex \( \mu : \Delta^1 \to \mathbb{R} \) we have

\[
(\delta \alpha_\mathbb{R})(\mu) = \alpha_\mathbb{R}(\partial \mu) = \alpha_\mathbb{R}(\mu(0,1) - \mu(1,0)) = \mu(0,1) - \mu(1,0)
\]

definition of \( \delta \)
see page 1079

\[
\delta \alpha_\mathbb{Z}(\mu) = \alpha_\mathbb{Z}(\partial \mu) = \alpha_\mathbb{Z}(\mu(0,1) - \mu(1,0)) = \mu(0,1) - \mu(1,0)
\]

definition of \( \alpha_\mathbb{Z} \)

In most cases we drop the adjective “singular” and we just talk of the \( n \)-th cohomology group of \( (X, A) \) with coefficients in \( G \). We only refer to it as singular cohomology when we want to distinguish it from de Rham cohomology.
and, slightly more interesting, it follows immediately from the above discussion and the definition of $\alpha_Z$ that

\[
(\delta \alpha_Z)(\mu) = \alpha_Z(\partial \mu) = \begin{cases}
\#\{n \in \mathbb{Z} | \mu(1,0) - n < \mu(0,1)\}, & \text{if } \mu(0,1) \geq \mu(1,0) \\
-\#\{n \in \mathbb{Z} | \mu(0,1) - n < \mu(0,1)\}, & \text{if } \mu(1,0) \geq \mu(0,1).
\end{cases}
\]

In a somewhat informal way we can say that the cochain $\delta \alpha_Z : C_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex $\mu$ measures how many integers the simplex $\mu$ "crosses from left to right". We refer to Figure 1118 for an illustration of $\delta \alpha_Z$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1118.png}
\caption{Figure 1118}
\end{figure}

(2) Now we consider the topological space $X = S^1$. As usual we denote by $p : \mathbb{R} \to S^1$, $t \mapsto e^{2\pi i t}$ the universal covering of $S^1$. Let $\sigma : \Delta^1 \to S^1$ be a singular 1-simplex. Since $\Delta^1$ is simply connected it follows from Proposition 29.5 that $\sigma$ lifts to a map $\tilde{\sigma} : \Delta^1 \to \mathbb{R}$. The lift is not unique, but it is straightforward to see that any two lifts differ by addition by an integer. For a singular 1-simplex $\sigma : \Delta^1 \to S^1$ we pick a lift $\tilde{\sigma} : \Delta^1 \to \mathbb{R}$ of $\sigma$ and we define

\[
\theta_{\mathbb{R}}(\sigma) := (\delta \alpha_{\mathbb{R}})(\tilde{\sigma}) = \tilde{\sigma}(0,1) - \tilde{\sigma}(1,0)
\]

and we also define

\[
\theta_{\mathbb{Z}}(\sigma) := (\delta \alpha_{\mathbb{Z}})(\tilde{\sigma}) = \begin{cases}
\#\{n \in \mathbb{Z} | \tilde{\sigma}(1,0) - n < \tilde{\sigma}(0,1)\}, & \text{if } \tilde{\sigma}(0,1) \geq \tilde{\sigma}(1,0) \\
-\#\{n \in \mathbb{Z} | \tilde{\sigma}(0,1) - n < \tilde{\sigma}(0,1)\}, & \text{if } \tilde{\sigma}(1,0) \geq \tilde{\sigma}(0,1).
\end{cases}
\]

Since any two lifts of $\sigma$ differ by addition by an integer we see that $\theta_{\mathbb{R}}(\sigma)$ and $\theta_{\mathbb{Z}}(\sigma)$ are both well-defined, i.e. independent of the choice of the lift $\tilde{\sigma}$. The definitions of $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are illustrated in Figure 1119.

As we had explained on page 1824, these two maps $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ actually define singular 1-cochains in $C^1(\mathbb{R})$ and $C^1(\mathbb{Z})$.

\[\text{\textsuperscript{102}}\text{Here is an alternative description of the singular 1-cochain } \theta: \text{ We denote by } \Phi : [0,1] \to \Delta^1 \text{ the homeomorphism that is given by } \Phi(t) = (1-t,t). \text{ Then for any singular 1-simplex } \sigma : \Delta^1 \to S^1 \text{ we have}
\]

\[
\theta_{\mathbb{R}}(\sigma) = \frac{1}{2\pi i} \int_{\sigma \circ \Phi} \frac{1}{z} \, dz,
\]

where the right-hand side denotes the path integral of the holomorphic function $\frac{1}{z}$ over the continuous path $\sigma \circ \Phi : [0,1] \to S^1$. We leave it as an amusing exercise to verify this equality using complex analysis.
\[ \theta_\mathbb{Z}(\sigma) = 2 \quad \theta_\mathbb{R}(\sigma) = \bar{\sigma}(0,1) - \bar{\sigma}(1,0) \]

\[ \bar{\sigma} \]

\[ p(t) = e^{2\pi it} \]

\[ \text{Figure 1119} \]

As an example we consider the singular 1-simplex

\[ \mu: \Delta^1 \to S^1 \quad \text{that is defined by} \quad \mu(1-t,t) = e^{2\pi it}. \]

A lift of \( \mu \) to the above universal covering \( \mathbb{R} \to S^1 \) is given by the singular 1-simplex

\[ \tilde{\mu}: \Delta^1 \to \mathbb{R} \quad \text{that is defined by} \quad \tilde{\mu}(1-t,t) = t. \]

It follows immediately from the definitions that \( \theta_\mathbb{R}(\mu) = \theta_\mathbb{Z}(\mu) = 1. \)

The following lemma shows that \( \theta_\mathbb{R} \) and \( \theta_\mathbb{Z} \) are actually quite interesting singular 1-cochains.

**Lemma 73.10.** We continue with the notation from the previous example.

(1) The singular 1-cochains \( \theta_\mathbb{R} \) and \( \theta_\mathbb{Z} \) are cocycles, in particular \( \theta_\mathbb{R} \) defines an element in \( H^1(S^1; \mathbb{R}) \) and \( \theta_\mathbb{Z} \) defines an element in \( H^1(S^1; \mathbb{Z}) \).

(2) The singular 1-cochain cochains \( \theta_\mathbb{R} \) and \( \theta_\mathbb{Z} \) are not the coboundary of a singular 0-cochain, i.e. the cohomology classes \( [\theta_\mathbb{R}] \in H^1(S^1; \mathbb{R}) \) and \( [\theta_\mathbb{Z}] \in H^1(S^1; \mathbb{Z}) \) are non-trivial.

**Proof.**

(1) We will first prove that the singular 1-cochain \( \theta_\mathbb{R} \) is a cocycle. Thus we have to show that \( \delta \theta_\mathbb{R} = 0 \in C^2(S^1, \mathbb{R}) = \text{Hom}(C_2(S^1), \mathbb{R}) \). So let \( \sigma: \Delta^2 \to S^1 \) be a singular 2-simplex. We have to show that \( (\delta \theta_\mathbb{R})(\sigma) = \theta_\mathbb{R}(\partial \sigma) = 0. \)

As before we denote by \( p: \mathbb{R} \to S^1, t \mapsto e^{2\pi it} \) the universal covering of \( S^1 \). Since \( \Delta^2 \) is simply connected we can apply Proposition 29.2 to obtain a lift of \( \sigma: \Delta^2 \to S^1 \) to a map \( \bar{\sigma}: \Delta^2 \to \mathbb{R} \). We refer to Figure 1120 for an illustration. Then

\[
\theta_\mathbb{R}(\partial \sigma) = \theta_\mathbb{R} \left( \sum_{j=0}^{2} (-1)^j \cdot \sigma \circ i_j^2 \right) = \delta \alpha_\mathbb{R} \left( \sum_{j=0}^{2} (-1)^j \cdot \bar{\sigma} \circ i_j^2 \right) = \alpha_\mathbb{R}(\partial(\bar{\sigma})) = 0.
\]

Exactly the same argument applies to \( \theta_\mathbb{Z} \).

(2) We still need to show that the singular 1-cochain cochains \( \theta_\mathbb{R} \) and \( \theta_\mathbb{Z} \) are not the coboundary of a singular 0-cochain. So let \( \beta \) be a singular 0-cochain. As usual we
view $\beta$ as a function $S^1 \to \mathbb{R}$. We consider again the singular 1-simplex $\mu: \Delta^1 \to S^1$ that is defined by $\mu(1-t,t) = e^{2\pi i t}$. Then
\[
(\delta_0 \beta)(\mu) = \beta(\partial(\mu)) = \beta(\mu(0,1) - \mu(1,0)) = 0.
\]

But in the previous example we saw that $\theta_{\mathbb{R}}(\mu) = \theta_{\mathbb{Z}}(\mu) = 1$. \hfill $\blacksquare$

**Remark.** Note that in Lemma 73.10 we have just given a mysteriously simple proof that $H^1(S^1; \mathbb{R}) \neq 0$ and also that $H^1(S^1; \mathbb{Z}) \neq 0$.

We continue with another example of cochains.

**Example.** We return to the topological space $X = \mathbb{R}$. We fix a point $y \in \mathbb{R}$. We consider the cochain
\[
\varphi_y: C_0(\mathbb{R}) \to \mathbb{Z}
\]
that is determined by the function
\[
\mathbb{R} \to \mathbb{Z}, \quad x \mapsto \begin{cases} 0, & \text{if } x \leq y, \\ 1, & \text{else.} \end{cases}
\]

For any singular 1-simplex $d: \Delta^1 \to X = \mathbb{R}$ we have
\[
(\delta_0 \varphi_y)(d) = \varphi_y(\partial d) = \varphi_y(d(0,1)) - \varphi_y(d(1,0)) = \begin{cases} 0, & \text{if } d(0,1), d(1,0) \leq y, \\ 0, & \text{if } d(0,1), d(1,0) \geq y, \\ 1, & \text{if } d(1,0) \leq y < d(0,1) \\ -1, & \text{if } d(0,1) \leq y < d(1,0). \end{cases}
\]
In a slightly informal way we can say that the homomorphism $\delta_0 \varphi_y: C_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex $d$ equals $+1$ if the simplex “crosses $y$ from right to left” and it equals $-1$ if the simplex “crosses $y$ from left to right”. We will make use of this singular 1-cochain on several occasions, hence we give it its own notation, namely we write
\[
\gamma_y := \delta_0 \varphi_y \in C^1(\mathbb{R}; \mathbb{Z}).
\]
We illustrate the singular 1-cochain $\gamma_y = \delta_0 \varphi_y \in C^1(\mathbb{R}; \mathbb{Z})$ in Figure 1121.

After this long discussion of explicit cochains and cohomology classes we want to turn to more general results. The only two instances where we could compute homology groups
without any problems was the 0-th homology group of a path-connected space, see Proposition 41.5 and the homology groups of a point, see Lemma 41.6. Not surprisingly we can also deal with the same situations with cohomology groups.

First of all we have the following analogue of Proposition 41.5.

**Proposition 73.11.** Let $X$ be a non-empty path-connected topological space and let $G$ be an abelian group. Then the map

$$G \to H^0(X; G)$$

$$g \mapsto [\text{0-cochain that assigns to each } x \in X \text{ the value } g]$$

is a well-defined map that is in fact an isomorphism. For any point $P \in X$ an inverse is given by the map

$$H^0(X; G) \to G$$

$$[f] \mapsto f(P)$$

**Remark.** At times we will use the isomorphism from Proposition 73.11 to identify the 0-th cohomology $H^0(X; G)$ of a path-connected topological space $X$ with $G$.

**Proof.** We consider the “right-hand end” of the chain complex of $C_*(X)$ and of the cochain complex $\text{Hom}(C_*(X), G)$:

$$C_1(X) \xrightarrow{\partial_1} C_0(X) \to 0 \quad \text{and} \quad \text{Hom}(C_1(X), G) \xleftarrow{\delta_0 = \partial_1^*} \text{Hom}(C_0(X), G) \leftarrow 0.$$
Now we calculate that
\[ \text{ker} \left\{ \frac{\text{Hom}(C_0(X), G)}{\text{Hom}(C_1(X), G)} \rightarrow \left( f \circ \partial_1 : C_1(X) \rightarrow G \right) \right\} \]

since the singular 1-simplices form a basis of \( C_1(X) \)

\[ = \{ \text{maps } f : X \rightarrow G \mid f(\partial_1(\sigma)) = 0 \text{ for all singular } 1\text{-simplices } \sigma : \Delta^1 \rightarrow X \} \]

by Lemma 73.1 we have the natural identification

\[ \text{Hom}(C_0(X), G) = \text{maps from } X \text{ to } G = G. \]

\[ \text{since } X \text{ is path-connected and since } \Delta^1 \cong [0, 1] \]

The remaining statements of the proposition can be verified easily. \[ \square \]

In Exercise 73.3, we will prove the following lemma which can be viewed as an analogue of Lemma 41.6.

**Lemma 73.12.** Let \( X = \{x\} \) be a topological space that consists of a single point \( x \). For any abelian group \( G \) we have

\[ H^n(X; G) = \begin{cases} 0, & \text{if } n \geq 1, \\ G, & \text{if } n = 0. \end{cases} \]

We want to conclude this section with a short discussion of relative cohomology classes. Before we do so we make the following observations:

**Observation.**

1. Given an abelian group \( C \), a subgroup \( D \) and an abelian group \( G \) we have a natural isomorphism

\[ \text{Hom}(C/D, G) \cong \text{all homomorphisms } C \rightarrow G \text{ that vanish on } D \]

\[ (\varphi : C/D \rightarrow G) \mapsto (C \rightarrow C/D \overset{\varphi}{\rightarrow} G). \]

We will use this isomorphism to identify the left-hand and right-hand sides.

2. If \( S \) is a set and \( T \) is a subset, then for any abelian group \( G \) the identification from Lemma 73.1 restricts to an isomorphism

\[ \{ f \in \text{Hom}(\mathbb{Z}^{(S)}, G) \mid f \text{ vanishes on } \mathbb{Z}^{(T)} \} = \text{all maps } S \rightarrow G \text{ that are trivial on } T. \]

3. It follows immediately from Lemma 73.1 and from (1) and (2) that given a pair of topological spaces \((X, A)\) and an abelian group \( G \) we have for every \( n \in \mathbb{N}_0 \) a natural isomorphism

\[ \text{Hom}(C_n(X, A), G) = \text{all maps } S_n(X) \rightarrow G \text{ that are trivial on } S_n(A). \]

We will often use this natural isomorphism to identify the left-hand side with the right-hand side.
Examples.

(1) In Exercise 73.4 we will modify the argument of Proposition 73.11 to show that for any path-connected topological space with non-empty subset $A$ we have

$$H^0(X, A; G) = 0$$

for any abelian group $G$.

(2) We write $I = [0, 1]$. In this example we want to construct a non-trivial element in $H^1(I, \partial I)$. We consider the function

$$f: I \to \mathbb{Z}$$

$$x \mapsto \begin{cases} 0, & \text{if } x \in [0, \frac{1}{2}) \\ 1, & \text{otherwise} \end{cases}$$

which we use to define the singular 1-cochain

$$\rho: C_1(I) \to \mathbb{Z}$$

$$\langle \sigma: \Delta^1 \to I \rangle \mapsto f(\sigma(0, 1)) - f(\sigma(1, 0)).$$

Loosely speaking, similar to the singular 1-cochain $\varphi_\nu$ from page 1827 the singular 1-cochain $\rho(\sigma)$ measures whether $\sigma$ crosses $\frac{1}{2}$, and if yes, in what direction. We refer to Figure 1122 for an illustration. Since $\Delta^1$ is connected and since $\{0, 1\}$ is discrete it follows from Lemma 2.61 that any singular 1-simplex $\sigma: \Delta^1 \to \partial I = \{0, 1\}$ is constant. In particular in this case we have $\rho(\sigma) = 0$. Thus we see, using the above observation, that $\rho$ defines a map

$$\rho: C_1(I, \partial I) \to \mathbb{Z}.$$ 

In Exercise 73.8 we will see that $\rho$ is a singular 1-cocycle and that it defines a non-trivial element in $H^1(I, \partial I; \mathbb{Z})$.

![Graph of f](image)

**Figure 1122**

73.5. **Basic properties of cohomology groups.** Now we will see that maps between pairs of topological spaces induce maps on cohomology groups.

**Definition.** Let $G$ be an abelian group and let $f: (X, A) \to (Y, B)$ be a map between pairs of topological spaces. Recall that $f$ induces a chain map $f_*: C_\ast(X, A) \to C_\ast(Y, B)$. For each $n \in \mathbb{N}_0$ we denote by

$$f^*: H^n(Y, B; G) \to H^n(X, A; G)$$

the induced map of cohomology groups that we obtain from Lemma 73.8 (1).

**Example.** We will see in Exercise 73.6 that any map $f: X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*: H^0(Y; G) \to H^0(X; G)$. A very similar argument shows that if $Y$ is path-connected and $X$ is non-empty, then $f^*: H^0(Y; G) \to H^0(X; G)$ is a monomorphism.
Notation. Let $X$ be a topological space and let $A$ be a subset. Furthermore let $G$ be an abelian group. We denote by $i: A \to X$ the inclusion map. Sometimes we refer to $i^*: H^n(X; G) \to H^n(A; G)$ as the restriction map.

We summarize some basic properties of the induced maps in the following lemma.

**Lemma 73.13.** Let $G$ be an abelian group and let $n \in \mathbb{N}_0$.

1. The maps
   \[
   (X, A) \mapsto H^n(X, A; G)
   \]
   define a contravariant functor from the category of pairs of topological spaces to the category of abelian groups. (If $G$ is a commutative ring, then this is in fact a functor to the category of $G$-modules.)

2. Let $f, g: (X, A) \to (Y, B)$ be maps between pairs of topological spaces. If $f$ and $g$ are homotopic, then they induce the same maps
   \[
   f^* = g^*: H^n(Y, B; G) \to H^n(X, A; G).
   \]

3. If $f: X \to Y$ is a homotopy equivalence between two topological spaces, then the induced map
   \[
   f^*: H^n(Y; G) \xrightarrow{\cong} H^n(X; G)
   \]
   is an isomorphism. In particular the cohomology groups of homotopy equivalent topological spaces are isomorphic.

4. Let $X$ be a topological space, let $A \subset B$ be subsets of $X$ and let $n \in \mathbb{N}_0$. If $A$ is a deformation retract of $B$, then the inclusion induced map
   \[
   H^n(X, B; G) \to H^n(X, A; G)
   \]
   is an isomorphism. Similarly, if $B$ is a deformation retract of $X$, then the inclusion induced map
   \[
   H^n(X, A; G) \to H^n(B, A; G)
   \]
   is an isomorphism.

**Example.** Lemma 73.13 (4), together with Lemma 73.12 and the discussion on page 548 implies that for any $n \geq 1$, any abelian group $G$ and any $k \in \mathbb{N}_0$ we have
   \[
   H^n(\mathbb{R}^k; G) = H^n(B^k; G) = H^n(B^k; G) = H^n(\Delta^k; G) = 0.
   \]

**Proof.**

1. This statement follows immediately from Lemma 73.8 (2) together with the fact that the map $(X, A) \mapsto C_*(X, A)$ defines a covariant functor from the category $\text{PairTop}$ of pairs of topological spaces to the category $\text{ChCplx}$ of chain complexes.

2. This statement is an immediate consequence of Proposition 43.17 together with Lemma 73.8 (3).

3. This statement follows from (1) and (2).

4. This statement is proved almost verbatim the same way as Corollary 43.18 (2a) and (2b).
Many of the statements about homology groups can be modified to give corresponding statements about cohomology groups. For example we have the following lemma.

**Lemma 73.14.** Let $X$ be a topological space and let $G$ be an abelian group.

1. We denote by $\{X_j\}_{j \in J}$ the path-components of $X$. The inclusion maps $\iota_j : X_j \to X$, $j \in J$, induce an isomorphism
   \[
   \prod_{j \in J} \iota_j^* : H^n(X; G) \cong \prod_{j \in J} H^n(X_j; G).
   \]

2. Suppose that $X$ has finitely many path-components $X_1, \ldots, X_k$. If for $j = 1, \ldots, k$ we pick a point $P_j \in X_j$, then the map
   \[
   H^0(X; G) \to G^k = G \times \cdots \times G, \quad [f] \mapsto (f(P_1), \ldots, f(P_k))
   \]
   is an isomorphism.

**Proof.** Let $X$ be a topological space with path-components $\{X_j\}_{j \in J}$ and let $G$ be an abelian group. We have the following isomorphisms of cochain complexes:

\[
\begin{align*}
\text{Hom}(C^\bullet(X), G) & \xrightarrow{\left(\bigoplus_{j \in J} \iota_j^*\right)^*} \text{Hom}\left(\bigoplus_{j \in J} C_\ast(X_j), G\right) \xrightarrow{\cong} \prod_{j \in J} \text{Hom}(C_\ast(X_j), G). \\
\uparrow & \text{Lemma 41.14} \quad \uparrow \text{Lemma 73.2}
\end{align*}
\]

The first statement now follows easily from this observation together with the fact that cohomology commutes with direct products, see Lemma 73.7.

The second statement follows from the first statement together with the calculation of 0-th cohomology groups of path-connected topological spaces in Proposition 73.11. □

**Lemma 73.15.** Given a triple $(X, B, A)$ of topological spaces and an abelian group $G$ we obtain a long exact sequence

\[
\cdots \to \delta_{n-1} : H^n(X, B; G) \to H^n(X, A; G) \xrightarrow{i^*} H^n(B, A; G) \to H^{n+1}(X, B; G) \xrightarrow{p^*} \cdots
\]

hereby the maps are given as follows:

1. $p^*$ is the map induced by the map $p : (X, A) \to (X, B)$,
2. $i^*$ is the map induced by the map $i : (B, A) \to (X, A)$,
3. the connecting homomorphism $\delta_n : H^n(B, A; G) \to H^{n+1}(X, B; G)$ is natural and it is given by the map

\[
[\sigma : C_n(B, A) \to G] \mapsto \left[ C_{n+1}(X, B) \to G, \begin{array}{c}
\sigma \mapsto f(q(\partial_n(\sigma))) \\
\uparrow \text{with } \sigma \in C_{n+1}(X)
\end{array}\right]
\]
Remark.

(1) An equivalent approach to expressing the connecting homomorphism is given as follows:
(a) take a cocycle \( f \in C^n(B, A; G) = \text{Hom}(C_n(B, A), G) \),
(b) denote by \( \pi : C_n(B) \to C_n(B, A) \) the projection map,
(c) denote by \( \tilde{f} \) the result of extending \( f \circ \pi : C_n(B) \to G \) to a map \( C_n(X) \to G \) by sending all singular simplices that do not lie in \( B \) to zero (sometimes we call \( \tilde{f} \) the trivial extension of \( f \circ \pi \)),
(d) then consider the coboundary \( \delta \tilde{f} \in C^{n+1}(X; G) \), since \( f \) is a cocycle it follows that \( \delta \tilde{f} \) actually defines an element in \( C^{n+1}(X, B; G) \) that we also denote by \( \delta \tilde{f} \), and which turns out to be a cocycle,
(e) then \( \delta[f] = [\delta \tilde{f}] \in H^{n+1}(X, B; G) \).

(2) One of the difficulties with the long exact sequence of cohomology groups is that all maps seem to point the wrong way. You should use the Lucky Luke approach to cohomology: if Rantanplan (i.e. your intuition) points one way, you should take the opposite direction.

(3) The most frequent application of Lemma 73.15 is that given a pair \( (X, B) \) of topological spaces, i.e. given the triple \( (X, B, \varnothing) \) and given an abelian group \( G \) we obtain a natural long exact sequence
\[
\cdots \to \delta_{n-1} H^n(X, B; G) \xrightarrow{p^*} H^n(X; G) \xrightarrow{i^*} H^n(B; G) \xrightarrow{b_n} H^{n+1}(X, B; G) \xrightarrow{p^*} \cdots
\]

Proof. Let \( (X, B, A) \) be a triple of topological spaces. As in the proof of Proposition 43.15 we note that
\[
0 \to C_*(B, A) \xrightarrow{i} C_*(X, A) \xrightarrow{p_*} C_*(X, B) \to 0
\]
is a short exact sequence of chain complexes. Now let \( G \) be an abelian group. Recall that we pointed out on page 1120 that the chain groups \( C_*(X, B) \) are free abelian groups. Thus we deduce from Lemma 73.4 that the following induced sequence of cochain complexes is
also exact:

\[ 0 \to \text{Hom}(C_*(X, B), G) \xrightarrow{\delta^*} \text{Hom}(C_*(X, A), G) \xrightarrow{i^*} \text{Hom}(C_*(B, A), G) \to 0. \]

The lemma now follows easily from Proposition 73.6 and the construction of the connecting homomorphism. We leave the details to the reader. ■

**Examples.**

(1) Let \( X \) be a path-connected topological space and let \( A \) be any non-empty subset of \( X \). We denote by \( i: A \to X \) the inclusion map. By the above remark we have a long exact sequence

\[ 0 \to H^0(X, A; G) \to H^0(X; G) \xrightarrow{i^*} H^0(A; G) \to \ldots \]

Thus it follows that \( H^0(X, A; G) = 0 \). In Exercise 73.4 we will provide an alternative proof for this fact using only the definitions of cohomology groups.

(2) Let \( b \in \mathbb{R}_{>0} \). We consider the long exact sequence in cohomology with \( \mathbb{Z} \)-coefficients of the pair \( (\mathbb{R}, \mathbb{R}\setminus [-b, b]) \). Together with (1) and Lemma 73.4 we obtain the following commutative diagram where the top horizontal sequence is exact:

\[
\begin{array}{ccccccccc}
0 & \to & H^0(\mathbb{R}; \mathbb{Z}) & \xrightarrow{i^*} & H^0(\mathbb{R}\setminus [-b, b]; \mathbb{Z}) & \xrightarrow{\delta} & H^1(\mathbb{R}, \mathbb{R}\setminus [-b, b]; \mathbb{Z}) & \to & H^1(\mathbb{R}; \mathbb{Z})
\end{array}
\]

The cokernel of the bottom horizontal map is easily seen to be isomorphic to \( \mathbb{Z} \) and it is generated by the element \((0,1) \in \mathbb{Z}^2\). Put differently, the cokernel of the map \( i^* : H^0(\mathbb{R}; \mathbb{Z}) \to H^0(\mathbb{R}\setminus [-b, b]; \mathbb{Z}) \) is represented by the singular 0-cochain given by

\[
\psi : \mathbb{R}\setminus [-b, b] \to \mathbb{Z}
\]

\[
x \mapsto \begin{cases} 
0, & \text{if } x \leq -b, \\
1, & \text{if } x \geq b.
\end{cases}
\]

Now we want to determine \( \delta \psi \in H^1(\mathbb{R}, \mathbb{R}\setminus [-b, b]; \mathbb{Z}) \). It is perhaps helpful to consider the following commutative diagram of short exact sequences:

\[
\begin{array}{ccc}
0 & \to & \text{Hom}(C_1(\mathbb{R}, \mathbb{R}\setminus [-b, b]), \mathbb{Z}) \xrightarrow{\delta^*} \text{Hom}(C_1(\mathbb{R}), \mathbb{Z}) \xrightarrow{i^*} \text{Hom}(C_1(\mathbb{R}\setminus [-b, b]), \mathbb{Z}) \to 0 \\
& \uparrow{\delta_0} & \uparrow{\delta_0} & \uparrow{\delta_0} & \\
0 & \to & \text{Hom}(C_0(\mathbb{R}, \mathbb{R}\setminus [-b, b]), \mathbb{Z}) \xrightarrow{\delta^*} \text{Hom}(C_0(\mathbb{R}), \mathbb{Z}) \xrightarrow{i^*} \text{Hom}(C_0(\mathbb{R}\setminus [-b, b]), \mathbb{Z}) \to 0.
\end{array}
\]

We start with the map \( \psi : \mathbb{R}\setminus [-b, b] \to \mathbb{Z} \). We need to pick an extension to a map \( \mathbb{R} \to \mathbb{Z} \). We might as well take the map \( \varphi_0 : \mathbb{R} \to \mathbb{Z} \) from page 1827. Then it follows from the discussion of the connecting homomorphism that the coboundary \( \gamma_0 := \delta \varphi_0 \)
represents an element in $H^1(\mathbb{R}, \mathbb{R} \setminus [-b, b]; \mathbb{Z})$, and that $\delta \psi = [\gamma_0]$ is a generator of $H^1(\mathbb{R}, \mathbb{R} \setminus [-b, b]; \mathbb{Z}) \cong \mathbb{Z}$.

73.6. Reduced cohomology groups. We saw on several occasions that the reduced homology groups $\tilde{H}_k(X)$ of a non-empty topological space can be convenient for expressing calculations and results. In this last section we quickly introduce the reduced cohomology groups.

**Definition.** Let $X$ be a topological space. By Lemma 41.4 (1) we know that the following is a chain complex

$$
\cdots \to C_2(X) \xrightarrow{\partial_2} C_1(X) \xrightarrow{\partial_1} C_0(X) \xrightarrow{\epsilon} \mathbb{Z} \to 0.
$$

Let $G$ be an abelian group. In a fashion similar to reduced homology we now define the $k$-th reduced cohomology group $\tilde{H}^k(X; G)$ of $X$ to be the $k$-th cohomology group of the above chain complex.

The following lemma is the analogue of Lemma 43.1 and Lemma 43.14. For brevity’s sake we leave the proof to the reader.

**Lemma 73.16.** Let $G$ be an abelian group.

1. Let $f: X \to Y$ be a map between two topological spaces. For every $n \in \mathbb{N}_0$ the map $f$ induces a map $f^*: \tilde{H}^n(Y; G) \to \tilde{H}^n(X; G)$ in the obvious way. For every $n \in \mathbb{N}_0$ the maps

$$
X \mapsto \tilde{H}^n(X; G)
$$

$$(f: X \to Y) \mapsto (f^*: \tilde{H}^n(Y; G) \to \tilde{H}^n(X; G))
$$

define a functor from the category of topological spaces to the category of abelian groups.

2. For each $n \in \mathbb{N}_0$ the maps

$$
H^n(X; G) \to \tilde{H}^n(X; G)
$$

$$
[\varphi] \mapsto [\varphi]
$$

define a natural transformation from the functor $X \mapsto H^n(X; G)$ to the functor that is given by $X \mapsto \tilde{H}^n(X; G)$.

3. For every non-empty topological space $X$ we have

$$
H^n(X; G) \cong \begin{cases} 
\tilde{H}^0(X; G) \oplus G, & \text{if } n = 0, \\
\tilde{H}^n(X; G), & \text{if } n \neq 0.
\end{cases}
$$

The isomorphism is natural for $n \geq 1$.

4. If $X$ is a topological space with $n \in \mathbb{N}$ path-components, then $\tilde{H}^0(X; G) \cong G^{n-1}$. 
Remark. We will see later on in Exercise 75.8 that the analogous statement with the roles of homology and cohomology swapped does not hold. In particular there exist topological spaces $X$ and $Y$ such that $H^n(X; \mathbb{Z}) \cong H^n(Y; \mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $H_1(X; \mathbb{Z})$ is not isomorphic to $H_1(Y; \mathbb{Z})$. 

73.7. Isomorphic homology groups implies isomorphic cohomology groups. In this short section we will see that the isomorphism type of cohomology groups cannot be used to extract more information from chain complexes than we already extracted from homology groups.

**Proposition 73.18.** Suppose $(C_*, \partial_*)$ and $(C'_*, \partial'_*)$ are two chain complexes of free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $H_n(C_*)$ and $H_n(C'_*)$ are isomorphic. Then for each $n \in \mathbb{N}_0$ and any abelian group $G$ the cohomology groups $H^n(C; G)$ and $H^n(C'; G)$ are also isomorphic.

Proof. Suppose $(C_*, \partial_*)$ and $(C'_*, \partial'_*)$ are two chain complexes of free abelian groups. By our hypothesis there exist isomorphisms $\gamma_n : H_n(C_*) \rightarrow H_n(C'_*)$, $n \in \mathbb{N}_0$. By Proposition 49.1 these isomorphisms can be realized by a chain map $f : C_* \rightarrow C'_*$. But by Proposition 49.2 this chain map is a chain homotopy equivalence. The statement of the proposition follows immediately from Lemma 73.8.

This proposition gives us a rather sobering corollary. It says that if our only goal is to distinguish (pairs of) topological spaces, then cohomology groups do not contain more information than homology groups.

**Corollary 73.19.** Let $(X, A)$ and $(Y, B)$ be topological spaces and let $G$ be an abelian group. Then

\[ H_n(X, A) \text{ and } H_n(Y, B) \text{ are isomorphic for all } n \in \mathbb{N}_0 \quad \Rightarrow \quad H^n(Y, B; G) \text{ and } H^n(X, A; G) \text{ are isomorphic for all } n \in \mathbb{N}_0. \]

Proof. Suppose $(C_*, \partial_*)$ and $(C'_*, \partial'_*)$ are two chain complexes of free abelian groups. By our hypothesis there exist isomorphisms $\gamma_n : H_n(C_*) \rightarrow H_n(C'_*)$, $n \in \mathbb{N}_0$. By Proposition 49.1 these isomorphisms can be realized by a chain map $f : C_* \rightarrow C'_*$. But by Proposition 49.2 this chain map is a chain homotopy equivalence. The statement of the proposition follows immediately from Lemma 73.8.

Remark. We will see later on in Exercise 75.8 that the analogous statement with the roles of homology and cohomology swapped does not hold. In particular there exist topological spaces $X$ and $Y$ such that $H^n(X; \mathbb{Z}) \cong H^n(Y; \mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $H_1(X; \mathbb{Z})$ is not isomorphic to $H_1(Y; \mathbb{Z})$. 

**Lemma 73.17.** Let $X$ be a topological space and let $B \subset X$ be a non-empty subset. Then given any abelian group $G$ there exists a natural long exact sequence

\[
\cdots \rightarrow H^n(X, B; G) \overset{\delta^n}{\rightarrow} H^n(X; G) \overset{i^*}{\rightarrow} H^n(B; G) \overset{\partial_n}{\rightarrow} H^{n+1}(X, B; G) \overset{p^*}{\rightarrow} \cdots
\]

Proof. The lemma follows immediately from Lemma 73.15 applied to the triple $(X, B, \{P\})$ where $P$ is a point in $B$, together with Lemma 73.16(5). 

Finally the following lemma plays the role of Corollary 43.16.

**Corollary 73.19.** Let $(X, A)$ and $(Y, B)$ be topological spaces and let $G$ be an abelian group. Then

\[ H_n(X, A) \text{ and } H_n(Y, B) \text{ are isomorphic for all } n \in \mathbb{N}_0 \quad \Rightarrow \quad H^n(Y, B; G) \text{ and } H^n(X, A; G) \text{ are isomorphic for all } n \in \mathbb{N}_0. \]
The proof follows immediately from Proposition 73.18 and the observation from page 1120 that relative singular chain groups are free abelian groups.

The previous corollary does not specify how the isomorphism of the cohomology groups is given. If we already start out with a map \( f: (X, A) \to (Y, B) \) that induces an isomorphism of homology groups, then we can be more precise, namely we have the following corollary which is similar in spirit to Corollary 57.20.

**Corollary 73.20.** Let \( f: (X, A) \to (Y, B) \) be a map between pairs of topological spaces and let \( G \) be an abelian group. Then

\[
\text{the induced map } \quad f_*: H_n(X, A) \to H_n(Y, B) \quad \text{is an isomorphism for all } n \in \mathbb{N}_0
\]

\[
\text{the induced map } \quad f^*: H^n(Y, B; G) \to H^n(X, A; G) \quad \text{is an isomorphism for all } n \in \mathbb{N}_0.
\]

**Remark.** In Proposition 75.14 we will see that the converse to Corollary 73.20 also holds.

**Proof.** Let \( f: (X, A) \to (Y, B) \) be a map between pairs of topological spaces and let \( G \) be an abelian group. If \( f_*: H_n(X, A) \to H_n(Y, B) \) is an isomorphism for all \( n \in \mathbb{N}_0 \), then it follows from Proposition 49.2 that \( f_*: C_*(X, A) \to C_*(Y, B) \) is already a chain homotopy equivalence. (Here, as in the previous proof we use that relative singular chain groups are free abelian groups.) Now we get the desired conclusion from Lemma 73.8.

The upshot of this short section is that we will need to work to justify spending so many pages on cohomology.

**Exercises for Chapter 73**

**Exercise 73.1.** Let \( f: B \to C \) be a homomorphism between abelian groups such that \( \text{im}(f) \) is a summand of \( C \). Let \( \{k_1, \ldots, k_m\} \) be a generating set for \( \ker(f) \). Finally suppose that we are given homomorphisms \( \varphi_1, \ldots, \varphi_m: B \to \mathbb{Z} \) such that for all \( i, j \in \{1, \ldots, m\} \) we have \( \varphi_i(k_j) = \delta_{ij} \). Show that the map

\[
\Phi: \mathbb{Z}^m \to \text{coker}(f: \text{Hom}(C, \mathbb{Z}) \to \text{Hom}(B, \mathbb{Z}))
\]

\[
e_i \mapsto [\varphi_i]
\]

is an isomorphism.

**Exercise 73.2.** Let \( \varphi: C_1 \to C_0 \) be a homomorphism between two finitely generated free abelian groups.

(a) Suppose that \( A \) is an \((n \times m)\)-matrix that represents \( \varphi \). Show that the transpose \( A^T \) represents the map \( \varphi^*: \text{Hom}(C_0, \mathbb{Z}) \to \text{Hom}(C_1, \mathbb{Z}) \).

(b) We consider the chain complex \( C_* := 0 \to C_1 \xrightarrow{\varphi} C_0 \to 0 \). Show that

\[
\text{Tor}(H^1(C_*; \mathbb{Z})) \cong \text{Tor}(H_1(C)) \quad \text{and} \quad \text{FH}^1(C_*; \mathbb{Z}) \cong \text{FH}_1(C).
\]

**Remark.** Statement (b) can be seen as a special case of the Universal Coefficient Theorem [75.12] for Cohomology Groups that we will prove later on.
Exercise 73.3. Let $X = \{x\}$ be a topological space that consists of a single point $x$. Show that for any abelian group $G$ we have

$$H^n(X; G) \cong \begin{cases} 0, & \text{if } n \geq 1, \\ G, & \text{if } n = 0. \end{cases}$$

Exercise 73.4. Let $X$ be a path-connected topological space and let $A$ be a non-empty subset of $X$. Show that

$$H^0(X, A; G) = 0,$$

using only the definitions of cohomology groups.

Exercise 73.5. Let $X$ be a path-connected topological space and let $A$ and $B$ be two disjoint non-empty subsets of $X$. Give an explicit example of a map $f: X \to \mathbb{Z}$ such that the map

$$C_1(X, A \cup B) \to \mathbb{Z}$$

$$[\sigma: \Delta^1 \to X] \mapsto f(\sigma((0,1)) - f(\sigma((1,0)))$$

is cocycle that represents a non-zero element in $H^1(X, A; \mathbb{Z})$.

Exercise 73.6. Show that any map $f: X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*: H^0(Y; G) \to H^0(X; G)$.

Exercise 73.7. Let $X$ be a topological space. Is the 0-th homology group $H_0(X; \mathbb{Z})$ necessarily isomorphic to the 0-th cohomology group $H^0(X; \mathbb{Z})$?

Exercise 73.8. We write $I = [0,1]$. As on page 1830 we consider the function

$$f: I \to \mathbb{Z}$$

$$x \mapsto \begin{cases} 0, & \text{if } x \in [0,\frac{1}{2}) \\ 1, & \text{otherwise}. \end{cases}$$

This map gives rise to the following singular 1-cochain:

$$\rho: C_1(I) \to \mathbb{Z}$$

$$(\sigma: \Delta^1 \to I) \mapsto f(\sigma(0,1)) - f(\sigma(1,0)).$$

As we pointed out on page 1830 the map $\rho$ actually defines a cochain $\rho: C_1(I, \partial I) \to \mathbb{Z}$.

(a) Show that $\rho \in C_1(I, \partial I)$ is a singular 1-cocycle.

(b) Show that $\rho$ defines a non-trivial element in $H^1(I, \partial I; \mathbb{Z})$.

Exercise 73.9. Let $X = \mathbb{R}^2$. We consider the singular 2-cochain $\varphi: C_2(\mathbb{R}^2; \mathbb{F}_2)$ that is given by

$$\varphi(\sigma) := \begin{cases} 1, & \text{if } (0,0) \text{ lies in the interior of the convex hull} \\ & \text{of the three points } \sigma(1,0,0), \sigma(0,1,0), \sigma(0,0,1), \\ 0, & \text{otherwise}. \end{cases}$$

Is $\varphi$ a cocycle?
Exercise 73.10. Let \( f : S^2 \to \mathbb{F}_2 \) be a function such that \( f(-x) = 1 - f(x) \) for all \( x \in S^2 \). Given a singular simplex \( \tau : \Delta^1 \to S^2 \) we write \( \mu(\tau) = 0 \) if \( f \) is constant on \( \tau(\Delta^1) \) and otherwise we write \( \mu(\tau) = 1 \). We denote by \( p : S^2 \to \mathbb{RP}^2 = S^2 / x \sim -x \) the projection map. We consider the following cochain

\[
\varphi : C_2(\mathbb{RP}^2) \to \mathbb{F}_2 \\
(\sigma : \Delta^2 \to \mathbb{RP}^2) \mapsto \text{pick a lift } \tilde{\sigma} : \Delta^2 \to S^2 \text{ of } \sigma \text{ and calculate} \\
\mu(\tilde{\sigma} \circ i_0^2) + \mu(\tilde{\sigma} \circ i_1^2) + \mu(\tilde{\sigma} \circ i_2^2).
\]

(a) Show that \( \varphi \) is well-defined, i.e. show that \( \varphi(\sigma) \) does not depend on the choice of the lift \( \tilde{\sigma} \).

Remark. Note that if \( \tilde{\sigma} : \Delta^2 \to S^2 \) is a lift of \( \sigma \), then the only other one is given by \( \nu \circ \tilde{\sigma} \) where \( \nu : S^2 \to S^2 \) is the map defined by \( \nu(x) = -x \) for all \( x \in S^2 \).

(b) Show that \( \varphi \) is a cocycle in \( C^2(\mathbb{RP}^2; \mathbb{F}_2) \).

(c) Does \( \varphi \) represent a non-zero cohomology class?
74. Properties of cohomology groups

After the disappointment of Corollary 73.19 one might be tempted to drop cohomology groups and move on to a different subject. But later on we will see that cohomology groups can be very interesting after all. The key, as we will see, is that cohomology is a contravariant functor whereas homology is a covariant functor.

Therefore we now persevere with the study of cohomology groups. In this chapter we want to extend the following deep theorems and theories from the homological setup to the cohomological setting:

(1) The Excision Theorem 43.19,
(2) the isomorphism between singular homology and cellular homology from Proposition 48.4,
(3) the Mayer-Vietoris Theorem 46.5.

These theorems will allow us in particular to give many more calculations of cohomology groups.

74.1. Excision theorems for cohomology groups. We start out with the analogue of the Excision Theorem 43.19

**Theorem 74.1. (Excision Theorem for Cohomology Groups)** Let $X$ be a topological space and let $Z \subset A \subset X$ be subsets such that the closure of $Z$ is contained in the interior of $A$. Then the inclusion

\[ i : (X \setminus Z, A \setminus Z) \to (X, A) \]

induces for each $n \in \mathbb{N}_0$ and every abelian group $G$ an isomorphism

\[ i^* : H^n(X, A; G) \xrightarrow{\cong} H^n(X \setminus Z, A \setminus Z; G). \]

**Proof.** In the original Excision Theorem 43.19 we showed that the inclusion induced map

\[ i_* : H_n(X \setminus Z, A \setminus Z) \to H_n(X, A) \]

is an isomorphism for every $n \in \mathbb{N}_0$. But then it follows immediately from Corollary 73.20 that the inclusion induced maps

\[ i^* : H^n(X, A; G) \xrightarrow{\cong} H^n(X \setminus Z, A \setminus Z; G). \]

are also isomorphisms.

**Remark.** Using Corollary 73.20 we also obtain the “cohomological” versions of the various other excision theorems, e.g. Theorem 43.20 and Theorem 44.10. For example, let $X$ be an $m$-dimensional topological manifold and let $B$ be a compact $m$-dimensional submanifold of $X$. We write $\hat{B} := B \setminus \partial_0 B$. For every $n \in \mathbb{N}_0$ and any abelian group $G$ the inclusion induced map

\[ H^n(X, B; G) \xrightarrow{\cong} H^n(X \setminus \hat{B}, \partial_0 B; G) \]

is an isomorphism.

\[ ^{1073} \text{We refer to page 1154 for the definition of } \partial_0 B. \]
Psychologically it is often helpful to replace relative homology groups by the homology groups of a quotient space. In Proposition 43.22 we had seen that we can perform this switch for reasonable subsets. The following proposition does the same for cohomology groups.

**Proposition 74.2.** Let $G$ be an abelian group. Let $X$ be a topological space and let $A \subset X$ be a non-empty subset. We denote by $p: (X, A) \to (X/A, A/A)$ the obvious projection map. We consider the following map:

\[
\tilde{H}^n(X/A; G) \cong H^n(X/A, A/A; G) \xrightarrow{p^*} H^n(X, A; G)
\]

The following two statements hold:

1. The composition of the above maps from left to right define a natural transformation from the contravariant functor $(X, A) \mapsto \tilde{H}^n(X, A)$ to the contravariant functor $(X, A) \mapsto H^n(X, A; G)$.
2. If $A$ is a non-empty good subset, then the above map $\tilde{H}^n(X/A; G) \to H^n(X, A; G)$ is an isomorphism.

**Proof.** At this stage we have all the tools to rewrite the proof of Proposition 43.22. In particular we can use the above Excision Theorem 74.1 for Cohomology Groups to replace the Excision Theorem 43.19. We leave it to the reader to verify that nothing goes wrong. ■

**Example.** Let $G$ be an abelian group. From the calculation of the cohomology groups of finitely many points, see Lemmas 73.12 and 73.14 we obtain that

\[
H^k(S^0, G) \cong \begin{cases} G^2, & \text{if } k = 0, \\
0, & \text{if } k \neq 0.
\end{cases}
\]

Similar to the proof of Proposition 43.4 we can use Proposition 74.2 to calculate, via an induction argument, that for $n \geq 1$ we have

\[
H^k(S^n, G) \cong \begin{cases} G, & \text{if } k = 0 \text{ or } k = n, \\
0, & \text{if } k \neq 0, n.
\end{cases}
\]

We will give an alternative calculation of the cohomology groups of spheres in the next section using cellular cohomology.

74.2. **Cellular cohomology.** In Chapter 48 we introduced the cellular homology of a CW-complex. We saw that it is naturally isomorphic to singular homology and we saw that in many examples it is straightforward to compute cellular homology. Now we will repeat the trick and introduce cellular cohomology.

First we recall some definitions and some notation. Let $X$ be a CW-complex.

1. Recall that given $n \in \mathbb{N}_0$ we denote by $X^n$ the $n$-skeleton of $X$.
2. We write $C^n_c(X) := H_n(X^n, X^{n-1})$ and we denote by $d_n: C^n_c(X) \to C^n_{c-1}(X)$ the cellular boundary map from page 1259.

---

\[1074\] Recall according to the definition on page 1107 this means that $A$ is closed and that there exists an open neighborhood $U$ of $A$ in $X$ such that $A$ is a deformation retract of $U$. 
(3) We refer to
\[ \cdots \xrightarrow{d_{n+1}} C^\text{CW}_{n+1}(X) \xrightarrow{d_n} C^\text{CW}_n(X) \xrightarrow{d_{n-1}} C^\text{CW}_{n-1}(X) \xrightarrow{d_{n-2}} \cdots \]
as the \textit{cellular chain complex}.

(4) Let $G$ be an abelian group. We remark that for a finite CW-complex we have
\[ \text{Hom}(C^\text{CW}_n(X), G) \cong \text{maps from the set of $n$-cells to } G = G^{\# \text{n-cells}}. \]

We refer to elements in $\text{Hom}(C^\text{CW}_n(X), G)$ as \textit{cellular $n$-cochains}.

\textbf{Example.} Given a CW-complex $X$ an integral cellular 1-cochain in $\text{Hom}(C^\text{CW}_1(X), \mathbb{Z})$ assigns to \textit{every} 1-cell an integer. We refer to Figure 1124 for an illustration. In contrast an element in $C^\text{CW}_1(X)$ can be viewed as a formal linear combination of 1-cells which is the same as saying that an element in $C^\text{CW}_1(X)$ assigns a non-zero integer to only \textit{finitely many} 1-cells.

![Diagram of a cellular 1-cochain](image)

\textbf{Definition.} Let $G$ be an abelian group and let $n \in \mathbb{N}_0$.

(1) Let $X$ be a CW-complex. We write $f_n := d^*_n$. We refer to
\[ \cdots \leftarrow \text{Hom}(C^\text{CW}_{n+1}(X), G) \xleftarrow{f_n} \text{Hom}(C^\text{CW}_n(X), G) \xleftarrow{f_{n-1}} \cdots \]
as the \textit{cellular cochain complex}. We define the \textit{$n$-th cellular cohomology group of $X$ with $G$-coefficients} as
\[ H^n_{\text{CW}}(X; G) := H^n(C^\text{CW}_n(X), G) = \frac{\ker(f_n: \text{Hom}(C^\text{CW}_n(X), G) \rightarrow \text{Hom}(C^\text{CW}_{n+1}(X), G))}{\text{im}(f_{n-1}: \text{Hom}(C^\text{CW}_{n-1}(X), G) \rightarrow \text{Hom}(C^\text{CW}_n(X), G))}. \]

(2) If $f: X \rightarrow Y$ is a cellular map, then by Lemma 48.3 we get an induced chain map $f^*: C_*^\text{CW}(X) \rightarrow C_*^\text{CW}(Y)$ and thus we obtain from Lemma 73.8 (1) an induced map $f^*: H^*_{\text{CW}}(Y; G) \rightarrow H^*_{\text{CW}}(X; G)$.

For completeness’ sake we jot down the following fairly self-evident lemma.

\textbf{Lemma 74.3.} (\textit{\textasteriskcentered}) \textit{Let $G$ be an abelian group and let $n \in \mathbb{N}_0$. The maps}
\[ X \mapsto H^n_{\text{CW}}(X) \quad \text{and} \quad (f: X \rightarrow Y) \mapsto (f^*: H^*_{\text{CW}}(Y; G) \rightarrow H^*_{\text{CW}}(X; G)) \]
\textit{define a contravariant functor from the category of CW-complexes to the category of abelian groups.}

\textbf{Proof.} This lemma follows immediately from Lemmas 48.3 and 73.8 (2). \hfill \blacksquare
Perhaps not surprisingly we have the following theorem which plays a similar role as Proposition 48.4.

**Proposition 74.4.** For every CW-complex $X$, any abelian group $G$ and any $n \in \mathbb{N}_0$ there exists a natural isomorphism

$$H^n(X; G) \xrightarrow{\cong} H^n_{CW}(X; G).$$

**Remark.** An alternative proof of this theorem is given in [Hat02, p. 203].

**First proof of Proposition 74.4.** Let $X$ be a CW-complex. Recall that on page 1290 we introduced the intermediate cellular chain complex that is given by

$$C^\text{int}_n(X) := \ker \left( C_n(X^n) \xrightarrow{\partial} C_{n-1}(X^n) \to C_{n-1}(X^n, X^{n-1}) \right) \quad \text{for } n \in \mathbb{N}_0.$$

We consider the two natural chain maps

$$i: C^\text{int}_*(X) \hookrightarrow C_*(X) \quad \text{and} \quad p: C^\text{int}_*(X) \to C^\text{CW}_*(X),$$

which are given by the obvious inclusion and the obvious projection. In Proposition 49.10 we had seen that these two chain maps are chain homotopy equivalences. Thus it follows from Lemma 73.8 (4) that we get isomorphisms

$$H^n(X; G) = H^n(C_*(X); G) \xrightarrow{i^*} H^n(C^\text{int}_*(X); G) \xleftarrow{p^*} H^n(C^\text{CW}_*(X); G) = H^n_{CW}(X; G).$$

As pointed out above, the two chain maps $i$ and $p$ are natural. Therefore we see that the above isomorphism $H^n(X; G) \to H^n_{CW}(X; G)$ is in fact natural. ■

**Alternative proof of Proposition 74.4 without “natural”.** Let $X$ be a CW-complex. We denote by $C_* = C_*(X)$ the singular chain complex and we denote by $D_* = C^\text{CW}_*(X)$ the cellular chain complex. In Proposition 48.4 we showed that all the homology groups of the chain complexes $C_*$ and $D_*$ are isomorphic. It follows from Proposition 73.18 that for any abelian group $G$ and any $n \in \mathbb{N}_0$ the cohomology groups $H^n(X; G) = H^n(C_*(X); G)$ and $H^n_{CW}(X; G) = H^n(D_*(X); G)$ are isomorphic. This approach to proving Proposition 74.4 circumvents the use of Proposition 49.10. But it is not clear how this approach can be used to show that there exists a natural isomorphism. Of course for many applications this is not an issue. ■

**Examples.** Let $G$ be an abelian group.

1. We use cellular cohomology to once again compute the cohomology groups of spheres. As we saw on page 935 we can view $S^n$, $n \geq 1$, as a CW-complex with one 0-cell and one other cell of dimension $n$. Furthermore the cellular boundary maps are the zero maps.\footnote{Here “natural” means that there exists a natural transformation between the contravariant functors $X \mapsto H^n(X; G)$ and $X \mapsto H^n_{CW}(X; G)$ from the category of CW-complexes to the category of abelian groups.} Thus we see that the cellular chain complex is of the form

$$0 \to \mathbb{Z} \xrightarrow{0} \cdots \xrightarrow{0} \mathbb{Z} \to 0.$$

\footnote{For $n \geq 2$ this follows by definition, for $n = 1$ this is a consequence of Lemma 48.6}
The dual cochain complex is then given by

\[ 0 \leftarrow \text{Hom}(\mathbb{Z}, G) \leftarrow \cdots \leftarrow \text{Hom}(\mathbb{Z}, G) \leftarrow G \]

Summarizing, precisely as on page 1841 we obtain that

\[ H^k(S^n; G) \cong \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise}. \end{cases} \]

(2) Let \( \Gamma \) be a connected finite topological graph. It follows from Proposition 18.31 (2) that \( \Gamma \) is homotopy equivalent to a CW-complex \( X \) with one 0-cell and \( \chi(\Gamma) + 1 \) 1-cells, see Figure 1125. The unique cellular boundary map in the cellular chain complex of \( X \) is zero by Lemma 48.6. Summarizing we see that for any \( n \in \mathbb{N}_0 \) we have

\[ H^n(\Gamma; G) \cong H^n(X; G) \cong H^n_c(X; G) \cong \text{Hom}(C^n_c(X); G) \cong \begin{cases} G, & \text{if } n = 0, \\ G^{\chi(\Gamma)+1}, & \text{if } n = 1, \\ 0, & \text{if } n \geq 2. \end{cases} \]

Figure 1125

(3) Given \( g \in \mathbb{N}_0 \) and \( m \in \mathbb{N}_0 \) we denote by \( \Sigma_{g,m} \) the surface of genus \( g \) minus \( m \) open disks. On page 1675 we had argued that for \( m \geq 1 \) the topological space \( \Sigma_{g,m} \) is homotopy equivalent to the wedge of \( 2g + m - 1 \) circles. The previous example, together with Lemma 73.13, thus gives us the calculation of the cohomology groups of \( \Sigma_{g,m} \) for \( m \geq 1 \).

(4) Let \( \Sigma_g \) be the surface of genus \( g \). In Figure 600 we showed that we can view \( \Sigma_g \) as a CW-complex with one 0-cell, \( 2g \) 1-cells and one 2-cell. On page 1270 we saw that the cellular boundary maps are all zero. Hence for any abelian group \( G \) and any \( n \in \mathbb{N}_0 \) we have

\[ H^n(\Sigma_g; G) \cong H^n_c(\Sigma_g; G) = \text{Hom}(C^n_c(\Sigma_g); G) \cong \begin{cases} G, & \text{if } n = 0 \text{ or } n = 2, \\ G^{2g}, & \text{if } n = 1, \text{ and} \\ 0, & \text{if } n \neq 0, 1, 2. \end{cases} \]

In all the examples so far the cohomology groups are isomorphic to the corresponding homology groups that we had calculated earlier. Now we will see an example where the homology and cohomology groups differ.

**Examples.**

(1) We consider the \( n \)-dimensional projective space \( \mathbb{R}P^n \). In the proof of Proposition 48.10 we saw that there exists a CW-structure on \( \mathbb{R}P^n \) such that the corresponding cellular...
chain complex is of the following form:

\[
0 \to \mathbb{Z} \xrightarrow{(1+(-1)^n)} \mathbb{Z} \to \ldots \to 0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to 0 \to \mathbb{Z} \to 0
\]

which allowed us to compute the homology groups of \(\mathbb{R}P^n\). Now let \(G\) be an abelian group. We dualize this chain complex, i.e. we apply the functor \(\text{Hom}(-, G)\). Using the isomorphism \(\text{Hom}(\mathbb{Z}, G) \to G\) from Lemma 73.1 we see that the cochain complex is isomorphic to the following cochain complex:

\[
0 \leftarrow G \xleftarrow{(1+(-1)^n)} G \leftarrow \ldots \leftarrow 0 \leftarrow G \xleftarrow{2} G \leftarrow 0 \leftarrow G \leftarrow 0.
\]

For \(G = \mathbb{Z}\) we thus obtain from Proposition 74.4 that for any \(k \in \{0, \ldots, n\}\) we have

\[
H^k(\mathbb{R}P^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = 0, \\
\mathbb{Z}_2, & \text{if } k \text{ is even and } k \neq 0, \\
0, & \text{if } k \text{ is odd and } k \neq n, \\
\mathbb{Z}_2, & \text{if } k \text{ is odd and } k \neq n, \\
0, & \text{if } k \text{ is even and } k \neq 0, \\
\mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd}
\end{cases}
\]

where on the right-hand side we recall the calculation of the homology groups using the above cellular chain complex, see also Proposition 48.10. Therefore we see that for \(n \geq 2\) the isomorphism types of the homology groups and the cohomology groups of \(\mathbb{R}P^n\) with \(\mathbb{Z}\)-coefficients do not coincide.

(2) To add to the confusion we also compute the cohomology of \(\mathbb{R}P^n\) with \(\mathbb{F}_2\)-coefficients. The corresponding dual cellular cochain complex is then given by

\[
0 \to \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \leftarrow \ldots \leftarrow \mathbb{F}_2 \xleftarrow{2} \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \to 0
\]

and we see that

\[
H^k(\mathbb{R}P^n; \mathbb{F}_2) \cong \begin{cases} 
\mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\
0, & \text{otherwise}.
\end{cases}
\]

If we compare this result with the calculation on page 1403 of the homology of \(\mathbb{R}P^n\) with \(\mathbb{F}_2\)-coefficients we see that we get the same result. More precisely, the homology and the cohomology groups of \(\mathbb{R}P^n\) with \(\mathbb{F}_2\)-coefficients are isomorphic.

One can easily modify the above argument and apply it to \(\mathbb{R}P^\infty\), which we can view as a CW-complex with precisely one cell in each dimension, see 942. We then obtain easily that for each \(k \in \mathbb{N}_0\) we have

\[
H^k(\mathbb{R}P^\infty; \mathbb{F}_2) \cong \mathbb{F}_2
\]

(3) We recall that in Lemma 36.1 we showed that we can view \(\mathbb{C}P^n\) as a CW-complex which admits exactly one cell in dimensions 0, 2, \ldots, 2n and which admits no odd-dimensional cells. It follows easily from Proposition 74.4 that

\[
H^k(\mathbb{C}P^n; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\
0, & \text{otherwise}.
\end{cases}
\]
By Lemma 36.6 (2) we can view the infinite-dimensional complex projective space \( \mathbb{CP}^\infty \) as a CW-complex that has precisely one cell in each even dimension and no cells in odd dimensions. Using Proposition 74.4 we obtain that

\[
H^k(\mathbb{CP}^\infty; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k \text{ even,} \\ 0, & \text{if } k \text{ odd.} \end{cases}
\]

Given \( k < l \in \mathbb{N} \cup \{\infty\} \) we have an inclusion \( \mathbb{CP}^k \to \mathbb{CP}^l \). Since the isomorphism of Proposition 74.4 is natural and since the cellular chain complexes of \( \mathbb{CP}^n \) and \( \mathbb{CP}^\infty \) agree up to the dimension \( 2n + 1 \) we obtain almost immediately that the inclusion induced maps \( H^k(\mathbb{CP}^\infty; \mathbb{Z}) \to H^k(\mathbb{CP}^n; \mathbb{Z}) \) are actually isomorphisms up to dimension \( 2n \).

We conclude this section with the following fairly reasonably immediate corollary to Proposition 74.4. This corollary can be viewed as an analogue of Proposition 48.5 and Proposition 64.6.

**Corollary 74.5.** Let \( X \) be a topological space. Suppose we are in one of the following two situations:

1. \( X \) is homotopy equivalent to a retract of a finite CW-complex,
2. \( X \) is a compact topological manifold.

Then for every \( n \in \mathbb{N}_0 \) the cohomology group \( H^n(X; \mathbb{Z}) \) is a finitely generated group.

**Proof.** Statement (2) is an immediate consequence of Statement (1) and Theorem 85.12. We will prove Statement (1) in Exercise 74.1.

### 74.3. Explicit generators of cohomology groups

In the previous section we had used cellular cohomology to compute the isomorphism types of the cohomology groups of many different topological spaces. But this calculation of the isomorphism types does not give us any explicit generators of the cohomology groups. For example on page 1825 we introduced a singular 1-cochain \( \theta_z: C_1(S^1) \to \mathbb{Z} \) and we showed in Lemma 73.10 that \( \theta_z \) defines a non-zero cohomology class \([\theta_z] \in H^1(S^1; \mathbb{Z}) \). By the discussion on page 1844 we now also know that \( H^1(S^1; \mathbb{Z}) \cong \mathbb{Z} \), but we do not know whether \([\theta_z] \in H^1(S^1; \mathbb{Z}) \) is a generator.

On the other hand in earlier chapters we had obtained a pretty good understanding of generators of homology groups. The idea now is to translate information on homology groups to information on cohomology groups. The key tool relating homology and cohomology is given by the Kronecker pairing that we now introduce.

**Lemma 74.6.** Let \( C_\ast \) be a chain complex.

1. Let \( G \) be an abelian group. The map

\[
\langle \ , \rangle: \ H^n(C; G) \times H_n(C) \to G
\]

\[
([\varphi], [c]) \mapsto \langle [\varphi], [c] \rangle := \varphi(c)
\]

here \( \varphi \in \text{Hom}(C_n, G) \) and \( c \in C_n \), so \( \varphi(c) \in G \) is defined.
is well-defined and bilinear. In particular, if \((X, A)\) is a pair of topological spaces, then the map
\[
\langle \cdot, \cdot \rangle_X : H^n(X, A; G) \times H_n(X, A) \to G
\]
\[
\langle [\varphi], [c] \rangle \mapsto \langle [\varphi], [c] \rangle_X := \varphi(c)
\]
is well-defined and bilinear. We refer to both pairings as the Kronecker pairing.

(2) This statement follows immediately from the definitions.

(3) Let \(f : C_* \to D_*\) be a chain map between two chain complexes and let \(G\) be an abelian group. Then for any \(c \in H_n(C)\) and \(\varphi \in H^n(D; G)\) we have
\[
\langle f^*(\varphi), c \rangle_X = \langle \varphi, f_*(c) \rangle_Y.
\]

This calculation shows that the definition of the Kronecker pairing does not depend on the choices of the representatives of the cohomology and the homology classes. Finally note that it is clear that the Kronecker pairing is bilinear.

(2) This statement follows immediately from the definitions.

(3) The statement also follows immediately from the definitions. Indeed, if \([c] \in H_n(C)\) and \([\varphi] \in H^n(D; G)\), then
\[
\langle f^*([\varphi]), [c] \rangle = \langle [f^*\varphi], [c] \rangle = \langle f^*\varphi(c) \rangle = \varphi(f_*(c)) = \langle [\varphi], [f_*(c)] \rangle = \langle [\varphi], f_*(c) \rangle.
\]

Proof. Let \(C_*\) be a chain complex.

(1) Let \(G\) be an abelian group. Let \(\varphi \in \text{Hom}(C_n, G)\) be a cocycle and let \(c \in C_n\) be a cycle. Furthermore let \(\alpha \in \text{Hom}(C_{n-1}, G)\) and let \(d \in C_{n+1}\). Then the following equalities hold in \(G\):
\[
(\varphi + \delta \alpha)(c) = \varphi(c) + \alpha(\partial c) = \varphi(c) \quad \text{and} \quad \varphi(c + \partial d) = \varphi(c) + (\delta \varphi)(d) = \varphi(c).
\]
\[\uparrow \quad \text{definition of } \delta \quad \text{since } c \text{ is a cycle} \quad \text{definition of } \delta \quad \text{since } \varphi \text{ is a cocycle}
\]

In general, given a commutative ring \(R\) a map \(\Theta : U \times V \to W\) between \(R\)-modules is called bilinear, if for all \(u, u' \in U\), \(v, v' \in V\) and \(r \in R\) we have
\[
\Theta(u + u', v) = \Theta(u, v) + \Theta(u', v) \quad \text{and} \quad \Theta(ru, v) = r\Theta(u, v), \quad \text{and}
\]
\[
\Theta(u, v + v') = \Theta(u, v) + \Theta(u, v') \quad \text{and} \quad \Theta(u, rv) = r\Theta(u, v).
\]

In our special case we consider the case of \(\mathbb{Z}\)-modules.

1078 Often we drop the subscript \(X\) in the notation.

1079 Leopold Kronecker (1823-1891) was a German mathematician who worked on number theory. I don’t know how his name got attached to this pairing.
The statement regarding maps between pairs of topological spaces is an immediate consequence of the purely algebraic statement. □

Now we state the lemma which will allow us in many situations to show that given cocycles form a basis for cohomology groups.

**Lemma 74.7.** Let $X$ be a topological space and let $n \in \mathbb{N}_0$. Suppose that $H^n(X; \mathbb{Z})$ and $H_n(X; \mathbb{Z})$ are free abelian groups of rank $k$ and suppose we are given $\varphi_1, \ldots, \varphi_k \in H^n(X; \mathbb{Z})$ and $c_1, \ldots, c_k \in H_n(X; \mathbb{Z})$. If

$$\det \left( \langle \varphi_i, c_j \rangle_{i,j=1,\ldots,k} \right) = \pm 1,$$

then $\varphi_1, \ldots, \varphi_k \in H^n(X; \mathbb{Z})$ and $c_1, \ldots, c_k \in H_n(X; \mathbb{Z})$ are both bases.

**Example.** Let $X = S^1$. We denote by $\theta_Z : C_1(S^1) \to \mathbb{Z}$ the singular 1-cocycle that we introduced on page 1825. We consider the singular cycle $\mu : \Delta^1 \to S^1$ that is given by $(1-\tau,t) \mapsto e^{2\pi i \tau}$. As on page 1826 we see that

$$\langle [\theta_Z], [\mu] \rangle = \theta_Z(\mu) = \alpha_Z \left( \text{boundary of lift } \tilde{\mu} : \Delta^1 \to \mathbb{R} \text{ of } \mu \right) = 1.$$

From Proposition 43.4 we know that $H_1(S^1; \mathbb{Z}) \cong \mathbb{Z}$ and by the discussion on page 1841 we know that $H^1(S^1; \mathbb{Z}) \cong \mathbb{Z}$. Therefore it follows from Lemma 74.7 that $[\theta_Z] \in H^1(S^1; \mathbb{Z})$ is in fact a generator. In particular we have an equality $H^1(S^1; \mathbb{Z}) = \mathbb{Z} \cdot [\theta_Z]$.

**Remark.** Lemma 74.7 is really quite generous, it gives us as output that both sets are bases. In particular to apply the lemma we do not even have to verify that the $c_i$ form a basis.

Lemma 74.7 is an immediate consequence of the following purely algebraic lemma.

**Lemma 74.8.** Let $A$ and $B$ be two free abelian groups of rank $k$, let $a_1, \ldots, a_k \in A$ and let $b_1, \ldots, b_k \in B$. Furthermore let $\langle \ , \ \rangle : A \times B \to \mathbb{Z}$ be a bilinear pairing. If

$$\det(\langle a_i, b_j \rangle_{i,j=1,\ldots,k}) = \pm 1,$$

then both $a_1, \ldots, a_k$ and $b_1, \ldots, b_k$ are bases.

**Proof.** We denote by $S$ the free abelian group generated by the set $\{a_1, \ldots, a_k\}$ and we denote by $T$ the free abelian group generated by the set $\{b_1, \ldots, b_k\}$. We denote by $i : S \to A$ and by $j : T \to B$ the obvious maps given by $a_i \mapsto a_i$ and $b_i \mapsto b_i$. We denote by $\Phi : A \to \text{Hom}(B, \mathbb{Z})$ the homomorphism given by $a \mapsto (b \mapsto \langle a, b \rangle)$. The claim follows from the following three observations:

1. Let $\gamma : G \to H$ be a homomorphism between two finitely generated free abelian groups of the same rank. Lemma 19.8 (5) says that if $\gamma$ is an epimorphism, then $\gamma$ is already an isomorphism.

\[1080\]

It also follows from Lemma 74.7 that the singular 1-simplex $\mu : \Delta^1 \to S^1$ represents a generator for $H_1(S^1) \cong \mathbb{Z}$. We had obtained that result in Lemma 43.4.

\[1081\] The fact that $\langle \ , \ \rangle$ is bilinear implies that $b \mapsto \langle a, b \rangle$ is a homomorphism and that $\Phi : A \to \text{Hom}(B, \mathbb{Z})$ is a homomorphism.
(2) We consider the following sequence of homomorphisms

\[ S \xrightarrow{i} A \xrightarrow{\phi} \text{Hom}(B, \mathbb{Z}) \xrightarrow{j^*} \text{Hom}(T, \mathbb{Z}). \]

With respect to the basis \( a_1, \ldots, a_k \) of \( S \) and the dual basis \( b_1^*, \ldots, b_k^* \) of \( \text{Hom}(T, \mathbb{Z}) \) this linear map is represented by the matrix \( \langle a_i, b_j \rangle_{i,j=1,\ldots,k} \). Thus by our hypotheses this map is an isomorphism. Furthermore by our hypotheses each of the individual groups is a free abelian group of rank \( k \).

(3) Since the map in (2) is an isomorphism it is in particular an epimorphism. Starting from the right and using (1) three times in a row we see that all maps are in fact isomorphisms. In particular we have \( S = A \). The same argument turned around shows that \( T = B \).

Now we will use Lemma 74.9 to determine explicit bases for the first cohomology groups of surfaces. We start out with the torus.

**Lemma 74.9.** We consider the two projection maps

\[ p: S^1 \times S^1 \to S^1 \quad \text{and} \quad q: S^1 \times S^1 \to S^1 \]

\( (v, w) \mapsto v \quad \text{and} \quad (v, w) \mapsto w. \)

Then \( p^*([\theta]) \) and \( q^*([\theta]) \) form a basis for \( H^1(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}^2 \).

**Proof.** We denote as usual by \( \mu: \Delta^1 \to S^1 \) our favorite singular 1-cycle of \( S^1 \) that is given by \( \mu(1-t,t) = e^{2\pi i t}. \) For simplicity we write \( \theta = \theta_{\mathbb{Z}} \). We denote by

\[ i: S^1 \to S^1 \times S^1 \quad \text{and} \quad j: S^1 \to S^1 \times S^1 \]

\( z \mapsto (z,1) \quad \text{and} \quad z \mapsto (1,z) \)

the two obvious inclusion maps. We calculate that

\[
\left( \begin{array}{c}
\langle [p^* \theta], [i_*(\mu)] \rangle \\
\langle [q^* \theta], [i_*(\mu)] \rangle
\end{array} \right) = \left( \begin{array}{c}
\theta(p_*(i_*(\mu))) \\
\theta(q_*(i_*(\mu)))
\end{array} \right) = \left( \begin{array}{cc}
\theta(\mu) & \theta(1) \\
\theta(1) & \theta(\mu)
\end{array} \right) = \left( \begin{array}{cc}
1 & 0 \\
0 & 1
\end{array} \right).
\]

since \( p \circ i = \text{id} \) and \( q \circ j = \text{id} \) and since \( p \circ j \equiv 1 \in S^1 \) and \( q \circ i \equiv 1 \in S^1 \)

here we denote by \( 1 \) also the constant singular 1-simplex given by \((1-t,t) \mapsto 1\). We know from Lemma 46.12 that \( H_1(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}^2 \). Furthermore we saw on page 1844 that \( H^1(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}^2 \). The above calculation, together with Lemma 74.7 shows that \( p^*([\theta]) \) and \( q^*([\theta]) \) form a basis for \( H^1(S^1 \times S^1; \mathbb{Z}) \). 

\[ \text{Torus } S^1 \times S^1 \]

\[ S^1 \times \{1\} = i(S^1) \]

\[ \{1\} \times S^1 = j(S^1) \]

\[ \xrightarrow{p} \]

\[ \xrightarrow{q} \]

\[ \xrightarrow{j} \]

\[ \xrightarrow{i} \]

\[ \text{Figure 1126} \]
Together with Proposition 73.11 we have now found explicit generators for the cohomology groups of the torus in dimensions 0 and 1. The following question arises:

**Question 74.10.** Can we find an explicit generator of $H^2(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}$?

Now we turn to surfaces of higher genus. As usual, given $g \in \mathbb{N}$ we denote by $\Sigma_g$ the surface of genus $g$. In Figure 1127 we show projection maps $p_i: \Sigma_g \to S^1 \times S^1$, $i = 1, \ldots, g$. The following lemma is a generalization of Lemma 74.9.

![Figure 1127](image)

**Lemma 74.11.** We denote by $\alpha, \beta \in H^1(S^1 \times S^1; \mathbb{Z})$ the basis given by Lemma 74.9. A basis for $H^1(\Sigma_g; \mathbb{Z}) \cong \mathbb{Z}^{2g}$ is given by $p_i^*(\alpha), p_i^*(\beta)$, $i = 1, \ldots, g$.

**Proof.** As we will see, the proof of the lemma is very similar to the proof of Lemma 74.9. For $i = 1, \ldots, g$ we write $\varphi_i = p_i^*(\alpha)$ and $\psi_i := p_i^*(\beta)$. We consider the singular 1-cycles $x_1, \ldots, x_g$ and $y_1, \ldots, y_g$ that are indicated in Figure 1128. As in the proof of Lemma 74.9 it follows easily from the definitions that (for $g = 2$) we have

$$
\begin{pmatrix}
\langle \varphi_1, x_1 \rangle & \langle \varphi_1, y_1 \rangle & \langle \varphi_1, x_2 \rangle & \langle \varphi_1, y_2 \rangle \\
\langle \psi_1, x_1 \rangle & \langle \psi_1, y_1 \rangle & \langle \psi_1, x_2 \rangle & \langle \psi_1, y_2 \rangle \\
\langle \varphi_2, x_1 \rangle & \langle \varphi_2, y_1 \rangle & \langle \varphi_2, x_2 \rangle & \langle \varphi_2, y_2 \rangle \\
\langle \psi_2, x_1 \rangle & \langle \psi_2, y_1 \rangle & \langle \psi_2, x_2 \rangle & \langle \psi_2, y_2 \rangle
\end{pmatrix}
= \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}.
$$

The lemma now follows immediately from Lemma 74.7.

![Figure 1128](image)

74.4. **Excisive triads and the Mayer–Vietoris Theorem for cohomology groups.** Before we state and prove the Mayer–Vietoris Theorem for cohomology groups it is helpful to introduce the following definition.

\footnote{In fact for $g = 2$ we already saw this map in Figure 307}
Definition.

(1) A triad of topological spaces is a triple \( (X, A_1, A_2) \) where \( X \) is a topological space and where both \( A_1 \) and \( A_2 \) are subsets of \( X \).

(2) A map \( f: (X, A_1, A_2) \to (Y, B_1, B_2) \) of triads is a map \( f: X \to Y \) with \( f(A_1) \subseteq B_1 \) and \( f(A_2) \subseteq B_2 \).

(3) Given a triad \( (X, A_1, A_2) \) of topological spaces we consider the following subgroup of \( C_n(A_1 \cup A_2) \):

\[
C_n^{(A_1, A_2)}(A_1 \cup A_2) := \left\{ \sum_{j=1}^{k} a_j \sigma_j \in C_n(A_1 \cup A_2) \mid \text{for each } j \text{ there exists an } i \in \{1, 2\} \text{ such that the image of } \sigma_j \text{ lies in } A_i \right\}.
\]

The usual boundary map on the groups \( C_*(A_1 \cup A_2) \) restricts to a boundary map on \( C_*(A_1, A_2)(A_1 \cup A_2) \), so we can view \( C_*(A_1, A_2)(A_1 \cup A_2) \) as a chain complex. We denote the corresponding homology groups by \( H_*(A_1, A_2)(A_1 \cup A_2) \).

(4) We say a triad \( (X, A_1, A_2) \) is excisive if the inclusion map

\[
C_*(A_1, A_2)(A_1 \cup A_2) \to C_*(A_1 \cup A_2)
\]

is a chain homotopy equivalence of chain complexes.

Example. In Exercise 74.2 we will see that the triad \( (X, A_1, A_2) := (\mathbb{R}, (\infty, 0], (0, \infty)) \) is not excisive.

After this negative example we want to collect some positive examples of excisive triads.

Proposition 74.12. Let \( (X, A_1, A_2) \) be a triad of topological spaces. The triad is excisive if one of the following conditions is satisfied:

1. \( A_1 \subseteq A_2 \) or \( A_2 \subseteq A_1 \),
2. \( A_1 = \emptyset \) or \( A_2 = \emptyset \) or \( A_1 = A_2 \),
3. \( A_1 \cup A_2 = \overset{\circ}{A_1} \cup \overset{\circ}{A_2} \) where we denote by \( \overset{\circ}{A_1} \) and \( \overset{\circ}{A_2} \) the interiors of \( A_1 \) and \( A_2 \) in \( A_1 \cup A_2 \),
4. \( A_1 \) and \( A_2 \) are both open subsets of \( A_1 \cup A_2 \),
5. \( A_1 \cup A_2 \) is a topological manifold and \( A_1 \) and \( A_2 \) are submanifolds such that each component of \( A_1 \cap A_2 \) is a boundary component of \( A_1 \) and a boundary component of \( A_2 \), and such that \( A_1 \) and \( A_2 \) are closed subsets,
6. \( X \) is a CW-complex and \( A_1 \) and \( A_2 \) are both subcomplexes.

In the proof of Proposition 74.12 we will need the following lemma which gives us several criteria for a triad to be excisive.

---

1083 This definition should not be confused with the definition of a *triple* of topological spaces, which was defined as a triple \( (X, B, A) \) where \( X \) is a topological space and \( A \subseteq B \subseteq X \) are subsets. In a triad we do not demand that the third set is contained in the second set.

1084 The definition is basically the same as on page 1133 except that this time we do not demand that the interiors of \( A_1 \) and \( A_2 \) cover all of \( X \).
Lemma 74.13. Let \((X, A_1, A_2)\) be a triad of topological spaces. The following statements are equivalent:

1. the triad is excisive,
2. for every \(n \in \mathbb{N}_0\) the inclusion induced map
   \[H_n^{[A_1, A_2]}(A_1 \cup A_2) \to H_n(A_1 \cup A_2)\]
   is an isomorphism,
3. for every \(n \in \mathbb{N}_0\) the inclusion induced map
   \[H_n(A_1, A_1 \cap A_2) \to H_n(A_1 \cup A_2, A_2)\]
   is an isomorphism.

Now suppose that the triad is excisive.

(a) Given any abelian group \(G\) the statements (2) and (3) also hold for \(G\)-coefficients.
(b) Given any abelian group \(G\) the analogue of (2) also holds for cohomology groups,
   i.e. given any \(n \in \mathbb{N}_0\) and given any abelian group \(G\) the inclusion induced map
   \[H^n(A_1 \cup A_2, A_2; G) \to H^n(A_1, A_1 \cap A_2; G)\]
   is an isomorphism.

Proof. Let \((X, A_1, A_2)\) be a triad of topological spaces. The equivalence of (1) and (2) is an immediate consequence of Corollary 42.3 and Proposition 49.2.

Now we turn to the proof that (2) and (3) are equivalent. We write \(Y = A_1 \cup A_2\). We consider the following sequences of chain complexes:

- (I) \[0 \to C_*(A_1, A_2)(Y) \to C_*(Y) \to C_*(Y)/C^{[A_1, A_2]}_*(Y) \to 0\]
- (II) \[0 \to C_*(A_1)/C_*(A_1 \cap A_2) \to C_*(Y)/C_*(A_2) \to C_*(Y)/C^{[A_1, A_2]}_*(Y) \to 0\]

The top sequence is exact by definition. It is easy to see that the bottom sequence is also exact. We can thus apply Proposition 43.11 to get the corresponding long exact sequences of homology groups:

- (I) \[\to H_n\left(C_*(A_1, A_2)(Y)\right) \to H_n(Y) \to H_n\left(C_*(Y)/C^{[A_1, A_2]}_*(Y)\right) \xrightarrow{\partial} H_{n-1}\left(C_*(A_1, A_2)(Y)\right)\]
- (II) \[\to H_n(A_1, A_1 \cap A_2) \to H_n(Y, A_2) \to H_n\left(C_*(Y)/C^{[A_1, A_2]}_*(Y)\right) \xrightarrow{\partial} H_{n-1}(A_1, A_1 \cap A_2)\]

But using these long exact sequences we see that

(2) holds \(\iff\) \[H_n\left(C_*(Y)/C^{[A_1, A_2]}_*(Y)\right) = 0\] for all \(n \in \mathbb{N}_0\) \(\iff\) (3) holds.

\[\text{long exact sequence (I)} \quad \text{long exact sequence (II)}\]
Finally we turn to the proofs of the addenda (a) and (b). Thus suppose that \((X, A_1, A_2)\) is excisive and that \(G\) is an abelian group.

(a) The fact that the map in (2) is also an isomorphism with \(G\)-coefficients follows from basically the same argument as above. Furthermore, if (2) holds for \(G\)-coefficients, then again the same argument as above shows that also (3) holds with \(G\)-coefficients.

(b) This statement follows from the above “(1) \(\Rightarrow\) (3)” implication together with Corollary 73.20.

Now we turn to the proof of Proposition 74.12.

**Proof of Proposition 74.12.** Let \((X, A_1, A_2)\) be a triad of topological spaces.

1. If \(A_1 \subseteq A_2\), then \(C_*^{(A_1,A_2)}(A_1 \cup A_2) = C_*(A_2) = C_*(A_1 \cup A_2)\), so the triad is excisive. The same argument applies if \(A_2 \subseteq A_1\).
2. This case is just a special case of (1).
3. If \(A_1 \cup A_2 = \tilde{A}_1 \cup \tilde{A}_2\), then the desired statement follows immediately from Proposition 49.5.
4. The case that \(A_1\) and \(A_2\) are both open subsets of \(A_1 \cup A_2\) is a special case of (3).
5. Suppose that \(A_1 \cup A_2\) is a compact topological manifold and that \(A_1\) and \(A_2\) are submanifolds such that each component of \(A_1 \cap A_2\) is a boundary component of \(A_1\) and a boundary component of \(A_2\). The Excision Theorem 44.10 for topological manifolds implies that for every \(n \in \mathbb{N}_0\) the inclusion induced map

\[ H_n(A_1, A_1 \cap A_2) \rightarrow H_n(A_1 \cup A_2, A_2) \]

is an isomorphism. By Lemma 74.13 (3) \(\Rightarrow\) (1) this implies that the triad \((X, A_1, A_2)\) is excisive.
6. Suppose that \(X\) is a CW-complex and that \(A_1\) and \(A_2\) are both subcomplexes. The proof of the Excision Theorem 44.10 for Topological Manifolds can easily be modified to give the corresponding statement for CW-complexes. More precisely, in the proof of the Excision Theorem 44.10 for Topological Manifolds we need to replace the Collar Neighborhood Theorem 8.12 by Proposition 36.10 (8). Furthermore we need to replace Proposition 6.27 (3) by Lemma 36.18 (2). We then proceed as in (5). We leave it to the reader to fill in the details.

Now we can formulate the following theorem, which in view of Proposition 74.12 is a generalization of the various Mayer–Vietoris Theorems 46.5, 46.10 and 46.11 that we had formulated earlier.

**Theorem 74.14. (Mayer–Vietoris Theorem)** Given any excisive triad \((X, A, B)\) with \(X = A \cup B\) there exists a natural long exact sequence

\[ \cdots \rightarrow H_n(A \cap B) \xrightarrow{i_\Delta B + i_\Delta^B} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \rightarrow \cdots \]

where the various maps denoted by \(i\) are the obvious inclusion induced maps. The same long exact sequence also exists for homology with coefficients in any abelian group \(G\).
Proof. Let \((X, A, B)\) be a triad with \(X = A \cup B\). In the proof of the original Mayer–Vietoris Theorem \[46.5\] we showed that the sequence
\[
0 \to C_*(A \cap B) \xrightarrow{i_{A \cap B} \oplus -i_{A \cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{(A, B)}(X) \to 0
\]
of chain maps is exact. We deduce from Proposition \[43.11\] that we get a long exact sequence of the form
\[
\cdots \to H_n(A \cap B) \xrightarrow{i_{A \cap B} \oplus -i_{A \cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n^{(A, B)}(X) \xrightarrow{p_n} H_{n-1}(A \cap B) \to \cdots
\]
Recall that the connecting homomorphism is natural by Proposition \[43.11\]. Now we suppose that \((X, A, B)\) is in fact excisive. By definition, and since \(X = A \cup B\), this means that the inclusion map
\[
C_*^{(A, B)}(X) \to C_*(X)
\]
is a chain homotopy equivalence, hence for every \(n \in \mathbb{N}_0\) it induces a natural isomorphism
\[
\Phi_n: H_n^{(A, B)}(X) \xrightarrow{\cong} H_n(X).
\]
For each \(n \in \mathbb{N}_0\) we now replace \(H_n^{(A, B)}(X)\) by \(H_n(X)\) and we write \(\partial_n := p_n \circ \Phi_n^{-1}\) and we finally get the desired natural long exact sequence.

The argument for homology with \(G\)-coefficients is very similar, see also page \[1401\]. We leave the details to the dedicated reader. \[\square\]

We also have the following analogue for cohomology groups.

**Theorem 74.15. (Mayer–Vietoris Theorem for Cohomology Groups)** Let \((X, A, B)\) be an excisive triad with \(X = A \cup B\) and let \(G\) be an abelian group. Then there exists a natural long exact sequence
\[
\cdots \to H^n(X; G) \xrightarrow{i^* \oplus -i^*} H^n(A; G) \oplus H^n(B; G) \xrightarrow{i^* - i^*} H^n(A \cap B; G) \to H^{n+1}(X; G) \to \cdots
\]
where the maps \(i^*\) are the restrictions to the various subspaces.

**Proof.** Let \((X, A, B)\) be an excisive triad with \(X = A \cup B\) and let \(G\) be an abelian group. We start out with the following claim.

**Claim.** The inclusion map
\[
C_*^{(A, B)}(X) \to C_*(X)
\]
induces for each \(n \in \mathbb{N}_0\) a natural isomorphism
\[
H^n(X; G) \to H^n(C_*^{(A, B)}(X); G).
\]

Here “natural” means that given a map \(f: (X, A, B) \to (Y, C, D)\) of excisive triads with \(X = A \cup B\) and \(Y = C \cup D\) the following diagram commutes:
\[
\begin{array}{ccc}
\cdots & \xrightarrow{f_*} & \cdots \\
H_n(A \cap B) & \xrightarrow{i_{A \cap B} \oplus -i_{A \cap B}} & H_n(A) \oplus H_n(B) \\
\downarrow f_* & & \downarrow f_* \\
H_n(C \cap D) & \xrightarrow{i_{C \cap D} \oplus -i_{C \cap D}} & H_n(C) \oplus H_n(D)
\end{array}
\]

The meaning of “natural” is evidently totally analogous to the interpretation given in Footnote \[1085\].

Footnote 1085: The meaning of “natural” is evidently totally analogous to the interpretation given in Footnote 1085.
The claim follows immediately from the definition of an excisive triad together with Lemma 73.8 (3).

Now we turn to the actual proof of the Mayer–Vietoris Theorem for Cohomology Groups. Exactly as in the proof of the Mayer–Vietoris Theorem 74.14 we start out with the fact that the following sequence is exact:

\[ 0 \to C_*(A \cap B) \xrightarrow{i_A \cap B \mathbin{\oplus} - i_A \cap B} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{(A,B)}(X) \to 0. \]

The groups \( C_*^{(A,B)}(X) \) are clearly free abelian groups. Thus we deduce from Lemma 73.4 and Proposition 73.6 that there exists a natural long exact sequence

\[
\begin{align*}
H^n(C_*^{(A,B)}(X); G) &\to H^n(A; G) \oplus H^n(B; G) \to H^n(A \cap B; G) \to H^{n+1}(C_*^{(A,B)}(X); G) \to H^n(X; G)
\end{align*}
\]

As an application of the Mayer–Vietoris Theorem 74.15 for Cohomology Groups we will determine the cohomology groups of the wedge of two topological spaces. We will not make use of this example.

**Lemma 74.16.** (*) Let \( X \) and \( Y \) be topological spaces and let \( x \in X \) and \( y \in Y \) be good points. We use these points to define the wedge \( X \vee Y \). Then \( (X \vee Y, X, Y) \) is an excisive triad.

**Figure 1130**

**Proof** (*). We denote by \( z \) the point in \( X \vee Y \) that is given by identifying \( x \) with \( y \). For each \( k \in \mathbb{N}_0 \) we consider the following diagram

\[
\begin{array}{ccc}
0 & \to & H_k(Y, \{y\}; Z) \\
& & \downarrow \\
0 & \to & H_k(X, \{x\}; Z) \oplus H_k(Y, \{y\}; Z) \\
& & \downarrow \\
& & H_k(X \vee Y, \{z\}; Z) \\
& & \downarrow \\
& & H_k(X \vee Y, Y; Z)
\end{array}
\]

where all the maps are the obvious maps. The top horizontal sequence is evidently exact. The bottom horizontal sequence is an excerpt from the long exact sequence of the triple \( \langle \{y\} = \{z\}, Y, X \vee Y \rangle \), see Proposition 43.15. The excerpt shown is also exact since \( (Y, \{y\}) \) is a retract of \( (X \vee Y, \{z\}) \), which implies that for any \( l \in \mathbb{N}_0 \) the inclusion induced map \( H_l(Y, \{y\}; Z) \to H_l(X \vee Y, \{z\}; Z) \) is a monomorphism.

The middle vertical map in the above diagram is an isomorphism by Proposition 47.8 and the left vertical map is the identity. It follows from the Five Lemma 43.12 that the right vertical hand map is an isomorphism. We obtain from Lemma 74.13 (3) \( \Rightarrow (1) \) that \( (X \vee Y, X, Y) \) is an excisive triad.

---

\[\text{Recall that according to the definition on page 604 we say that a point } x \text{ in a topological space } X \text{ is good, if } \{x\} \text{ is a closed subset and if there exists an open neighborhood } U \text{ of } x \text{ such that } \{x\} \text{ is a deformation retract of } U.\]
We prove the following proposition that is the analogue of Proposition 47.9.

**Proposition 74.17.** (*) Let \( \{A_k\}_{k \in K} \) be a family of topological spaces. For each \( k \in K \) suppose that we are given a good point \( a_k \in A_k \). Let \( G \) be an abelian group. Given \( j \in K \) we denote by

\[
i_j : A_j \to \bigvee_{k \in K} A_k \quad \text{respectively} \quad p_j : \bigvee_{k \in K} A_k \to A_j
\]

the natural inclusion map respectively the natural projection map that we introduced on page 561. Then for every \( n \in \mathbb{N}_0 \) the map

\[
\prod_{k \in K} i_k^* : \tilde{H}^n \left( \bigvee_{k \in K} A_k ; G \right) \to \prod_{k \in K} \tilde{H}^n (A_k ; G)
\]

is an isomorphism where the inverse is given by

\[
\prod_{k \in K} p_k^* : \prod_{k \in K} \tilde{H}^n (A_k ; G) \to \tilde{H}^n \left( \bigvee_{k \in K} A_k ; G \right)
\]

**Proof (\( * \)).**

1. First we consider the case we are given just two topological spaces. By Lemma 74.16 we can use the Mayer–Vietoris Theorem 74.15 for Cohomology Groups to prove, completely analogously to Proposition 47.8, the desired statement.

2. The case that we are dealing with finitely many topological spaces follows from (1) by induction.

3. The case that \( K \) is infinite is more tricky. There are two possible approaches:
   (a) In the proof of Proposition 47.9, that deals with the corresponding statement for homology groups, we gave two different proofs. The first proof generalizes to the present setting. It is not clear to me how the second proof can be generalized. But fortunately providing one proof is enough.
   (b) Alternatively we can consider the map

\[
\bigoplus_{k \in K} i_k^* : \bigoplus_{k \in K} C_n(A_k) \to C_n \left( \bigvee_{k \in K} A_k \right).
\]

By Proposition 47.9 this chain map induces an isomorphism of chain complexes. It follows from Proposition 49.2 that this map is in fact a chain homotopy equivalence. It follows from Lemma 73.8 that the above map induces an isomorphism of dual cochain complexes. The desired statement now follows from throwing Lemmas 73.2 and 73.7 into the bargain. The same logic applies to the projections. 

Recall that in Lemma 46.8 we showed that for any \( k \in \mathbb{Z} \) and any topological space \( X \) we have a natural isomorphism

\[
\Sigma_X : \tilde{H}_k(X) \xrightarrow{\sim} \tilde{H}_{k+1}(\Sigma(X)).
\]

Not surprisingly we have a totally analogous statement in cohomology:

\[\text{In fact the proof of Proposition 47.9 that we sketched in Exercise 47.2 can also be generalized to the present context.}\]
Lemma 74.18. (*) Let \( k \in \mathbb{Z} \) and let \( G \) be an abelian group. Given any topological space \( X \) we have a natural isomorphism

\[
\Sigma_X : \tilde{H}^k(\Sigma(X); G) \to \tilde{H}^k(X; G)
\]

which has the property that for any \( \varphi \in H^k(X; G) \) and any \( \sigma \in H_k(X) \) we have

\[
\langle \Sigma_X(\varphi), \Sigma_X(\sigma) \rangle_{\Sigma(X)} = \langle \varphi, \sigma \rangle_X \in G.
\]

Proof (*). The construction of the isomorphism \( \Sigma_X \) is basically the same as the construction of the corresponding isomorphism in cohomology. In the Lemma 46.8 we just need to replace the Mayer–Vietoris Theorem 46.5 by the Mayer–Vietoris Theorem 74.15 for Cohomology Groups. We leave it to the reader to fill in the details.■

Example. Let \( n \in \mathbb{N} \). Let \( \Sigma(S^n) \to S^{n+1} \) be the homeomorphism from page 695. On page 1180 we showed that

\[
\Sigma(S^n) \left( [S^n] \right) = (-1)^{n+1} \cdot [S^{n+1}] \in H_{n+1}(S^{n+1}; \mathbb{Z}).
\]

From the equality in Lemma 74.18 we obtain the corresponding equality

\[
\Sigma(S^n) \left( [S^n]^* \right) = (-1)^{n+1} \cdot [S^{n+1}]^* \in H_{n+1}(S^{n+1}; \mathbb{Z}).
\]

Exercises for Chapter 74

Exercise 74.1. Let \( X \) be a topological space which is homotopy equivalent to a retract of a finite CW-complex. Show that for every \( n \in \mathbb{N}_0 \) the cohomology group \( H^n(X; \mathbb{Z}) \) is a finitely generated group.

Exercise 74.2. Show that the triad \( (X, A_1, A_2) := (\mathbb{R}, (-\infty, 0], (0, \infty)) \) is not excisive.

Exercise 74.3. Use cellular cohomology to determine the isomorphism types of the cohomology groups of the Klein bottle with \( \mathbb{F}_2 \)-coefficients, with \( \mathbb{F}_3 \)-coefficients and with \( \mathbb{Z} \)-coefficients.

Exercise 74.4. Let \( \{A_k\}_{k \in K} \) be a family of CW-complexes. Suppose that for each \( k \in K \) suppose that we are given a point in the 0-skeleton of \( A_k \). Provide a proof for Proposition 74.17 using cellular cohomology. More precisely, provide a proof along the following lines:

(a) Equip \( X := \bigvee_{k \in K} A_k \) with the CW-structure provided by Lemma 36.32

(b) Determine the relationship between the reduced cellular chain complexes of \( X \) and of the \( A_i \).

(c) Make use of Proposition 49.10

(d) Make use of Lemmas 73.2 and 73.7
75. The Universal Coefficient Theorems for Cohomology Groups

75.1. The Ext group. One of the questions that arises from the last chapter is, how can we explain the erratic relationship between homology groups and cohomology groups that we saw on page 1845. Furthermore it would be interesting to know whether given a chain complex one can determine the cohomology groups with $G$-coefficients from the usual homology group.

These questions are purely in the realm of algebra. More precisely, let $(C_*, \partial_*)$ be a chain complex of free abelian groups and let $G$ an abelian group. We want to find a connection between the cohomology groups $H^*(C; G)$ and the homology groups $H_*(C)$. This problem, and later on its solution, is very similar to the problem we faced in Chapter 57 where we showed that we can determine homology groups of a chain complex with $G$-coefficients from the usual homology group of the chain complex.

As usual we denote by $\mathbf{AbGr}$ the category of abelian groups. On page 1405 we defined what it means for a covariant functor $F: \mathbf{AbGr} \to \mathbf{AbGr}$ to be exact, left-exact and right-exact. Basically the same way we can introduce these notions for contravariant functors $F: \mathbf{AbGr} \to \mathbf{AbGr}$.

**Definition.** A contravariant functor $F: \mathbf{AbGr} \to \mathbf{AbGr}$ is called left-exact if for all exact sequences

$$A \xrightarrow{i} B \xrightarrow{j} C \xrightarrow{} 0$$

of abelian groups the sequence

$$0 \longrightarrow F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A)$$

is also exact. Furthermore a contravariant functor $F: \mathbf{AbGr} \to \mathbf{AbGr}$ is called right-exact, if for all exact sequences

$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C$$

the sequence

$$F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A) \longrightarrow 0$$

is also exact.

In Lemma 57.10 we saw that the covariant functor $- \otimes G$ is right-exact but that in general it is not left-exact. With the contravariant functor $\text{Hom}(-, G)$ the situation is precisely the converse. More precisely, in the next lemma we will show that this functor is left-exact and immediately afterwards we will give an example that shows that the contravariant functor $\text{Hom}(-, G)$ is in general not right-exact.

**Lemma 75.1.** For any abelian group $G$ the contravariant functor $\text{Hom}(-, G)$ is left-exact.

---

1089 Admittedly one could also refer to this definition as “right”-exact, since the direction changes. But the definition we give is the one which is commonly used in the literature.
Proof (*). Let $G$ be an abelian group and let

$$A \xrightarrow{\alpha} B \xrightarrow{\beta} C \rightarrow 0$$

be an exact sequence of abelian groups. We need to show that the sequence

$$0 \rightarrow \text{Hom}(C, G) \xrightarrow{\beta^*} \text{Hom}(B, G) \xrightarrow{\alpha^*} \text{Hom}(A, G) \rightarrow 0$$

is also exact. It is clear that $\beta^*$ is injective and that $\alpha^* \circ \beta^* = (\beta \circ \alpha)^* = 0$, i.e. we have $\text{im}(\beta^*) \subset \ker(\alpha^*)$. It remains to show that $\ker(\alpha^*) \subset \text{im}(\beta^*)$. So let $f: B \rightarrow G$ be a homomorphism such that $\alpha^*(f) = 0$. We consider the following diagram:

$$
\begin{array}{ccc}
A & \xrightarrow{\alpha} & B & \xrightarrow{\beta} & C & \rightarrow & 0 \\
\downarrow{f} & & \downarrow{\pi} & & \downarrow{\pi} & & \\
G & \leftarrow & B/\alpha(A) & \rightarrow & & &
\end{array}
$$

We make the following observations:

1. Since $\alpha^*(f)$ we know that $f$ vanishes on $\alpha(A)$. We denote by $\overline{f}: B/\alpha(A) \rightarrow G$ the resulting homomorphism given by $[b] \mapsto f(b)$.
2. We denote $\pi: B \rightarrow B/\alpha(A)$ the projection.
3. By the exactness of the original sequence the homomorphism $\beta$ induces an isomorphism $\overline{\beta}: B/\alpha(A) \rightarrow C$.
4. By construction the above diagram commutes.
5. Now we see that $f = \overline{f} \circ \overline{\beta}^{-1} \circ \beta$, i.e. we have $f = \beta^*(\overline{f} \circ \overline{\beta}^{-1})$. ■

Now we give the example, promised above, that shows that the contravariant functor $\text{Hom}(-, G)$ is in general not right-exact.

Example. We consider the chain complex

$$0 \rightarrow \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{p} \mathbb{Z}_2$$

where $p: \mathbb{Z} \rightarrow \mathbb{Z}_2$ denotes the obvious projection map. We apply the contravariant functor $\text{Hom}(-, \mathbb{F}_2)$. The resulting cochain complex is of the form

$$\mathbb{F}_2 \xrightarrow{p^*} \mathbb{F}_2 \xrightarrow{(2)^*} \mathbb{F}_2 \rightarrow 0.$$ 

Since this cochain complex is not exact it follows that the functor $\text{Hom}(-, \mathbb{F}_2)$ is not right-exact.

In Chapter 57.4 we introduced the torsion groups $\text{Tor}(H, G)$ which “measure” to what degree the functor $- \otimes G$ fails to be a left-exact functor. The same way we now introduce the so called Ext-groups $\text{Ext}(H, G)$ which “measure” to what degree the functor $\text{Hom}(-, G)$ fails to be right-exact.

---

Here we use the identification $\text{Hom}(\mathbb{Z}, G) = G$ from Lemma 73.1 and we use that multiplication by 2 is the zero endomorphism of $\mathbb{F}_2$. 
Definition. Let $G$ and $H$ be abelian groups. We denote by

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

the canonical free resolution from page 1408. We define the $n$-th $G$-Ext-group of $H$ as

$$\text{Ext}_n(H, G) := H^n(F_*, G).$$

Remark. Let $n \in \mathbb{N}_0$. On page 1413 we saw that $\text{Tor}_n(H, G)$ is covariantly functorial in both $G$ and $H$. Now we will see that the groups $\text{Ext}_n(H, G)$ are contravariantly functorial in $H$ and covariantly functorial in $G$:

1. Let $\alpha : H \to H'$ be a homomorphism between abelian groups and let $G$ be an abelian group. Then it follows from Lemmas 57.13 and 73.8 together with the definition of the $G$-Ext groups that $\alpha$ induces a homomorphism

$$\alpha^* : \text{Ext}_n(H', G) \to \text{Ext}_n(H, G).$$

It is now straightforward to show that

$$H \mapsto \text{Ext}_n(H, G)$$

$$(\alpha : H \to H') \mapsto (\alpha^* : \text{Ext}_n(H', G) \to \text{Ext}_n(H, G))$$

is a contravariant functor from the category of abelian groups to the category of abelian groups.

2. On the other hand, if $\beta : G \to G'$ is a homomorphism between abelian groups then one sees easily that $\beta$ induces a homomorphism

$$\beta_* : \text{Ext}_n(H, G) \to \text{Ext}_n(H, G').$$

Furthermore one can easily prove that

$$G \mapsto \text{Ext}_n(H, G)$$

$$(\beta : G \to G') \mapsto (\beta_* : \text{Ext}_n(H, G) \to \text{Ext}_n(H, G'))$$

is a covariant functor from the category of abelian groups to the category of abelian groups.

The following proposition is the analogue of Proposition 57.12. The proof is almost the same as the proof of Proposition 57.12. We leave it to the reader to make the necessary changes.

**Proposition 75.2.** Let $G$ and $H$ be abelian groups and let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be a free resolution of $H$. Then for each $n \in \mathbb{N}_0$ there exists a canonical isomorphism

$$\text{Ext}_n(H, G) \cong H^n(F_*, G).$$

In particular if

$$0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$
is a free resolution of $H$ of length one, then there exist canonical isomorphisms

$$\text{Ext}_1(H,G) \cong \text{coker} \left( \text{Hom}(F_0,G) \xrightarrow{f_1} \text{Hom}(F_1,G) \right)$$

and

$$\text{Ext}_0(H,G) \cong \text{ker} \left( \text{Hom}(F_0,G) \xrightarrow{f_1} \text{Hom}(F_1,G) \right)$$

In Lemma 57.16 we saw that the higher torsion groups of abelian groups vanish. The same statement, with basically the same proof, also holds for Ext groups. More precisely, we have the following corollary.

**Corollary 75.3.** For every choice of abelian groups $G$ and $H$ we have $\text{Ext}_n(H,G) = 0$ for $n \geq 2$.

**Proof.** As we pointed out in the proof of Lemma 57.16 any abelian group $H$ admits a free resolution of length 2:

$$0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0.$$  

The corollary now follows immediately from Proposition 75.2. □

In Lemma 57.15 we saw that the 0-th Torsion functor is an old acquaintance. More precisely we saw that for all abelian groups $G$ and $H$ there exists a natural isomorphism $\text{Tor}_0(H,G) \cong H \otimes G$. The following lemma gives us the analogous result for the 0-th Ext functor.

**Lemma 75.4.** Let $G$ and $H$ be abelian groups, then there exists a natural isomorphism $\text{Ext}_0(H,G) \cong \text{Hom}(H,G)$.

**Proof (⋆).** The proof of Lemma 75.4 is, not surprisingly, rather similar to the proof of Lemma 57.15. Let $G$ and $H$ be abelian groups. Let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be the canonical free resolution of $H$. We know from Lemma 75.1 that the sequence

$$\begin{align*}
0 & \to \text{Hom}(H,G) \xrightarrow{f_0} \text{Hom}(F_0,G) \xrightarrow{f_1} \text{Hom}(F_1,G)
\end{align*}$$

is exact. Now we obtain the following isomorphism

(by definition)

$$\text{Ext}_0(H,G) \cong H^0 \left( \cdots \leftarrow \text{Hom}(F_1,G) \xrightarrow{f_1} \text{Hom}(F_0,G) \leftarrow 0 \right) \right)$$

$$= \text{ker} \left( \text{Hom}(F_1,G) \xrightarrow{f_1} \text{Hom}(F_0,G) \right) \xrightarrow{f_0} \text{Hom}(H,G).$$

isomorphism since (⋆) is exact

It is straightforward to verify that these isomorphisms are in fact natural. □

---

Footnote 1091: Here by “natural” we mean that these isomorphisms define a natural isomorphism from the contravariant functor $H \mapsto \text{Ext}_0(H,G)$ to the contravariant functor $H \mapsto \text{Hom}(H,G)$ and that they also define a natural transformation from the covariant functor $G \mapsto \text{Ext}_0(H,G)$ to the covariant functor $G \mapsto \text{Hom}(H,G)$. 

Definition. Given abelian groups $G$ and $H$ we refer to

$$\text{Ext}(H,G) := \text{Ext}_1(H,G)$$

as the $G$-Ext-group of $H$.

Remark. Let $G$ and $H$ be two abelian groups. An extension of $H$ by $G$ is a short exact sequence of the form

$$0 \to G \xrightarrow{\alpha} K \xrightarrow{\beta} H \to 0.$$

We say that two such extensions given by $K$ and $K'$ are equivalent if there exists a homomorphism $\varphi: K \to K'$ that makes the following diagram commute

$$\begin{array}{c}
0 \to G \xrightarrow{\alpha} K \xrightarrow{\beta} H \to 0 \\
\downarrow \hspace{1cm} \downarrow \hspace{1cm} \downarrow \\
0 \to G \xrightarrow{\alpha'} K' \xrightarrow{\beta'} H \to 0.
\end{array}$$

In [HS97, Theorem II.3.4] it is shown that there is a natural bijection from the set of equivalence classes of extensions of $H$ by $G$ with the set $\text{Ext}(H,G)$. This fact is the origin of the name "Ext-group".

In light of Corollary [75.3] and Lemma [75.4] the remaining task is to compute the Ext-group $\text{Ext}(H,G) = \text{Ext}_1(H,G)$. The following lemma allows us in particular to determine the Ext-group for all finitely generated abelian groups.

Lemma 75.5. Let $G, H$ and $G_1, \ldots, G_k, H_1, \ldots, H_k$ be abelian groups. The following statements hold:

1. There exists a natural isomorphism

$$\text{Ext} \left( \bigoplus_{i=1}^k H_i, G \right) \cong \bigoplus_{i=1}^k \text{Ext}(H_i, G).$$

2. There exists a natural isomorphism

$$\text{Ext} \left( H, \bigoplus_{i=1}^k G_i \right) \cong \bigoplus_{i=1}^k \text{Ext}(H, G_i).$$

3. If $H$ is a free abelian group, then $\text{Ext}(H,G) = 0$.

4. For all $n \in \mathbb{N}$ we have a natural isomorphism $\text{Ext}(\mathbb{Z}_n, G) \cong G/nG$.

5. If $H$ is a finitely generated abelian group, then we have a natural isomorphism

$$\text{Ext}(H, \mathbb{Z}) \cong \text{torsion subgroup of } H := \{ h \in H \mid \text{there exists an } n \in \mathbb{N} \text{ with } nh = 0 \}.$$ 

In particular $\text{Ext}(H, \mathbb{Z})$ is a finite group.

6. For $n, m \in \mathbb{N}$ we have $\text{Ext}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\text{gcd}(n,m)}$.

Remark.

(a) The first two statements of the lemma also generalize to the case of infinitely many groups, but some care needs to be taken. Indeed, some of the finite direct sums are
secretly finite direct products and hence they generalize to infinite direct products. More precisely, the following holds:

(1') If \( \{ H_i \}_{i \in I} \) is a family of abelian groups and if \( G \) is an abelian group, then

\[
\text{Ext} \left( \bigoplus_{i \in I} H_i, G \right) \cong \prod_{i \in I} \text{Ext}(H_i, G).
\]

(2') If \( H \) is an abelian group and if \( \{ G_i \}_{i \in I} \) is a family of abelian groups, then

\[
\text{Ext} \left( H, \prod_{i \in I} G_i \right) \cong \prod_{i \in I} \text{Ext}(H, G_i).
\]

We refer to \([\text{Rot09}, \text{Propositions 7.21 and 7.22}]\) for a proof. We will not make use of these more general statements.

(b) The statements of Lemma \([75.5]\) look very similar to the statements of Lemma \([57.17]\). But there are some differences:

(i) In Lemma \([57.17]\) we saw that for every abelian group we have \( \text{Tor}(H, \mathbb{Z}) = 0 \) whereas we have now shown in Lemma \([75.5]\) (5) that for every finite abelian group we have \( \text{Ext}(H, \mathbb{Z}) \cong H \).

(ii) In Lemma \([57.17]\) we saw that \( \text{Tor}(H, G) = 0 \) not only whenever \( H \) is a free abelian group but also for all torsion-free abelian groups \( H \). Here the situation is different, the statement of Lemma \([75.5]\) (3) does not generalize to torsion-free abelian groups. For example in \([\text{Rot09}, \text{p. 428}]\) it is shown that there exists an abelian group \( G \) such that \( \text{Ext}(\mathbb{Q}, G) \neq 0 \). But this issue is of no concern to us.

**Proof.** The first three statements are proved almost the same way as we proved Lemma \([57.17]\). We leave it to the reader to fill in the details. We turn to the final three statements.

(4) Let \( G \) be an abelian group and let \( n \in \mathbb{N} \). We have

\[
\text{Proposition } [75.2] \text{applied to the free resolution } 0 \rightarrow \mathbb{Z} \xrightarrow{n} \mathbb{Z} \rightarrow \mathbb{Z}_n \rightarrow 0
\]

\[
\text{Ext}(\mathbb{Z}_n, G) = \text{coker} \left( \text{Hom}(\mathbb{Z}, G) \xrightarrow{(n)} \text{Hom}(\mathbb{Z}, G) \right) = \text{coker} \left( G \xrightarrow{n} G \right) = G/nG.
\]

by the isomorphism \( \text{Hom}(\mathbb{Z}, G) = G \) given by \( f \mapsto f(1) \)

(5) This statement follows immediately from (1), (3) and (4) together with the classification of finitely generated abelian groups, see Theorem \([19.4]\).

(6) This statement follows immediately from (4) and the calculation on page \([1409]\) ■

We have one more general result for calculating \( \text{Ext} \)-groups. Before we can state the result we need one more definition.

**Definition.** An abelian group \( G \) is called *divisible* if for every \( g \in G \) and \( n \in \mathbb{N} \) there exists an \( h \in G \) with \( n \cdot h = g \).

**Examples.**

(1) The groups \( \mathbb{Q}, \mathbb{R} \) and \( \mathbb{C} \) are divisible.

(2) Every quotient of a divisible group is easily seen to be divisible again. For example the quotient group \( \mathbb{Q}/\mathbb{Z} \) is also divisible\(^{1002}\). This example also shows, using the

\(^{1002}\) Odd as it may sound, this example will actually be important later in Section ??.
notation of the definition, that \( h \) is not necessarily unique. For example, for \( g = [0] \) and \( n = 3 \) we could take \( g = [0] \) or \( g = \left[ \frac{1}{3} \right] \).

(3) The group \( \mathbb{Z} \) is not divisible, and the only finite group that is divisible is the trivial group.

**Proposition 75.6.** Let \( G \) and \( H \) be abelian groups. If \( G \) is divisible, then \( \text{Ext}(H, G) = 0 \).

In the proof of Proposition 75.6 it is useful to introduce the following notion.

**Definition.** An abelian group \( G \) is called **injective** if for all abelian groups \( A \) and \( B \), every injective homomorphism \( \varphi: B \to A \) and every homomorphism \( \beta: B \to G \) there exists a homomorphism \( \alpha: A \to G \) such that the following diagram commutes

\[
\begin{array}{ccc}
0 & \longrightarrow & B \\
\phantom{0} & \downarrow{\beta} & \vert_{\varphi} \\
\phantom{0} & \longrightarrow & A \\
\end{array}
\]

The following lemma shows why we are interested in injective groups.

**Lemma 75.7.** Let \( G \) and \( H \) be abelian groups. If \( G \) is injective, then \( \text{Ext}(H, G) = 0 \).

**Proof.** Let \( H \) be an abelian group. As we pointed out in the proof of Lemma 57.16 the abelian group \( H \) admits a free resolution of length 2:

\[
0 \to F_1 \xrightarrow{\varphi_1} F_0 \xrightarrow{\varphi_0} H \to 0.
\]

By Proposition 75.2 the group \( \text{Ext}(H, G) \) is isomorphic to the cokernel of the map

\[
\text{Hom}\left( F_1 \downarrow_{G} \right) \leftarrow_{\varphi_1^*} \text{Hom}\left( F_0 \downarrow_{G} \right).
\]

But by definition of \( G \) being injective this map \( \varphi_1^* \) is in fact an epimorphism. Thus we have shown that \( \text{Ext}(H, G) = 0 \). \( \blacksquare \)

To provide a proof for Proposition 75.6 it remains to prove the following proposition.

**Proposition 75.8.** Every abelian group that is divisible is also injective.

**Remark.** It is straightforward to prove the converse to Proposition 75.8 namely every injective abelian group is also divisible.

In the proof of Proposition 75.8 we will need Zorn’s Lemma which we now recall for the reader’s convenience.

**Lemma 75.9. (Zorn’s Lemma)** Suppose a partially ordered set \((P, \leq)\) has the property that every chain has an upper bound in \( P \). Then the set \( P \) contains at least one maximal element.

We also recall the definitions in the statement of Zorn’s Lemma:

(1) A partially ordered set \((P, \leq)\) is a set together with a preorder \( \leq \) (see page 726) that has the property that \( a \leq b \) and \( b \leq a \) implies that \( a = b \).

(2) A chain in \( P \) is a subset \( Q \) such that for any two elements \( q, q' \in Q \) we have \( q \leq q' \) or \( q' \leq q \).

(3) An upper bound of a subset \( Q \) is an element \( q \in Q \) such that \( p \leq q \) for all \( q \in Q \).
(4) A maximal element of a subset $Q$ is an element $q \in Q$ such that there is no $r \in Q$ with $q < r$.\footnote{1093}

We refer to \cite{Cie97} Theorem 4.3.4 for a proof of Zorn’s Lemma. Perhaps it is more fun to look at Zorn’s Lemma in “The Simpsons”, see \url{http://www.simonsingh.net/Simpsons_Mathematics/zorns-lemma/}.

Now we can give the proof of Proposition \ref{prop:universal_coefficients}.

**Proof of Proposition \ref{prop:universal_coefficients} (\ast).** Let $G$ be an abelian group that is divisible. Suppose we are given a diagram

$$
\begin{array}{ccc}
0 & \to & B \\
\downarrow{\beta} & & \downarrow{?\alpha?} \\
& & A
\end{array}
$$

Since $\varphi$ is a monomorphism we can assume that $B$ is in fact a subgroup of $A$ and that $\varphi$ is the inclusion map.

We denote by $P$ the set of all pairs $(C_i, \gamma_i)$ where $C_i$ is a subgroup of $A$ which contains $B$ and where $\gamma_i : C_i \to G$ is a homomorphism such that $\gamma_i|_B = \beta$. This family of pairs is non-empty since $(B, \beta)$ satisfies the required conditions. We define $(C_i, \gamma_i) < (C_j, \gamma_j)$ if $C_i \subset C_j$ and if $\gamma_j|_{C_i} = \gamma_i$. Given a chain $(C_j, \gamma_j)_{j \in J}$ in $P$ we get an upper bound by setting

$$
C := \bigcup_{j \in J} C_j \text{ and } \gamma : C \to G \quad c \mapsto \gamma_j(c) \text{ if } j \in J \text{ with } c \in C_j.
$$

Since $(C_j, \gamma_j)_{j \in J}$ is a chain one can easily verify that $C$ is in fact a subgroup of $A$ which contains $B$ and that $\gamma$ is a homomorphism with $\gamma|_B = \beta$.

Therefore we can apply Zorn’s Lemma to this family and we obtain a maximal pair $(C_m, \gamma_m)$. It remains to prove the following claim.

**Claim.** We have $C_m = A$.

Suppose that this is not the case. Then there exists an $a \in A \setminus C_m$. We denote by $\langle\langle C_m, a \rangle\rangle$ the subgroup of $A$ generated by $C_m$ and $a$, i.e. $\langle\langle C_m, a \rangle\rangle$ is the smallest subgroup of $A$ that contains $C_m$ and $a$. To obtain a contradiction it suffices to show that there exists a homomorphism $\delta : \langle\langle C_m, a \rangle\rangle \to G$ that extends $\gamma_m$. We distinguish two cases:

(1) If there exists no $n \in \mathbb{N}$ such that $n \cdot a \in C_m$, then one can show easily that we have $\langle\langle C_m, a \rangle\rangle = C_m \oplus \langle a \rangle$. We extend $\gamma_m$ to $\langle\langle C_m, a \rangle\rangle = C_m \oplus \langle a \rangle$ by setting $\delta(a) = 0$.

(2) Otherwise there exists a minimal $n \in \mathbb{N}$ such that $n \cdot a \in C_m$. We denote by $r \in \mathbb{N}_0$ the order of $n \cdot a \in C_m$. Here we say that the order is 0 if $n \cdot a \in C_m$ has infinite order. We consider the maps

$$
\begin{array}{cccc}
0 & \to & \mathbb{Z}_r & \xrightarrow{\Psi} & C_m \oplus \mathbb{Z}_r & \xrightarrow{\Psi} & \langle\langle C_m, a \rangle\rangle & \to & 0 \\
& & k & \mapsto & (k \cdot n \cdot a, -k \cdot n) & \mapsto & (c, l) & \mapsto & c + l \cdot a
\end{array}
$$

\footnote{1093} Aren’t “upper bound” and “maximal element” the same?
It is clear that $\Phi$ is injective and that $\Psi \circ \Phi = 0$. Note that the image of $\Psi$ lies a priori in $A$, but it is straightforward to see that the image of $\Psi$ is precisely $\langle (C_m,a) \rangle$. By definition of $n$ we have that $\ker(\Psi) \subset \im(\Phi)$. Put differently, the sequence is exact. Since $G$ is divisible there exists an $h \in G$ such that $n \cdot h = \gamma(n \cdot a)$. We denote by $\alpha: C_m \oplus \mathbb{Z}_{nr} \to G$ the homomorphism that is given by setting $\alpha(c) = \gamma(c)$ for $c \in C_m$ and $\alpha(k) = k \cdot h$ for $k \in \mathbb{Z}$. One can easily verify that $\im(\Phi)$ is contained in $\ker(\alpha)$. It is now straightforward to show that the homomorphism

$$
\delta: \langle (C_m,a) \rangle \to (C_m \oplus \mathbb{Z}_{nr})/\im(\Phi) \to G
$$

$x \mapsto \Psi^{-1}(x) [y] \mapsto \alpha(y)$

has the desired properties.

This concludes the proof of the claim and thus of the lemma.

The following proposition gives arguably slightly weird example.

**Proposition 75.10.** The group $\text{Ext}(\mathbb{Q}, \mathbb{Z})$ is isomorphic to the additive group $(\mathbb{R}, +)$.

**Remark.** Note that this proposition is not totally pointless, for example it follows from the existence of Moore spaces, see Proposition [47.11] that there exist topological spaces $X$ with $H_n(X) \cong (\mathbb{Q}, +)$. Thus even unexpected abelian groups can appear in topology.

**Proof.** This proposition is proved in [Wie69]. Alternatively the proposition is almost proved in [Bre97] Lemma 14.8. We also refer to [Boar10] for the calculation of $\text{Ext}(\mathbb{Q}, \mathbb{Z})$.

This example also shows that $\text{Ext}$-groups can be quite large. In fact the following proposition holds.

**Proposition 75.11.** Let $G$ be an abelian group. If $G$ is not a finitely generated group, then $\text{Hom}(G, \mathbb{Z})$ is uncountable or $\text{Ext}(G, \mathbb{Z})$ is uncountable.

**Proof.** We will barely make use of this proposition, thus we refer to [Hat02] Proposition 3.F.12] instead for a proof.

75.2. **The Universal Coefficient Theorem for Cohomology Groups.** Finally we want to explore the connection between the cohomology groups of a chain complex $C$ and the usual homology groups of the chain complex. The key to relating homology groups to cohomology groups is given by the following evaluation homomorphism.

**Definition.** Let $(C_\ast, \partial_\ast)$ be a chain complex and let $G$ be an abelian group. We refer to the map

$$
ev: H^n(C;G) \to \text{Hom}(H_n(C), G)$$

$$[\varphi: C_n \to G] \mapsto \left( H_n(C) \to G \right)$$

$$[c] \mapsto \langle [\varphi], [c] \rangle = \varphi(c)$$

as the **evaluation homomorphism**.

---

1094 This map is well-defined by Lemma 74.6.
Remark. It follows immediately from Lemma 74.6 (3) that the evaluation homomorphisms in natural in the chain complex $C_*$ in the sense that if $f : C_* \to D_*$ is a chain map, then for any $n \in \mathbb{N}_0$ and any abelian group $G$ the following diagram commutes

$$
\begin{array}{cccc}
H^n(C; G) & \xrightarrow{ev} & \text{Hom}(H_n(C), G) \\
\downarrow f^* & & \downarrow (f_*)^* \\
H^n(D; G) & \xrightarrow{ev} & \text{Hom}(H_n(D), G).
\end{array}
$$

Furthermore, it follows easily from the definitions that the evaluation map is natural in $G$, in the sense that if $\varphi : G_1 \to G_2$ is homomorphism of abelian groups, then for any $n \in \mathbb{N}_0$ and any chain complex $C_*$ the following diagram commutes

$$
\begin{array}{cccc}
H^n(C; G_1) & \xrightarrow{ev} & \text{Hom}(H_n(C), G_1) \\
\downarrow \varphi_* & & \downarrow \varphi_* \\
H^n(C; G_2) & \xrightarrow{ev} & \text{Hom}(H_n(C), G_2).
\end{array}
$$

Here the map on the left is the one we had introduced on page 1823.

Recall that in Lemma 46.9 we saw that $H_2(\mathbb{RP}^2; \mathbb{Z}) = 0$ and that on page 1845 we showed that $H^2(\mathbb{RP}^2; \mathbb{Z}) \cong \mathbb{Z}_2$. These calculations imply that the evaluation homomorphism $ev : H^n(X; G) \to \text{Hom}(H_n(X), G)$ is in general not a monomorphism. The following theorem relates homology groups and cohomology groups via the evaluation homomorphism and the Ext-groups.

**Theorem 75.12. (Universal Coefficient Theorem for Cohomology Groups)** Let $(C_*, \partial_*)$ be a chain complex of free abelian groups and let $G$ be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence

$$
0 \to \text{Ext}(H_{n-1}(C), G) \to H^n(C; G) \xrightarrow{ev} \text{Hom}(H_n(C), G) \to 0,
$$

which is natural in the chain complex $C_*$ and natural in the abelian group $G$. This short exact sequence splits and there exists therefore an isomorphism $1095$

$$
H^n(C; G) \cong \text{Ext}(H_{n-1}(C), G) \oplus \text{Hom}(H_n(C), G).
$$

Before we provide the proof of the above Universal Coefficient Theorem for Cohomology Groups let us formulate the most important application, namely let us apply it to the chain complex of a pair of topological spaces.

**Theorem 75.13. (Universal Coefficient Theorem for Cohomology Groups)** Let $(X, A)$ be a pair of topological spaces and let $G$ be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence

$$
0 \to \text{Ext}(H_{n-1}(X,A), G) \to H^n(X,A; G) \xrightarrow{ev} \text{Hom}(H_n(X,A), G) \to 0,
$$

1095 Once again the short exact sequence is natural, whereas the isomorphism is not natural. More precisely, the discussion on page 1423 can easily be modified to show that there exists no natural isomorphism

$$
H^n(C; G) \cong \text{Ext}(H_{n-1}(C), G) \oplus \text{Hom}(H_n(C), G).
$$

We will discuss this issue in Exercise 75.1.
which is natural in the chain complex $C_\ast$ and natural in the abelian group $G$. This short exact sequence splits and there exists therefore an isomorphism

$$H^n(X, A; G) \cong \text{Ext}(H_{n-1}(X, A), G) \oplus \text{Hom}(H_n(X, A), G).$$

Remark. The Universal Coefficient Theorem 75.13 for Cohomology Groups is the analogue of the Algebraic Universal Coefficient Theorem 57.18 together with Theorem 57.24.

Proof of Theorem 75.13 assuming Theorem 75.12. As the reader will have noticed there is really not much to say, except that we recall that we pointed out on page 1120 that the chain groups $C_n(X, A), n \in \mathbb{N}_0$ are free abelian groups.

Remark.

1. Here is one straightforward but interesting consequence to the Universal Coefficient Theorem 75.13 for Cohomology Groups. Given any pair $(X, A)$ of topological spaces we see that

$$H^1(X; \mathbb{Z}) \cong \text{Ext}(H_0(X, A), \mathbb{Z}) \oplus \text{Hom}(H_1(X, A), \mathbb{Z}) = \text{Hom}(H_1(X, A), \mathbb{Z}) = \text{torsion-free}.$$  

by Lemma 75.5 and Corollary 41.13 since $\text{Hom}(G, \mathbb{Z})$ is always torsion free

2. The Universal Coefficient Theorem 75.13 for Cohomology Groups implies in particular that topological spaces with isomorphic homology groups also have isomorphic cohomology groups. In other words, if our only goal is to distinguish homeomorphism types of topological spaces, then cohomology groups will not be of much help.

3. The fact that cohomology groups are determined by homology groups is also immediate consequence of the combination of Propositions 49.1 and 49.2 together with Lemma 73.5.

Now we turn to the proof of the purely algebraic Universal Coefficient Theorem 75.12 for Cohomology Groups. The proof is, perhaps not surprisingly, rather similar to the proofs of the Universal Coefficient Theorem 57.19 and Proposition 57.23.

Proof (*). Let $(C_\ast, \partial_\ast)$ be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \text{im}(\partial_{n+1})$. Note that it follows from Lemma 19.2 that $B_n$ and $Z_n$ are free abelian groups.

As in the proof of the Universal Coefficient Theorem 57.19 we consider the following short exact sequence of vertical chain complexes:

$$\begin{array}{ccccccc}
0 & \longrightarrow & Z_n & \longrightarrow & C_n & \longrightarrow & B_{n-1} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & Z_{n-1} & \longrightarrow & C_{n-1} & \longrightarrow & B_{n-2} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\vdots & & \vdots & & \vdots & & \vdots & & \vdots 
\end{array}$$
Now let $G$ be an abelian group. We apply the functor $\text{Hom}(-, G)$ to the above short exact sequence of chain complexes and we obtain the following diagram:

\[
\begin{array}{ccccccc}
0 & \rightarrow & \text{Hom}(B_{n-1}, G) & \xrightarrow{\partial_n^*} & \text{Hom}(C_n, G) & \rightarrow & \text{Hom}(Z_n, G) & \rightarrow & 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow & & \\
0 & \rightarrow & \text{Hom}(B_{n-2}, G) & \xrightarrow{\partial_{n-1}^*} & \text{Hom}(C_{n-1}, G) & \rightarrow & \text{Hom}(Z_{n-1}, G) & \rightarrow & 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow & & \\
\vdots & & \vdots & & \vdots & & \vdots & & \\
\end{array}
\]

This is again a sequence of cochain complexes. Since the $Z_n$ are free abelian we obtain from Lemma 73.4 that the above horizontal sequences of cochain complexes are still exact. Therefore we can apply Proposition 73.6 to obtain the following long exact sequence

\[
\rightarrow \text{Hom}(Z_{n-1}, G) \xrightarrow{d_n} \text{Hom}(B_{n-1}, G) \rightarrow H^n(C; G) \xrightarrow{\partial_n} \text{Hom}(Z_n, G) \xrightarrow{d_{n-1}} \text{Hom}(B_n, G) \rightarrow \ldots
\]

where the maps $d_n$ are the connecting homomorphisms of the long exact sequence. One can show easily that the connecting homomorphism $d_n : \text{Hom}(Z_n, G) \rightarrow \text{Hom}(B_n, G)$ is the map $d_n = i_n^*$ where $i_n : B_n \rightarrow Z_n$ is the inclusion map. By Lemma 46.4 we obtain the following short exact sequence

\[
0 \rightarrow \text{coker}(\text{Hom}(Z_{n-1}, G) \rightarrow \text{Hom}(B_{n-1}, G)) \rightarrow H^n(C; G) \rightarrow \ker(\text{Hom}(Z_n, G) \rightarrow \text{Hom}(B_n, G)) \rightarrow 0.
\]

We have to show that the expressions left and right coincide with the desired expressions. Both equalities follow immediately from Proposition 75.2 (together with Lemma 73.4 for the right-hand term) and the observation that for each $l \in \mathbb{N}_0$ a free resolution of $H_l(C)$ is given by $0 \rightarrow B_l \xrightarrow{i_l} Z_l \rightarrow H_l(C)$. We have thus shown the existence of the desired short exact sequence

\[
0 \rightarrow \text{Ext}(H_{n-1}(C), G) \rightarrow H^n(C; G) \xrightarrow{\text{ev}} \text{Hom}(H_n(C), G) \rightarrow 0.
\]

The statement that the short exact sequence is natural follows easily from the definitions and Lemma 57.13. We leave the verification of the details to the reader.

It remains to show that the above short exact sequence splits. By definitions this means that we need to construct a homomorphism $\eta : \text{Hom}(H_n(C), G) \rightarrow H^n(C; G)$ such that $\text{ev} \circ \eta$ is the identity on $\text{Hom}(H_n(C), G)$.

We consider again the short exact sequence

\[
0 \rightarrow Z_n \xrightarrow{i_n} C_n \xrightarrow{\partial_n} B_{n-1} \rightarrow 0.
\]

Since $B_{n-1}$ is a free abelian group we obtain from Lemmas 46.1 and 46.2 that there exists a homomorphism $p_n : C_n \rightarrow Z_n$ such that $p_n$ is the identity on $Z_n \subset C_n$. 

In the proof of Proposition 57.23 we showed that the following diagram commutes:

\[
\begin{array}{cccccc}
\vdots & \rightarrow & C_{n+1} & \xrightarrow{\partial_{n+1}} & C_n & \xrightarrow{\partial_n} & C_{n-1} & \\
\uparrow p_{n+1} & \downarrow p_n & \uparrow \downarrow & \uparrow p_n & \uparrow \downarrow & \uparrow p_n & \\
Z_{n+1} & \rightarrow & Z_n & \rightarrow & Z_{n-1} & \\
\downarrow q_{n+1} & \downarrow q_n & \downarrow q_n & \downarrow q_n & \\
\vdots & \rightarrow & H_{n+1}(C) & \xrightarrow{0} & H_n(C) & \xrightarrow{0} & H_{n-1}(C) & \rightarrow & \vdots
\end{array}
\]

where the maps \( q_n \) are just the obvious projection maps.

The top and the bottom horizontal sequences of the above diagram are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

Now we apply the functor \( \text{Hom}(\_, G) \) to the top and the bottom horizontal sequences and we obtain the following diagram of cochain complexes.

\[
\begin{array}{cccccc}
\vdots & \leftarrow & \text{Hom}(C_{n+1}, G) & \xleftarrow{\partial_{n+1}^*} & \text{Hom}(C_n, G) & \xleftarrow{\partial_n^*} & \text{Hom}(C_{n-1}, G) & \leftarrow & \vdots \\
\uparrow (q_{n+1} \circ p_{n+1})^* & \downarrow (q_n \circ p_n)^* & \uparrow (q_{n-1} \circ p_{n-1})^* & \\
\vdots & \leftarrow & \text{Hom}(H_{n+1}(C), G) & \xleftarrow{0} & \text{Hom}(H_n(C), G) & \xleftarrow{0} & \text{Hom}(H_{n-1}(C), G) & \leftarrow & \vdots
\end{array}
\]

The induced maps on the cohomology groups of these two cochain complexes give us a homomorphism

\[ \eta: \text{Hom}(H_n(C), G) = H^n(\text{lower sequence}) \rightarrow H^n(\text{upper sequence}) = H^n(C; G). \]

It remains to prove the following claim.

**Claim.** The composition \( \text{ev} \circ \eta \) is the identity on \( \text{Hom}(H_n(C), G) \).

Let \( \varphi: H_n(C) \rightarrow G \) be homomorphism. We need to show that \( (\text{ev} \circ \eta)(\varphi) = \varphi \) in \( \text{Hom}(H_n(C), G) \). So let \( [\sigma] \in H_n(C) \) with \( \sigma \in Z_n \). Then

\[
\left( (\text{ev} \circ \eta)(\varphi) \right)([\sigma]) = \left( \begin{array}{c}
\varphi \circ q_n \circ p_n \\
\eta(\varphi)
\end{array} \right)(\sigma) = \varphi(\sigma) = \varphi([\sigma]).
\]

Definition of \( \text{ev} \) \hspace{1cm} Definition of \( \eta \) and \( \langle \_, \_ \rangle \) \hspace{1cm} Since \( p_n = \text{id} \) on \( Z_n \) \hspace{1cm} Since \( q_n(\sigma) = [\sigma] \)

**Example.** We consider again the projective space \( P := \mathbb{R}P^2 \). As a reminder, we showed on page 1216 that \( H_2(P) = 0 \), \( H_1(P) \cong \mathbb{Z}_2 \) and \( H_0(P) \cong \mathbb{Z} \). It follows from the Universal Coefficient Theorem and from the properties of the Ext-group that we had listed in Lemma 75.5 that

\[
\begin{align*}
H^2(P; \mathbb{Z}) & \cong \text{Hom}(H_2(P), \mathbb{Z}) \cong \mathbb{Z}_2 \oplus \text{Ext}(H_1(P), \mathbb{Z}) = 0 \oplus \mathbb{Z}_2 = \mathbb{Z}_2 \\
H^1(P; \mathbb{Z}) & \cong \text{Hom}(H_1(P), \mathbb{Z}) \cong \mathbb{Z}_2 \oplus \text{Ext}(H_0(P), \mathbb{Z}) = 0 \oplus 0 = 0 \\
H^0(P; \mathbb{Z}) & \cong \text{Hom}(H_0(P), \mathbb{Z}) = \mathbb{Z} \cong \text{Hom}(\mathbb{Z}, \mathbb{Z}) \cong \mathbb{Z}
\end{align*}
\]
and
\[ H^2(P; \mathbb{Z}_2) \cong \text{Hom}(H_2(P; \mathbb{Z}_2)) \oplus \text{Ext}(H_1(P; \mathbb{Z}_2)) \cong \text{Hom}(0; \mathbb{Z}_2) \oplus \text{Ext}(\mathbb{Z}_2; \mathbb{Z}_2) = 0 \oplus \mathbb{Z}_2 = \mathbb{Z}_2 \]
\[ H^1(P; \mathbb{Z}_2) \cong \text{Hom}(H_1(P; \mathbb{Z}_2)) \oplus \text{Ext}(H_0(P; \mathbb{Z}_2)) \cong \text{Hom}(\mathbb{Z}_2; \mathbb{Z}_2) \oplus \text{Ext}(\mathbb{Z}; \mathbb{Z}_2) = \mathbb{Z}_2 \oplus 0 = \mathbb{Z}_2 \]
\[ H^0(P; \mathbb{Z}_2) \cong \text{Hom}(H_0(P; \mathbb{Z}_2)) \]

Fortunately this coincides with the calculations from page 1845.

Example. We return to the study of lens spaces. In Lemma 66.9 we saw that
\[ H_n(L(p, q); \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases} \]

As in the previous example we can now use the Universal Coefficient Theorem 75.13 and Lemma 75.5 to compute the cohomology groups of \( L(p, q) \). We leave it to the reader to verify that
\[ H^n(L(p, q); \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3 \\ 0, & \text{if } n = 1 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 2. \end{cases} \]

This shows, as was already foreshadowed by Corollary 73.19, that cohomology groups also cannot distinguish between two lens spaces of the form \( L(p, q) \) and \( L(p, r) \). In particular we have not made any progress on Question 16.7 since the introduction of the fundamental group. All the extra invariants, namely higher homotopy groups, homology groups and cohomology groups (with any coefficients) have proved useless.

We conclude this section with the following proposition that gives in particular a converse to Corollary 73.20.

**Proposition 75.14.**

1. Let \( C_* \) be a chain complex. The following two statements are equivalent:
   1. \( \text{H}_k(C_*) = 0 \) for all \( k \in \mathbb{N}_0 \).
   2. \( \text{H}^k(C_*; \mathbb{Z}) = 0 \) for all \( k \in \mathbb{N}_0 \).

2. Let \( f: D_* \to E_* \) be a chain map. The following two statements are equivalent:
   1. All the induced map \( f_*: \text{H}_k(D_*) \to \text{H}_k(E_*) \) are isomorphisms.
   2. All the induced map \( f^*: \text{H}^k(E_*; \mathbb{Z}) \to \text{H}^k(D_*; \mathbb{Z}) \) are isomorphisms.

**Proof.**

(1) We start out with the following claim.

Claim. Let \( A \) be an abelian group. If \( A \) is non-trivial, then \( \text{Hom}(A, \mathbb{Z}) \) or \( \text{Ext}(A, \mathbb{Z}) \) is non-trivial.

Let \( A \) be a non-trivial abelian group. If \( A \) is finitely generated, then it follows from the Classification \[19.4\] of Finitely Generated Abelian Groups together with Lemma \[75.5\] that \( \text{Hom}(A, \mathbb{Z}) \) or \( \text{Ext}(A, \mathbb{Z}) \) is non-trivial. Furthermore, if \( A \) is infinitely generated, then the desired conclusion follows from Proposition \[75.11\].

\[ \text{Note that the } \mathbb{Z}_p \text{ shifted from } n = 1 \text{ in homology to } n = 2 \text{ in cohomology.} \]
The equivalence of (a) and (b) follows immediately from the claim together with
the Universal Coefficient Theorem \[75.12\] for Cohomology Groups.

(2) Let \( f : D_* \to E_* \) be a chain map. We denote by \((M(f), \partial_*')\) the corresponding algebraic mapping cone as defined on page 1284. By Lemma \[49.7\] there exists a long exact sequence of the form

\[ \cdots \to H_k(D_*) \xrightarrow{f_*} H_k(E_*) \to H_k(M(f)) \to H_{k-1}(D_*) \xrightarrow{f_*} \cdots \]

Basically the same argument also shows that there exists a long exact sequence of the form

\[ \cdots \leftarrow H^k(D_*; \mathbb{Z}) \xleftarrow{f^*} H^k(E_*; \mathbb{Z}) \leftarrow H^k(M(f); \mathbb{Z}) \leftarrow H^k(D_; \mathbb{Z}) \xrightarrow{f^*} \cdots \]

Thus we see that the equivalence of (2a) and (2b) is an immediate consequence of the equivalence of (1a) and (1b) applied to \( C_* = M(f) \).

75.3. **Cohomology groups of topological manifolds.**

**Proposition 75.15.** Let \( M \) be a connected \( n \)-dimensional topological manifold. Let \( G \) be an abelian group.

1. Let \( x \in M \setminus \partial M \). For \( i \neq n \) we have \( H_i(M, M \setminus \{x\}; G) = 0 \). Furthermore the map
   
   \[ \text{ev} : H^n(M, M \setminus \{x\}; G) \to \text{Hom}(H_n(M, M \setminus \{x\}; \mathbb{Z}), G) \]

   is an isomorphism.

2. If \( M \) is compact but not closed, then \( H^n(M; G) = 0 \).
3. If \( M \) is closed orientable and non-empty, then \( H^n(M; G) \cong G \).
4. If \( M \) is closed non-orientable and non-empty, then \( H^n(M; G) \cong G/2G \).
5. For any \( k > n \) we have \( H^k(M; G) = 0 \).

**Proof.** Let \( M \) be a compact connected \( n \)-dimensional topological manifold and let \( G \) be an abelian group.

1. This statement follows immediately from Lemma \[86.4\] and the Universal Coefficient Theorem \[75.13\].

2. We suppose that \( M \) has non-empty boundary. Then

   \[ H^n(M; G) \cong \text{Hom}(H_n(M; \mathbb{Z}), G) \oplus \text{Ext}(H_{n-1}(M; \mathbb{Z}), G) = \text{Ext}(\mathbb{Z}^k, G) = 0. \]

   By Theorem \[75.13\], we have \( H_n(M; \mathbb{Z}) = 0 \) and by Proposition \[75.5\] \((1)\) we have \( H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k \)

   for some \( k \in \mathbb{N}_0 \).

3. Suppose that \( M \) is closed orientable and non-empty. The argument is very similar to the proof of (2). We just need to use that we know from Theorem \[87.1\] that \( H_n(M; \mathbb{Z}) \cong \mathbb{Z} \) and that from Proposition \[87.22\] \((1)\) we know that \( H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k \)

   for some \( k \).

4. Next suppose that \( M \) is closed non-orientable and non-empty. This time we use that we know from Theorem \[87.1\] and Proposition \[87.22\] \((2)\) that \( H_n(M; \mathbb{Z}) \cong 0 \) and that \( H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k \oplus \mathbb{Z}_2 \) for some \( k \). Here we also use Lemma \[75.5\] \((4)\) which says that \( \text{Ext}(\mathbb{Z}_2, G) \cong G/2G \).
(5) So let $k > n$. This time we use that by Theorem 87.3 we know that $H_k(M; \mathbb{Z}) = 0$ and that we know from Theorems 87.1 and 87.3 that $H_{k-1}(M; \mathbb{Z})$ is either zero or isomorphic to $\mathbb{Z}$. The desired statement follows again from the Universal Coefficient Theorem 75.13 and the fact that by Lemma 75.5 we have $\text{Ext}(\mathbb{Z}, G) = 0$. ■

**Lemma 75.16.** Let $M$ be a compact oriented connected non-empty $n$-dimensional topological manifold. Then we have $H^n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$. Furthermore there exists a unique generator $[M]^* \in H^n(M, \partial M; \mathbb{Z})$ with $\langle [M]^*, [M] \rangle_M = 1$.1097

**Proof (•).** Let $M$ be a compact oriented connected $n$-dimensional non-empty topological manifold.

It follows from the Universal Coefficient Theorem 75.13 for Cohomology Groups together with Proposition 87.22 that the map

$$H^n(M, \partial M; \mathbb{Z}) \xrightarrow{\text{ev}} \text{Hom}(H_n(M, \partial M; \mathbb{Z}), \mathbb{Z})$$

is an isomorphism. By Corollary 87.4 (3) we have the equality $H_n(M, \partial M; \mathbb{Z}) = \mathbb{Z} \cdot [M]$. Hence there exists a unique element $[M]^* \in H^n(M, \partial M; \mathbb{Z})$ with $\text{ev}([M]^*)(([M])) = 1$, i.e. with $\langle [M]^*, [M] \rangle_M = 1$. ■

**Definition.**

1. Given a compact oriented connected non-empty $n$-dimensional topological manifold $M$ we refer to the uniquely determined element $[M]^* \in H^n(M, \partial M; \mathbb{Z})$ from Lemma 75.16 as the dual fundamental class of $M$.

2. Given a compact oriented $n$-dimensional non-empty topological manifold $M$ with finitely many components $M_1, \ldots, M_k$ we define its dual fundamental class to be

$$[M]^* := [M_1]^* + \cdots + [M_k]^* \in H^n(M_1, \partial M_1; \mathbb{Z}) \oplus \cdots \oplus H^n(M_k, \partial M_k; \mathbb{Z}).$$

**Example.** We consider the smooth manifold $S^1$ with the usual orientation. We saw on page 1714 that the singular simplex $\mu: \Delta^1 \to S^1$ that is given by $(1-t, t) \mapsto e^{2\pi i t}$ represents the fundamental class of $S^1$. On page 1826 we introduced a cocycle $\theta_\mathbb{Z} \in C^1(S^1; \mathbb{Z})$ and we had explicitly calculated that $\langle [\theta_\mathbb{Z}], [S^1] \rangle = \theta_\mathbb{Z}(\mu) = 1$. This shows immediately that $[\theta_\mathbb{Z}] \in H^1(S^1; \mathbb{Z})$ is the dual fundamental class of $S^1$.

Later on we will need the following lemma.

**Lemma 75.17.** Let $f: M \to N$ be a map between closed oriented connected non-empty $n$-dimensional topological manifolds. Then

$$f^*([N]^*) = \text{deg}(f) \cdot [M]^*.$$  

**Proof.** Let $f: M \to N$ be a map between closed, oriented connected $n$-dimensional non-empty topological manifolds. It follows from Lemma 75.16 that any class in $\varphi = H^n(M; \mathbb{Z})$
is of the form \( \varphi = k \cdot [M]^* \) for some \( k \in \mathbb{Z} \) and it follows from \( \langle [M]^*, [M] \rangle = 1 \) and the bilinearity of the Kronecker pairing that \( k = \langle \varphi, [M] \rangle_M \). In our case we have

\[
\langle f^*([N]^*), [M] \rangle = \langle [N]^*, f_*([M]) \rangle = \langle [N]^*, \deg(f) \cdot [N] \rangle = \deg(f) \cdot \langle [N]^*, [N] \rangle = \deg(f).
\]

Lemma 74.6 (3) by definition of \( \deg(f) \) since \( \langle , \rangle \) is bilinear

It follows from the above discussion that \( f^*([N]^*) = \deg(f) \cdot [M]^* \).■

Next we record the following useful consequence of the Universal Coefficient Theorem 75.13 for Cohomology Groups:

**Proposition 75.18.** Let \( X \) be a path-connected topological space, let \( x_0 \in X \) and let \( G \) be an abelian group. Then the Hurewicz homomorphism \( \pi_1(X, x_0) \to H_1(X) \) from page 1314 and the evaluation homomorphism \( ev: H^1(X; G) \to \text{Hom}(H_1(X); G) \) induce natural isomorphisms

\[
H^1(X; G) \cong \text{Hom}(H_1(X); G) \cong \text{Hom}(\pi_1(X, x_0), G).
\]

One often uses the natural isomorphisms from Proposition 75.18 to identify these groups.

**Proof.** As we pointed out on page 1867 and Proposition 52.2 (4), both maps are natural. So it remains to show that both maps are isomorphisms.

We insert one extra map into the above sequence of maps to see that the maps are indeed isomorphisms:

\[
H^1(X; G) \xrightarrow{ev} \text{Hom}(H_1(X); G) \xrightarrow{\cong} \text{Hom}(\pi_1(X, x_0)_{ab}, G) \xleftarrow{\cong} \text{Hom}(\pi_1(X, x_0), G).
\]

isomorphism by Theorem 75.13 Hurewicz Theorem 52.5 by Proposition 21.20 (2)

since \( H_0(X) \cong \mathbb{Z} \) by Proposition 41.5 since \( G \) is abelian ■

### 75.4. Cohomology with field coefficients.

Before we continue we introduce a slight variation on the Kronecker pairing defined in Lemma 74.6. More precisely, let \( C^* \) be a chain complex and let \( R \) be a commutative ring. We consider the map

\[
\langle , \rangle: H^n(C; R) \times H_n(C; R) \to R
\]

\[
\left( [\varphi], \left[ \sum_{i=1}^k c_i \otimes a_i \right] \right) \mapsto \sum_{i=1}^k \varphi(c_i) \cdot a_i.
\]

We leave it to the reader to verify that this map is well-defined and bilinear. We refer to this pairing also as the Kronecker pairing.

The next proposition relates homology and cohomology with coefficients in a field \( \mathbb{F} \).

**Proposition 75.19.** Let \( (X, A) \) be a pair of topological spaces and let \( \mathbb{F} \) be a field. The map

\[
ev: H^n(X, A; \mathbb{F}) \to \text{Hom}_\mathbb{F}(H_n(X, A; \mathbb{F}), \mathbb{F})
\]

\[
\varphi \mapsto \left( H_n(X, A; \mathbb{F}) \to \mathbb{F}
\sigma \mapsto \langle \varphi, \sigma \rangle \right)
\]

is a natural isomorphism of \( \mathbb{F} \)-vector spaces.
We postpone the proof of Proposition 75.19 to the next section. In most applications we are only interested in the following corollary to Proposition 75.19.

**Corollary 75.20.** Let \((X, A)\) be a pair of topological space and let \(k \in \mathbb{N}_0\) such that \(H_k(X, A; \mathbb{Z})\) and \(H_{k-1}(X, A; \mathbb{Z})\) are finitely generated. (By Proposition 85.13 (4) we know if \(X\) and \(A\) are compact topological manifolds, then this condition is satisfied.)

1. Given any field \(\mathbb{F}\) the homology and cohomology groups \(H_k(X, A; \mathbb{F})\) and \(H^k(X, A; \mathbb{F})\) are finite-dimensional \(\mathbb{F}\)-vector spaces with
   \[
   \dim_{\mathbb{F}}(H_k(X, A; \mathbb{F})) = \dim_{\mathbb{F}}(H^k(X, A; \mathbb{F})).
   \]
2. For any subfield \(\mathbb{F}\) of \(\mathbb{C}\) we have
   \[
   \dim_{\mathbb{F}}(H_k(X, A; \mathbb{F})) = \dim_{\mathbb{F}}(H^k(X, A; \mathbb{F})) = b_n(X, A).
   \]

**Remark.** Note that in Corollary 75.20 we only claim that the homology and cohomology groups are abstractly isomorphic. We do not claim that there is a natural isomorphism. In fact it does not make sense to ask for a natural isomorphism since the homology groups of a topological space \(X\) with \(\mathbb{F}\)-coefficients are covariant in \(X\) whereas the cohomology groups of \(X\) with \(\mathbb{F}\)-coefficients are contravariant in \(X\).

**Proof.** First note that Statement (2) is an immediate consequence of Statement (1) and the discussion on page 1422. So let turn to the proof of Statement (1). To simplify the notation we only consider the case \(A = \emptyset\). Let \(X\) be a topological space and let \(k \in \mathbb{N}_0\) such that \(H_k(X; \mathbb{Z})\) and \(H_{k-1}(X; \mathbb{Z})\) are finitely generated. Let \(p\) be a prime number. By the classification of finitely generated abelian groups, see Theorem 19.4, we can make the identifications

\[
H_{k-1}(X; \mathbb{Z}) = \mathbb{Z}^r \oplus \bigoplus_{i=1}^{\alpha} \mathbb{Z}_{a_i} \oplus \bigoplus_{i=1}^{\beta} \mathbb{Z}_{b_i}, \quad \text{and} \quad H_k(X; \mathbb{Z}) = \mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma} \mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta} \mathbb{Z}_{d_i}
\]

where all the \(a_i, b_i, c_i\) and \(d_i\) are non-zero, and where each \(a_i\) and each \(c_i\) is divisible by \(p\) and none of the \(b_i\) and \(d_i\) are divisible by \(p\). We start out with the following claim:

**Claim.** We have

\[
\dim_{\mathbb{F}}(H_k(X, \mathbb{F})) = \begin{cases} 
    s, & \text{if } \mathbb{F} \text{ is a field of characteristic zero,} \\
    s + \alpha + \gamma, & \text{if } \mathbb{F} \text{ is a field of characteristic } p.
\end{cases}
\]

First assume that \(\mathbb{F}\) is a field of characteristic zero. In this case we have

\[
H_k(X; \mathbb{F}) \cong H_k(X; \mathbb{Z}) \otimes \mathbb{F} = \left( \mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma} \mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta} \mathbb{Z}_{d_i} \right) \otimes \mathbb{F} \cong \mathbb{F}^s.
\]

by Theorem 57.19 and Lemma 57.17 (4) since \(\mathbb{F}\) is torsion-free see page 1398.

Note that “natural” makes sense since \((X, A) \mapsto H^k(X, A; \mathbb{F})\) and \((X, A) \mapsto \text{Hom}_{\mathbb{F}}(H_k(X, A; \mathbb{F}), \mathbb{F})\) both define contravariant functors from the category of pairs of topological spaces to the category of \(\mathbb{F}\)-vector spaces.
Now suppose that $\mathbb{F}$ is a field of characteristic $p$. We make the following observation. For any $n \in \mathbb{N}$ we have

$$Z_n \otimes \mathbb{F} = \text{coker} \left( \mathbb{F} \rightarrow \mathbb{F} \right) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else} \end{cases} \quad \text{and} \quad \text{Tor}(Z_n, \mathbb{F}) = \text{ker} \left( \mathbb{F} \rightarrow \mathbb{F} \right) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else}. \end{cases}$$

Lemma 57.3 (3) \quad \text{Lemma 57.17 (6)}

Then

$$H_k(X; \mathbb{F}) \cong H_k(X; \mathbb{Z}) \otimes \mathbb{F} \oplus \text{Tor}(H_{k-1}(X; \mathbb{Z}), \mathbb{F}) \cong \mathbb{F}^n \oplus \mathbb{F}^n \oplus \mathbb{F}^n.$$ 

by Theorem 57.19 \quad \text{by Lemma 57.17} \quad \text{the discussion on page 1396}

and the above observations \quad \blacklozenge

Now we have

$$\dim_\mathbb{F}(H^k(X; \mathbb{F})) = \dim_\mathbb{F}(\text{Hom}(H_k(X; \mathbb{F}), \mathbb{F})) \cong \dim_\mathbb{F}(H_k(X; \mathbb{F}))$$

\quad Proposition 75.19 \quad \text{since by the claim } H_k(X; \mathbb{F}) \text{ is finite-dimensional} \quad \blacksquare

We could also prove the equality $\dim_\mathbb{F}(H^k(X; \mathbb{F})) = \dim_\mathbb{F}(H_k(X; \mathbb{F}))$ without appealing to Proposition 75.19. Indeed, using Theorem 75.13 the fact that for any abelian group $G$ we have $\text{Hom}(\mathbb{Z}_n, G) \cong \ker(G \rightarrow \mathbb{Z})$ and Proposition 75.6 one can easily compute $\dim_\mathbb{F}(H^k(X; \mathbb{F}))$ and one ends up with the same calculation as in the above claim. We leave it to the reader to fill in the details.

75.5. **Proof of Proposition 75.19** (*). In this section we give the proof of Proposition 75.19. Before we can provide the proof we need to prepare the ground.

Let $\mathbb{F}$ be a field. We define a \textit{chain complex over $\mathbb{F}$} to be a chain complex $(V_*, v_*)$ where all chain groups are $\mathbb{F}$-vector spaces and all boundary maps are $\mathbb{F}$-homomorphisms. For example, if $(C_*, \partial_*)$ is a chain complex of abelian groups, then $(C_* \otimes \mathbb{F}, \partial_* \otimes \text{id})$ is easily seen to be a chain complex over $\mathbb{F}$.

Given a chain complex $(V_*, v_*)$ over the field $\mathbb{F}$ and given $n \in \mathbb{N}_0$ its $n$-homology

$$H_n(V) := \frac{\ker(v_n: V_n \rightarrow V_{n-1})}{\text{im}(v_{n+1}: V_{n+1} \rightarrow V_n)}.$$

is an $\mathbb{F}$-vector space in a natural way.

We also define cochain complexes and cochain maps over $\mathbb{F}$ in the obvious way. For example, if $(C_*, c_*)$ is a chain complex, then the dual cochain complex $(\text{Hom}(C_*(X, \mathbb{F})), c^*)$ is a cochain complex over $\mathbb{F}$.

Given a chain complex $(V_*, v_*)$ over $\mathbb{F}$ we obtain a cochain complex by considering $(\text{Hom}_\mathbb{F}(V_*, \mathbb{F}), v^*)$ and we define its $n$-th cohomology group to be the $\mathbb{F}$-vector space

$$H^n(V; \mathbb{F}) := \frac{\ker(v^*_n: \text{Hom}_\mathbb{F}(V_n, \mathbb{F}) \rightarrow \text{Hom}_\mathbb{F}(V_{n+1}, \mathbb{F}))}{\text{im}(v^*_{n+1}: \text{Hom}_\mathbb{F}(V_{n-1}, \mathbb{F}) \rightarrow \text{Hom}_\mathbb{F}(V_n, \mathbb{F}))}.$$

The proof of the Universal Coefficient Theorem 75.12 for Cohomology Groups can be modified fairly easily to provide the following theorem.
Theorem 75.21. Let $F$ be a field and let $(V, v_*)$ be a chain complex over $F$. Then the map
\[ ev_F : H^k(V; F) \mapsto \text{Hom}_F(H_k(V), F), \]
\[ (\varphi : V_k \to F) \mapsto \left( H_k(V) \to F 
\begin{array}{c} [c] \\
\varphi(c) \end{array} \right) \]
is well-defined and it is an isomorphism.

A proof of that theorem is provided by any self-respecting book on homological algebra, see e.g. [DaK01, Corollary 2.31].

We will also need the following lemma.

Lemma 75.22. Let $C$ be an abelian group and let $F$ be a field. Then the map
\[ \Phi_C : \text{Hom}_Z(C, F) \to \text{Hom}_F(C \otimes F, F) \]
\[ (\varphi : C \to F) \mapsto \left( \begin{array}{c} C \otimes F \to F \\
\sum_{i=1}^{k} c_i \otimes a_i \mapsto \sum_{i=1}^{k} \varphi(c_i) \cdot a_i \end{array} \right) \]
is an isomorphism.

Proof. It is straightforward to verify that an inverse map to $\Phi_C$ is given by the following homomorphism of $F$-vector spaces:
\[ \Psi_C : \text{Hom}_F(C \otimes F, F) \to \text{Hom}_Z(C, F) \]
\[ (\varphi : C \otimes F \to F) \mapsto (C \xrightarrow{\varphi} C \otimes F \xrightarrow{\cdot} F). \]

Corollary 75.23. Let $C_*$ be a chain complex and let $F$ be a field. The maps
\[ \Phi_{C_k} : \text{Hom}_Z(C_k, F) \to \text{Hom}_F(C_k \otimes F, F) \]
with $k \in \mathbb{N}_0$
from the previous lemma define an isomorphism of cochain complexes of $F$-vector spaces, in particular for each $k \in \mathbb{N}_0$ they induce an isomorphism
\[ \Phi : H^k(C; F) \to H^k(C \otimes F; F) \]
of $F$-vector spaces.

Proof. By Lemma 75.22 the maps $\Phi_{C_k}, k \in \mathbb{N}_0$, are isomorphisms of the cochain vector spaces. It is straightforward to see that these maps are also cochain maps.

Now we can finally provide the proof of Proposition 75.19.

Proof of Proposition 75.19. Let $(X, A)$ be a pair of topological spaces and let $F$ be a field. We write $C_* = C_*(X, A)$. Given $k \in \mathbb{N}_0$ we consider the diagram
\[ \begin{array}{ccc}
H^k(C \otimes F; F) & \xrightarrow{\Phi} & H^k(C; F) \\
\downarrow{ev} & & \downarrow{ev} \\
\text{Hom}_F(H_n(C \otimes F), F) & \xrightarrow{ev_{\varphi}} & \text{Hom}_F(H_n(C \otimes F), F).
\end{array} \]

Note that to the left we consider homomorphisms of $\mathbb{Z}$-modules, i.e. homomorphisms of abelian groups whereas to the right we consider homomorphisms of $F$-vector spaces.
It follows easily from the definitions that for any representative in \( H^k(C; \mathbb{F}) \) the image under the composition of the two diagonal maps agrees with the image under the map \( \text{ev} \). This implies that \( \text{ev} \) is well-defined and that the diagram commutes.

Also note that the left diagonal map is an isomorphism by Corollary 75.23 whereas the right diagonal map is an isomorphism by Theorem 75.21. In particular the bottom map is an isomorphism. But that is exactly what we had wanted to show. ■

### 75.6. Change of coefficients in cohomology (*)

Let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups and let \( G \) be an abelian group. By the Algebraic Universal Coefficient Theorem 57.18 we can relate the homology groups of \( C_\ast \otimes G \) to the homology groups of \( C_\ast \). Furthermore, by the Universal Coefficient Theorem for Cohomology Groups 75.12 we can relate the cohomology groups \( H^*(C_\ast; G) \) to the homology groups \( H_*(C) \). The following question arises.

**Question 75.24.** Can we relate the cohomology groups \( H^*(C; G) \) to the cohomology groups \( H^*(C; \mathbb{Z}) \)?

It turns out that the question is slightly subtle. To formulate the answer we need the following lemma.

**Lemma 75.25.** Let \( G \) be an abelian group.

1. For any abelian group \( H \) the map
   \[
   \mu: \text{Hom}(H, \mathbb{Z}) \otimes G \to \text{Hom}(H, G),
   \]
   \[
   \sum_{i=1}^m \varphi_i \otimes g_i \mapsto \left( H \to G \right)
   \]
   is a well-defined natural homomorphism.

2. Given a chain complex \((C_\ast, \partial_\ast)\) the map
   \[
   H^n(C; \mathbb{Z}) \otimes G \xrightarrow{\mu} H^n(C; G),
   \]
   \[
   \sum_{i=1}^m [\varphi_i] \otimes g_i \mapsto \sum_{i=1}^m [\mu(\varphi_i \otimes g_i)]
   \]
   is well-defined.

**Proof.** The proof is elementary and is left to the reader. ■

The following theorem gives an affirmative answer to Question 75.24 albeit only under an extra hypothesis.

**Theorem 75.26. (Universal Coefficient Theorem)** Let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups and let \( G \) be an abelian group. We suppose that all cohomology groups \( H^*(C_\ast; \mathbb{Z}) \) are finitely generated. Then for each \( n \in \mathbb{N}_0 \) there exists a short exact sequence of the form

\[
0 \to H^n(C; \mathbb{Z}) \otimes G \xrightarrow{\mu} H^n(C; G) \to \text{Tor}(H^{n+1}(C; \mathbb{Z}), G) \to 0.
\]

Furthermore the short exact sequence splits.
The key to proving the Universal Coefficient Theorem \(75.26\) is the following elementary but subtle lemma.

**Lemma 75.27.** Let \(G\) be an abelian group. If \(H\) is a free abelian group of finite rank, then the map

\[
\mu: \text{Hom}(H, \mathbb{Z}) \otimes G \rightarrow \text{Hom}(H, G)
\]

is an isomorphism.

**Proof.** Let \(v_1, \ldots, v_n\) be a basis for the finitely generated free abelian group \(H\). We denote by \(\varphi_1, \ldots, \varphi_n\) the dual basis of \(\text{Hom}(H, \mathbb{Z})\). In other words, these are the homomorphisms that are uniquely determined by \(\varphi_i(v_j) = \delta_{ij}\). We leave it to the reader to verify that the map

\[
\nu: \text{Hom}(H, G) \rightarrow \text{Hom}(H, \mathbb{Z}) \otimes G
\]

\[
\psi \mapsto \sum_{i=1}^{n} \varphi_i \otimes \psi(v_i)
\]

is an inverse to the homomorphism \(\mu\). \(\blacksquare\)

We will also need the following lemma.

**Lemma 75.28.** Let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups. If all cohomology groups \(H^n(C_\ast; \mathbb{Z})\) are finitely generated, then all homology groups \(H_n(C_\ast)\) are also finitely generated.

**Proof of Lemma 75.28.** Let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups such that all cohomology groups \(H^n(C_\ast; \mathbb{Z})\) are finitely generated. By the Universal Coefficient Theorem \(75.12\) for Cohomology Groups there exists an isomorphism

\[
H^n(C_\ast; \mathbb{Z}) \cong \text{Ext}(H_{n-1}(C_\ast), \mathbb{Z}) \oplus \text{Hom}(H_n(C_\ast), \mathbb{Z})
\]

for every \(n \in \mathbb{N}_0\).

We see that all the groups \(\text{Ext}(H_{n-1}(C_\ast), \mathbb{Z})\) and \(\text{Hom}(H_n(C_\ast), \mathbb{Z})\) are finitely generated, in particular they are countable. But by Proposition \(75.11\) this implies that all the homology groups \(H_n(C_\ast)\) are finitely generated. \(\blacksquare\)

**Proof of the Universal Coefficient Theorem 75.26.** Let \(G\) be an abelian group. Furthermore let \((C_\ast, \partial_\ast)\) be a chain complex of free abelian groups such that all cohomology groups \(H^n(C_\ast; \mathbb{Z})\) are finitely generated. It follows from Lemma \(75.28\) that all homology groups \(H_n(C_\ast)\) are also finitely generated. Thus we obtain from Lemma \(49.6\) that there exists a chain homotopy equivalence \(h: C_\ast \rightarrow D_\ast\) from \((C_\ast, \partial_\ast)\) to a chain complex \((D_\ast, \partial_\ast)\) such that each chain group \(D_n\) is a finitely generated free abelian group. Now we consider

\[\text{1100 As always, the splitting is not natural. In fact in this theorem we do not even claim that the short exact sequence is natural. The reason is that the construction of the short exact sequence involves a choice of the chain complex } D_\ast \text{ and we do not intend to discuss the question how that choice affects the map on the right hand side.}\]
the following diagram:

\[
\begin{array}{cccc}
& = H^n(D; \mathbb{Z}) \text{ by def.} & \vdash & = H^{n+1}(D; \mathbb{Z}) \text{ by def.} \\
0 \rightarrow H_n(\text{Hom}(D_*, \mathbb{Z})) \otimes G \rightarrow H_n(\text{Hom}(D_*, \mathbb{Z}); G) \rightarrow \text{Tor}(H_{n+1}(\text{Hom}(D_*, \mathbb{Z})), G) \rightarrow 0. \\
& \uparrow & \downarrow \mu & \uparrow \\
H^n(D; \mathbb{Z}) \otimes G \rightarrow H^n(\text{Hom}(D_*; G)) \rightarrow \text{Tor}(H^{n+1}(D; \mathbb{Z}); G) \rightarrow 0. \\
& \uparrow & \downarrow h^* & \uparrow \\
H^n(C; \mathbb{Z}) \otimes G \rightarrow H^n(C; G) \rightarrow \text{Tor}(H^{n+1}(C; \mathbb{Z}); G) \rightarrow 0. \\
\end{array}
\]

We make the following clarifications:

1. The horizontal sequence on the top is the short exact sequence obtained from the Algebraic Universal Coefficient Theorem 57.18 which we applied to the chain complex \(E_* = \text{Hom}(D_{*-}; \mathbb{Z}).\) We need to invert the sign of the degrees twice, thus we end up with the degree \(n + 1 = -(n) - 1\) on the right hand side. We know by Proposition 57.23 that the short exact sequence splits.

2. It follows from Lemma 75.27 that the middle vertical map between the first two rows is an isomorphism. Here we use that each chain group of \(D_*\) is a free abelian group of finite rank.

3. One can easily verify that the diagram commutes.

4. By Lemma 73.8 (4) the bottom vertical maps are isomorphisms.

It is now clear that we obtain the desired short exact sequence. 

The following theorem gives a practical “topological” version of the Universal Coefficient Theorem 75.26.

**Theorem 75.29. (Universal Coefficient Theorem)** Let \(X\) be a topological space and let \(G\) be an abelian group. If all homology groups \(H_n(X)\) of \(X\) are finitely generated (e.g. \(X\) could be a compact topological manifold or \(X\) could be a CW-complex that has only finitely many cells in each dimension\(^{110}\)), then for each \(n \in \mathbb{N}_0\) there exists a short exact sequence of the form

\[
0 \rightarrow H^n(X; \mathbb{Z}) \otimes G \rightarrow H^n(X; G) \rightarrow \text{Tor}(H^{n+1}(X; \mathbb{Z})); G) \rightarrow 0.
\]

Furthermore the short exact sequence splits.

**Proof.** This theorem follows immediately from applying the Universal Coefficient Theorem 75.26 to the singular chain complex of \(X.\)

**Remark.** In general the hypothesis on \(X\) that we put into the Universal Coefficient Theorem 75.29 cannot be dropped. For example consider the infinite string of circles \(X\) as shown in Figure 1131 and we take \(G = \mathbb{Q}.\) By Lemma 57.17 (4) we know that all Tor-groups \(\text{Tor}(H, \mathbb{Q})\) vanish. In Exercise 75.10 we will see that the groups \(H^1(X; \mathbb{Z}) \otimes \mathbb{Q}\) and

\(^{110}\)By Proposition 85.13 (4) and Proposition 48.5 (1) such topological spaces qualify.
$H^1(X;\mathbb{Q})$ are not isomorphic. This shows that in this setting the sequence stated in the Universal Coefficient Theorem 75.29 is not exact.

\[ X = \bullet \longrightarrow \mathbb{Q} \longrightarrow \mathbb{Q} \longrightarrow \mathbb{Q} \longrightarrow \bullet \]

\[ \text{Figure 1131} \]

The following lemma gives a convenient interpretation of the map $\mu$ appearing in the Universal Coefficient Theorem 75.29.

**Lemma 75.30.** Let $X$ be a topological space, let $G$ be an abelian group and let $f: \mathbb{Z} \rightarrow G$ be a homomorphism. The following diagram commutes:

\[
\begin{array}{ccc}
H^n(X;\mathbb{Z}) & \xrightarrow{\omega \mapsto \omega \otimes f(1)} & H^n(X;\mathbb{Z}) \\
\downarrow & & \downarrow \\
H^n(X;\mathbb{Z}) \otimes G & \xrightarrow{f_*} & H^n(X;G).
\end{array}
\]

**Proof.** The statement follows immediately from explicitly writing down the homomorphisms. $\blacksquare$

**Example.** Let $n \in \mathbb{N} \cup \{\infty\}$. We denote by $f: \mathbb{Z} \rightarrow \mathbb{Z}$ the obvious group homomorphism. It follows from the Universal Coefficient Theorem 75.29, from Lemma 75.30, from the calculations of the cohomology groups $H^n(\mathbb{C}P^n;\mathbb{Z})$ on page 1843 and from the properties of Tor-groups, see Lemma 57.17, that for any $k \in \mathbb{N}_0$ the map $f_*: H_*(\mathbb{C}P^n;\mathbb{Z}) \rightarrow H_*(\mathbb{C}P^n;\mathbb{Z}_2)$ is an epimorphism.

We conclude this chapter with the following lemma which unwittingly gets used frequently.

**Lemma 75.31.** $(\ast)$ We denote by $\varphi: \mathbb{Z} \rightarrow \mathbb{Q}$ the obvious inclusion. Let $n \in \mathbb{N}_0$.

1. Let $X$ be a topological space such that all homology groups are finitely generated. We suppose that $H^n(X;\mathbb{Z})$ is a finitely generated free abelian group. If $v_1, \ldots, v_m$ is a basis of $H^n(X;\mathbb{Z})$, then $\varphi_*(v_1), \ldots, \varphi_*(v_m)$ is a basis of $H^n(X;\mathbb{Q})$.
2. Let $f: X \rightarrow Y$ be a map between topological spaces. We suppose that all homology groups of $X$ and $Y$ are finitely generated and we suppose that $H^n(X;\mathbb{Z})$ and $H^n(Y;\mathbb{Z})$ are free abelian groups. We consider the following commutative diagram:

\[
\begin{array}{ccc}
H^n(Y;\mathbb{Z}) & \xrightarrow{f^*} & H^n(X;\mathbb{Z}) \\
\downarrow & & \downarrow \\
H^n(Y;\mathbb{Q}) & \xrightarrow{f^*} & H^n(X;\mathbb{Q}).
\end{array}
\]

Suppose $v_1, \ldots, v_r$ is a basis for $H^n(X;\mathbb{Z})$ and that $w_1, \ldots, w_s$ is a basis for $H^n(Y;\mathbb{Z})$. The matrix that represents $f^*: H^n(Y;\mathbb{Z}) \rightarrow H^n(X;\mathbb{Z})$ with respect to the given bases also represents $f^*: H^n(Y;\mathbb{Q}) \rightarrow H^n(X;\mathbb{Q})$ with respect to the bases $\varphi_*(v_1), \ldots, \varphi_*(v_r)$ and $\varphi_*(w_1), \ldots, \varphi_*(w_s)$.
Proof (*).

(1) This statement follows easily from the Universal Coefficient Theorem 75.29 together
with Lemma 57.17 (4) and Lemma 75.30

(2) The fact that the diagram commutes is an immediate consequence of Lemma 73.9.
The remaining statement is just a psychologically helpful reinterpretation of the fact
that the diagram commutes.

Exercises for Chapter 75

Exercise 75.1. Let $C_*$ be a chain complex of free abelian groups and let $n \in \mathbb{N}$. Show
that there does not exist a natural isomorphism

$$H^n(C; G) \cong \text{Ext}(H_{n-1}(C), G) \oplus \text{Hom}(H_n(C), G).$$

Exercise 75.2. Let $\{A_n\}_{n \in \mathbb{N}}$ be a sequence of finitely generated abelian groups. We assume
that $A_0$ and $A_1$ are free abelian groups. Show that there exists a connected CW-complex
$X$ such that for any $n \in \mathbb{N}$ we have $H^n(X; \mathbb{Z}) \cong A_n$.

Hint. Use Proposition 47.10.

Remark. The statement is not true if we drop the hypothesis that the groups are finitely
generated, in fact as is shown in [Luc78] (see also [KaW61]) there is no topological space
$X$ with $H^n(X; \mathbb{Z}) \cong \mathbb{Q}$ for some $n \in \mathbb{N}_0$.

Exercise 75.3. Let $(P, \leq)$ be a partially ordered set and let $Q$ be a subset. Is an upper
bound necessarily a maximal element? And conversely, is a maximal element necessarily
an upper bound?

Exercise 75.4. Let $X$ and $Y$ are topological spaces. Suppose that $H_n(X; \mathbb{Z}) \cong H_n(Y; \mathbb{Z})$
for some $n \in \mathbb{N}_0$. Does it follow that $H^n(X; \mathbb{Z})$ and $H^n(Y; \mathbb{Z})$ are also isomorphic?

Exercise 75.5. Redo Exercise 74.3 More precisely, use the Universal Coefficient Theorem 75.13
for Cohomology Groups to determine the isomorphism types of the cohomology
groups of the Klein bottle with $\mathbb{F}_2$-coefficients, with $\mathbb{F}_3$-coefficients and with $\mathbb{Z}$-coefficients.

Exercise 75.6. Give an explicit example of a cocycle $\varphi : C_1(\mathbb{R}P^2) \to \mathbb{F}_2$ that represents a
generator of $H^1(\mathbb{R}P^2; \mathbb{F}_2) \cong \mathbb{F}_2$.

Exercise 75.7. Let $M$ be a compact oriented connected $n$-dimensional topological manifold
with non-empty connected boundary. Show that $\delta([\partial M]^*) = [M]^* \in H^n(M, \partial M; \mathbb{Z})$
where $\delta$ denotes the connecting homomorphism in the long exact sequence of cohomology groups
of the pair $(M, \partial M)$.

Hint. Use Proposition 87.27.

Exercise 75.8.

(a) Let $G$ and $H$ be $\mathbb{Q}$-vector spaces. Let $\varphi : G \to H$ be a homomorphism of abelian
groups. Show that $\varphi$ is also a homomorphism of $\mathbb{Q}$-vector spaces.

(b) Show that the abelian groups $\mathbb{Q}$ and $\mathbb{Q}^2$ are not isomorphic.

(c) Show that the abelian groups $\mathbb{R}$ and $\mathbb{R}^2$ are isomorphic.
(d) Use (a) and (b), together with the existence of Moore spaces, see Proposition 47.11 and together with the Universal Coefficient Theorem 75.13 for Cohomology Groups and Proposition 75.10 to conclude that there exist topological spaces $X$ and $Y$ such that $H^n(X;\mathbb{Z}) \cong H^n(Y;\mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $H_1(X;\mathbb{Z})$ is not isomorphic to $H_1(Y;\mathbb{Z})$.

**Remark.** This exercise shows that in Corollary 73.19 the roles of homology and cohomology are not symmetric.

**Exercise 75.9.** Let $H$ be a free abelian group and let $G$ be an abelian group. As in Lemma 75.27 we consider the map
\[
\text{Hom}(H, \mathbb{Z}) \otimes G \to \text{Hom}(H, G)
\]
\[\sum_{i=1}^m \phi_i \otimes g_i \mapsto \left( \begin{array}{c} H \to G \\ h \mapsto \sum_{i=1}^m \phi_i(h) \cdot g_i \end{array} \right).
\]
Show that this map is in general not an isomorphism.

**Exercise 75.10.** We consider the topological space $X$ shown in Figure 1131. Show that the map
\[\mu: H^1(X;\mathbb{Z}) \otimes \mathbb{Q} \to H^1(X;\mathbb{Q})\]
from Lemma 75.25 is not an isomorphism.

**Exercise 75.11.** Show that there exists a topological space $X$ such that the two groups $H^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $H^1(X;\mathbb{Q})$ are not isomorphic.

**Hint.** You could make use of Proposition 47.10 to find unusual topological spaces.

**Exercise 75.12.** Let $X$ be a topological space which is $\mathbb{Z}$-finite in the sense of the definition on page 1623, i.e. all homology groups $H_i(X)$ are finitely generated abelian groups and all but finitely many homology groups $H_i(X)$ are zero. Let $\varphi: X \to X$ be a map. Show that
\[\sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{tr}(\varphi_*: H_k(X;\mathbb{Z}) \to H_k(X;\mathbb{Z})) = \sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{tr}(\varphi^*: H^k(X;\mathbb{Z}) \to H^k(X;\mathbb{Z})).
\]

Lefschetz number $\Lambda(\varphi)$ as defined on page 1628.
76. Cohomology groups and limits

76.1. Direct limits of direct systems. In the intermediate future direct limits of direct systems and inverse limits of inverse systems will play a large role. To fortify us for these discussions we recall the definitions and we prove some fairly elementary but useful lemmas regarding limits.

First we recall the following definition from page \[726\]

\textbf{Definition.} A directed set is a set \( I \) together with a relation \( \leq \) on \( I \) which satisfies the following three conditions:

1. the relation is reflexive, i.e. for any \( i \in I \) we have \( i \leq i \).
2. the relation is transitive, i.e. for any \( i,j,k \in I \) we have \( i \leq j \) and \( j \leq k \) \( \implies \) \( i \leq k \).
3. for any \( i,j \in I \) there exists a \( k \in I \) with \( i \leq k \) and \( j \leq k \).

\textbf{Examples.}

(a) Evidently the natural numbers \( \mathbb{N} \) together with the usual \( \leq \) relation form a directed set \((\mathbb{N}, \leq)\).

(b) Let \( M \) be a set. We denote by \( \mathcal{P}(M) \) the power set of \( M \), i.e. the set of all subsets of \( M \). Then the relation given by \( \subseteq \) turns \( \mathcal{P}(M) \) into a directed set. To prove this claim it only remains to verify (3). But this also holds, since for any \( X,Y \in \mathcal{P}(M) \), i.e. for any subsets \( X,Y \) of \( M \) we can take \( Z = X \cup Y \) and we then have \( X \subseteq Z \) and \( Y \subseteq Z \).

Next we recall the following definition from page \[728\]

\textbf{Definition.} Let \((I, \leq)\) be a directed set and let \( \mathcal{C} \) be a category. A direct system over the directed set \((I, \leq)\) is a family of objects \( \{X_i\}_{i \in I} \) in \( \mathcal{C} \), together with a family of morphisms \( \{f_{ij} : X_i \rightarrow X_j\} \) for all \( i,j \in I \) with \( i \leq j \) such that the following two conditions are satisfied:

\[ (1) \quad f_{ii} = \text{id}_{X_i} \quad \text{for all} \quad i \in I, \]
\[ (2) \quad f_{ik} = f_{jk} \circ f_{ij} \quad \text{for all} \quad i,j,k \in I \text{ with } i \leq j \leq k. \]

\textbf{Example.} Let \( \mathcal{C} \) be a category and let

\[ X_1 \xrightarrow{g_1} X_2 \xrightarrow{g_2} X_3 \xrightarrow{g_3} X_4 \xrightarrow{g_4} \ldots \]

be a sequence of morphisms in the category \( \mathcal{C} \). For \( i \in \mathbb{N}_0 \) we set \( f_{ii} = \text{id} \) and for \( i \leq j \) we set \( f_{ij} = g_{j-1} \circ \cdots \circ g_{i+1} \circ g_i : X_i \rightarrow X_j \). It is clear that \((\{X_i\}_{i \in \mathbb{N}}, \{f_{ij} : i \leq j\})\) is a direct system over the directed set \((\mathbb{N}, \leq)\). By a slight abuse of notation we refer to such a sequence \((\{X_i\}_{i \in \mathbb{N}}, \{g_i : X_i \rightarrow X_{i+1}\}_{i \in \mathbb{N}})\) also as a direct system.

Finally we also recall the definition of a direct limit from page \[729\]

\[1102\] On page \[728\] we had also considered direct systems that are defined over preordered sets, but for the remainder of this course we are only interested in direct systems over directed sets.
Definition. Let \((I, \leq)\) be a directed set and let \(\mathcal{C}\) be a category. Suppose we are given a direct system \((\{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})\) in the category \(\mathcal{C}\). A direct limit of the direct system is an object \(\lim X_i\) in \(\mathcal{C}\) together with morphisms \(h_i: X_i \to \lim X_i, i \in I\) in the category \(\mathcal{C}\) such that the following two conditions are satisfied:

1. For all \(k \leq l\) we have \(h_l \circ f_{kl} = h_k: X_k \to \lim X_i\), i.e. for all \(k \leq l\) the following diagram commutes:

\[
\begin{array}{ccc}
X_l & \xrightarrow{h_t} & \lim X_i \\
\downarrow{f_{kl}} & & \downarrow{h_k} \\
X_k & \xrightarrow{h_t} & \lim X_i
\end{array}
\]

2. If we are given another object \(Y\) and morphisms \(h'_i: X_i \to Y, i \in I\) that satisfy (1), then there exists a unique morphism \(F: \lim X_i \to Y\) such that for all \(k \leq l\) the following diagram commutes:

\[
\begin{array}{ccc}
X_l & \xrightarrow{h'_t} & Y \\
\downarrow{h_l} & & \downarrow{F} \\
X_k & \xrightarrow{h'_t} & Y
\end{array}
\]

As we pointed out on page 730, the direct limit of direct system, if it exists, is in an appropriate sense unique up to isomorphism.

The following proposition is a variation on Proposition 25.1.

**Proposition 76.1.** Let \((I, \leq)\) be a directed set and let \((\{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})\) be a direct system over one of the following categories:

1. the category of abelian groups,
2. the category of \(R\)-modules, where \(R\) is a commutative ring,
3. the category of chain complexes,
4. the category of cochain complexes.

Then \(\lim X_i := \left( \bigsqcup_{i \in I} X_i \right) / \sim\) where \(x \sim f_{ij}(x)\) for all \(i \leq j, x \in X_i\) with the obvious maps \(X_i \to \lim X_i\) is a direct limit. Here we view \(\lim X_i\) as a group as follows: if we are given \(a \in X_i\) and \(b \in X_j\), then by definition of a directed set there exists a \(k \in I\) with \(i \leq k\) and \(j \leq k\), and we define

\[
[a] + [b] := \left[ f_{ik}(a) + f_{jk}(b) \right] \in \lim X_i.
\]

Depending on the category we are dealing with we can also equip \(\lim X_i\) with an \(R\)-module structure or we can equip it with (co) boundary maps.
Proof. This explicit construction of the direct limit was already given on page 733. The proof of the proposition is a not overly exciting exercise in going through all the definitions. We leave this task to the reader.

Now we give three lemmas which will be helpful in getting direct limits “under control”.

**Lemma 76.2.** Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i \in I}, \{f_{ij} : X_i \to X_j\}_{i \leq j})$ be a direct system over $I$ in one of the four categories that we had considered in Proposition 76.1. Then the following four statements hold:

1. Every element in $\lim_{\to} X_i$ lies in the image of one of the maps $X_j \to \lim_{\to} X_i$.
2. Let $a_j \in X_j$ and let $a_k \in X_k$. The images of $a_j$ and $a_k$ in $\lim_{\to} X_i$ agree if and only if there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.
3. Let $a_j \in X_j$. The image of $a_j$ in $\lim_{\to} X_i$ is zero if and only if there exists a $k \geq j$ such that $f_{jk}(a_j) = 0 \in X_k$.
4. If all maps $f_{ij} : X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \lim_{\to} X_i$ is an isomorphism.

Proof.

(1) The first statement follows immediately from the explicit description of the direct limit given in Proposition 76.1.

(2) The second statement will be proved in Exercise 76.1. For the exercise it is useful to note that the symbol “$\sim$” in the definition of $\lim_{\to} X_i$ in Proposition 76.1 is only a relation and we really have to work with the equivalence relation generated by this relation, see page 197 for more information.

(3) The third statement is a special case of the second statement.

(4) The last statement will be proved in Exercise 76.1.

The second lemma is useful for simplifying calculations.

**Lemma 76.3.** Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i \in I}, \{f_{ij} : X_i \to X_j\}_{i \leq j})$ be a direct system over $I$ in one of the four categories that we had considered in Proposition 76.1. Let $J$ be a subset of $I$ such that $(J, \leq)$ is again a directed set.

1. There exists a unique map $\lim_{\to} X_j \to \lim_{\to} X_i$.

---

1103 The construction of the direct limit that we gave in Proposition 25.1 was different, and arguably more complicated, since there we had considered direct systems over arbitrary preordered sets.

1104 It is straightforward to verify that this definition does not depend on the choice of $k$. 

such that for any \( j \in J \) the following diagram commutes:

\[
\begin{array}{ccc}
X_j & \xrightarrow{f_j} & X_i \\
\downarrow & & \downarrow \\
\lim_{j \in J} X_j & \xrightarrow{\lim f_j} & \lim_{i \in I} X_i
\end{array}
\]

(2) If \( J \) has the property that given any \( i \in I \) there exists a \( j \in J \) with \( i \leq j \), then the above map

\[
\lim_{j \in J} X_j \longrightarrow \lim_{i \in I} X_i
\]

is an isomorphism.

The first part of the lemma is just an immediate consequence of the definition of the direct limit over the directed set \( J \). As we will see, the second statement is a fairly straightforward consequence of the next lemma. But it is also a good exercise to prove the above second statement "by hand".

The following definition is a generalization of the definition on page 1243.

**Definition.** Let \((I, \leq)\) and \((J, \leq)\) be directed sets.

1. A **morphism** between the directed sets \((I, \leq)\) and \((J, \leq)\) is a map \( \varphi: I \to J \) such that for any \( i_1 \leq i_2 \) in \( I \) we have \( \varphi(i_1) \leq \varphi(i_2) \).

2. A morphism \( \varphi: I \to J \) is called **cofinal** if given any \( j \in J \) there exists an \( i \in I \) with \( \varphi(i) \geq j \).

3. Let \((\{K_i\}_{i \in I}, \{\chi_{i_1,i_2}\}_{i_1 \leq i_2})\) and \((\{L_j\}_{j \in J}, \{\lambda_{j_1,j_2}\}_{j_1 \leq j_2})\) be direct systems in one of the four categories that we had considered in Proposition 76.1. A **homomorphism between the direct systems** is a family \( \{f_i: K_i \to L_{\varphi(i)}\}_{i \in I} \) of homomorphisms that has the property that for any \( i_1 \leq i_2 \) the following diagram commutes:

\[
\begin{array}{ccc}
K_{i_2} & \xrightarrow{f_{i_2}} & L_{\varphi(i_2)} \\
\uparrow_{\chi_{i_1,i_2}} & & \uparrow_{\lambda_{\varphi(i_1),\varphi(i_2)}} \\
K_{i_1} & \xrightarrow{f_{i_1}} & L_{\varphi(i_1)}
\end{array}
\]

4. The maps \( K_i \xrightarrow{j_i} L_{\varphi(i)} \to \lim_{j \in J} L_j \) induce, by the universal property of a direct limit, a map

\[
\lim_{i \in I} K_i \to \lim_{j \in J} L_j
\]

which is uniquely determined by the property that for any \( i \in I \) the following diagram commutes

\[
\begin{array}{ccc}
K_i & \xrightarrow{f_i} & L_{\varphi(i)} \\
\downarrow & & \downarrow \\
\lim_{i \in I} K_i & \xrightarrow{\lim f_i} & \lim_{j \in J} L_j
\end{array}
\]
Lemma 76.4. Let \( \{ f_i : K_i \to L_{\varphi(i)} \}_{i \in I} \) be a homomorphism between two direct systems \( \{ (K_i)_{i \in I}, \{ \iota_{ij} \}_{i \leq j} \} \) and \( \{ (L_j)_{j \in J}, \{ \lambda_{ji} \}_{j \leq i} \} \) in one of the four categories that we had considered in Proposition 76.1. Suppose the following two conditions are satisfied:

1. the morphism \( \varphi : I \to J \) is cofinal, and
2. for each \( i \in I \) the map \( f_i : K_i \to L_{\varphi(i)} \) is an isomorphism.

Then the induced map

\[
\lim_{i \in I} K_i \to \lim_{j \in J} L_j
\]

is an isomorphism.

**Sketch of proof.** Let \( j \in J \). Since \( \varphi : I \to J \) is cofinal we can pick \( i \in I \) with \( f(i) \geq j \).

We define

\[
g_j : L_j \to \lim_{i \in I} K_i
\]

\[
x \mapsto [f_i^{-1}(\lambda_{j,f(i)}(x))].
\]

It is straightforward to verify that this map does not depend on the choice of \( i \). Using this observation it is elementary to verify that for any \( j_1 \leq j_2 \) the following diagram commutes:

\[
\begin{array}{ccc}
L_{j_2} & \xrightarrow{g_{j_2}} & \lim_{i \in I} K_i \\
\lambda_{j_1,j_2} \downarrow & & \downarrow \\
L_{j_1} & \xrightarrow{g_{j_1}} & \lim_{i \in I} K_i
\end{array}
\]

But by the universal property of the direct limit this implies that we get an induced

\[
\lim_{j \in J} L_j \to \lim_{i \in I} K_i.
\]

We leave it to the reader to verify that this map is an inverse to the map under consideration.  

\[\square\]

76.2. **Inverse limits of inverse systems.** We recall the following definition from page 745.

**Definition.** Let \((I, \leq)\) be a directed set and let \(C\) be a category. An inverse system in the category \(C\) over \(I\) is a family of objects \(\{X_i\}_{i \in I}\) in \(C\), together with a family of morphisms \(\{f_{ji} : X_j \to X_i\}\) for all \(i, j \in I\) with \(i \leq j\) such that the following two conditions are satisfied:

1. \(f_{ii} = \text{id}_{X_i}\) for all \(i \in I\),
2. \(f_{kj} \circ f_{ji} = f_{ki}\) for all \(i, j, k \in I\) with \(i \leq j \leq k\).

**Example.** Let \(C\) be a category and let

\[\ldots \xrightarrow{g_4} X_4 \xrightarrow{g_3} X_3 \xrightarrow{g_2} X_2 \xrightarrow{g_1} X_1\]

\[\text{So in an inverse system, given } i \leq j \text{ we have a morphism } X_j \to X_i, \text{ whereas in a direct system we had a morphism } X_i \to X_j.\]
be a sequence of morphisms in the category \( C \). For \( i \in \mathbb{N} \) we set \( f_{ii} = \text{id} \) and for \( i \leq j \) we set 
\[ f_{ji} = g_i \circ \cdots \circ g_{j-1} : X_j \to X_i. \]
It is clear that \( \{X_i\}_{i \in I}, \{f_{ji}\}_{i \leq j} \) is an inverse system over the directed set \( (\mathbb{N}, \leq) \). It is also clear that any inverse system over \( (\mathbb{N}, \leq) \) arises that way. By a slight abuse of notation we refer to such a sequence \( \{X_i\}_{i \in \mathbb{N}}, \{g_i : X_{i+1} \to X_i\}_{i \in \mathbb{N}} \) also as an inverse system.

Using the convention from the previous example we can now reformulate in our context the original definition of an inverse limit from page 745.

**Definition.** Let \( \{X_i\}_{i \in \mathbb{N}}, \{g_i : X_{i+1} \to X_i\}_{i \in \mathbb{N}} \) be an inverse system in a category \( C \). An inverse limit of the inverse system is an object \( \lim_{\leftarrow} X_i \) in \( C \) together with morphisms \( h_i : \lim_{\leftarrow} X_i \to X_i, i \in I, \) in the category \( C \) such that the following two conditions are satisfied:

1. For all \( i \in \mathbb{N} \) we have \( g_i \circ h_{i+1} = h_i : \lim_{\leftarrow} X_i \to X_i, \) i.e. for all \( i \in \mathbb{N} \) the following diagram commutes

\[
\begin{array}{ccc}
\lim_{\leftarrow} X_i & \xrightarrow{h_i} & X_i \\
\downarrow & & \downarrow g_i \\
X_{i+1} & \xrightarrow{h_{i+1}} & X_i
\end{array}
\]

2. If we are given another object \( Y \) and morphisms \( h'_i : Y \to X_i, i \in \mathbb{N}, \) that satisfy (1), then there exists a unique morphism \( F : Y \to \lim_{\leftarrow} X_i \) such that for all \( i \in \mathbb{N} \) the following diagram commutes

\[
\begin{array}{ccc}
Y & \xrightarrow{F} & \lim_{\leftarrow} X_i \\
\downarrow h'_i & & \downarrow g_i \\
& \xrightarrow{h_i} & X_i
\end{array}
\]

Throughout the remainder of this course we will only be interested in inverse systems over the directed set \( (\mathbb{N}, \leq) \). In the following proposition we give an explicit description of inverse limits for this special case. The proposition can be viewed as a slight variation on Proposition 25.15.

**Proposition 76.5.** Let \( \{X_i\}_{i \in \mathbb{N}}, \{g_i : X_{i+1} \to X_i\}_{i \in \mathbb{N}} \) be an inverse system over one of the following categories:

1. the category of abelian groups,
2. the category of \( R \)-modules, where \( R \) is a commutative ring,
3. the category of chain complexes,
4. the category of cochain complexes.

Then
\[
\lim_{\leftarrow} X_i := \{(x_i)_{i \in \mathbb{N}} \in \prod_{i \in \mathbb{N}} X_i \mid g_i(x_{i+1}) = x_i \text{ for all } i \in \mathbb{N}\}
\]
with the obvious projection maps \( \lim_{\leftarrow} X_i \to X_i \) is a direct limit.

**Proof.** This proposition is implicitly proved on page 750. 

**Remark.** Proposition 76.5 can be summarized as saying that, under the hypothesis of the proposition, we have

\[
\lim_{\leftarrow} X_i = \text{all infinite sequences } (x_1, x_2, x_3, \ldots) \text{ of the form } x_3 \in X_3 \\
\downarrow \quad \downarrow g_2 \\
x_2 \in X_2 \\
\downarrow \quad \downarrow g_1 \\
x_1 \in X_1.
\]

**Example.** For each \( i \in \mathbb{N} \) we define \( X_i := \mathbb{Z}^i \) and we denote by

\[
g_i: \mathbb{Z}^{i+1} \to \mathbb{Z}^i \\
(x_1, \ldots, x_{i+1}) \mapsto (x_1, \ldots, x_i)
\]

the projection map. Then \( (\{\mathbb{Z}^i\}_{i \in \mathbb{N}}, \{g_i\}_{i \in \mathbb{N}}) \) forms an inverse system in the category of abelian groups. As we had already pointed out on page 751, using the description of the inverse limit provided in Proposition 76.5 one can show fairly easily that

\[
\lim_{\leftarrow} \mathbb{Z}^i = \{(x_1, x_2, x_3, \ldots) | x_j \in \mathbb{Z}\} \simeq \mathbb{Z}^\mathbb{N}.
\]

We conclude this section with the following analogue of Lemma 25.2.

**Lemma 76.6.** Let \( f_n: X_n \to X_{n+1} \) be a sequence of morphisms in any category. Suppose there exists an \( N \in \mathbb{N} \) such that all \( f_n \) for \( n \geq N \) are isomorphisms. Then \( \lim_{\leftarrow} X_n \) exists and the natural map \( \lim_{\leftarrow} X_n \to X_N \) is an isomorphism.

**Proof.** We leave it to the reader to prove this elementary lemma. 

76.3. **Cohomology groups and inverse limits.** In Propositions 25.7 and 47.4 we saw that in favorable situations the fundamental group and the homology groups of a union of topological spaces are the direct limit of the corresponding fundamental groups and homology groups. In this section we will try to extend these results to cohomology groups. The results will not only be useful for computing cohomology groups, but they will also play an essential role in many proofs later on. For example the proof that de Rham cohomology is isomorphic to singular cohomology with real coefficients will build on the somewhat technical results of this section.

We recall that Proposition 47.4 was a consequence of the following two lemmas. The first lemma is of topological nature.

**Lemma 47.5.** Let \( X \) be a topological space and let \( X_1 \subset X_2 \subset X_3 \subset \ldots \) be a sequence of subsets such that every compact subset of \( X \) is already contained in one of the \( X_i \). Then the chain complexes \( C_*(X_i), i \in \mathbb{N} \) together with the inclusion induced chain maps \( C_*(X_i) \to C_*(X_j) \) for \( i \leq j \) form a direct system of chain complexes. Furthermore the
inclusion induced maps \( C_*(X_i) \to C_*(X) \) induce an isomorphism

\[
\lim C_*(X_i) \xrightarrow{\cong} C_*(X)
\]

of chain complexes.

The second lemma is purely algebraic.

**Lemma 47.6.** Let \( \{C_i\}_{i \in \mathbb{N}}, \{g_i : C_i \to C_{i+1}\}_{i \in \mathbb{N}} \) be a direct system of chain complexes. Then for each \( n \in \mathbb{N}_0 \) we obtain an induced direct system \( \{H_n(C_i)\}_{i \in \mathbb{N}}, \{g_i^* : H_n(C_i) \to H_n(C_{i+1})\}_{i \in \mathbb{N}} \) of abelian groups. Furthermore, given any \( n \in \mathbb{N}_0 \) the maps \( H_n(C_i) \to H_n(\lim C_i) \) induce an isomorphism

\[
\lim H_n(C_i) \xrightarrow{\cong} H_n(\lim C_i).
\]

Let \( \{C_i\}_{i \in \mathbb{N}}, \{g_i : C_i \to C_{i+1}\}_{i \in \mathbb{N}} \) be a direct system of chain complexes. The last lemma can be summarized as follows: for every \( j \in \mathbb{N} \) and any \( n \in \mathbb{N}_0 \) we have the following diagram

\[
\begin{array}{ccc}
H_n(C_{j+1}) & \xrightarrow{g_{j+1}} & H_n(C_j) \\
\downarrow g_j & & \downarrow g_j \\
\lim H_n(C_i) & \xrightarrow{\cong} & H_n(\lim C_i)
\end{array}
\]

Now we turn to cohomology groups. Let \( G \) be an abelian group. Whereas homology is a covariant functor, cohomology is a contravariant functor. This implies that from the above direct system of chain complexes we obtain for each \( n \in \mathbb{N}_0 \) an inverse system \( \{H^n(C_i; G)\}_{i \in \mathbb{N}}, \{g_i^* : H^n(C_i) \to H^n(C_{i+1}; G)\}_{i \in \mathbb{N}} \) of abelian groups. Furthermore the maps \( C_i \to \lim C_i \) induce maps \( H^n(\lim C_i; G) \to H^n(C_i; G) \). Put differently, for any \( j \in \mathbb{N} \) we are in the following situation

\[
\begin{array}{ccc}
H^n(\lim C_i; G) & \xrightarrow{g_j^*} & H^n(C_j; G) \\
\downarrow & & \downarrow
\end{array}
\]

where the dotted arrow exists by the definition of the inverse limit of the groups \( H^n(C_i; G) \). The question is whether the dotted arrow is in fact an isomorphism, put differently, the following question arises.

**Question 76.7.** Let \( \{C_i\}_{i \in \mathbb{N}}, \{g_i : C_i \to C_{i+1}\}_{i \in \mathbb{N}} \) be a direct system of chain complexes. Is the above map

\[
H^n(\lim C_i; \mathbb{Z}) \to \lim H^n(C_i; \mathbb{Z})
\]

always an isomorphism?
It turns out that this is not necessarily the case. To formulate the relationship between the two sides of the above question it is useful to rewrite the inverse limit from Proposition 76.5. More precisely, given an inverse system \(\{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}}\) of abelian groups we consider the map

\[
\mu : \prod_{i \in \mathbb{N}} D_i \to \prod_{i \in \mathbb{N}} D_i
\]

\[
(x_i)_{i \in \mathbb{N}} \mapsto (x_i - g_i(x_{i+1}))_{i \in \mathbb{N}}.
\]

Proposition 76.5 can be reformulated as saying that

\[
\lim_{\leftarrow} D_i = \ker(\mu).
\]

This leads us to the following definition.

**Definition.** Let \(\{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}}\) be an inverse system of abelian groups. Using the above notation we define

\[
\lim^1 D_i := \text{coker}(\mu).
\]

**Example.** We consider the inverse system

\[
D_* : \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \ldots.
\]

In Exercise 76.2 we will see that \(\lim D_* = 0\) and \(\lim^1 D_* = 0\). Furthermore, we also consider the inverse system

\[
E_* : \ldots \xrightarrow{5} \mathbb{Z} \xrightarrow{4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \ldots.
\]

In Exercise 76.2 we will see that \(\lim^1 E_* \neq 0\). Furthermore in Exercise 76.3 we will see that this inverse system arises “in nature”, i.e. we will see that there exists a nested sequence of topological spaces \(X_i\) such that for each \(i \in \mathbb{N}\) we have \(H^1(X_i; \mathbb{Z}) \cong \mathbb{Z}\) and such that for each \(i \in \mathbb{N}\) the map \(H^1(X_{i+1}; \mathbb{Z}) \to H^1(X_i; \mathbb{Z})\) is given by multiplication by \(i + 1\).

We cannot proceed without introducing the following somewhat technical definition.

**Definition.** We say an inverse system of abelian groups \(\{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}}\) satisfies the Mittag-Leffler condition if given any \(i \in \mathbb{N}\) there exists an \(n \geq i\) such that for all \(s \geq n\) we have

\[
\text{im}(g_i \circ \cdots \circ g_{s-1} : D_s \to D_i) = \text{im}(g_i \circ \cdots \circ g_{n-1} : D_n \to D_i).
\]

\[\cdots D_{s+2} \xrightarrow{g_{s+1}} D_{s+1} \xrightarrow{g_s} D_s \xrightarrow{g_{s-1}} D_{s-1} \xrightarrow{g_{s-2}} \ldots, \quad D_{i+1} \xrightarrow{g_i} D_i \xrightarrow{g_{i-1}} \ldots\]

**Figure 1132**

\[\text{same images}\]

\[1106\] If \(R\) is a commutative ring and if \(\{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}}\) is an inverse system of \(R\)-modules, then \(\lim \ D_i\) is also an \(R\)-module in an obvious way.
Example. It is straightforward to verify that the above inverse system \( D_* \) satisfies the Mittag-Leffler condition whereas the above inverse system \( E_* \) does not satisfy the Mittag-Leffler condition.

In many situations one can ignore the precise definition of the Mittag-Leffler condition and instead one can appeal to the following lemma which in fact follows immediately from the definitions.

**Lemma 76.8.** Let \( \{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}} \) be an inverse system of abelian groups. If there exists an \( m \in \mathbb{N} \) such that for all \( i \in \mathbb{N} \) the map \( g_i : D_{i+1} \to D_i \) is an epimorphism, then the inverse system satisfies the Mittag-Leffler condition.

Our main interest in the Mittag-Leffler condition arises from the fact that if a direct system satisfies this condition, then the pesky \( \lim^1 \)-limit vanishes.

**Lemma 76.9.** Let \( \{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}} \) be an inverse system of abelian groups. If this inverse system satisfies the Mittag-Leffler condition, then

\[
\lim^1 D_i = 0.
\]

**Proof.** Let \( \{D_i\}_{i \in \mathbb{N}}, \{g_i : D_{i+1} \to D_i\}_{i \in \mathbb{N}} \) be an inverse system of abelian groups that satisfies the Mittag-Leffler condition. This means that given given any \( i \in \mathbb{N} \) there exists an \( n(i) \geq i \) such that for all \( s \geq n(i) \) we have

\[
\text{im}(g_i \circ \cdots \circ g_{s-1} : D_s \to D_i) = \text{im}(g_i \circ \cdots \circ g_{n(i)-1} : D_{n(i)} \to D_i).
\]

Without loss of generality we can assume that \( n(i) \) is monotonously increasing in \( i \). We have to show that the map

\[
\mu : \prod_{i \in \mathbb{N}} D_i \to \prod_{i \in \mathbb{N}} D_i
\]

\[
(x_i)_{i \in \mathbb{N}} \mapsto (x_i - g_i(x_{i+1}))_{i \in \mathbb{N}}
\]

is an epimorphism.

Given \( j \geq i \) we now write \( f_{ji} := g_i \circ \cdots \circ g_{j-1} : D_j \to D_i \). First we consider \( \{a_i\}_{i \in \mathbb{N}} \in \prod_{i \in \mathbb{N}} D_i \) with the property that for all \( i \in \mathbb{N} \) we have \( a_i \in \text{im}(f_{n(i),i} : D_{n(i)} \to D_i) \). To show that \( \{a_i\}_{i \in \mathbb{N}} \) lies in the image of \( \mu \) it suffices to prove the following claim.

**Claim.** There exist \( b_i \in \text{im}(f_{n(i),i} : D_{n(i)} \to D_i) \) with \( i \in \mathbb{N} \) such that for each \( i \) we have \( a_i = b_i - g_i(b_{i+1}) \).

We define the \( b_i \) inductively. We set \( b_0 = a_0 \). Suppose \( b_0, \ldots, b_k \) are already defined with the desired properties. By our hypothesis we have \( a_k \in \text{im}(f_{n(k),k}) \) and by our choice of \( b_k \) we have \( b_k \in \text{im}(f_{n(k),k}) \). By the Mittag-Leffler condition and since we arranged that \( n(k+1) \geq n(k) \) we have \( \text{im}(f_{n(k+1),k}) = \text{im}(f_{n(k),k}) \). Thus can we pick \( c \in D_{n(k+1)} \) with \( f_{n(k+1),k}(c) = a_k - b_k \). Now we put

\[
b_{k+1} = -f_{n(k+1),k+1}(c).
\]
Then
\[ b_k - g_{k+1}(b_{k+1}) = b_k + g_{k+1}(f_{n(k+1), k+1}(c)) = b_k + (g_{k+1} \circ f_{n(k+1), k+1})(c) = b_k + (a_k - b_k) = a_k. \]

We have thus shown that \( b_0, \ldots, b_{k+1} \) have the desired properties.

Now let \((b_i)_{i \in \mathbb{N}} \in \prod_{i \in \mathbb{N}} D_i\) be an arbitrary element. For each \( i \in \mathbb{N} \) we set
\[ c_i = b_i + \sum_{j=i+1}^{n(i)} f_{j,i}(b_j). \]

Claim. For each \( i \in \mathbb{N} \) we have \( b_i - (c_i - g_i(c_{i+1})) \in \text{im}(f_{n(i), i}) \).

Let \( i \in \mathbb{N} \). We have
\[
\begin{align*}
b_i - (c_i - g_i(c_{i+1})) &= b_i - b_i - \sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + g_i(b_{i+1} + \sum_{j=i+2}^{n(i+1)} f_{j,i+1}(b_j)) \\
&= - \sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + f_{i+1,i}(b_{i+1}) + \sum_{j=i+2}^{n(i+1)} f_{j,i}(b_j) - \sum_{j=n(i)+1}^{n(i+1)} f_{j,i}(b_j).
\end{align*}
\]

But by definition of \( n(i) \) we know that for each \( j \in \{n(i) + 1, \ldots, n(i + 1)\} \) we have \( f_{j,i}(b_j) \in \text{im}(f_{n(i), i}) \).

It follows from the claim and the above discussion that \((b_i - (c_i - g_i(c_{i+1})))_{i \in \mathbb{N}}\) lies in the image of \( \mu \). Evidently \((c_i - g_i(c_{i+1}))_{i \in \mathbb{N}}\) lies in the image of \( \mu \). Since \( \mu \) is a homomorphism we see that \((b_i)_{i \in \mathbb{N}}\) also lies in the image of \( \mu \).

We continue with the following definition.

**Definition.** Let \( R \) be a commutative ring and let \((X_i, f_i)_{i \in \mathbb{N}}\) and \((Y_i, g_i)_{i \in \mathbb{N}}\) be inverse systems of \( R \)-modules. A map of inverse systems from \((X_i, f_i)\) to \((Y_i, g_i)\) consists of a sequence of module homomorphisms \( u_i : X_i \to Y_i, i \in \mathbb{N} \) such that for each \( i \) we have \( g_i \circ u_i = u_{i-1} \circ f_i \).

**Remark.** A map \( u : (X_i, f_i) \to (Y_i, g_i) \) of inverse systems induces a map \( u_* : \lim X_i \to \lim Y_i \) and also a map \( u_* : \lim 1 X_i \to \lim 1 Y_i \) in the obvious way.

Now we can formulate the following proposition.

**Proposition 76.10.** Let \( \{\{C_i^k\}_{i \in \mathbb{N}}, \{f_i : C^k_{i+1} \to C^k_i\}_{i \in \mathbb{N}}\} \) be an inverse system of cochain complexes over \( \mathbb{N} \). If for each \( k \in \mathbb{N}_0 \) the inverse system of cochain groups \( \{C_i^k\}_{i \in \mathbb{N}} \) satisfies the Mittag-Leffler condition, then there exists a natural short exact sequence of the form
\[
0 \to \lim_{i \to \infty} H^{n-1}(C_i^*) \to H^n \left( \lim_{i \to \infty} C_i^* \right) \to \lim_{i \to \infty} H^n(C_i^*) \to 0
\]
where the right-hand map is the obvious map. If \( R \) is a commutative ring and if the \( C_i^* \) are cochain complexes of \( R \)-modules, then the maps in the short exact sequence are natural \( R \)-module homomorphisms.

---

\[1107\] Whatever obvious means.
Lemma 76.11. Given any short exact sequence
\[ 0 \to (X_i, f_i) \overset{u_i}{\to} (Y_i, g_i) \overset{v_i}{\to} (Z_i, h_i) \to 0 \]
of inverse systems of abelian groups there exists a natural exact sequence
\[ 0 \to \lim_{\leftarrow} X_i \overset{u}{\to} \lim_{\leftarrow} Y_i \overset{v}{\to} \lim_{\leftarrow} Z_i \overset{\delta}{\to} \lim_{\leftarrow} 1 X_i \overset{u}{\to} \lim_{\leftarrow} 1 Y_i \overset{v}{\to} \lim_{\leftarrow} 1 Z_i \to 0. \]

If \( R \) is a commutative ring and if all cochain complexes and all maps are in the category of \( R \)-modules, then the maps in short exact sequence are natural \( R \)-module homomorphisms.

Proof. We consider the following commutative diagram
\[
\begin{array}{ccccccccc}
0 & \to & \prod_{i \in \mathbb{N}} X_i & \overset{u}{\to} & \prod_{i \in \mathbb{N}} Y_i & \overset{v}{\to} & \prod_{i \in \mathbb{N}} Z_i & \to & 0 \\
& & \downarrow{\mu} & & \downarrow{\mu} & & \downarrow{\mu} & & \\
0 & \to & \prod_{i \in \mathbb{N}} X_i & \overset{u}{\to} & \prod_{i \in \mathbb{N}} Y_i & \overset{v}{\to} & \prod_{i \in \mathbb{N}} Z_i & \to & 0.
\end{array}
\]
The horizontal sequences are evidently exact. We can view the rows as chain complexes. The desired natural exact sequence now follows from the snake lemma that we proved in Exercise 43.9.

Now we can provide the proof of Proposition 76.10.

Proof of Proposition 76.10. Let \( \{ C^*_i \}_{i \in \mathbb{N}}, \{ f_i \}_{i \in \mathbb{N}} \) be an inverse system of cochain complexes such that for each \( k \in \mathbb{N}_0 \) the inverse system of cochain groups \( \{ C^k_i \}_{i \in \mathbb{N}} \) satisfies the Mittag-Leer condition. In the following, given \( m \in \mathbb{N}_0 \) and \( i \in \mathbb{N} \), we denote by \( B^m_i = \text{im}(C^{m-1}_i \to C^m_i) \) the image of the \((m-1)\)-st coboundary map and we denote by \( Z^m_i = \ker(C^m_i \to C^{m+1}_i) \) the kernel of the \( m \)-th coboundary map. These give rise to the following two short exact sequences of inverse systems
\[
\begin{align*}
(i) & \quad 0 \to B^m_i \to Z^m_i \to H^m(C_i) \to 0 \\
(ii) & \quad 0 \to Z^m_i \to C^m_i \to B^{m+1}_i \to 0.
\end{align*}
\]
Let \( m \in \mathbb{N}_0 \). By our hypothesis the inverse systems \( \{ C^*_i \}_{i \in \mathbb{N}} \) satisfy the Mittag-Leer condition. It is straightforward to see that then the inverse system \( \{ B^m_i \}_{i \in \mathbb{N}} \) also satisfies the Mittag-Leer condition. It follows from Lemma 76.9 that
\[
\lim_{\leftarrow} 1 B^{m+1}_i = 0 \quad \text{and} \quad \lim_{\leftarrow} 1 C^m_i = 0.
\]

As so often it requires a few moments of pondering to figure out what “natural” is actually supposed to mean.

Here it takes a little effort to figure out what the “obvious” map actually is supposed to be. By definition an inverse limit of cochain complexes comes with cochain maps \( \lim_{\leftarrow} C^*_i \to C^*_i \). Since cohomology of cochain complexes is covariant in cochain maps we get induced maps \( H^n(\lim_{\leftarrow} C_i) \to H^n(C^*_i) \) which then, by definition of the inverse limit, give rise to a map \( H^n(\lim_{\leftarrow} C_i) \to \lim_{\leftarrow} H^n(C^*_i) \).
(Here and throughout the proof all limits are taken over \( i \in \mathbb{N} \)) Using this data we obtain from Lemma \[76.11\] applied to the two short exact sequences (i) and (ii) of inverse systems above, the following two exact sequences

\[
0 \rightarrow \lim B^m_i \rightarrow \lim Z^m_i \rightarrow \lim H^m(C_i) \xrightarrow{\delta} \lim^1 B^m_i \rightarrow \lim^1 Z^m_i \rightarrow \lim^1 H^m(C_i) \rightarrow 0
\]

and

\[
0 \rightarrow \lim Z^m_i \rightarrow \lim C^m_i \rightarrow \lim B^{m+1}_i \xrightarrow{\delta} \lim^1 Z^m_i \rightarrow \lim^1 C^m_i \rightarrow \lim^1 B^{m+1}_i \rightarrow 0
\]

From these sequence we deduce that the maps

(i) \( \lim^1 Z^m_i \rightarrow \lim^1 H^m(C_i) \)

and

(ii) \( \lim Z^m_i \rightarrow Z^m(\lim C_i) := \ker(\lim C^m_i \rightarrow \lim B^{m+1}_i) \)

are isomorphisms and that the following sequences are exact

(i') \( 0 \rightarrow \lim B^m_i \rightarrow \lim Z^m_i \rightarrow \lim H^m(C_i) \rightarrow 0 \)

and

(ii') \( 0 \rightarrow B^m(\lim C_i) \rightarrow \lim B^m_i \rightarrow \lim^1 Z^{m-1}_i \rightarrow 0 \).

From (ii') and the isomorphism (ii) we obtain the inclusions

\[
B^m(\lim C_i) \subset \lim B^m_i \subset \lim Z^m_i = Z^m(\lim C_i)
\]

which gives rise to the short exact sequence

\[
0 \rightarrow \frac{\lim B^m_i}{B^m(\lim C_i)} \rightarrow \frac{Z^m(\lim C_i)}{B^m(\lim C_i)} \rightarrow \frac{\lim Z^m_i}{\lim B^m_i} \rightarrow 0.
\]

Here we use that a filtration \( P \subset Q \subset R \) of three abelian groups induces a short exact sequence

\[
0 \rightarrow Q/P \rightarrow R/P \rightarrow R/Q \rightarrow 0.
\]
(3) \( X \) is a CW-complex and each \( X_i \) is a subcomplex. Then for any \( n \in \mathbb{N}_0 \) and any abelian group \( R \) there exists a natural short exact sequence

\[
0 \rightarrow \lim_{i \in \mathbb{N}}^1 H^{n-1}(X_i; R) \rightarrow H^n(X; R) \rightarrow \lim_{i \in \mathbb{N}} H^n(X_i; R) \rightarrow 0
\]

where the right-hand map is induced by the restriction maps \( H^n(X; R) \rightarrow H^n(X_i; R) \). If \( R \) is a commutative ring, then all maps are \( R \)-module homomorphisms.

**Remark.** In many situations the term \( \lim_{i \in \mathbb{N}}^1 H^{n-1}(X_i; R) \) will be zero. But it can be non-zero and one should view the proposition as a warning that in general it is not true that “limits commute with everything”.

**Proof.** It follows easily from the Finiteness Theorem \[36.14\] and Lemma \[25.8\] we only have to prove the proposition under the hypothesis (1). Therefore suppose that we are given a topological space \( X \) and subspaces \( X_1 \subset X_2 \subset X_3 \subset \ldots \) with \( X = \bigcup_{i \in \mathbb{N}} X_i \) and such that the following condition holds:

(1) every compact subset of \( X \) is contained in one of the \( X_i \).

Furthermore let \( R \) be a commutative ring.

For \( i \in \mathbb{N} \) we now consider the cochain complex \( D^*_i := \text{Hom}(C_*(X_i), R) \) and for \( i \in \mathbb{N} \) we denote by \( f_i : D^*_{i+1} \rightarrow D^*_i \) the map that is induced by the inclusion \( X_i \rightarrow X_{i+1} \).

**Claim.** For every choice of \( k \in \mathbb{N} \) the inverse system of cochain groups that is given by \( \{D^k_i\}_{i \in \mathbb{N}}, \{f_i : D^k_{i+1} \rightarrow D^k_i\}_{i \in \mathbb{N}} \) satisfies the Mittag-Leffler condition.

Let \( k \in \mathbb{N}_0 \). By Lemma \[76.8\] it suffices to show that for every \( i \in \mathbb{N} \) the map

\[
D^k_{i+1} = \text{Hom}(C_n(X_{i+1}); R) \xrightarrow{f_i} \text{Hom}(C_n(X_i); R) = D^k_i
\]

is an epimorphism. Since \( X_i \subset X_{i+1} \) we know that the set of singular chains in \( X_i \) is a subset of the set of singular chains in \( X_{i+1} \). It follows from the discussion on page \[1816\] that the map \( \text{Hom}(C_n(X_{i+1}); R) \rightarrow \text{Hom}(C_n(X_i); R) \) is indeed an epimorphism. \( \square \)

Let \( n \in \mathbb{N}_0 \). From Proposition \[76.10\] we obtain the short exact sequence

\[
0 \rightarrow \lim_{i \in \mathbb{N}}^1 H^{n-1}(D^*_i) \rightarrow H^n(D^*_i) \rightarrow \lim_{i \in \mathbb{N}} H^n(D^*_i) \rightarrow 0
\]

of \( R \)-modules. Let \( i \in \mathbb{N} \). We make the following two observations:

(1) By definition we have \( H^k(D^*_i) = H^k(X_i; R) \) for every \( k \in \mathbb{N}_0 \).

(2) We have natural isomorphisms

\[
\lim_{i \in \mathbb{N}} D^*_i \xrightarrow{\text{def.}} \lim_{i \in \mathbb{N}} \text{Hom}(C_*(X_i); R) \xrightarrow{\text{def.}} \text{Hom}(\lim_{i \in \mathbb{N}} C_*(X_i), R) \xrightarrow{\text{def.}} \text{Hom}(C_*(X), R).
\]

by definition of the \( D_i \)

by Lemma \[73.3\]

by Lemma \[47.3\] and hypothesis (1)

Combining all of the above we obtain our desired short exact sequence

\[
0 \rightarrow \lim_{i \in \mathbb{N}}^1 H^{n-1}(X_i; R) \rightarrow H^n(X; R) \rightarrow \lim_{i \in \mathbb{N}} H^n(X_i; R) \rightarrow 0.
\]

We provide a few examples for the above proposition.
Examples.

(1) As in Lemma 47.7 we consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider

\[ X := (\mathbb{R} \cup S^2 \times \mathbb{Z}) / \sim \]

where given \( i \in \mathbb{Z} \) we identify \( i \in \mathbb{R} \) with \( ((0,0,-1), i) \in S^2 \times \mathbb{Z} \). (See Figure 1133 on the left.) Furthermore, given \( k \in \mathbb{N} \) we consider the open subset

\[ X_k := (\{ -k - \frac{1}{2}, k + \frac{1}{2} \} \cup S^2 \times \{-k, \ldots, k\}) / \sim . \]

We leave it to the reader to verify that we can make the identifications

\[ H^n(X_k) = \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{2k+1}, & \text{if } n = 2, \\ 0, & \text{else.} \end{cases} \]

such that for each \( k \in \mathbb{N} \) the inclusion maps \( X_k \to X_{k+1} \) induce the identity map on \( \mathbb{Z} = H^0(X_{k+1}) \to H^0(X_k) = \mathbb{Z} \) and such that the inclusions induce the map

\[ \mathbb{Z}^{2k+3} = H^2(X_{k+1}) \to H^2(X_k) = \mathbb{Z}^{2k+1} \]

\[ (a_1, \ldots, a_{2k+3}) \mapsto (a_2, \ldots, a_{2k+2}) \]

It follows from Lemma 76.8 and the above calculations that for each \( n \in \mathbb{N}_0 \) the direct system of cohomology groups \( \{H^n(X_k)\}_{k \in \mathbb{N}} \) satisfies the Mittag-Leffler condition. We obtain that

\[ H^n(X) = \lim_{\leftarrow} H^n(X_k) = \lim_{\leftarrow} \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^{2k+1}, & \text{if } n = 2, \\ 0, & \text{else.} \end{cases} \]

Proposition 76.12 and Lemma 76.9 see page 1890

Here we recall that \( \mathbb{Z}^\mathbb{N} = \{(x_1, x_2, \ldots) \mid x_i \in \mathbb{Z}\} \). Note that in Lemma 47.7 we saw that \( H_2(X) \cong \mathbb{Z}^\mathbb{N} \). In this case we see that \( H_2(X) \neq H^2(X) \) since the former group is countable whereas the latter group is uncountable.1112

(2) We consider again the surface \( \Sigma_\infty \) of infinite genus that we had already encountered on page 740 and in Lemma 48.4. (See also Figure 1133 on the right.) Using a variation on example (1) and the proof of Lemma 25.11 one can show that

\[ H^n(\Sigma_\infty) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z}^\mathbb{N}, & \text{if } n = 1, \\ 0, & \text{if } n \geq 2. \end{cases} \]

We leave the task of providing full details to the valiant reader.

We conclude this chapter with the following variation on Proposition 76.12. It can be viewed as the cohomological analogue of Lemma 48.1 (3).

\footnote{One possible approach to showing these statements is to use the Mayer–Vietoris Theorem 74.15 for Cohomology Groups.}

\footnote{Of course we could have obtained the same observation from the Universal Coefficient Theorem 75.13 for Cohomology Groups.}
Proposition 76.13. Let $X$ be a CW-complex and let $n \in \mathbb{N}$. For every $k > n$ and every abelian group $G$ the inclusion $i: X^k \to X$ induces an isomorphism
\[ i^*: H^n(X; G) \to H^n(X^k; G). \]

Remark. We will give a very different proof of this proposition in Proposition ??.

Proof. By Proposition 76.12 there exists a natural short exact sequence
\[ 0 \to \lim_{j \in \mathbb{N}} H^{n-1}(X_j; G) \xrightarrow{\tau} H^n(X; G) \to \lim_{j \in \mathbb{N}} H^n(X_j; G) \to 0 \]
where the right-hand map is induced by the restriction maps $H^n(X; G) \to H^n(X_i; G)$. It follows immediately from Lemmas 76.6 and Lemma 76.8 that is suffices to prove the following claim.

Claim. For any $j \geq k > n$ the inclusion induced map $H^n(X^j; G) \to H^n(X^k; G)$ is an isomorphism.

It follows from Lemma 48.1 the Universal Coefficient Theorem 75.13 for Cohomology Groups that for every $m \geq n$ we have $H^n(X^{m+1}, X^m; G) = 0$. Using the long exact sequence in cohomology of the pairs $(X^{m+1}, X^m), (X^{m+2}, X^m), \ldots$ one can now easily show that for any $j \geq k > n$ the inclusion induced map $H^n(X^j; G) \to H^n(X^k; G)$ is an isomorphism. ■

Exercises for Chapter 76

Exercise 76.1. Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i \in I}, \{f_{ij}: X_i \to X_j\}_{i \leq j})$ be a direct system of abelian groups over $I$.

(a) Let $a_j \in X_j$ and let $a_k \in X_k$. Prove the following statement: if the images of $a_j$ and $a_k$ in $\lim X_i$ agree, then there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.

(b) Show that if all maps $f_{ij}: X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \lim X_i$ is an isomorphism.

Exercise 76.2. We consider the inverse systems
\[ D_*: \ldots \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to 0 \]
and
\[ E_*: \ldots \to \mathbb{Z} \xrightarrow{4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to 0. \]

(a) Show that $\lim D_* = 0,$
(b) show that $\lim \overset{\leftarrow}{D_*} = 0$,
(c) show that $\lim \overset{\leftarrow}{E_*} \neq 0$.

**Exercise 76.3.** Show that there exists a nested sequence of topological spaces $X_i$ such that for each $i \in \mathbb{N}$ we have $H^1(X_i; \mathbb{Z}) \cong \mathbb{Z}$ and such that for each $i \in \mathbb{N}$ the map $H^1(X_{i+1}; \mathbb{Z}) \to H^1(X_i; \mathbb{Z})$ is given by multiplication by $i + 1$.

Put differently, we want topological spaces and maps such that the inverse system

$$H^1(X_4) \to H^1(X_3) \to H^1(X_2) \to H^1(X_1)$$

is isomorphic to the inverse system $E_*$ from Exercise 76.2.
77. Cohomology with compact support and bounded cohomology

77.1. The definition of cohomology with compact support and basic properties.
In this section we introduce “cohomology with compact support”, which is an interesting
variation on the usual cohomology groups. Later on it will be a key tool in proving the
Poincaré Duality Theorem, which is the most important result regarding homology and
cohomology groups of topological manifolds.

We start out with the following definition.

Definition. Let $X$ be a topological space and let $G$ be an abelian group.

1. Given a subset $A \subseteq X$ we say that a cochain $\varphi \in C^i(X; G) = \text{Hom}(C_i(X), G)$
   vanishes on $A$ if $\varphi(c) = 0$ for all singular $i$-simplices $c: \Delta^i \to X$ in $A$, i.e. if $\varphi$
   vanishes on the image of $C_i(A) \to C_i(X)$.

2. Given a subset $B \subseteq X$ we say that a cochain vanishes outside $B$ if the cochain
   vanishes on $X \setminus B$.

3. We say that a cochain $\varphi \in C^i(X; G) = \text{Hom}(C_i(X), G)$ has compact support if there
   exists a compact set $K \subseteq X$ such that $\varphi$ vanishes outside of $K$. We denote the set
   of all $i$-cochains with compact support by $C^i_c(X; G)$.

\[ \varphi \text{ is a cohomology class that vanishes outside of a compact subset } K \]

Remark. Let $X$ be a topological space and let $G$ be an abelian group.

1. Let $A$ be a subset of $X$ and let $n \in \mathbb{N}_0$. The inclusion $(X, \emptyset) \to (X, X \setminus A)$ induces
   an epimorphism $C_n(X) \to C_n(X, X \setminus A)$ and thus it also induces a monomorphism
   $C^n(X, X \setminus A; G) \to C^n(X; G)$. We have

\[ \text{im}(C^n(X, X \setminus A; G) \to C^n(X; G)) = \text{all maps of the form } C_n(X) \to \overline{C_n(X, X \setminus A)} \to G \]

\[ = \{ \varphi \in \text{Hom}(C_n(X), G) | \varphi \text{ vanishes on } X \setminus A \} \]

\[ = \{ \varphi \in \text{Hom}(C_n(X), G) | \varphi \text{ vanishes outside } A \} \].

2. On page 1824 we had made the identification

\[ C^0(X; G) = \{ \text{maps from } X \text{ to } G \}. \]

With this identification we can now write

\[ C^0_c(X; G) = \{ \text{maps } f: X \to G | \text{ there exists a compact subset } K \}
\text{ with } f|_{X \setminus K} \equiv 0 \}. \]
The first question that arises is whether cochains with compact support give again rise to cohomology groups. The following lemma shows in particular that this is indeed the case.

**Lemma 77.1.** Let $X$ be a topological space and let $G$ be an abelian group.

1. A cochain $\phi \in C^i(X; G)$ has compact support if and only if there exists a compact subset $K$ such that $\phi$ lies in the image of the map $C^i(X, X \setminus K; G) \to C^i(X; G)$.
2. The set of cochains that have compact support form a subcomplex $(C^*_c(X; G); \delta)$ of the cochain complex $(C^*(X; G); \delta)$.
3. For any compact subset $K$ of $X$ the map $i_K : C^*_c(X \setminus K; G) \to C^*_c(X; G)$ from (1) is a cochain map.

**Proof.** Let $X$ be a topological space and let $G$ be an abelian group. The first statement of the lemma follows immediately from the above remark.

We turn to the proof of the second statement.

**Claim.** Let $A, B \subset X$ be two subsets.

(a) If $\phi \in C^i(X; G)$ vanishes outside $A$ and if $\psi \in C^i(X; G)$ vanishes outside $B$, then for any $r, s \in \mathbb{Z}$ the linear combination $r\phi + s\psi \in C^i(X; G)$ vanishes outside the union $A \cup B$.

(b) If $\phi \in C^i(X; G)$ vanishes outside $A$, then $\delta \phi \in C^{i+1}(X; G)$ also vanishes outside $A$.

The first statement is obvious. Now we turn to the proof of the second statement. Suppose we are given a cochain $\phi \in C^i(X; G)$ that vanishes outside $A$. We need to show that $\delta \phi \in C^{i+1}(X; G)$ also vanishes outside $A$. So let $c$ be a singular $(i+1)$-simplex in $X \setminus A$. Then

$$
(\delta \phi)(c) = \phi(\partial c) = \sum_{j=0}^{n} (-1)^j \cdot \phi(c \circ i^n_j) = 0.
$$

The image of each $c \circ i^n_j$ also lies in $X \setminus A$ and $\phi$ vanishes outside $A$.

The second statement is now an immediate consequence of the above claim and the observation that given two compact subsets $K, L \subset X$ the union $K \cup L$ is again a compact subset of $X$.

Finally the last statement is an immediate consequence of the definitions.

**Definition.** Let $X$ be a topological space and let $G$ be an abelian group. We define the $n$-th cohomology group with compact support $H^*_c(X; G)$ to be the cohomology of the cochain complex $(C^*_c(X; G); \delta)$. 

\[\Phi: \mathbb{R} \to \mathbb{R}\] has compact support

**Figure 1135**
Remark.

(1) If $X$ is a compact topological space, then every cochain has compact support, in particular the cohomology groups with compact support are just the usual cohomology groups.

(2) Let $X$ be a path-connected topological space. Then

$$H^n_c(X; G) := \frac{\ker(\delta_n : C^n_c(X; G) \to C^{n+1}_c(X; G))}{\text{im}(\delta_{n-1} : C^{n-1}_c(X; G) \to C^n_c(X; G))},$$

Example. We consider the topological space $X = \mathbb{R}$. As on page 1827 we consider the singular 0-cochain

$$\varphi_0 : C_0(X) \to \mathbb{Z}$$

that is uniquely determined by the property that for any singular 0-simplex $x \in X$ we have

$$x \mapsto \begin{cases} 0, & \text{if } x \leq 0, \\ 1, & \text{if } x > 0. \end{cases}$$

It is clear that this 0-cochain does not have compact support. As on page 1827 we also consider the coboundary $\gamma_0 := \delta \varphi_0 \in C^1(\mathbb{R}; \mathbb{Z})$. Since $\gamma_0$ is a coboundary, it is in particular a cocycle. By definition $\gamma_0 = \delta \varphi_0$ is uniquely determined by the property that for any singular 1-simplex $d : \Delta^1 \to \mathbb{R}$ we have

$$(\delta \varphi_0)(d) = \varphi_0(\partial d) = \varphi_0(d(0, 1)) - \varphi_0(d(1, 0)).$$

We claim that $\gamma_0 = \delta \varphi_0$ has compact support. In fact, we will now see that we can take $K$ to be the compact set given by $K := \{0\}$. Indeed, if $d : \Delta^1 \to \mathbb{R} \setminus \{0\}$ is a singular 1-simplex, then it follows from the fact that $\Delta^1$ is homeomorphic to the interval $[0, 1]$ and the intermediate value theorem that either $d(0, 1) = 0$ or $d(1, 0) = 0$, both lie to the left of 0 or both lie to the right of 0. In both cases we obtain from the above formula that $\gamma_0(d) = (\delta \varphi_0)(d) = 0$. Thus we see that $\gamma_0 = \delta \varphi_0$ defines an element in $H^1_c(\mathbb{R})$.

Now we claim that $[\gamma_0] \in H^1_c(\mathbb{R}; \mathbb{Z})$ is non-zero. This means that we have to show that there is no $\psi \in C^0_c(\mathbb{R}; \mathbb{Z})$ with $\delta \psi = \gamma_0$. So let $\psi \in C^0_c(\mathbb{R}; \mathbb{Z})$. Following the discussion on page 1901 we view $\psi$ as a function $\mathbb{R} \to \mathbb{Z}$ which is zero outside of a compact subset of $\mathbb{R}$. This implies that there exists a $C > 0$ such that $\psi(x) = 0$ for all $x \not\in [-C, C]$. Now we consider the singular 1-chain $d : \Delta^1 \to \mathbb{R}$ that is given by $d(1 - t, t) = -2C + 4C \cdot t$ with $t \in [0, 1]$. (See Figure 1136 for an illustration.) Then we have

$$\gamma_0(d) = (\delta \varphi_0)(d) = \varphi_0(d(0, 1)) - \varphi_0(d(1, 0)) = \varphi_0(-2C) - \varphi_0(2C) = 0 - 1 = -1$$

but on the other hand we have

$$(\delta \psi)(d) = \psi(d(0, 1)) - \psi(d(1, 0)) = \psi(-2C) - \psi(2C) = 0 - 0 = 0.$$

Since $\psi$ is zero outside $[-C, C]$
This concludes the proof that \( \gamma_0 = \delta \varphi_0 \) is non-trivial in \( H^1_c(\mathbb{R}; \mathbb{Z}) \).

\[
\begin{align*}
\text{graph of } \psi : \mathbb{R} \to \mathbb{Z} \\
\end{align*}
\]

\textbf{Figure 1136}

The following lemma is an almost immediate consequence of Lemma \([77.1](1)\).

\textbf{Lemma 77.2.} Let \( X \) be a topological space and let \( G \) be an abelian group. Given any \( \varphi \in H^i_c(X; G) \) there exists a compact subset \( K \) such that \( \varphi \) lies in the image of the map \( H^i(X, X \setminus K; G) \to H^i_c(X; G) \).

\textbf{Proof.} Let \([\varphi] \in H^i_c(X; G)\). By Lemma \([77.1](1)\) there exists a compact subset \( K \) such that \( \varphi \) lies in the image of the map \( C^i(X, X \setminus K; G) \to C^i_c(X; G) \). Since \( C^\ast(X, X \setminus K; G) \) can be viewed as a subcomplex of \( C^\ast_c(X; G) \) we see that \( \varphi \) is also a cocycle in \( C^\ast(X, X \setminus K; G) \), in particular \( \varphi \) lies in the image of the map \( H^i(X, X \setminus K; G) \to H^i_c(X; G) \). \hfill \blacksquare

We conclude this section with the discussion of induced maps on cohomology groups with compact support.

Let \( f : X \to Y \) be a map between topological spaces and let \( G \) be an abelian group. We saw that \( f \) induces a map \( f^* : C^\ast(Y; G) \to C^\ast(X; G) \). But in general this map does not restrict to a map \( f^* : C^\ast_c(Y; G) \to C^\ast_c(X; G) \). For example, if \( f : \mathbb{R} \to \{ P \} \) is the map that sends every point in \( \mathbb{R} \) to the point \( P \) and if \( \varphi : C_0(\{ P \}) \to \mathbb{Z} \) is the map given by \( P \mapsto 1 \), then \( f^* \varphi : C_0(\mathbb{R}) \to \mathbb{Z} \) corresponds to the map that takes the value 1 on all of \( \mathbb{R} \), in particular it does not have compact support.

A moment of reflection shows that if we want to get induced maps on cohomology groups with compact support, we have to restrict ourselves to “proper maps”:

\textit{Definition.} A map \( f : X \to Y \) between topological spaces is called \textit{proper} if the preimage of every compact subset of \( Y \) is a compact subset of \( X \). 

\textbf{Examples.}

1. In Figure \([1137]\) we show graphs of functions \( \mathbb{R} \to \mathbb{R} \), some of the functions are proper and some are not proper.

\textbf{Figure 1137}

2. A map from a non-compact topological space to a compact topological space \textit{cannot} be proper. In particular inclusion maps are not necessarily proper, for example the inclusion \( i : (0, 1] \to [-2, 2] \) is not proper.
(3) Every homeomorphism is proper.
(4) Every map from a compact topological space to a Hausdorff space is proper. This statement follows immediately from Lemma 2.17 (1) and (2).

Remark. On page 342 we already introduced the adjective “proper” in a somewhat different way. Namely, given a compact topological manifold $N$ and given any topological manifold $M$ we defined on page 342 a map $\varphi: N \to M$ to be proper if $\varphi^{-1}(\partial M) = \partial N$. The good news is that, as we pointed out in the last of the above examples, any such map is also proper in the above sense. Unfortunately the converse does not hold. For example the inclusion map $f: N = [-1, 1] \to \mathbb{R} = M$ is proper in the above sense, but not in the sense of the definition on page 342. Since both definitions of “proper” are commonly used in the literature we will have to live with this very unfortunate ambiguity. We will strive to make sure that, given a map between two topological manifolds, it is clear which of the two definitions of “proper” we are working with.

Lemma 77.3. Let $G$ be an abelian group.

(1) Let $f: X \to Y$ be a map between topological spaces. If $f$ is a proper map, then the cochain map $f^*: C^*(Y; G) \to C^*(X; G)$ restricts to a cochain map

$$f^*: C^*_c(Y; G) \to C^*_c(X; G).$$

In particular $f^*$ induces a well-defined homomorphism

$$H^*_c(Y; G) \to H^*_c(X; G).$$

(2) The maps $X \mapsto H^*_c(X; G)$ and $f \mapsto f^*$ define a contravariant functor from the category $\text{TopPropMap}$ where objects are topological spaces and morphisms are proper maps to the category $\text{AbGr}$ of abelian groups.

(3) Homeomorphic topological spaces have isomorphic cohomology groups with compact support.

Proof. Let $f: X \to Y$ be a proper map and let $G$ be an abelian group. Let $\varphi: C_n(Y) \to G$ be a cocycle with compact support. We pick a compact subset $K$ such that $\varphi$ vanishes on $Y \setminus K$. Then $f^*\varphi$ vanishes on $f^{-1}(Y \setminus K) = X \setminus f^{-1}(K)$, i.e. $f^*\varphi$ vanishes outside of the subset $f^{-1}(K)$. But $f^{-1}(K)$ is compact since $f$ is proper. This concludes the proof of the first statement. The second and third statement are obvious.

77.2. Cohomology with compact support and direct limits. Given a topological space $X$ we consider the set $\mathcal{K}(X)$ of all compact subsets of $X$. The set $\mathcal{K}(X)$ together with the relation “$\subset$” defined by inclusion is a directed set since the union of two compact subsets is again compact. Furthermore, given any two compact subsets $K \subset L$ and any $i \in \mathbb{N}_0$ we get induced maps

$$H^i(X, X \setminus K; G) \to H^i(X, X \setminus L; G).$$

---

The most confusing part about cohomology is to figure out which way the maps go. In this case $K \subset L$ implies $X \setminus L \subset X \setminus K$ which means that we have a map of pairs $(X, X \setminus L) \to (X, X \setminus K)$ given by inclusion, which by the discussion on page 1915 implies that we do indeed get an induced map $H^i(X, X \setminus K; G) \to H^i(X, X \setminus L; G)$.
Since cohomology groups are contravariantly functorial we see that these cohomology
groups form a direct system over the directed set \((\mathcal{K}(X), \subseteq)\) and we can form the direct
limit
\[
\lim_{\longleftarrow \mathcal{K} \in \mathcal{K}(X)} H^i(X, X \setminus K; G).
\]

Recall that given any compact subset \(K \subset X\) we have by Lemma \[77.1\] (3) a natural map
\(i_K*: H^i(X, X \setminus K; G) \to H^i_c(X; G)\). Given compact subsets \(L \subset M\) these maps give rise to
the following commutative diagram:

\[\begin{array}{ccc}
H^i(X, X \setminus M; G) & \xrightarrow{i_M*} & H^i(X, X \setminus K; G) \\
\psi_M \downarrow & & \lim_{\longleftarrow K \in \mathcal{K}(X)} \uparrow \psi_L & \xrightarrow{\exists \Phi} & H^i_c(X; G).
\end{array}\]

Since this diagram commutes for all compact subsets \(L \subset M\) we get the induced dotted
arrow by the universal property of the direct limit.

The following proposition says that the above dotted arrow is in fact an isomorphism. This gives in particular an often convenient reformulation of the concept of cohomology
with compact support.

**Proposition 77.4.** Let \(X\) be a topological space and let \(G\) be an abelian group. Then the
above map
\[
\Phi: \lim_{\longleftarrow K \in \mathcal{K}(X)} H^i(X, X \setminus K; G) \to H^i_c(X; G)
\]
defines a natural isomorphism.\[1114\]

**Proof.** We need to show that the map \(\Phi\) in the proposition is a bijection.

We first show that \(\Phi\) is surjective. So let \(\varphi \in H^i_c(X; G)\). By Lemma \[77.2\] there exists
a compact subset \(L\) such that \(\varphi\) lies in the image of \(H^i(X, X \setminus L; G) \to H^i(X; G)\). It
follows immediately from the above commutative diagram that \(\varphi\) also lies in the image of
\(\Phi: \lim_{\longleftarrow K \in \mathcal{K}(X)} H^i(X, X \setminus K; G) \to H^i_c(X; G)\).

Now we show that the map \(\Phi\) is injective. In the subsequent discussion, given a sub-
set \(A\) of \(X\), we identify the image of the monomorphism \(C^i(X, A; G) \to C^i(X; G)\) with
\(C^i(X, A; G)\), i.e. we view each \(C^i(X, A; G)\) as a subgroup of \(C^i(X)\).

Now suppose we are given an element \(c\) in the kernel of \(\Phi\). By Lemma \[76.2\] (1) we know
that the element \(c\) lies in the image of some \(H^i(X, X \setminus L; G)\). We pick a representative
\(\varphi \in C^i(X, X \setminus L; G)\). Since \(\varphi\) represents the zero class in \(H^i_c(X; G)\) there exists a compactly
supported \((i - 1)\)-cocycle \(\eta\) with \(\delta \eta = \varphi\). We pick a compact subset \(M\) of \(X\) such that \(\eta\)

\[1114\]Here the term “natural” refers to the fact that both sides define a contravariant functor from the
category where objects are topological spaces and morphisms are proper maps to the category of abelian
groups.
vanishes on $X \setminus M$, i.e. according to the above notation and the discussion on page 1901 we have $\eta \in C^{i-1}(X, X \setminus M)$. We consider the following commutative diagram:

\[
\begin{array}{ccc}
C^{i-1}(X; G) & \xrightarrow{\eta \mapsto \varphi} & C^{i}(X; G) \\
\downarrow & & \downarrow \\
C^{i-1}(X, X \setminus (M \cup L); G) & \xrightarrow{\delta} & C^{i}(X, X \setminus (M \cup L); G) \\
\downarrow & & \downarrow \\
C^{i-1}(X, X \setminus M; G) & \xrightarrow{\delta} & C^{i}(X, X \setminus L; G)
\end{array}
\]

It follows immediately from the diagram that in $C^{i}(X, X \setminus (M \cup L); G)$ we have $\delta \eta = \varphi$, which shows that $[\varphi]$ represents the zero class in $H^{i}(X, X \setminus (M \cup L); G)$. It follows from Lemma 76.2 (2) or alternatively from the commutative diagram from page 1906 that $\psi_{L}([\varphi]) = c$ is zero.

**Example.** Now we turn to a key example, namely for each $k \in \mathbb{N}_{0}$ we consider the cohomology with compact support $H^{k}_{c}(\mathbb{R}^{n}; \mathbb{Z})$ of $\mathbb{R}^{n}$. We have

\[
\begin{align*}
H^{k}_{c}(\mathbb{R}^{n}; \mathbb{Z}) &= \lim_{\substack{\rightarrow \kappa \in K(\mathbb{R}^{n}) \downarrow}} H^{k}(\mathbb{R}^{n}, \mathbb{R}^{n} \setminus K; \mathbb{Z}) \\
&= \lim_{\rightarrow} H^{k}(\mathbb{R}^{n}, \mathbb{R}^{n} \setminus B_{1}(0); \mathbb{Z}) \\
&\cong H^{k}(\mathbb{R}^{n}, \mathbb{R}^{n} \setminus B_{0}(0); \mathbb{Z}) \\
&\cong \begin{cases} 
\mathbb{Z}, & \text{if } k = n, \\
0, & \text{otherwise.} 
\end{cases}
\end{align*}
\]

by Lemma 43.18 (2) all vertical maps in the direct system are isomorphisms, hence we can apply Lemma 76.2.

We draw three interesting conclusions from this example:

1. This example shows that cohomology with compact support can be used to show that the topological spaces $\mathbb{R}^{n}$ and $\mathbb{R}^{m}$ are not homeomorphic for $n \neq m$.
2. The example also shows that cohomology with compact support, in contrast to basically all other invariants we have studied so far, is not the same for homotopy equivalent topological spaces.
3. Finally we consider the case $n = 1$ in more detail. We consider again the singular 1-cochain $\gamma_{0} := \delta \varphi_{0}$ from page 1827. On pages 1835 and 1903 we saw that $\gamma_{0}$ defines an element in each $H^{1}(\mathbb{R}, \mathbb{R} \setminus [-s, s]; \mathbb{Z})$ and an element in $H^{1}_{c}(\mathbb{R}; \mathbb{Z})$. Furthermore on page 1835 we saw that for each $s \in \mathbb{N}$ the class $[\gamma_{0}] \in H^{1}(\mathbb{R}, \mathbb{R} \setminus [-s, s]; \mathbb{Z})$ is a generator. The above argument now implies that $[\gamma_{0}] \in H^{1}_{c}(\mathbb{R}; \mathbb{Z})$ is also a generator.

**Example.** In Exercise 77.2 we will use cohomology with compact support to show that the topological spaces

\[X := B_{1}(0) \cup \text{x-axis} \quad \text{and} \quad Y := B_{1}(0) \cup \text{x-axis} \cup \text{y-axis}\]
that are illustrated in Figure \textbf{1138} are not homeomorphic.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1138}
\caption{Figure 1138}
\end{figure}

In the previous examples cohomology with compact support turns out to be "bigger" than ordinary cohomology. On the other hand, Let us once again consider the topological space

\[ X := (\mathbb{R} \cup S^2 \times \mathbb{Z})/\sim \]

where given \( i \in \mathbb{Z} \) we identify \( i \in \mathbb{Z} \subset \mathbb{R} \) with \( ((0,0,-1),i) \in S^2 \times \mathbb{Z} \). (See Figure \textbf{1139} for an illustration.) In Exercise \textbf{77.6} that

\[ H^2_c(X) \cong \mathbb{Z}^{(N)} \]

in particular \( H^2_c(X) \) is countable, whereas on page \textbf{1898} we saw that \( H^2(X) \cong \mathbb{Z}^N \) is uncountable.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1139}
\caption{Figure 1139}
\end{figure}

In the following we will see the rather surprising fact that under fairly mild hypotheses an inclusion \( U \to V \) of topological spaces induces for every \( n \in \mathbb{N}_0 \) a map \( H^n_c(U) \to H^n_c(V) \) which "goes the same way".

We recall that given a topological space \( X \) we denote by \( \mathcal{K}(X) \) the set of all compact subsets of \( X \). Suppose \( U \) is an open subset of a topological space \( V \) and suppose that \( V \) is Hausdorff. We denote by \( i_{UV} = i_* : H^n_c(U) \to H^n_c(V) \) the composition of the following maps

\begin{proposition}\textbf{77.4}
\end{proposition}

\[ H^n_c(U) \xrightarrow{\lim_{K \in \mathcal{K}(U)}} \lim_{K \in \mathcal{K}(U)} H^n(U,U \setminus K) \xleftarrow{\cong} \lim_{K \in \mathcal{K}(V)} H^n(V,V \setminus K) \xrightarrow{\lim_{K \in \mathcal{K}(V)}} H^n(V,V \setminus K) = H^n_c(V). \]

by the Excision Theorem 43.20 (2) the map \( H^n_c(V,V \setminus K) \to H^n_c(U,U \setminus K) \) is an isomorphism for every compact subset \( K \) of \( U \) given by Lemma \textbf{76.3} (1) and the fact that by Lemma \textbf{2.40} we have \( \mathcal{K}(U) \subset \mathcal{K}(V) \).

Note that, confusingly, the induced map on cohomology with compact support "goes the same direction" as the inclusion map \( i : U \to V \).
Lemma 77.5. Given a topological space \( X \) that is Hausdorff the above construction defines for each \( n \in \mathbb{N}_0 \) a covariant functor
\[
\text{category where the objects are open subsets of } X \text{ and where the morphisms are inclusions } \rightarrow \text{category of abelian groups.}
\]

Proof (*). Let \( X \) be a topological space that is Hausdorff and let \( U \subset V \subset W \) be open subsets. Let \( n \in \mathbb{N}_0 \). We have to show that \( i_{UW*} = i_{VW*} \circ i_{UV*} : H^n_c(U) \rightarrow H^n_c(W) \). We consider the following diagram:

It follows from the explicit description of the direct limits in Proposition 76.1 and the uniqueness statement in the universal property of the direct limits that the two smaller triangles and the rectangle commute. Hence the diagram commutes and we get the desired statement. \( \blacksquare \)

We conclude this section with the following proposition.

Proposition 77.6. Let \( X \) be a topological space that is Hausdorff. Let \( X_i, i \in \mathbb{N} \) be a sequence of subsets such that the following holds:
1. the sequence is nested, i.e. for each \( i \in \mathbb{N} \) we have \( X_i \subset X_{i+1} \),
2. each \( X_i \) is open in \( X \),
3. and \( X = \bigcup X_i \).

Then for any \( n \in \mathbb{N}_0 \) the above inclusion induced maps \( H^n_c(X_i) \rightarrow H^n_c(X) \) induce an isomorphism
\[
\lim_{i \in \mathbb{N}} H^n_c(X_i) \cong H^n_c(X).
\]

by Lemma 77.5 this is a direct system with the above inclusion induced maps

Proof (*). Using Proposition 77.4 we see that we have to show that the map
\[
\Phi: \lim_{i \in \mathbb{N}} \lim_{K \in \mathcal{K}(X_i)} H^n(X_i, X_i \setminus K) \rightarrow \lim_{K \in \mathcal{K}(X)} H^n(X, X \setminus K)
\]
is an isomorphism. We need to show that \( \Phi \) is injective and surjective. The key to the proof of these two statements are the following observations:

(a) it follows from (1) and (2), together with Lemma 2.41, that every compact subset \( L \) of \( X \) is already contained in some \( X_i \),

(b) it follows from the Excision Theorem 43.20 (2) that for each compact subset \( L \subset X \) we get an inclusion induced isomorphism \( H^n(X, X \setminus L) \to H^n(X_i, X_i \setminus L) \).

Now we prove that \( \Phi \) is surjective, the proof that \( \Phi \) is injective is fairly similar and we leave that part of the proof to the reader.

So let \( c \) be an element of the limit on the right-hand side. By Lemma 76.2 there exists a compact subset \( L \) of \( X \) and some \( \varphi \in H^n(X, X \setminus L) \) such that \( c \) is the image of \( \varphi \) under the map \( H^n(X, X \setminus L) \to \lim_{\to} H^n(X, X \setminus K) \). By (a) there exists an \( i \in \mathbb{N} \) with \( L \subset X_i \).

We consider the following commutative diagram

\[
\begin{array}{ccc}
\lim_{\to} H^n(X_i, X_i \setminus K) & \xrightarrow{\Phi} & \lim_{\to} H^n(X, X \setminus K) \\
\downarrow_{\beta} & & \downarrow_{\alpha} \\
H^n(X_i, X_i \setminus L) & \cong & H^n(X, X \setminus L).
\end{array}
\]

The bottom horizontal map is an isomorphism by (b). Since the diagram is commutative we now see that \( \Phi(\beta(\alpha(\varphi))) = c \).

77.3. **Bounded cohomology** (*). We had just seen that with a modest modification of the original definition of cohomology we obtain a new invariant which for non-compact topological spaces behaves quite differently from the usual cohomology groups.

In this section we will introduce another variation on cohomology, namely bounded cohomology. We will not make use of it later on, but it does play an important role in topology. A much more detail discussion of bounded cohomology is for example provided in [L610].

**Definition.** Let \( X \) be a topological space.

1. Let \( C \in \mathbb{R} \). We say that a cochain \( \rho \in C_n(X; \mathbb{R}) = \text{Hom}(C_n(X), \mathbb{R}) \) is **\( C \)-bounded** if for all singular \( n \)-simplices \( \sigma: \Delta^n \to X \) we have \( |\rho(\sigma)| \leq C \).
2. We say that a cochain \( \rho \in C_n(X; \mathbb{R}) = \text{Hom}(C_n(X), \mathbb{R}) \) is **bounded** if it is \( C \)-bounded for some \( C \in \mathbb{R} \).
3. Given \( i \in \mathbb{N}_0 \) we write

\[
C^n_b(X; \mathbb{R}) := \{ \text{all bounded cochains in } C^n(X; \mathbb{R}) \}.
\]

**Examples.**

1. Let \( X \) be a topological space. The 0-cochain that assigns to each point \( x \in X \) the same value \( c \in \mathbb{R} \) is bounded.
2. The singular 1-cochain \( \theta_\mathbb{R} \in C^1; \mathbb{R} \) defined on page 1825 is **not** bounded. Indeed, given \( n \in \mathbb{N} \) we denote by \( \mu_n: \Delta^1 \to S^1 \) the singular 1-simplex that is given by \( (1-t,t) \mapsto e^{2\pi i nt} \). It follows easily from the definition of \( \theta_\mathbb{R} \) that \( \theta_\mathbb{R}(\mu) = n \).
Lemma 77.7. Let $X$ be a topological space. The bounded cochains $C^*_b(X)$ form a subcomplex of the cochain complex $(C^*(X), \delta)$.

Proof. Suppose that $\rho \in C^n(X; \mathbb{R})$ is a cochain that is $C$-bounded. For any $\varphi: \Delta^{n+1} \to X$ we obtain that

$$|[\delta \rho](\varphi)| = |\rho(\partial \varphi)| = \left| \sum_{j=0}^{n+1} (-1)^j \cdot \rho(\varphi \circ i^{n+1}_j) \right| \leq \sum_{j=0}^{n+1} |\rho(\varphi \circ i^{n+1}_j)| \leq (n + 2) \cdot C.$$  

This shows that $\delta \rho$ is $C \cdot (n + 2)$-bounded, in particular it is bounded. This shows that bounded cochains $C^*_b(X)$ form a subcomplex of the cochain complex $(C^*(X), \delta)$.

This lemma leads us straight to the following definition.

Definition. Let $X$ be a topological space and let $n \in \mathbb{N}_0$. The $n$-th bounded cohomology group of $X$ is defined as

$$H^n_b(X; \mathbb{R}) := \ker(\delta_n: C^n_b(X; \mathbb{R}) \to C^{n+1}_b(X; \mathbb{R})) / \text{im}(\delta_{n-1}: C^n_b(X; \mathbb{R}) \to C^n_b(X; \mathbb{R})).$$

Examples.

(1) The proof of Proposition 73.11 can be used, without any changes, to show that 0-th bounded cohomology of a path-connected topological space agrees with 0-th cohomology with real coefficients.

(2) Every cochain on a topological space with finitely many points is bounded. Thus it follows from Lemma 73.12 that for a topological space $\{x_0\}$ consisting of a single point $x_0$ we have

$$H^n_b(\{x_0\}; \mathbb{R}) = H^n(\{x_0\}; \mathbb{R}) = \begin{cases} 0, & \text{if } n \geq 1, \\ \mathbb{R}, & \text{if } n = 0. \end{cases}$$

Proposition 77.8.

(1) Let $f: X \to Y$ be a map between topological spaces. The map $f^*: C^*(Y; \mathbb{R}) \to C^*(X; \mathbb{R})$ on singular cochains restricts to a cochain map $f^*: C^*_b(Y; \mathbb{R}) \to C^*_b(X; \mathbb{R})$. In particular the map $f^*$ induces a map

$$f^*: H^n_b(Y; \mathbb{R}) \to H^n_b(X; \mathbb{R}).$$

(2) For each $n \in \mathbb{N}_0$ the maps $X \mapsto H^n_b(X; \mathbb{R})$ and $f \mapsto f^*$ define a contravariant functor from the category of topological spaces to the category of real vector spaces.

(3) Homotopic maps induce the same maps on bounded cohomology.

(4) If $f: X \to Y$ is a homotopy equivalence, then the induced map

$$f^*: H^n_b(Y; \mathbb{R}) \xrightarrow{\cong} H^n_b(X; \mathbb{R})$$

is in fact an isomorphism.

Is this statement also true for topological spaces that are not path-connected?
Proof.

(1) It is obvious that the pullback of a bounded cohomology class is again bounded. The
first statement is an immediate consequence of this observation.

(2) This statement is obvious.

(3) Let \( f, g : X \to Y \) be two maps between topological spaces \( X \) and \( Y \). Furthermore
let \( F : X \times [0,1] \to Y \) be a homotopy between the maps \( f \) and \( g \). As on page 1102
we define

\[
P_n : C_n(X) \to C_{n+1}(Y)
\]

to be the map that is given by

\[
(\sigma : \Delta^n \to X) \mapsto \sum_{j=0}^{n} (-1)^j \cdot F \circ (\sigma \times \text{id}[0,1]) \circ [v_0, \ldots, v_j, w_j, \ldots, w_n].
\]

In the proof of Proposition 42.5 we saw that the maps \( P_n \) define a chain homotopy
between \( f^* \) and \( g^* \). It follows from this explicit description of \( P_n \) that for any cochain
\( \varphi \in C^{n+1}(Y; \mathbb{R}) \) that is \( C \)-bounded the chain \( P^* \varphi \in C^n(X; \mathbb{R}) \) is \( (n+1) \cdot C \)-bounded,
the map \( P^* : C^{n+1}(Y; \mathbb{R}) \to C^n(X; \mathbb{R}) \) restricts to a map \( C^{n+1}_0(Y; \mathbb{R}) \to C^n_0(X; \mathbb{R}) \).
As in the proof of Lemma 73.8 (3) one sees easily that the maps \( P^* \) form a cochain
homotopy between \( f^*, g^* : C^*_0(Y; \mathbb{R}) \to C^*_0(X; \mathbb{R}) \). The third statement now follows
from Lemma 73.5.

(4) This statement follows immediately from (2) and (3). \( \blacksquare \)

So far it seems like bounded cohomology might be quite similar to usual cohomology
with real coefficients. It turns out that this guess is dramatically misguided.

For example the following theorem was proved by Mikhail Gromov \cite{Grom83} p. 40, see also \cite{Iv87} Theorem 4.3.1116

**Theorem 77.9.** Let \( f : X \to Y \) be a map between two connected CW-complexes. If the
induced map \( f_* : \pi_1(X) \to \pi_1(Y) \) is an epimorphism of fundamental groups such that the
kernel \( \ker(f_* : \pi_1(X) \to \pi_1(Y)) \) is an amenable group, then for any \( n \in \mathbb{N}_0 \) the induced map

\[
f^* : H^n_0(Y; \mathbb{R}) \xrightarrow{\cong} H^n_0(X; \mathbb{R})
\]

is an isomorphism.

**Remark.** In the formulation of Theorem 77.9 we used the notion of an “amenable group”.
We will not give the definition of an “amenable group”, instead we refer to \cite{Pie84} or
\cite{CSC10}, Section 4 for the definition. What matters to us are the following two facts:

1. Groups that admit a finite index subgroup that is solvable are amenable, see \cite{Pie84}
   Propositions 13.3 and 13.4. In particular finite groups and solvable groups are
   amenable.

2. Groups that contain a free group on two generators are not amenable, see \cite{Pie84}
   Proposition 14.1.

\cite{Mikhail Gromov (1943) is a Russian-French mathematician who is easily one of the most influential
geometers alive. He won the Abel prize in 2009.}
Corollary 77.10. Let $X$ be a connected CW-complex such that $\pi_1(X)$ is amenable, e.g. such that $\pi_1(X)$ is solvable. Then $H^*_b(X; \mathbb{R}) = 0$ for any $n \geq 1$.

Example. If follows from Corollary 77.10 that the higher bounded cohomology groups of the $n$-tori $(S^1)^n$, the spheres $S^n$ and lens spaces all vanish. In particular this new invariant is also not useful in our attempt to answer Question 16.7.

Proof. We consider the map $f : X \to \{x_0\}$ that is given by sending every point in $X$ to the point $x_0$. Then for any $n \geq 1$ we have

$$H^n_b(X; \mathbb{R}) \xrightarrow{f^*} H^n_b(\{x_0\}; \mathbb{R}) = 0.$$

by Theorem 77.9 since see above example $\ker(f_*) = \pi_1(X)$ is amenable

We have thus proved the desired result.

The following vanishing result is in fact fairly easy to show, see e.g. [Frig17, Chapter 2].

Lemma 77.11. For any CW-complex $X$ we have $H^1_b(X; \mathbb{R}) = 0$.

On the other hand, if the fundamental group is not amenable, then we also see some totally unexpected behavior as is shown in the following proposition.

Proposition 77.12. Let $X$ be the wedge of two circles. Then $H^2_b(X; \mathbb{R})$ and $H^3_b(X; \mathbb{R})$ are vector spaces of uncountable dimension.

Proof. The statement regarding $H^2_b(X; \mathbb{R})$ is proved in [EF97]. An alternative fairly straightforward proof, using quasi-morphisms as introduced on page 600 is given in [Roll09, Corollary 2.3]. Furthermore the statement regarding $H^3_b(X; \mathbb{R})$ is proved in [So97, Theorem 3].

Somewhat shockingly the following question is still open:

Question 77.13. Let $X$ be the wedge of two circles. What are the bounded cohomology groups $H^k_b(X; \mathbb{R}) \neq 0$ for $k \geq 4$? Is any of the groups non-zero? Are all of them non-zero? Are all of them of uncountable dimension?

\[ \begin{align*}
\dim(H^1_b(X; \mathbb{R})) &= 0 \\
\dim(H^2_b(X; \mathbb{R})) &= \infty \\
\dim(H^3_b(X; \mathbb{R})) &= \infty \\
\dim(H^4_b(X; \mathbb{R})) &= ??? \\
\end{align*} \]

Figure 1140

Exercises for Chapter 77.
Exercise 77.1. We consider $X = \mathbb{R}$ and the singular $0$-cochain

$$\varphi_0 : C_0(X) \to \mathbb{Z}$$

that is uniquely determined by the property that for any singular $0$-simplex $x \in X = \mathbb{R}$ we have

$$x \mapsto \begin{cases} 1, & \text{if } x \leq 0, \\ 0, & \text{if } x > 0. \end{cases}$$

On page 1903 we saw that $\gamma_0 = \delta \varphi_0 : C_1(\mathbb{R}) \to \mathbb{Z}$ defines a class in $H^1_c(\mathbb{R}; \mathbb{Z})$. Prove, only using the definitions, that this class is non-zero.

Exercise 77.2. What is the cohomology with compact support of the topological spaces

$$X := \mathcal{B}_1(0) \cup x\text{-axis}$$

and

$$Y := \mathcal{B}_1(0) \cup x\text{-axis} \cup y\text{-axis}$$

that are illustrated in Figure 1138.

Exercise 77.3.

(a) Give an example of a path-connected topological space $X$ such that $H^1(X) = 0$ but such that $H^1_c(X) \cong \mathbb{Z}^{(n)}$. You do not have to justify why your example has the correct properties.

(b) Give an example of a path-connected topological space $X$ such that $H^2(X) = 0$ but such that $H^2_c(X) \cong \mathbb{Z}^3$. You do not have to justify why your example has the correct properties.

Exercise 77.4. Let $X$ be a topological space. We consider the set $K(X)$ of all compact subsets of $X$. The set $K(X)$ together with the relation "$\subset$" defined by inclusion is a directed set since the union of two compact subsets is again compact. Given any two compact subsets $K \subset L$ we get an induced map $H_n(X, X \setminus L; G) \to H_n(X, X \setminus K; G)$. As in Exercise 87.5 we define

$$\tilde{H}_n(X; \mathbb{Z}) := \lim_{\leftarrow} H_n(X, X \setminus K; \mathbb{Z}).$$

(a) Recall that on page 1903 we introduced cohomology group with compact support $H^\alpha_c(X; \mathbb{Z}) = H^\alpha_c(X; \mathbb{Z})$. Define a useful pairing $H^\alpha_c(X) \times \tilde{H}_n(X; \mathbb{Z}) \to \mathbb{Z}$.

*Remark.* You could make use of Exercise 25.21.

(b) Use (a) to show that $H^1_c(\mathbb{R}) \neq 0$.

Exercise 77.5. Let $M$ be a compact topological manifold. We write $\hat{M} = M \setminus \partial M$. The cohomology group $H^\alpha_c(\hat{M})$ is homeomorphic to some other cohomology group that might look more familiar. What is it? You do not have to justify your answer.

Exercise 77.6. Let us once again consider the topological space

$$X := (\mathbb{R} \cup (S^2 \times \mathbb{Z}))/\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{Z} \subset \mathbb{R}$ with $((0,0,-1), i) \in S^2 \times \mathbb{Z}$. On page 1898 we saw that $H^2(X) \cong \mathbb{Z}^N$. Show that $H^2_c(X) \cong \mathbb{Z}^{(N)}$.

Exercise 77.7. Show that for every path-connected topological space $X$ the boundary cohomology $H^1_b(X; \mathbb{R}) = 0$. 
78. De Rham cohomology of smooth manifolds

In this chapter we give a concise introduction to the de Rham cohomology groups of a smooth manifold. In particular we will prove several statements for de Rham cohomology which are reminiscent of properties that we had already proved for singular cohomology. In Chapter 79 we will explore the relationship between de Rham cohomology and singular cohomology.

78.1. Alternating forms and the wedge-product. An alternating $k$-form on a real vector space $V$ is a map

$$\omega: V^k \to \mathbb{R} \quad (v_1, \ldots, v_k) \mapsto \omega(v_1, \ldots, v_k)$$

with the following properties:

(i) $\omega$ is linear in each argument, i.e. for all $v, v' \in V$ and $\lambda \in \mathbb{R}$ we have

$$\omega(\ldots, v + v', \ldots) = \omega(\ldots, v, \ldots) + \omega(\ldots, v', \ldots)$$

$$\omega(\ldots, \lambda v, \ldots) = \lambda \cdot \omega(\ldots, v, \ldots),$$

(ii) swapping two arguments flips the signs, i.e. for any $v, v' \in V$ we have

$$\omega(\ldots, v, \ldots, v', \ldots) = -\omega(\ldots, v', \ldots, v, \ldots).$$

We denote the vector space of alternating $k$-forms on $V$ by $\wedge^k V^*$. A 0-form on $V$ is by definition a real number, i.e. we define $\wedge^0 V^* = \mathbb{R}$.

Example.

(1) An alternating 1-form is by definition simply a linear map $V \to \mathbb{R}$. In particular $\wedge^1 V^* = V^* := \text{Hom}(V, \mathbb{R})$ is the dual space of $V$.

(2) For $V = \mathbb{R}^n$ we denote by $dx_i$ the 1-form which is given by

$$dx_i(v_1, \ldots, v_n) = v_i.$$ 

Put differently, $dx_1, \ldots, dx_n$ is the basis of $(\mathbb{R}^n)^*$ that is dual to the standard basis $e_1, \ldots, e_n$ of $\mathbb{R}^n$.

(3) If $V = \mathbb{R}^n$, then for each $\lambda \in \mathbb{R}$ the map

$$\mathbb{R}^n \to \mathbb{R} \quad (v_1, \ldots, v_n) \mapsto \lambda \cdot \det(v_1 \ldots v_n)$$

is an alternating $n$-form. It follows easily from the uniqueness of the determinant, see e.g. [Lan93, Proposition XIII.4.6] that each alternating $n$-form on $\mathbb{R}^n$ is of this form, i.e. $\wedge^n (\mathbb{R}^n)^* \cong \mathbb{R}$.

Now we recall the wedge product of 1-forms. In the following let $V$ be an $n$-dimensional real vector space and let $\varphi_1, \ldots, \varphi_k \in V^*$ be 1-forms. We consider the map

$$\varphi_1 \wedge \cdots \wedge \varphi_k : V^k \to \mathbb{R} \quad (v_1, \ldots, v_k) \mapsto \det \begin{pmatrix} \varphi_1(v_1) & \cdots & \varphi_1(v_k) \\ \vdots & & \vdots \\ \varphi_k(v_1) & \cdots & \varphi_k(v_k) \end{pmatrix}.$$
One can easily verify that this is an alternating \( k \)-form. We refer to this alternating \( k \)-form as the wedge product of \( \varphi_1, \ldots, \varphi_k \).

Next let \( \varphi_1, \ldots, \varphi_n \) be a basis for \( V^* \) and let \( k \in \{0, \ldots, n\} \). It follows from [Lee02, Proposition 14.8] or [Lee14, Chapter 20.13] that the wedge products
\[
\varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} \quad \text{with} \quad i_1 < i_2 < \cdots < i_k
\]
form a basis of \( \wedge^k V^* \) and that \( \wedge^k V^* = 0 \) for \( k > \dim(V) \).

Now we can introduce the wedge product of general alternating forms. Let \( \omega \in \wedge^k V^* \) and \( \sigma \in \wedge^l V^* \). Then by the above we can write
\[
\omega = \sum_{i_1 < \cdots < i_k} \sum a_{i_1, \ldots, i_k} \cdot \varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k}
\]
and
\[
\sigma = \sum_{j_1 < \cdots < j_l} \sum b_{j_1, \ldots, j_l} \cdot \varphi_{j_1} \wedge \cdots \wedge \varphi_{j_l}.
\]

Finally we define
\[
\omega \wedge \sigma := \sum_{i_1 < \cdots < i_k} \sum_{j_1 < \cdots < j_l} a_{i_1, \ldots, i_k} b_{j_1, \ldots, j_l} \cdot \varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} \wedge \varphi_{j_1} \wedge \cdots \wedge \varphi_{j_l}.
\]

One can show easily that \( \omega \wedge \sigma \) is an alternating \((k + l)\)-form. The following lemma summarizes some of the key properties of the wedge product of alternating forms. The lemma is proved in [Lee02, Proposition 14.11], but it is also straightforward to deduce the statements of the lemma from the definitions.

**Lemma 78.1.** Let \( V \) be a real vector space.

1. For any \( \omega \in \wedge^k V^* \) and \( \sigma \in \wedge^l V^* \) we have
   \[
   \omega \wedge \sigma = (-1)^{kl} \cdot \sigma \wedge \omega.
   \]
2. The map
   \[
   \wedge^k V^* \times \wedge^l V^* \to \wedge^{k+l} V^*
   \]
   is bilinear and distributive.
3. For any \( \omega \in \wedge^k V^*, \sigma \in \wedge^l V^* \) and \( \tau \in \wedge^m V^* \) we have
   \[
   (\omega \wedge \sigma) \wedge \tau = \omega \wedge (\sigma \wedge \tau).
   \]

78.2. **The de Rham cohomology of a smooth manifold.** What are cohomology groups good for? The universal coefficient theorem [75.13] for cohomology group says that the cohomology groups do not contain more information than the homology groups. Furthermore cohomology groups have the “disadvantage” that the induced maps go the “wrong” direction which often leads to total confusion.

In this chapter we want to sketch one answer: the cohomology groups with \( \mathbb{R} \)-coefficients of a smooth manifold are isomorphic to the de Rham cohomology groups which are defined using differential forms.

Before we can show that such an isomorphism exists we first need to give the definition of de Rham cohomology groups and we need to state and prove some properties of de Rham cohomology groups.
Let $M$ be an $n$-dimensional smooth manifold.

(1) A \textit{differential $k$-form} on $M$ assigns to each point $P \in M$ an alternating $k$-form on the tangent space $T_P M$. Using charts one can introduce the notions of continuity and smoothness of differential $k$-forms. We refer to [Lee02, Chapter 14], [Tu11, Chapter 18.3] or [Frie16a] for details. It follows from the convention on page 1915 that differential 0-forms are precisely the same as smooth maps $M \to \mathbb{R}$.

(2) One of the key reasons for studying differential forms on smooth manifolds is that these are the right objects on an oriented smooth manifold to be integrated. More precisely, let $M$ be a compact oriented $k$-dimensional smooth manifold and let $\omega$ be a continuous differential $k$-form on $M$. We pick a finite atlas $\{\Phi_i : U_i \to V_i\}_{i=1, \ldots, m}$ for $M$ such that each $\Phi_i$ is orientation-preserving. By Theorem 6.57 there exists a partition of unity $f_1, \ldots, f_m$ subordinate to the open covering $M = U_1 \cup \cdots \cup U_m$. We set

$$\int_M \omega := \sum_{i=1}^m \int_{V_i} f(\Phi_i^{-1}(x)) \cdot \omega(D(\Phi_i^{-1})x(e_1), \ldots, D(\Phi_i^{-1})x(e_k)) \in \mathbb{R}.$$ 

We refer to [Lee02, Chapter 16] or to [Tu11, Chapter 22.3] for details of the definition and for a summary of the key properties. The integral has the following simple, but nonetheless essential property: if $M$ is a compact 0-dimensional smooth manifold, i.e. $M = \{P_1, \ldots, P_s\}$, where all points are given the positive orientation, then the integral of a differential 0-form, i.e. of a function $f : M \to \mathbb{R}$, is just given by the sum $f(P_1) + \cdots + f(P_s)$.

(3) Let $k \in \mathbb{N}_0$. We define the $k$-th de Rham group as the real vector space

$$C^k_{dR}(M) := \{\text{smooth differential $k$-forms on } M\}.$$ 

If $f : M \to N$ is a smooth map between smooth manifolds, then it follows from [Lee02, p. 360] that $f$ induces a homomorphism

$$f^* : C^k_{dR}(N) \to C^k_{dR}(M),$$

where $f^*$ sends a differential $k$-form $\omega$ which at a point $P \in M$ is given by

$$(T_P M)^k \to \mathbb{R},
(v_1, \ldots, v_k) \mapsto \omega(f_P)(D f_P(v_1), \ldots, D f_P(v_k))$$

\begin{itemize}
  \item [1117] Georges de Rham (1903-1990) was a Swiss mathematician. The subscript “dR” in our notation $C^k_{dR}(M)$ stands for de Rham. We use the subscript do distinguish it from the singular cochains $C^k(M; \mathbb{R})$.
  \item [1118] In most references, see e.g. [Lee02, BoT82, Frie16a] one writes $\Omega^k(M)$ for the set of all smooth differential $k$-forms on $M$. Since in a second we will view $C^k_{dR}(M) = \Omega^k(M)$ as the groups in a cochain complex we prefer the notation $C^k_{dR}(M)$.
  \item [1119] It is clear that $f^* \omega$ is a differential $k$-form on $M$, what one needs to show is that $f^* \omega$ is in fact a smooth differential $k$-form.
\end{itemize}
We refer to [Lee02, p. 363] for the definition of the differential
\[ d_k : C^k_{\text{dR}}(M) \to C^{k+1}_{\text{dR}}(M). \]

Often, when the subscript \( k \) is understood from the context, we just write \( d \) instead of \( d_k \). A smooth form \( \omega \) with \( d\omega = 0 \) is called closed. A smooth form \( \omega \) for which there exists a smooth form \( \mu \) with \( d\mu = \omega \) is called exact.

The following proposition summarizes some of the key properties of the integral of forms and of the differential.

**Proposition 78.2.**

1. Let \( f : M \to N \) be a diffeomorphism between compact oriented connected \( k \)-dimensional smooth manifolds and let \( \omega \) be a smooth differential \( k \)-form on \( N \). Then
   \[ \int_M f^* \omega = \epsilon \cdot \int_N \omega \]
   where \( \epsilon = \begin{cases} +1, & \text{if } f \text{ is orientation-preserving,} \\ -1, & \text{if } f \text{ is orientation-reversing.} \end{cases} \)

2. Let \( M \) be a compact oriented \( k \)-dimensional smooth manifold and let \( \omega \) be a smooth differential \( k \)-form on \( M \). If \( M = A \cup B \) where \( A \) and \( B \) are compact \( k \)-dimensional submanifolds such that \( A \cap B \) is a \((k-1)\)-dimensional submanifold, then
   \[ \int_M f^* \omega = \int_A f^* \omega + \int_B f^* \omega. \]

3. Let \( M \) be a smooth manifold. For every any \( k \in \mathbb{N}_0 \) the composition
   \[ d \circ d : C^k_{\text{dR}}(M) \to C^{k+2}_{\text{dR}}(M) \]
   is the zero map.

4. Let \( \omega \in C^0_{\text{dR}}(M) \) be a smooth differential 0-form, in other words, let \( \omega : M \to \mathbb{R} \) be a smooth map. In this case the differential \( d\omega \) equals the differential \( D\omega \) from Proposition 6.37. More precisely, given any \( P \in M \) and given any \( v \in T_P M \) we have \((d\omega(P))(v) = D\omega_P(v) \in \mathbb{R} = T_{\omega(P)} \mathbb{R}\).

5. Given any \( \mu \in C^k_{\text{dR}}(M) \) and given any \( \nu \in C^l_{\text{dR}}(M) \) we have
   \[ d(\mu \wedge \nu) = d\mu \wedge \nu + (-1)^k \cdot \mu \wedge d\nu. \]

6. Let \( f : M \to N \) be a smooth map between two smooth manifolds. Then for any smooth differential \( k \)-form \( \omega \in C^k_{\text{dR}}(N) \) on \( N \) we have
   \[ d(f^* \omega) = f^*(d\omega). \]

\[ ^{1120} \text{Here is a quick summary of the definition. Using a partition of unity and charts it suffices to define the differential for differential } k \text{-forms on an open subset } U \subset \mathbb{R}^n. \text{ We consider a differential } k \text{-form} \]
\[ \omega = \sum_{i_1 < \cdots < i_k} f_{i_1 \ldots i_k} \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_k} \]
where \( f_{i_1 \ldots i_k} \) are real-valued smooth functions on \( U \). The differential of \( \omega \) is then defined as the differential \((k+1)\)-form
\[ d\omega := \sum_{i_1 < \cdots < i_k} df_{i_1 \ldots i_k} \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_k}. \]
Proof. The first statement is [Lee02, Proposition 16.6]. The second statement follows fairly easily from the definitions and basic properties of the Lebesgue integral. We leave it to the reader to fill in the details. Finally the last four statements are proved in [Lee02, Theorem 14.24 and Proposition 14.26]. □

The next theorem is one of the key results on differential forms. We refer to [Lee02, Theorem 16.11] for a proof.

**Theorem 78.3. (Stokes’ Theorem)** If $M$ is a compact oriented $k$-dimensional smooth manifold with boundary $\partial M$ and if $\omega \in C^{k-1}_{dR}(M)$, then

$$\int_M d\omega = \int_{\partial M} \omega.$$  

![Figure 1141](image)

**Definition.** Let $M$ be a smooth manifold. As we had just pointed out in Proposition [78.2 (3)], the differentials $d_k: C^k_{dR}(M) \to C^{k+1}_{dR}(M)$ have the property that $d_{k+1} \circ d_k = 0$. Thus we obtain a cochain complex

$$0 \to C^0_{dR}(M) \xrightarrow{d_0} C^1_{dR}(M) \xrightarrow{d_1} C^2_{dR}(M) \xrightarrow{d_2} \cdots$$

in the sense of the discussion on page 1818. The $k$-th de Rham cohomology group of $M$ is defined as the cohomology of this cochain complex, i.e. it is defined as

$$H^k_{dR}(M) := \frac{\ker (d_k: C^k_{dR}(M) \to C^{k+1}_{dR}(M))}{\operatorname{im} (d_{k-1}: C^{k-1}_{dR}(M) \to C^k_{dR}(M))}.$$  

Note that $H^k_{dR}(M)$ is the quotient of a real vector space by a subspace, in particular $H^0_{dR}(M)$ is itself a real vector space.

The following proposition summarizes some basic properties of de Rham cohomology groups.

**Proposition 78.4.** Let $M$ be an $n$-dimensional smooth manifold. Then the following hold:

1. If $f: M \to N$ is a smooth map to another smooth manifold, then

$$f^*: H^k_{dR}(N) \to H^k_{dR}(M)$$

is a well-defined map.

2. If $M$ is connected, then the map

$$\mathbb{R} \to H^0_{dR}(M)$$

$$r \mapsto [\text{constant function } x \mapsto r]$$

is an isomorphism. We use this map to make the identification $H^0_{dR}(M) = \mathbb{R}$.

\[1121\] Here the right-hand side is understood to be zero if $\partial M = \emptyset$. 

---

78. DE RHAM COHOMOLOGY OF SMOOTH MANIFOLDS 1919
If \( f : M \to N \) is a smooth map between connected smooth manifolds, then the induced map \( f^* : H^0_{\text{dR}}(N) \to H^0_{\text{dR}}(M) \) is an isomorphism.

(4) \( H^k_{\text{dR}}(M) = 0 \) for \( k > n \).

(5) Suppose \( M \) consists of finitely many components \( M_1, \ldots, M_r \). Given \( j \in \{1, \ldots, r\} \) we denote by \( i_j : M_i \to M \) the inclusion maps. Then for each \( k \in \mathbb{N}_0 \) the map

\[
\bigoplus_{j=1}^{r} i_j^* : H^k_{\text{dR}}(M) \to \bigoplus_{j=1}^{r} H^k_{\text{dR}}(M_j)
\]

is an isomorphism.

(6) If \( M \) has finitely many components, then \( \dim_{\mathbb{R}}(H^0_{\text{dR}}(M)) \) equals the number of components of \( M \).

(7) If \( M \) is closed and oriented, then the map

\[
H^0_{\text{dR}}(M) \to \mathbb{R}
\]

\[
[\omega] \mapsto \int_M \omega
\]

is well-defined. If \( M \) is non-empty, then the map is an epimorphism.

(8) If \( M \) is closed orientable and non-empty, then \( H^n_{\text{dR}}(M) \neq 0 \).

**Sketch of proof.**

1. The first statement is an immediate consequence of Proposition 78.2 (6) together with Lemma 73.5 (1).
2. The second statement follows fairly easily from the definitions and elementary arguments.
3. The third statement follows immediately from the second statement.
4. The fourth statement is an immediate consequence of the fact that for any vector space \( V \) we have \( \wedge^k V^* = 0 \) for \( k > \dim(V) \), see page 1916.
5. The fifth statement follows easily from the definition.
6. The sixth statement is an immediate consequence of (2) and (5).
7. The seventh statement is a consequence of Stokes’ Theorem and a straightforward calculation.
8. Finally the last statement follows immediately from the seventh statement. ■

**Example.** If \( M = \{x\} \) is a smooth manifold consisting of a single point \( x \), then it follows immediately from Proposition 78.4 (2) and (4) that

\[
H^k_{\text{dR}}(\{x\}) = \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}
\]

Recall that we denote by \( \text{SmMfd} \) the category of smooth manifolds which is given by

\[
\text{Ob}(\text{SmMfd}) := \text{all smooth manifolds},
\]

\[
\text{Mor}(M,N) := \text{all smooth maps from } M \to N.
\]

It is straightforward to verify that for any \( k \in \mathbb{N}_0 \) the maps

\[
M \mapsto H^k_{\text{dR}}(M)
\]

\[
(f : M \to N) \mapsto (f^* : H^k_{\text{dR}}(N) \to H^k_{\text{dR}}(M))
\]
define a contravariant functor from the category $\text{SmMfd}$ of smooth manifolds to the category $\mathcal{V}_{CR}$ of real vector spaces.

78.3. The Poincaré Lemma. In the following two sections we will see that de Rham cohomology has properties that are quite similar to singular cohomology with real coefficients.

For example, in Lemma 73.13 we saw that homotopic maps $f, g: X \to Y$ between topological spaces induce the same map on cohomology groups. Now we will obtain a similar result for de Rham cohomology groups, but we will have to restrict ourselves to smooth homotopies.

**Proposition 78.5.** Let $M$ be a smooth manifold without boundary and let $N$ be any smooth manifold. Let $f$ and $g$ be two smooth maps between $M$ and $N$. If there exists a smooth homotopy between $f$ and $g$, then for any $k \in \mathbb{N}_0$ we have

$$f^* = g^*: H^k_{\text{dR}}(N) \to H^k_{\text{dR}}(M).$$

The key to the proof of the proposition is the following lemma.

**Lemma 78.6.** Let $M$ be a smooth manifold without boundary. For $r = 0, 1$ we denote by $i_r: M \to M \times [0, 1]$ the inclusion maps given by $i_r(z) = (z, r)$. Then for any $k \in \mathbb{N}_0$ we have

$$i_0^* = i_1^*: H^k_{\text{dR}}(M \times [0, 1]) \to H^k_{\text{dR}}(M).$$

We will first show that Lemma 78.6 implies Proposition 78.5.

**Proof of Proposition 78.5 assuming Lemma 78.6.** So suppose that we are given a smooth homotopy $F: M \times [0, 1] \to N$ between two maps $f, g: M \to N$. For $r = 0, 1$ let $i_r: M \to M \times [0, 1]$ be the inclusion maps given by $i_r(z) = (z, r)$.\(^{1122}\) Then

$$f^* = (F \circ i_0)^* = i_0^* \circ F^* = i_1^* \circ F^* = (F \circ i_1)^* = g^*.$$ 

\(\uparrow\) by functoriality \hspace{1cm} \(\uparrow\) by Lemma 78.6 \hspace{1cm} \(\uparrow\) by functoriality

We have thus shown that the two maps $f^*$ and $g^*$ agree.

\[\text{Figure 1142. Illustration for the proof of Proposition 78.5}\]

**Proof of Lemma 78.6.** Let $M$ be an $m$-dimensional smooth manifold without boundary. By Lemma 73.5 it suffices to show that there exists a cochain homotopy

$$P_*: C^*_\text{dR}(M \times [0, 1]) \to C^*_{\text{dR}}(M)$$

\(^{1122}\)Note that the smooth structure of the smooth manifold $M \times [0, 1]$ from Proposition 80.9 has the property that $i_0$ and $i_1$ are smooth maps. This implies that the maps $i_0^*$ and $i_1^*$ are actually defined.
from $i_0^*$ to $i_1^*$, i.e. we have to find maps $\{P_n : C^n_{dR}(M \times [0, 1]) \to C^{n-1}_{dR}(M)\}_{n \in \mathbb{N}_0}$ such that for each $n \in \mathbb{N}_0$ we have
\[ d_{n-1} \circ P_n + P_{n+1} \circ d_n = i_0^* - i_1^* : C^n_{dR}(M \times [0, 1]) \to C^n_{dR}(M). \]

For orientation we summarize in the following diagram all objects arising in the definition of a cochain homotopy:

\[
\begin{array}{cccc}
\leftarrow & d_{n+1} & C^{n+1}_{dR}(M \times [0, 1]) & \leftarrow \\
\downarrow & i_0^* & i_1^* & \\
\leftarrow & d_n & C^n_{dR}(M \times [0, 1]) & \leftarrow \\
\downarrow & P_{n+1} & & \downarrow P_n \\
\leftarrow & d_{n-1} & C^{n-1}_{dR}(M \times [0, 1]) & \leftarrow \\
\downarrow & i_0^* & i_1^* & \\
\leftarrow & d_{n-2} & C^{n-2}_{dR}(M) & \leftarrow \\
\end{array}
\]

Given any $(x,t) \in M \times [0, 1]$ we denote by $h \in T_{(x,t)}(M \times [0, 1])$ the tangent vector that is represented by the “horizontal” curve $s \mapsto (x,t+s)$. Given any $t \in [0, 1]$ we have the obvious inclusion map $M \to M \times [0, 1]$. Given any $x \in M$ this map induces an inclusion $T_xM \to T_{(x,t)}(M \times [0, 1])$. We use this map to view $T_xM$ as a subspace of $T_{(x,t)}(M \times [0, 1])$. Now we can write $T_{(x,t)}(M \times [0, 1]) = T_xM \oplus \mathbb{R} \cdot h$. This decomposition is illustrated in Figure 1143. Given $n \in \mathbb{N}_0$ we consider the map

\[
P_n : C^n_{dR}(M \times [0, 1]) \to C^{n-1}_{dR}(M)
\]

the $(n-1)$-form that at a point $x \in M$ is given by
\[
\omega \mapsto (v_1, \ldots, v_{n-1}) \mapsto (-1)^{n+1} \left< \int_0^t \omega_{(x,t)}(v_1, \ldots, v_{n-1}, h) \ dt \right> \text{ for } n \text{ vectors in } T_xM.
\]

It is straightforward to verify that this map is well-defined, i.e. the right-hand side is an $(n-1)$-form on $M$, and that this map is $\mathbb{R}$-linear. It remains to show that these maps $P_n$ define a cochain homotopy, i.e. we have to verify that for all $n \in \mathbb{N}_0$ we have
\[
(*) \quad d_{n-1} \circ P_n + P_{n+1} \circ d_n = i_1^* - i_0^* : C^n_{dR}(M \times [0, 1]) \to C^n_{dR}(M).
\]

The idea of the proof is to first prove the equality $(*)$ for $M = \mathbb{R}^m$, and then to reduce the case of a general $m$-dimensional smooth manifold to the case $M = \mathbb{R}^m$ via charts and a smooth partition of unity. So we start out with the following claim.

\[\text{Why do we have this decomposition?}\]
Claim. For any \( n \in \mathbb{N}_0 \) we have
\[
d_{n-1} \circ P_n + P_{n+1} \circ d_n = i_n^* - i_0^*: C^m_{\text{dr}}(\mathbb{R}^m \times [0, 1]) \to C^m_{\text{dr}}(\mathbb{R}^m).
\]

We first prove the claim for \( n \geq 1 \). For any point in \( \mathbb{R}^m \times [0, 1] \) we can identify its tangent space with \( \mathbb{R}^{m+1} \) and equip its dual space with the basis given by \( dx_1, \ldots, dx_m, dt \). It follows from the discussion of the basis of \( \bigwedge(\mathbb{R}^{m+1})^* \) on page 1916 that for \( n \geq 1 \) every differential \( n \)-form on \( \mathbb{R}^m \times [0, 1] \) is a real linear combination of forms of the form
\[
\eta = \varphi \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_n} \quad \text{and} \quad \mu = \psi \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}} \wedge dt
\]
where \( \varphi, \psi: \mathbb{R}^n \times [0, 1] \to \mathbb{R} \) are smooth functions. By the linearity of the terms in the claim it suffices to prove the claim for each such \( \eta \) and each such \( \mu \). It is straightforward to see that at each point \((x_1, \ldots, x_m) \in \mathbb{R}^m\) we have
\[
P_n(\eta) = 0 \quad \text{and} \quad P_n(\mu) = (-1)^p \cdot \left( \int_{t=0}^{t=1} \psi(x_1, \ldots, x_m, t) \, dt \right) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}}.
\]
From this we obtain that \((d_{n-1} \circ P_n)(\eta) = 0\) and that
\[
(P_{n+1} \circ d_n)(\eta) = P_{n+1}(d_0(\varphi) \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_n})
\]
\[
= P_{n+1}\left( \left( \sum_{i=1}^{n} \frac{\partial \varphi}{\partial x_i} \cdot dx_i + \frac{\partial \varphi}{\partial t} \cdot dt \right) \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_n} \right)
\]
\[
= (-1)^n \cdot P_{n+1}\left( \frac{\partial \varphi}{\partial t} \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_n} \wedge dt \right)
\]
\[
= \left( \int_{0}^{1} \frac{\partial \varphi}{\partial t} \, dt \right) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_n} = (i_{i_1}^*)(\eta) - (i_0^*)(\eta).
\]
We have thus proved the desired equality for \( \eta \).

Now we turn to \( \mu \). We have \( i_0^*(\mu) = i_1^*(\mu) = 0 \) since \( i_0^*(dt) = i_1^*(dt) = 0 \). We obtain that
\[
(d_{n-1} \circ P_n)(\mu) = (-1)^n \cdot \sum_{i=1}^{m} \left( \int_{t=0}^{t=1} \frac{\partial \psi}{\partial x_i} \, dx_i \right) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}},
\]
\[
(P_{n+1} \circ d_n)(\mu) = (-1)^{n+1} \cdot \sum_{i=1}^{m} \left( \int_{t=0}^{t=1} \frac{\partial \psi}{\partial x_i} \, dx_i \right) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}}.
\]
We have thus proved the claim for \( \mu \) and \( n \geq 1 \). It remains to prove the claim for \( n = 0 \). This follows immediately from the calculation that
\[
(d_{-1} \circ P_0)(\varphi) + (P_1 \circ d_0)(\varphi) = 0 + P_1\left( \sum_{i=1}^{m} \frac{\partial \varphi}{\partial x_i} \cdot dx_i + \frac{\partial \varphi}{\partial t} \cdot dt \right) = \int_{t=0}^{t=1} \frac{\partial \varphi}{\partial t} \, dt = (i_{i_1}^*)(\varphi) - (i_0^*)(\varphi).
\]

\[\Box\]

We have thus proved the desired equality for \( \eta \).

Now we turn to the case that \( M \) is any \( m \)-dimensional smooth manifold. We pick a smooth atlas \( \{\Phi_j: U_j \to \mathbb{R}^m\}_{j \in J} \) for the smooth manifold \( M \). By Theorem 6.57 we can

\[\text{Here by a smooth atlas for } M \text{ we mean an atlas } \{\Phi_j: U_j \to \mathbb{R}^n\}_{j \in J} \text{ such that all maps are smooth with respect to the given smooth structure on } M. \text{ Using the fact that any open ball is diffeomorphic to } \mathbb{R}^n \text{ one can easily show that such an atlas exists.}\]
pick a smooth partition of unity \( \{ f_j : M \to \mathbb{R} \}_{j \in J} \) that is subordinate to the open cover \( \{ U_j \}_{j \in J} \). We consider the diagram

\[
\begin{array}{cccc}
C^n_{\text{dr}}(M \times [0, 1]) & \xrightarrow{(d_{n-1} \circ p_n + p_{n+1} \circ d_n) - (i_1^* - i_0^*)} & C^n_{\text{dr}}(M) \\
\int \omega & \mapsto \int \omega \cdot f_j \omega |_{U_j} & \int \omega & \mapsto \int \omega \cdot f_j \omega |_{U_j} \\
\prod_{j \in J} C^n_{\text{dr}}(U_j \times [0, 1]) & \xrightarrow{\prod (d_{n-1} \circ p_n + p_{n+1} \circ d_n) - (i_1^* - i_0^*)} & \prod_{j \in J} C^n_{\text{dr}}(U_j) \\
\cong \downarrow \omega_j \mapsto (\Phi_j^{-1})^* (\omega_j) & & \cong \downarrow \omega_j \mapsto (\Phi_j^{-1})^* (\omega_j) \\
\prod_{j \in J} C^n_{\text{dr}}(\mathbb{R}^n \times [0, 1]) & \xrightarrow{\prod (d_{n-1} \circ p_n + p_{n+1} \circ d_n) - (i_1^* - i_0^*)} & \prod_{j \in J} C^n_{\text{dr}}(\mathbb{R}^n).
\end{array}
\]

One can show easily that the maps \( P_n \) and \( i_0^* \) and \( i_1^* \) are natural, i.e. they commute with induced maps given by smooth maps between smooth manifolds. This observation, together with Proposition 78.2 (6) implies that the horizontal maps are natural, i.e. they commute with smooth maps between smooth manifolds. Therefore it follows that the diagram commutes. The top vertical maps are monomorphisms since the \( f_j \) form a smooth partition of unity. The bottom vertical maps are isomorphisms since the \( \Phi_j \) are diffeomorphisms. We had just shown in the claim that the bottom map is the zero map. Hence the top map is also the zero map. But this is precisely what we had wanted to show.

The following result is known as the Poincaré Lemma. This humble name belies the fact that it is an extremely useful statement.

**Lemma 78.7. (Poincaré Lemma)** If \( U \subset \mathbb{R}^n \) is an open star-shaped set, then

\[
H^k_{\text{dR}}(U) = \begin{cases} 
\mathbb{R}, & \text{if } k = 0, \\
0, & \text{otherwise.}
\end{cases}
\]

**Proof.** By definition of a star-shaped subset of \( \mathbb{R}^n \) there exists an \( x \in U \) such that for every \( y \in U \) the segment \( \{ xt + y(1-t) \mid t \in [0,1] \} \) lies in \( U \). Let \( i : \{ x \} \to U \) be the inclusion map and let \( p : U \to \{ x \} \) the unique map from \( U \) to \( \{ x \} \). Evidently \( p \circ i = \text{id}_{\{x\}} \). Furthermore \( i \circ p \) and \( \text{id}_U \) are smoothly homotopic, in fact a smooth homotopy is given by \( F(y,t) = xt + y(1-t) \). It follows immediately from Proposition 78.5 and the functoriality of de Rham cohomology that \( i^* : H^k_{\text{dR}}(U) \to H^k_{\text{dR}}(\{ x \}) \) and \( p^* : H^k_{\text{dR}}(\{ x \}) \to H^k_{\text{dR}}(U) \) are isomorphisms. The corollary now follows from the calculation of the de Rham cohomology groups for a point that we gave on page 1920.

The following corollary is an immediate consequence of the Poincaré Lemma 78.7 and the functoriality of de Rham cohomology.
Corollary 78.8. If $M$ is an $n$-dimensional smooth manifold that is diffeomorphic to an open star-shaped subset of $\mathbb{R}^n$, e.g. that is diffeomorphic to $\mathbb{R}^n$ or the open $n$-ball $B^n$, then
\[
H^k_{\text{dR}}(M) = \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise}. \end{cases}
\]

78.4. Applications of the Poincaré Lemma to classical vector calculus ($\ast$). In this section we apply the Poincaré Lemma to classical vector calculus. Let $U \subset \mathbb{R}^3$ be an open set. We denote by $C^\infty(U) := \text{all smooth maps } U \to \mathbb{R}$ and $\mathcal{V}(U) := \text{all smooth maps } U \to \mathbb{R}^3$ the set of all smooth real-valued functions respectively smooth vector fields on $U$. We recall that there are three classical maps relating smooth functions and smooth vector fields:
\[
\begin{align*}
\text{grad}: C^\infty(U) &\to \mathcal{V}(U) \\
\text{curl}: \mathcal{V}(U) &\to \mathcal{V}(U) \\
\text{div}: \mathcal{V}(U) &\to C^\infty(U)
\end{align*}
\]

\[
\begin{align*}
F = \begin{pmatrix} F_x \\ F_y \\ F_z \end{pmatrix} &\mapsto - \begin{pmatrix} \frac{\partial F_y}{\partial x} - \frac{\partial F_z}{\partial y} \\ \frac{\partial F_z}{\partial x} - \frac{\partial F_x}{\partial z} \\ \frac{\partial F_x}{\partial y} - \frac{\partial F_y}{\partial x} \end{pmatrix} \\
F = \begin{pmatrix} F_x \\ F_y \\ F_z \end{pmatrix} &\mapsto \frac{\partial F_y}{\partial x} + \frac{\partial F_z}{\partial y} + \frac{\partial F_x}{\partial z}.
\end{align*}
\]

Given $f \in C^\infty(U)$ we refer to $\text{grad}(f)$ as the gradient of $f$ and given $F \in \mathcal{V}(U)$ we refer to $\text{curl}(F)$ as the curl of $f$ and we refer to $\text{div}(F)$ as the divergence of $F$. It is straightforward to verify that $\text{curl} \circ \text{grad} = 0$ and $\text{div} \circ \text{curl} = 0$. Put another way, the following sequence of maps is in fact a chain complex:
\[
0 \to C^\infty(U) \xrightarrow{\text{grad}} \mathcal{V}(U) \xrightarrow{\text{curl}} \mathcal{V}(U) \xrightarrow{\text{div}} C^\infty(U) \to 0.
\]

Now we will relate the above discussion to forms. A smooth function is by definition the same as a differential 0-form. A smooth function also gives rise to a 3-form, more precisely we have the following simple-minded isomorphism
\[
\Theta: C^\infty(U) \to C^3_{\text{dR}}(U) \\
f \mapsto f \cdot dx \wedge dy \wedge dz.
\]

More interestingly, a smooth vector field gives rise to a differential 1-form on $U$ and also a 2-form on $U$. More precisely we have the following maps
\[
\begin{align*}
\Phi: \mathcal{V}(U) &\to C^1_{\text{dR}}(U) \\
\text{differential 1-form that} \\
\text{at } x \text{ is given by} \\
w &\mapsto T_x U = \mathbb{R}^3 \to \mathbb{R} \\
v &\mapsto v \cdot w \\
\text{scalar product}
\end{align*}
\]

\[
\begin{align*}
\Psi: \mathcal{V}(U) &\to C^2_{\text{dR}}(U) \\
\text{differential 2-form that at a} \\
\text{point } x \in U \text{ is given by} \\
w &\mapsto (T_x U)^2 = (\mathbb{R}^3)^2 \to \mathbb{R} \\
(v_1, v_2) &\mapsto (v_1 \times v_2) \cdot w. \\
\text{cross product}
\end{align*}
\]

It is straightforward to see that these maps are well-defined and that they are isomorphisms.
Summarizing we obtain the following diagram:

$$
\begin{array}{ccccccc}
0 & \rightarrow & C^\infty(U) & \xrightarrow{\text{grad}} & \mathcal{V}(U) & \xrightarrow{\text{curl}} & \mathcal{V}(U) & \xrightarrow{\text{div}} & C^\infty(U) & \rightarrow & 0 \\
\cong \downarrow \text{id} & \approx \downarrow \Phi & \cong \downarrow \psi & \approx \downarrow \varphi & & \approx \downarrow \Theta \\
0 & \rightarrow & C^0_{\text{dr}}(U) & d & C^1_{\text{dr}}(U) & d & C^2_{\text{dr}}(U) & d & C^3_{\text{dr}}(U) & \rightarrow & 0.
\end{array}
$$

A heroic calculation, see e.g. [Weint14, Theorem 3.8], shows that the diagram commutes.

If \(U\) is star-shaped then we showed in the Poincaré Lemma 78.7 that the cohomology of the lower sequence vanishes for \(k = 1, 2, 3\). Since the diagram commutes and since all vertical maps are isomorphisms we have thus proved the following classical theorem.

**Theorem 78.9.** Let \(U\) be a star-shaped open subset of \(\mathbb{R}^3\).

1. Every smooth vector field on \(U\) with vanishing rotation is the gradient of a smooth function.
2. Every smooth vector field on \(U\) with vanishing divergence is the curl of a smooth vector field.
3. Every smooth function on \(U\) is the divergence of a smooth vector field.

78.5. **More properties of the de Rham cohomology groups.** In this section we will continue the theme from the Section 78.3 and we will prove two more statements regarding de Rham cohomology groups that we had already proved for singular cohomology groups.

One of the key tools in computing singular homology and cohomology groups are the Mayer–Vietoris Theorems 46.5 and 74.15. The following theorem is the de Rham cohomology version of these two theorems.

**Theorem 78.10.** *(Mayer–Vietoris Theorem for de Rham cohomology groups)* Let \(M\) be a smooth manifold and let \(U, V\) be open subsets with \(M = U \cup V\). Let \(j_U : U \rightarrow M\), \(j_V : V \rightarrow M\), \(i_U : U \cap V \rightarrow U\) and \(i_V : U \cap V \rightarrow V\) be the inclusion maps. Then the following two statements hold:

1. The following sequence of cochain complexes is exact
   
   $$
   0 \rightarrow C^*_\text{dr}(M) \xrightarrow{j_U^* \oplus j_V^*} C^*_\text{dr}(U) \oplus C^*_\text{dr}(V) \xrightarrow{i_U^* + i_V^*} C^*_\text{dr}(U \cap V) \rightarrow 0.
   $$

2. There exists a natural long exact sequence of the form
   
   $$
   \ldots \rightarrow H^k_{\text{dr}}(M) \xrightarrow{j_U^* \oplus j_V^*} H^k_{\text{dr}}(U) \oplus H^k_{\text{dr}}(V) \xrightarrow{i_U^* + i_V^*} H^k_{\text{dr}}(U \cap V) \xrightarrow{\delta} H^{k+1}_{\text{dr}}(M) \rightarrow \ldots
   $$

In the proof of Theorem 78.10 we will require the following lemma.

**Lemma 78.11.** Let \(W\) be a smooth manifold, let \(U \subset W\) be an open subset and let \(\varphi\) be a smooth form on \(U\). We define

$$
\epsilon(\varphi, W) := \text{the form on } W \text{ that is given by } \varphi \text{ on } U \text{ and that is zero on } W \setminus U.
$$

If \(\text{supp}(\varphi) \subset U\), then \(\epsilon(\varphi, M)\) is a smooth form on \(W\).

**Proof.** To show that a form \(\mu\) on a smooth manifold \(W\) is smooth it suffices to show that there exists an open cover \(\{W_i\}_{i \in I}\) such that the restriction of \(\mu\) to each \(W_i\) is smooth. In our case we consider the open cover of \(U\) given by \(U\) and by \(W \setminus \text{supp}(\varphi)\). Note that this
is indeed a covering since supp(\(\varphi\)) \(\subseteq U\). The restriction of the form \(\varepsilon(\varphi, W)\) to \(U\) equals \(\varphi\), hence it is smooth. The restriction of \(\varepsilon(\varphi, W)\) to \(W \setminus \text{supp}(\varphi)\) is also smooth since it is by definition identically zero on \(W \setminus \text{supp}(\varphi)\).

Now we can provide the proof of Theorem 78.10.

Proof of Theorem 78.10. Not surprisingly we first prove statement (1). Since \(M = U \cup V\) it is clear that the left-hand map \(j_U^* \oplus -j_V^*\) is a monomorphism. It is obvious that the composition of the two maps is zero and that the image of the left-hand map \(j_U^* \oplus -j_V^*\) is the kernel of \(i_U^* + i_V^*\). It remains to prove the following claim.

Claim. The map \(i_U^* + i_V^* : C^*_{dR}(U) \oplus C^*_{dR}(V) \to C^*_{dR}(U \cap V)\) is in fact an epimorphism.

Let \(\eta \in C^*_{dR}(U \cap V)\). By Theorem 6.57 there exists a smooth partition of unity \(\varphi_U, \varphi_V\) that is subordinate to the open cover of \(M\) given by \(U\) and \(V\). We refer to Figure 1146 for an illustration.

We consider the forms \(\varepsilon(\eta \cdot \varphi_V, U)\) on \(U\) and \(\varepsilon(\eta \cdot \varphi_U, V)\). Both are smooth by Lemma 78.11. Now we have

\[
(i_U^* + i_V^*)(\varepsilon(\eta \cdot \varphi_V, U) + \varepsilon(\eta \cdot \varphi_U, V)) = \varepsilon(\eta \cdot \varphi_V, U)|_{U \cap V} + \varepsilon(\eta \cdot \varphi_U, V)|_{U \cap V} = \eta \cdot \varphi_V + \eta \cdot \varphi_U = \eta.
\]

by definition of \(i_U^*\) and \(i_V^*\) by definition of \(\varphi_U\) and \(\varphi_V\) since \(\varphi_U + \varphi_V = 1\)

This concludes the proof of the claim and thus also of statement (1).

The existence and naturality of the long exact sequence of statement (2) is an immediate consequence of statement (1) together with Proposition 73.6.

Using the Mayer–Vietoris Theorem 78.10 for de Rham cohomology groups and some of our earlier results one can now compute many de Rham cohomology groups. The following lemma gives a sample calculation.

Lemma 78.12. For any \(n \geq 1\) we have

\[
H^k_{dR}(S^n) \cong \begin{cases} 
\mathbb{R}, & \text{if } k = 0, n, \\
0, & \text{otherwise}.
\end{cases}
\]
Proof. By induction we will prove the following statement: for any \( n \geq 1 \) we have

\[
H^k_{\text{dR}}(S^n) \cong \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{if } k = n, \\ \oplus & \text{otherwise}. \end{cases}
\]

For \( n = 0 \) the statement holds by Proposition 78.4 (5) and the calculation of de Rham cohomology for a point that we gave on page 1920.

Given \( S^n \) with \( \geq 1 \) we write

\[
U := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \neq -1\} \quad \text{and} \quad V := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \neq +1\}.
\]

The stereographic projection that we defined in Lemma 2.44 gives diffeomorphisms from \( U \) and \( V \) to \( \mathbb{R}^n \). We refer to Figure 1147 for an illustration. In particular we know from Corollary 78.8 that

\[
H^k_{\text{dR}}(U) \cong H^k_{\text{dR}}(V) \cong \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise}. \end{cases}
\]

Using Proposition 78.5 it is also fairly straightforward to show that the inclusion map

\[
\iota: S^{n-1} \to U \cap V \quad P \mapsto (P, 0)
\]

induces an isomorphism of de Rham cohomology groups.

Now we perform the induction step from \( n = 0 \) to \( n = 1 \). We consider the long exact Mayer–Vietoris sequence coming from Theorem 78.10 that corresponds to the decomposition \( S^1 = U \cup V \):

\[
0 \to H^0_{\text{dR}}(S^1) \to H^0_{\text{dR}}(U) \oplus H^0_{\text{dR}}(V) \to H^0_{\text{dR}}(U \cap V) \to H^1_{\text{dR}}(S^1) \to H^1_{\text{dR}}(U) \oplus H^1_{\text{dR}}(V) \to \ldots
\]

We recall that in Proposition 78.4 (3) we saw that inclusion induced maps between connected smooth manifolds induce isomorphisms on 0-th de Rham cohomology. Using this observation and using the long exact sequence it is now straightforward to show that the de Rham cohomology of \( S^1 \) is precisely as predicted.\footnote{Alternatively one can also use Lemma 55.4 to deduce that \( H^1_{\text{dR}}(S^1) \cong \mathbb{R} \).}

The induction step for \( n \geq 2 \) from \( n - 1 \) to \( n \) is even easier, since one does not have to worry about 0-th de Rham cohomology. More precisely, for \( k \geq 1 \) the above Mayer–Vietoris sequence now looks as follows:

\[
\ldots \to H^k_{\text{dR}}(S^n) \to H^k_{\text{dR}}(U) \oplus H^k_{\text{dR}}(V) \to H^k_{\text{dR}}(U \cap V) \to H^{k+1}_{\text{dR}}(S^n) \to H^{k+1}_{\text{dR}}(U) \oplus H^{k+1}_{\text{dR}}(V) \to \ldots
\]

It is now straightforward to prove the induction step. \( \blacksquare \)

Using the calculation from Lemma 78.12 and the Mayer–Vietoris Theorem 78.10 for de Rham cohomology groups one can now fairly easily modify the arguments in Lemmas 46.9, 46.12 and 46.13 to compute the de Rham cohomology of the real projective plane.
\[ H^n_{dR}(\mathbb{R}P^2) \cong \begin{cases} 0, & \text{if } n \geq 1, \\ \mathbb{R}, & \text{if } n = 0, \end{cases} \]
\[ H^n_{dR}(T) \cong \begin{cases} \mathbb{R}, & \text{if } n = 0, 2, \\ \mathbb{R}^2, & \text{if } n = 1, \\ 0, & \text{otherwise}, \end{cases} \]
\[ H^n_{dR}(K) \cong \begin{cases} \mathbb{R}, & \text{if } n = 0, \\ \mathbb{R}, & \text{if } n = 1, \\ 0, & \text{otherwise}. \end{cases} \]

We conclude this discussion of de Rham cohomology with the following proposition which is very similar in nature to Proposition 76.12 for singular cohomology.

**Proposition 78.13.** Let \( M \) be a smooth manifold and let \( \{U_i\}_{i \in \mathbb{N}} \) be a sequence of open subsets of \( M \) that satisfy the following three conditions:

1. For each \( i \in \mathbb{N} \) the closure \( \overline{U}_i \) of \( U_i \) is compact,
2. For each \( i \in \mathbb{N} \) we have \( U_i \subset U_{i+1} \), and
3. \( M = \bigcup_{i \in \mathbb{N}} U_i \).

Then for every \( n \in \mathbb{N}_0 \) there exists a natural short exact sequence
\[ 0 \to \lim_\leftarrow H^{n-1}_{dR}(U_i) \xrightarrow{\rho} H^n_{dR}(M) \to \lim_\leftarrow H^n_{dR}(U_i) \to 0 \]
where the right-hand map is induced by the obvious maps \( H^n_{dR}(M) \to H^n_{dR}(U_i) \).

**Proof.** For each \( k \in \mathbb{N}_0 \) we consider the inverse system
\[ C^k_{dR}(U_1) \leftarrow C^k_{dR}(U_2) \leftarrow C^k_{dR}(U_3) \leftarrow \ldots \]
where all the maps are induced by the inclusion, put differently, they are all restriction maps.

*Claim.* The inverse system satisfies the Mittag-Leffler condition from page 1892.

Given any \( j \geq i \) we denote by \( \rho_{ji} : C^k_{dR}(U_j) \to C^k_{dR}(U_i) \) the restriction map. Now let \( i \in \mathbb{N} \). We have to show that there exists an \( n \geq i \) such that for all \( r \geq n \) we have
\[ \text{im} \left( \rho_{ri} : C^k_{dR}(U_r) \to C^k_{dR}(U_i) \right) = \text{im} \left( \rho_{ni} : C^k_{dR}(U_n) \to C^k_{dR}(U_i) \right). \]
Since \( U_i \) is compact, since the \( U_j \) are nested and since \( U_i \) is contained in the union of all \( U_j \) there exists an \( n \) such that \( U_i \subset U_n \). We refer to Figure 1148 for an illustration. We claim that \( n \) has the desired property. So let \( r \geq n \). We have to show that
\[ \text{im} \left( \rho_{ri} : C^k_{dR}(U_r) \to C^k_{dR}(U_i) \right) = \text{im} \left( \rho_{ni} : C^k_{dR}(U_n) \to C^k_{dR}(U_i) \right). \]
Clearly we have the inclusion "\( \subseteq \)". It remains to prove the reverse inclusion. So suppose \( \eta \in C^k_{dR}(U_i) \) is the restriction of some \( \mu \in C^k_{dR}(U_n) \). Note that \( U_n \) and \( M \setminus U_i \) form an
open cover for $M$. It follows immediately from Theorem 6.57 that there exists a smooth function $\varphi: M \to \mathbb{R}$ with $\varphi|_{\mathcal{U}_i} \equiv 1$ and such that $\text{supp}(\varphi) \subset U_n$. Let $r \geq n$. We see that

$$\eta = \mu|_{U_i} = (\varphi \cdot \mu)|_{U_i} = \epsilon(\varphi \cdot \mu, U_i)|_{U_i}.$$ 

since $\varphi \equiv 1$ on $U_i$.

We have thus shown that $\eta$ is also the restriction of some smooth form on $U_r$.

By the claim we can apply Proposition 76.10 to the inverse system $\{C^*_{dR}(U_i)\}_{i \in \mathbb{N}}, \{\rho_{ij}\}_{i \geq j}$ of cochain complexes over $\mathbb{N}$ and we obtain the short exact sequence

$$0 \to \lim_{i \in \mathbb{N}} H^{n-1}(C^*_{dR}(U_i)) \to H^n \left( \lim_{i \in \mathbb{N}} C^*_{dR}(U_i) \right) \to \lim_{i \in \mathbb{N}} H^n(C^*_{dR}(U_i)) \to 0.$$ 

We have thus obtained the desired short exact sequence.

Exercises for Chapter 78

Exercise 78.1. Let $\Sigma$ be the surface of genus 2 equipped with some orientation. Furthermore let $\gamma: S^1 \to \Sigma$ be a smooth embedding. We write $C = \gamma(S^1)$ and we view $C$ as an oriented curve on $\Sigma$. By the Tubular Neighborhood Theorem 8.24, we can pick a tubular neighborhood $[-2, 2] \times C$ for $C$. We denote by $dt$ the usual differential 1-form on $[-2, 2] \subset \mathbb{R}$. Let $f: [-2, 2] \to \mathbb{R}_{\geq 0}$ be a smooth function with $\text{supp}(f) \subset [-1, 1]$ and $\int_{t=0}^{t=1} f(t) dt = 1$. We denote by $p: [-2, 2] \times C \to [-2, 2]$ the projection. Finally denote by $\omega$ the smooth closed differential 1-form on $\Sigma$ that is given by $p^*(f \cdot dt)$ on $[-2, 2] \times C$ and that is extended to all of $\Sigma$ by setting it zero outside of $C \times [-2, 2]$. (Some of the objects are illustrated in Figure 1149.)

Given a closed oriented curve $D \subset \Sigma$ we obtain the integral $\int_D \omega$.

(a) Show that the integral is an integer.
(b) What is the geometric interpretation of this integer?
Exercise 78.2. Let $M$ be a smooth manifold and let $\{U_i\}_{i \in \mathbb{N}}$ be a sequence of open subsets of $M$ that satisfy the following three conditions:

1. for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of $U_i$ is compact,
2. for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and
3. $M = \bigcup_{i \in \mathbb{N}} U_i$.

In the proof of Proposition 78.13 we show that for each $k \in \mathbb{N}_0$ the inverse system

$$\cdR(U_1) \hookrightarrow \cdR(U_2) \hookrightarrow \cdR(U_2) \hookrightarrow \cdots$$

satisfies the Mittag-Leffler condition. Now let $i \in \mathbb{N}$. Does there exist an $n \geq i$ such that for all $r \geq n$ the map

$$\cdR(U_r) \to \cdR(U_i)$$

is an epimorphism?

Exercise 78.3. Let $M$ be a closed connected smooth manifold. Use Proposition 63.36 to show that for any $k \in \mathbb{N}_0$ the de Rham cohomology group $H^k_{\text{dR}}(M)$ is finite-dimensional.

Exercise 78.4. Let $n \in \mathbb{N}$. As on page 1915 we consider the 1-forms $dx_1, \ldots, dx_n$ on $\mathbb{R}^n$. We denote by $p: \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ the obvious projection.

(a) Show that there exist closed 1-forms $\omega_1, \ldots, \omega_n$ on the smooth manifold $\mathbb{R}^n/\mathbb{Z}^n$ such that for each $i \in \{1, \ldots, n\}$ we have $dx_i = p^*(\omega_i)$.

(b) We equip $\mathbb{R}^n/\mathbb{Z}^n$ with the standard orientation induced by $\mathbb{R}^n$. Show that the integral of the $n$-form $\omega_1 \wedge \cdots \wedge \omega_n$ over $\mathbb{R}^n/\mathbb{Z}^n$ equals $+1$.

Exercise 78.5. On $S^2$ we consider the 2-form

$$\omega: T_P M \times T_P M \to \mathbb{R}$$

$$(v, w) \mapsto \det((P \ v \ w)).$$

We equip $S^2$ with the usual orientation introduced on page 299. Show that the integral of $\omega$ over $S^2$ equals $4\pi$. 
79. The relationship between de Rham cohomology and singular cohomology

In this chapter we want to find the connection between the de Rham cohomology groups from Chapter 78 and the singular cohomology groups that we defined earlier in Chapter 73.

To avoid a repetitive use of suffixes we will use the following convention.

Convention. In this chapter by a “manifold” we always mean a smooth manifold without boundary, unless we say explicitly otherwise.

79.1. Smooth cohomology theories. To a smooth manifold $M$ we can associate the singular cohomology groups $H^i(M; \mathbb{R})$ and also the de Rham cohomology groups $H^i_{dR}(M)$.

In the last chapter we had in particular seen that these two cohomologies have many properties in common, for example they both satisfy a Mayer–Vietoris type theorem. Now we want to put both cohomologies in a common framework.

Definition. A smooth cohomology theory is a contravariant functor

$$
\mathcal{H}^* : \text{category of smooth manifolds} \rightarrow \text{category of } \mathbb{N}_0\text{-graded real vector spaces}
$$

$$
M \mapsto \mathcal{H}^*(M) = \bigoplus_{n \in \mathbb{N}_0} \mathcal{H}^n(M)
$$

$$(f : M \to N) \mapsto \{f^* = \mathcal{H}^n(f) : \mathcal{H}^n(N) \to \mathcal{H}^n(M)\}_{n \in \mathbb{N}_0}$$

that satisfies the following three axioms:

1. (Smooth homotopy invariance) Let $f, g : M \to N$ be smooth maps between smooth manifolds. If $f$ and $g$ are smoothly homotopic, then for all $n \in \mathbb{N}_0$ we have

$$
\mathcal{H}^n(f) = \mathcal{H}^n(g) : \mathcal{H}^n(N) \to \mathcal{H}^n(M).
$$

2. (Mayer–Vietoris sequence) If $M$ is a smooth manifold and $U$ and $V$ are open subsets such that $M = U \cup V$, then there exists a natural long exact sequence of the form

$$
\ldots \to \mathcal{H}^k(M) \xrightarrow{j_U^* + j_V^*} \mathcal{H}^k(U) \oplus \mathcal{H}^k(V) \xrightarrow{i_U^* + i_V^*} \mathcal{H}^k(U \cap V) \xrightarrow{\delta} \mathcal{H}^{k+1}(M) \to \ldots
$$

where $j_U : U \to M$, $j_V : V \to M$, $i_U : U \cap V \to U$ and $i_V : U \cap V \to V$ denote the inclusion maps.

3. (Limit property) Let $M$ be a smooth manifold and let $\{U_i\}_{i \in \mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:

(a) for each $i \in \mathbb{N}$ the closure $\overline{U_i}$ of $U_i$ is compact,

(b) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and

(c) $M = \bigcup_{i \in \mathbb{N}} U_i$.

Then for every $n \in \mathbb{N}_0$ there exists a natural short exact sequence

$$
0 \to \lim_{\leftarrow} H^{n-1}(U_i) \xrightarrow{\tau} H^n(M) \to \lim_{\leftarrow} \mathcal{H}^n(U_i) \to 0
$$

where the right-hand map is induced by the maps $\mathcal{H}^n(M) \to \mathcal{H}^n(U_i)$ which in turn are induced by the inclusions $U_i \to M$. 
This time it is easy to give examples for our new definition.

**Proposition 79.1.**

1. Singular cohomology with real coefficients is a smooth cohomology theory.
2. De Rham cohomology is a smooth cohomology theory.

**Proof.**

(1) It follows from Lemma 73.13, Theorem 74.15, together with Proposition 74.12 and Proposition 76.12 (1), that singular cohomology with real coefficients is a smooth cohomology theory.

(2) It follows from Proposition 78.5, Theorem 78.10 and Proposition 78.13 that de Rham cohomology is a smooth cohomology theory.

One might now be optimistic and hope that smooth cohomology theories are necessarily isomorphic. As it stands this thought though is too optimistic. For example other smooth cohomology theories are given by $H^n(M) = 0$ for all $n \in \mathbb{N}_0$ or by $H^n(M) = H^{n+5}(M; \mathbb{R})$ or by $H^n(M) = H^n(M; \mathbb{R}) \oplus H^n(M; \mathbb{R})$. This shows that if we want to prove that smooth cohomology theories are isomorphic we have to add some extra hypotheses, for example we could demand that the 0-th cohomology groups of a point are isomorphic.

**Notation.** In the following $\star$ denotes the topological space consisting of a single point. Evidently $\star$ is a 0-dimensional smooth manifold.

On page 488 we introduced the notion of a natural transformation between two covariant functors. Almost the same definition can also be applied to contravariant functors. For completeness’ sake we write down the formal definition.

**Definition.** Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F, G : \mathcal{C} \to \mathcal{D}$ be two contravariant functors. A natural transformation between the contravariant functors $F$ and $G$ assigns to each object $X \in \text{Ob}(\mathcal{C})$ a morphism $\Phi_X : F(X) \to G(X)$ in $\mathcal{D}$ such that for each morphism $f : X \to Y$ in $\mathcal{C}$ the following diagram commutes:

\[
\begin{array}{ccc}
F(Y) & \xrightarrow{F^*(f)} & F(X) \\
\downarrow{\Phi_Y} & & \downarrow{\Phi_X} \\
G(Y) & \xrightarrow{G^*(f)} & G(X).
\end{array}
\]

If all the maps $\Phi_X$ are isomorphisms we also say it is a natural isomorphism.

**Example.** Given $n \in \mathbb{N}_0$ we consider the two contravariant functors $X \mapsto H^n(X; \mathbb{Z})$ and $X \mapsto \text{Hom}(H_n(X), \mathbb{Z})$ from the category of topological spaces to the category of abelian groups. It follows from the discussion on page 1867 that the evaluation homomorphisms $\text{ev} : H^n(X; \mathbb{Z}) \to \text{Hom}(H_n(X), \mathbb{Z})$ define a natural transformation between the two contravariant functors, i.e. given any map $f : X \to Y$ between topological spaces the following

\footnote{Given a smooth map $f : M \to N$ the contravariant functor provides for each $n \in \mathbb{N}_0$ a morphism $H^n(f) : H^n(N) \to H^n(M)$. As usual, when there is no danger of confusion we just write $f^*$ instead of $H^n(f)$.}

\footnote{We refer to page 1427 for the definition of the category of $\mathbb{N}_0$-graded real vector spaces.}
diagram commutes:

\[ \begin{array}{c}
\text{H}^n(Y; \mathbb{Z}) \xrightarrow{f^*} \text{H}^n(X; \mathbb{Z}) \\
\downarrow \text{ev} \quad \downarrow \text{ev}
\end{array} \]

\[ \begin{array}{c}
\text{Hom(H}_n(Y), \mathbb{Z}) \xrightarrow{f^*} \text{Hom(H}_n(X), \mathbb{Z}).
\end{array} \]

With this notation and this definition we can now formulate the following theorem.

**Theorem 79.2.** Let \( \mathcal{H}^* \) and \( \mathcal{K}^* \) be smooth cohomology theories and let \( t: \mathcal{H}^* \to \mathcal{K}^* \) be a natural transformation. Suppose \( t \) has the following three properties:

(i) the natural transformation \( t \) is compatible with the connecting homomorphism in the Mayer-Vietoris sequence, i.e. with the obvious notation we always have a commutative diagram

\[ \begin{array}{c}
\ldots \to \mathcal{H}^n(M) \xrightarrow{j_U^* - j_V^*} \mathcal{H}^n(U) \oplus \mathcal{H}^n(V) \xrightarrow{i_U^* + i_V^*} \mathcal{H}^n(U \cap V) \xrightarrow{\delta} \mathcal{H}^{n+1}(M) \to \ldots \\
\downarrow t \quad \downarrow t \oplus t \quad \downarrow t \quad \downarrow t \\
\ldots \to \mathcal{K}^n(M) \xrightarrow{j_U^* - j_V^*} \mathcal{K}^n(U) \oplus \mathcal{K}^n(V) \xrightarrow{i_U^* + i_V^*} \mathcal{K}^n(U \cap V) \xrightarrow{\delta} \mathcal{K}^{n+1}(M) \to \ldots
\end{array} \]

(ii) the natural transformation \( t \) is compatible with the map \( \tau \) appearing in the limit property, i.e. with the obvious notation we always have a commutative diagram

\[ \begin{array}{c}
0 \xrightarrow{} \lim^1 \mathcal{H}^{n-1}(U_i) \xrightarrow{\tau} \mathcal{H}^n(M) \xrightarrow{} \lim \mathcal{H}^n(U_i) \xrightarrow{} 0 \\
\downarrow t \quad \downarrow t \quad \downarrow t \\
0 \xrightarrow{} \lim^1 \mathcal{K}^{n-1}(U_i) \xrightarrow{\tau} \mathcal{K}^n(M) \xrightarrow{} \lim \mathcal{K}^n(U_i) \xrightarrow{} 0.
\end{array} \]

(iii) for all \( n \in \mathbb{N}_0 \) the map \( t^n(\cdot): \mathcal{H}^n(\cdot) \to \mathcal{K}^n(\cdot) \) is an isomorphism.

Then for every smooth manifold \( M \) and every \( n \in \mathbb{N}_0 \) the map

\[ t: \mathcal{H}^n(M) \to \mathcal{K}^n(M) \]

is an isomorphism.

**Proof.** Let \( \mathcal{H}^* \) and \( \mathcal{K}^* \) be smooth cohomology theories, which means they both satisfy

(a) smooth homotopy invariance,

(b) the Mayer-Vietoris sequence,

(c) the limit property.

Furthermore let \( t: \mathcal{H}^* \to \mathcal{K}^* \) be a natural transformation that has the above properties (i), (ii) and (iii). We need to prove the following statement:

**Statement.** Let \( m \in \mathbb{N}_0 \). For every \( m \)-dimensional smooth manifold \( M \) and every \( n \in \mathbb{N}_0 \) the map

\[ t^n(M): \mathcal{H}^n(M) \to \mathcal{K}^n(M) \]

is an isomorphism.

\[ ^{1128} \text{Note that the left and right vertical maps are given by the remark on page 1894.} \]
We start out with the following two observations:

(A) Suppose $M$ is an $m$-dimensional smooth manifold and $U$ and $V$ are open subsets with $M = U \cup V$. If all $t^n$ are isomorphisms for $U$, $V$ and $U \cap V$, then it follows from (β), (i) and the Five Lemma 43.12 that all the $t^n$ are also isomorphisms for $M$.

(B) Let $M$ be an $m$-dimensional smooth manifold and let $\{U_i\}_{i \in \mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:

(a) for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of $U_i$ is compact,

(b) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and

(c) $M = \bigcup_{i \in \mathbb{N}} U_i$.

If all the $t^n$ are isomorphisms for all $U_i$, then it follows from (γ) and the Five Lemma 43.12 that all the $t^n$ are also isomorphisms for $M$.

After these preparations we will prove the desired statement in four surprisingly easy steps:

(1) Let $M$ be an open convex subset of $\mathbb{R}^m$. We pick an inclusion $f : \ast \to M$. As in the proof of the Poincaré Lemma 78.7 we see that $f$ is a smooth homotopy equivalence. Given $n \in \mathbb{N}_0$ we consider the diagram

$$
\begin{array}{ccc}
\mathcal{H}^n(M) & \xrightarrow{f^*} & \mathcal{H}^n(\ast) \\
\downarrow{t} & & \downarrow{\cong t} \\
\mathcal{K}^n(M) & \xrightarrow{f^*} & \mathcal{K}^n(\ast).
\end{array}
$$

The diagram commutes since $t$ is a natural transformation. It follows easily from (α) that the horizontal maps are isomorphisms. By (iii) the right vertical map is also an isomorphism. It follows that the left vertical map is, as desired, an isomorphism.

(2) We claim that $t$ is an isomorphism for every subset $M$ of $\mathbb{R}^m$ that is the union of $k$ open convex subsets of $\mathbb{R}^m$. We prove this by induction on the number $k$ of open convex subsets:

(a) If $k = 1$, then $M$ itself is an open convex subset of $\mathbb{R}^m$, hence the statement follows from (1).

(b) Suppose the statement holds whenever $M$ is the union of $k - 1$ open convex subsets. Now let $M$ be the union of $k$ open convex subsets $U_1, \ldots, U_k$. We write $V = U_1 \cup \cdots \cup U_{k-1}$. By induction the statement holds for $V$ and also for $U_k$. Furthermore since the intersection of two convex open subsets is again convex and open we see that $V \cap U_k = (U_1 \cap U_k) \cup \cdots \cup (U_{k-1} \cap U_k)$ is the union of $k - 1$ open convex subsets, i.e. by induction the statement holds for $V \cap U_k$. But then it follows from (A) that the statement also holds for $U$.

(3) Let $M$ be an open subset of $\mathbb{R}^m$. By Lemma 2.7 we can write $M$ as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we define $U_i := \bigcup_{j \leq i} B_j$. By (2) the statement holds for each $U_i$, but then it follows from (B) that the statement holds for $M$. 

(4) Finally let $M$ be any $m$-dimensional smooth manifold. We say a subset $W$ of $M$ is small if it is open, if $\overline{W}$ is compact and if $W$ is contained in the domain of some chart for $M$. We make the following observations:

(a) Since $\mathcal{H}$ and $\mathcal{K}$ are diffeomorphism invariants we obtain from (2) that the statement holds for every small subset of $W$ (viewed as a smooth manifold in its own right).

(b) The same induction argument as in (2) shows that the statement holds for finite unions of small subsets (here the key observation is that the intersection of two small subsets is again small).

(c) Finally it follows easily from the fact that the smooth manifold $M$ is second-countable, the existence of charts around every point and Lemma 2.25 that there exist small sets $W_i, i \in \mathbb{N}$ which cover $M$. As in (3) we consider $U_i := \bigcup W_j$. We had just seen in (b) that the statement holds for all the $U_i$. But then it follows from (B) that the statement holds for $M$. ■

### 79.2. Smooth singular cohomology.

One might think that it follows immediately from Proposition 79.1 and Theorem 79.2 (together with the calculations of the cohomology groups of a point in Lemma 73.12 and on page 1920) that the singular real valued cohomology and the de Rham cohomology groups of smooth manifolds are always isomorphic.

But recall that to apply Theorem 79.2 we need to find a natural transformation

$$t: \text{de Rham cohomology} \rightarrow \text{real valued singular cohomology}$$

that has the property that

$$H^n_{\text{dR}}(\ast) \cong H^n(\ast; \mathbb{R}) \quad \text{for all } n \in \mathbb{N}_0.$$ 

Here is an idea: on page 1917 we had mentioned that given a compact oriented $n$-dimensional smooth manifold $W$ and a smooth differential $n$-form $\omega$ on $W$ there exists an

$$\int_W \omega \in \mathbb{R}$$

that has many good properties. So given some smooth manifold $M$ (with no restrictions on the dimension) we could try to define a map

$$t: C^n_{\text{dR}}(M) \rightarrow \text{Hom}(C_n(M); \mathbb{R})$$

$$\omega \mapsto \left( \sum_{i=1}^k a_i \cdot (f_i: \Delta^n \rightarrow M) \mapsto \sum_{i=1}^k a_i \cdot \int_{\Delta^n} f_i^* \omega \right).$$

Unfortunately, there are several problems with this “definition”:

1. The first question that arises is the following: what does it mean to integrate a form over $\Delta^n$? After all, it is not clear in what sense $\Delta^n$ is a smooth manifold. With some luck that should not be too much of an issue, since $\Delta^n$ is clearly pretty close to being a smooth manifold.

---

Here we implicitly use the following statement: if $A$ and $B$ are subsets of $M$ such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact. We will prove this statement in Exercise 79.2.
(2) Let us suppose that we have resolved (1). Now let \( f : \Delta^n \to M \) be a singular \( n \)-chain.

If the map \( f \) is not smooth, then \( f^* \omega \) just does not make any sense.\(^{1130}\)

(3) After fixing the previous issues, why should \( t \) be a cochain map?

Arguably the most serious issue is (2). The only way around it is to only work with smooth singular simplices. This immediately leads us to the following definition:

**Definition.** Let \( n \in \mathbb{N}_0 \).

1. As in Lemma 41.1 we consider the planar simplex
   \[
   \Delta_n := \left\{ (t_1, \ldots, t_n) \in \mathbb{R}^n_{\geq 0} \left| \sum_{i=1}^n t_i \in [0,1] \right. \right\}.
   \]

2. In Lemma 41.1 we saw that the map \footnote{\( n \)-form on \( M \).}
   \[
   \Theta_n : \Delta_n \to \Delta^n
   \]
   \[
   (t_1, \ldots, t_n) \mapsto \left( t_1, \ldots, t_n, 1 - \sum_{i=1}^n t_i \right)
   \]
   is a homeomorphism.

Now let \( M \) be a smooth manifold.

3. Recall that by the definition on page 278 a map \( f : \Delta^n \to M \) is smooth if given any \( a \in \Delta_n \) there exists an open neighborhood \( U \) in \( \mathbb{R}^n \) of \( a \) and a smooth map \( \tilde{f} : U \to M \) which coincides with \( f \) on \( A \). We define the differential of \( f \) at \( a \in \Delta_n \) to be the differential of \( \tilde{f} \).

4. We say a singular \( n \)-simplex \( \sigma : \Delta^n \to M \) is smooth if the map \( \sigma \circ \Theta_n : \Delta_n \to M \) is smooth. We illustrate the definition in Figure 1151.

5. We write
   \[
   C^\text{smooth}_n(M) = \{ \text{the free abelian group generated by the} \}
   \]
   \[
   \{ \text{set of smooth singular} \ n\text{-simplices in} \ M. \}
   \]
   This is a subgroup of \( C_n(M) \) and it is straightforward to verify that the boundary map \( \partial_n : C_n(M) \to C_{n-1}(M) \) restricts to a map \( \partial_n : C^\text{smooth}_n(M) \to C^\text{smooth}_{n-1}(M) \).

6. Given an abelian group \( G \) we write
   \[
   C^\text{smooth}_n(M;G) := \text{Hom}(C^\text{smooth}_n(M),G)
   \]
   and we define \( \delta_n : C^\text{smooth}_n(M;G) \to C^\text{smooth}_{n+1}(M;G) \) as the map \( \delta_n := \partial^*_n+1 \).

7. We define the \( n \)-th smooth singular cohomology group of a smooth manifold \( M \) with \( G \)-coefficients as
   \[
   H^\text{smooth}_n(M;G) := \frac{\ker(\delta_n : C^\text{smooth}_n(M;G) \to C^\text{smooth}_{n+1}(M;G))}{\text{im}(\delta_{n-1} : C^\text{smooth}_{n-1}(M;G) \to C^\text{smooth}_n(M;G))}.
   \]

\(^{1130}\)Recall that if \( f : N \to M \) is a smooth map between smooth manifolds and \( \omega \) is a smooth differential \( n \)-form on \( M \), then \( f^* \omega \) is defined to be the differential \( n \)-form that for \( v_1, \ldots, v_n \in T_P N \) has the value
   \[
   (f^* \omega)_P(v_1, \ldots, v_n) = \omega_{f(P)}(Df_P(v_1), \ldots, Df_P(v_n)).
   \]
   But if \( f \) is not differentiable, then there is no differential \( Df_P : T_P N \to T_{f(P)} M \).
Remark.

(1) Let $f: M \to N$ be a smooth map between two smooth manifolds. Evidently the induced map $f_*: C^n(M) \to C^n(N)$ restricts to a map $f_*: C^\text{smooth}(M) \to C^\text{smooth}(N)$. In particular we get an induced map $f^*: C^m(C^\text{smooth}(N,G) \to C^m(C^\text{smooth}(M,G))$. Thus we obtain for each $n \in \mathbb{N}_0$ an induced map

$$f^*: H^n(\text{smooth}; N,G) \to H^n(\text{smooth}; M,G).$$

(2) Every map $\Delta^n \to \star$ is smooth, so there is no difference between ordinary singular cohomology and smooth singular cohomology for smooth manifold $\star$.

**Proposition 79.3.** Smooth singular cohomology with real coefficients is a smooth cohomology theory.

**Sketch of proof.** We need to verify that smooth singular cohomology with real coefficients satisfies the properties of a smooth cohomology theory.

(0) It is clear that smooth singular cohomology with real coefficients is a contravariant functor from the category of smooth manifolds to the category of $\mathbb{N}_0$-graded real vector spaces.

(1) Suppose $f, g: M \to N$ are two smooth maps between two smooth manifolds and suppose we are given a smooth homotopy $F$ between $f$ and $g$. Some thought shows that the chain homotopy

$$P_n: C_n(M) \to C_{n+1}(N), \quad n \in \mathbb{N}_0$$

from the proof of Proposition 412.3 restricts to a chain homotopy

$$C^\text{smooth}_n(M) \to C^\text{smooth}_{n+1}(N), \quad n \in \mathbb{N}_0.$$

Now we can once again appeal to Lemma 13.8 to conclude that the induced maps on smooth singular cohomology are the same.

(2) Let $M$ be a smooth manifold and let $U$ and $V$ be open subsets with $M = U \cup V$. The key to proving the existence of the Mayer–Vietoris sequence for ordinary singular cohomology was to show that the inclusion map

$$C^\{U,V\}_n(M) \to C_n(M)$$

is a smooth map.

\[\text{\footnotemark[1]}\]

\[^{131}\text{Put differently, } \Theta_n \text{ is the inverse of the obvious projecton map } \Delta^n \to \Delta_n.\]

\[^{132}\text{It is straightforward to verify that this definition does not depend on the choice of } U \text{ and } \bar{f}.\]
is a chain homotopy equivalence. This in turn we showed using Proposition 43.24. In the proof of Proposition 43.24 we introduced the subdivision maps

\[ u_n : C_n(M) \to C_n(M), \quad n \in \mathbb{N}_0. \]

It follows immediately from the definitions that these maps restrict to maps

\[ u_n : C^\text{smooth}_n(M) \to C^\text{smooth}_n(M), \quad n \in \mathbb{N}_0. \]

Using this observation the proof of the existence of a Mayer-Vietoris sequence for smooth singular cohomology is otherwise identical to the proof for ordinary singular cohomology.

(3) The limit property is proved the same way as Proposition 76.12 (1). We only have to replace the fact, proved in Lemma 47.5 that \( C_\ast(M) = \lim \longrightarrow C_\ast(U_i) \) by the observation that the same argument as in Lemma 47.5 shows that \( C^\text{smooth}_\ast(M) = \lim \longrightarrow C^\text{smooth}_\ast(U_i) \).

\[ \blacksquare \]

Now we can easily show that smooth singular cohomology with real coefficients and ordinary singular cohomology with real coefficients are naturally isomorphic. More precisely, we have the following proposition.

**Proposition 79.4.** There exists a natural isomorphism from smooth singular cohomology with real coefficients to ordinary singular cohomology with real coefficients. In particular for any smooth manifold \( M \) and any \( n \in \mathbb{N}_0 \) we have a natural isomorphism

\[ H^n(M; \mathbb{R}) \isom H^\text{smooth}_n(M; \mathbb{R}). \]

**Proof.** For any smooth manifold \( M \) we have the natural inclusion

\[ C^\text{smooth}_\ast(M) \to C_\ast(M) \]

which evidently respects the boundary maps. These maps thus give rise to natural maps

\[ C^\ast(M; \mathbb{R}) \to C^\text{smooth}_\ast(M; \mathbb{R}) \]

which respect the coboundary maps. Thus we obtain a natural map

\[ t(M) : H^\ast(M; \mathbb{R}) \to H^\text{smooth}_\ast(M; \mathbb{R}). \]

As we pointed out above, for \( \ast \) there is no difference between smooth and ordinary singular cohomology, i.e.

\[ t(\ast) : H^\ast(\ast; \mathbb{R}) \to H^\text{smooth}_\ast(\ast; \mathbb{R}) \]

is an isomorphism. Since the natural transformation is induced by the inclusion map it follows easily that the natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map \( \tau \) appearing in the limit property. The proposition now follows immediately from Theorem 79.2.

\[ \blacksquare \]

Now we also want to relate smooth singular cohomology to de Rham cohomology. The key for doing so is the following definition and the subsequent lemma.
Definition. Given a smooth manifold $M$, given a smooth differential $n$-form $\omega$ on $M$ and a smooth singular $n$-simplex $\sigma: \Delta^n \rightarrow M$ we define

$$\int_{\sigma} \omega := (-1)^n \int_{\Delta_n} (\sigma \circ \Theta_n)^* (\omega) := (-1)^n \int_{\Delta_n} \omega(\sigma \circ \Theta_n)(x)(D_{\sigma \circ \Theta_n}(e_1), \ldots, D_{\sigma \circ \Theta_n}(e_n)).$$

We extend this definition linearly to define the integral of the smooth differential $n$-form $\omega$ over a smooth singular $n$-chain $\sum_{i=1}^k a_i \circ \sigma_i$.

Lemma 79.5. Let $M$ be a smooth manifold, let $\omega$ be a smooth differential $(n-1)$-form on $M$ and let $\sigma: \Delta^n \rightarrow M$ be a smooth singular $n$-simplex. Then

$$\int_{\sigma} d\omega = \int_{\partial \sigma} \omega.$$

In the following we provide a sketch of the proof of Lemma 79.5. A detailed proof is given in [War83, p. 147].

Sketch of the proof. The idea of the proof is of course to use Stokes’ Theorem 78.3. The fact that $\Delta^n$, or equivalently $\Delta_n$, are not smooth manifolds in an obvious way is a slight nuisance. Here is one way how we can circumvent this problem. In [Lee02, Chapter 16] or alternatively [Wall16, p. 30] the theory of smooth manifolds with corner is developed. Prime examples are cubes $[0,1]^n$, half-balls $\{(x_1, \ldots, x_n) \in \overline{B}^n \mid x_n \geq 0\}$ and most interestingly for us, the standard $n$-simplex $\Delta^n$ and equivalently also $\Delta_n$. Furthermore there is a version of Stokes’ Theorem 78.3 for smooth manifolds with corner, see [Lee02, Theorem 16.25].

In the following we provide the proof of Lemma 79.5 with an intuitive understanding of the concepts. All arguments can be made rigorous using the techniques developed in [Lee02, Chapter 16].

---

1133 The Lebesgue integral is defined since $\Delta_n$ is a compact subset of $\mathbb{R}^n$ and since the integrand is continuous.

1134 Recall that on page 1075 we had equipped $\Delta^n$ with an orientation. The factor $(-1)^n$ is motivated by the fact that the restriction of the map $\Theta_n: \Delta_n \rightarrow \Delta^n$ to the interiors is orientation-preserving if and only if $n$ is even.

1135 Note that on the left we integrate a smooth differential $n$-form over a smooth singular $n$-simplex and that on the right we integrate a smooth $(n-1)$-form over a smooth singular $(n-1)$-chain.
Let $M$ be a smooth manifold, let $\omega$ be a smooth $(n-1)$-form and let $\sigma: \Delta^n \to M$ be a smooth singular $n$-simplex. Then

$$\int d\omega = (-1)^n \cdot \int (\sigma \circ \Theta)^*(d\omega) = (-1)^n \cdot \int d(\sigma \circ \Theta)^*(\omega) = (-1)^n \cdot \int (\sigma \circ \Theta_n)^*(\omega)$$

by definition

Proposition 78.2 (6) Stokes Theorem for smooth manifolds with corner applied to $\Delta_n$

$$= \sum_{j=0}^{n} (-1)^j \cdot \int_{\Delta_{n-1}} (-1)^{n-1} \cdot (\sigma \circ i_j^n \circ \Theta_{n-1})^*(\omega) = \sum_{j=0}^{n} (-1)^j \cdot \int_{\sigma \circ i_j^n} \omega = \int_{\partial \sigma} \omega.$$ 

since $\Theta_{n-1} \circ i_j^n \circ \Theta_{n-1}: \Delta_{n-1} \to \partial \Delta_n$ is orientation-reversing if and only if $j$ is even (here we use Proposition 78.2 (1)) of a smooth $(n-1)$-form over a smooth singular $(n-1)$-simplex by definition of the integral by definition of $\partial \sigma$

We refer to Figure 1152 for an illustration of the proof.

![Figure 1152. Illustration for the proof of Lemma 79.5](image)

79.3. The isomorphism between singular and de Rham cohomology. After the preparations in the previous sections we can now easily prove the theorem that we had been aiming for.

**Theorem 79.6. (De Rham Theorem)** There exists a natural isomorphism $u = u_M$ from de Rham cohomology to singular cohomology with real coefficients. In particular for any smooth manifold $M$ and any $k \in \mathbb{N}_0$ we have a natural isomorphism

$$u_M: H^k_{\text{dR}}(M) \xrightarrow{\cong} H^k(M; \mathbb{R})$$

which has the property that for any closed differential $k$-form $\omega$ and any smooth singular $k$-chain $\sigma$ that is a cycle we have

$$\left\langle u_M([\omega]), [\sigma] \right\rangle_M = \int_{\sigma} \omega.$$

(Here we stress, that according to the convention from page 1932 it is understood that the smooth manifolds have empty boundary.)

**Remark.** A rather different proof for Theorem 79.6 is given in [War83, p. 205] and [Ram05, Chapte 4.6]. More precisely, in [War83, Ram05] the equivalence of de Rham cohomology and real valued singular cohomology is proved by relating both to another type...
of cohomology theory, namely sheaf cohomology. We also refer to [BoT82] Theorems 8.9 and 15.8, [Dup78] Theorem 1.15, [?, Section 6.7.6] and [Ful95] Section 15C for other proofs.

**Proof.** We denote by $s$ the natural isomorphism from real-valued singular cohomology to real-valued smooth singular cohomology that we had constructed in the proof of Proposition 79.4.

Now we construct a natural isomorphism $t$ from de Rham cohomology to real-valued smooth singular cohomology. For any smooth manifold $M$ and any $k \in \mathbb{N}_0$ we have, by the above discussion, a map

$$C^k_{\text{dR}}(M) \to C^k_{\text{smooth}}(M; \mathbb{R})$$

$$\omega \mapsto \left( C^k_{\text{smooth}}(M) \to \mathbb{R} \sigma \mapsto \int_\sigma \omega \right)$$

Note that it follows basically immediately from the definitions that this map is natural in $M$. Also note that it is an immediate consequence of Lemma 79.5 that for given $M$ all these maps together form a cochain map $C^*_{\text{dR}}(M) \to C^*_{\text{smooth}}(M; \mathbb{R})$. Summarizing we see that we have constructed a natural map

$$t(M): H^*_{\text{dR}}(M) \to H^*_{\text{smooth}}(M; \mathbb{R}).$$

Furthermore, in the special case of $M = \star$ the map

$$t(\star): H^*_d(\star) \to H^*_d(\star; \mathbb{R})$$

is easily seen to be an isomorphism. Once one has unraveled all the definitions it becomes apparent that this natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map $\tau$ appearing in the limit property. Now we obtain from Theorem 79.2 that $t$ is a natural isomorphism from de Rham cohomology to real-valued smooth singular cohomology.

Finally we set $u := s^{-1} \circ t$. By the above $u$ is a natural isomorphism from de Rham cohomology to singular cohomology with real coefficients. It follows easily from the definitions of $s$ and $t$ that for any closed differential $k$-form $\omega$ and any smooth singular $k$-chain $\sigma$ that is a cycle we have

$$\langle u([\omega]), [\sigma] \rangle_M = \int_\sigma \omega.$$ 

The following proposition summarizes a few useful properties of the natural isomorphism $u_M: H^k_{\text{dR}}(M) \to H^k(M; \mathbb{R})$ from the above de Rham Theorem 79.6.

**Proposition 79.7.**

1. Let $M$ be a closed oriented connected $n$-dimensional smooth manifold. Furthermore let $\omega \in \Omega^n(M)$ be a smooth differential n-form.
   a. We have $\langle u_M([\omega]), [M] \rangle_M = \int_M \omega$.
   b. If $\int_M \omega = 1$, then $u_M([\omega]) = [M]^* \in H^n(M; \mathbb{R})$ where $[M]^*$ denotes the dual fundamental class that we introduced on page 1873.
Let \( f : M \to N \) be a smooth map between closed oriented connected \( n \)-dimensional smooth manifolds and let \( \omega \) be a smooth differential \( n \)-form on \( N \) with \( \int_N \omega = 1 \). Then

\[
\int_M f^* \omega = \deg(f : M \to N).
\]

**Proof.**

(1) (a) Let \( M \) be a closed oriented connected \( n \)-dimensional smooth manifold and let \( \omega \in \Omega_n(M) \) be a smooth differential \( n \)-form. As we explained in Algorithm 68.2 there exist smooth singular simplices \( \varphi_1, \ldots, \varphi_k : \Delta^n \to M \) with the following properties:

(i) We have \( \bigcup_{i=1}^k \varphi_i(\Delta^n) = M \).

(ii) For any \( i, j \in \{1, \ldots, k\} \) we have \( \varphi_i(\Delta^n) \cap \varphi_j(\Delta^n) = \varphi_i(\partial \Delta^n) \cap \varphi_j(\partial \Delta^n) \).

(iii) If for each \( i \in \{1, \ldots, k\} \) we set \( \epsilon_i = +1 \) if \( \varphi_i \) is orientation-preserving and \( \epsilon_i = -1 \) otherwise, then the singular chain \( \sigma := \epsilon_1 \cdot \varphi_1 + \cdots + \epsilon_k \cdot \varphi_k \) is a singular cycle that represents the fundamental class \([M]\).

As above we denote by \( \Theta_n : \Delta_n \to \Delta^n \) the inverse of the obvious projection map. We calculate that

\[
\int_M \omega = \sum_{i=1}^k (-1)^n \cdot \epsilon_i \cdot \int_{\Delta_n} (\varphi_i \circ \Theta_n)^*(\omega) = \int_M \omega = \langle u_M([\omega]), [M] \rangle_M.
\]

follows fairly easily from (i) (ii) see definition and our orientation conventions by Theorem 79.6

(b) This statement follows immediately from (a) and the definition of the dual fundamental class.

(2) Let \( f : M \to N \) be a smooth map between closed oriented connected \( n \)-dimensional smooth manifolds and let \( \omega \) be a smooth differential \( n \)-form on \( N \) with \( \int_N \omega = 1 \).

\[
\int_M f^* \omega = \deg(f) \cdot \langle u_N([\omega]), [M] \rangle_N = \deg(f) \cdot \int_N \omega = \deg(f) \cdot \langle u_N([\omega]), [M] \rangle_N.
\]

by definition of \( \deg(f) \) by (1a) by choice of \( \omega \)

Theorem 79.6 allows us to transport information from de Rham cohomology to real-valued singular cohomology and vice-versa. For example the many computational techniques that we had developed, e.g. cellular cohomology, for singular cohomology can now be used to calculate isomorphism types of de Rham cohomology groups. In particular we can easily prove the following corollary.
Corollary 79.8. If $M$ is a closed, oriented connected, non-empty $n$-dimensional smooth manifold, then the map
\[ H^n_{\text{dR}}(M) \to \mathbb{R} \]
\[ [\omega] \mapsto \int_M \omega \]
is an isomorphism.

Proof. By Proposition 78.4 (7) the map is well-defined and it is an epimorphism. On the other hand, by Proposition 75.15 and Theorem 79.6 we know that $H^n_{\text{dR}}(M) \cong \mathbb{R}$, which implies that the map is an isomorphism. ■

79.4. Realizing cohomology classes by maps to $S^1$. We start out this section with the following definition.

Definition. Let $G$ be a group, let $Y$ be a topological space and let $y_0 \in Y$ be a point with an identification $\pi_1(Y, y_0) = G$. Given another topological space $X$ and $x_0 \in X$ we say that a homomorphism $\varphi: \pi_1(X, x_0) \to G = \pi_1(Y, y_0)$ is realized by a map $g: X \to Y$ if $g(x_0) = y_0$ and if $g_* = \varphi$. If there is no danger of confusion we will drop the base points from the notation.

In the following we will mostly discuss the case $G = \mathbb{Z}$ and $Y = S^1$. Before we can continue we introduce the following conventions.

Convention.

(1) We use the diffeomorphism $\mathbb{R}/\mathbb{Z} \to S^1$ given by $[t] \mapsto e^{2\pi i t}$ to make the identification $\mathbb{R}/\mathbb{Z} = S^1$.

(2) By Proposition 16.17 we have an isomorphism $\mathbb{Z} \to \pi_1(S^1, 1)$ given by sending 1 to the equivalence class of the loop $t \mapsto e^{2\pi i t}$. We use this isomorphism to make the identification $\pi_1(\mathbb{R}/\mathbb{Z}, 0) = \pi_1(S^1, 1) = \mathbb{Z}$.

(3) Let $X$ be a path-connected topological space and let $x_0 \in X$. As shown in Proposition 75.18 we can use the Hurewicz homomorphism and the evaluation homomorphism to make the identifications $H^1(X; \mathbb{Z}) = \text{Hom}(H_1(X); \mathbb{Z}) = \text{Hom}(\pi_1(X, x_0), \mathbb{Z})$.

Now we can formulate the following question.

Question 79.9. Let $X$ be a path-connected topological space that is “reasonable”, e.g. that is a smooth manifold or a CW-complex. Let $x_0 \in X$ be a base point. Can every homomorphism $\varphi: \pi_1(X, x_0) \to \mathbb{Z} = \pi_1(S^1, 1)$ be realized by a map $(X, x_0) \to (S^1, 1)$?

The following proposition gives an affirmative answer if $X$ is a smooth manifold.

Proposition 79.10. Let $M$ be a connected smooth manifold (here for once we allow $M$ to have boundary) and let $P$ be a base point.

(1) Every class $\phi \in H^1(M; \mathbb{Z}) = \text{Hom}(\pi_1(M, P), \mathbb{Z})$ can be realized by a smooth map $g: M \to S^1$ with $g(P) = 1$.

(2) We suppose that $\partial M = \emptyset$. If $f, g: M \to S^1$ are two smooth maps with $g(P) = 1$, such that $f_* = g_*: \pi_1(M, P) \to \pi_1(S^1, 1)$, then $f$ and $g$ are homotopic.

(3) Let $\phi \in H^1(M; \mathbb{Z})$ and let $P \in \partial M$. If $f: \partial M \to S^1$ is a smooth map that realizes $\phi|_{\partial M}$, then there exists a smooth map $g: M \to S^1$ with $g|_{\partial M} = f$ that realizes $\phi$. 
Remark.

(1) Sometimes the following reformulation of Proposition 79.10 is quite useful: Let $M$ be a connected smooth manifold and let $P$ be a base point. Given any $\phi \in H^1(M; \mathbb{Z})$ there exists a smooth map $g: M \to S^1$ and a generator $\psi \in H^1(S^1; \mathbb{Z})$ with $\phi = g^*(\psi)$.

(2) Proposition 79.10(2) can be viewed as a partial converse to Proposition 78.3.

(3) Later on, in Proposition 120.15 we will prove an analogue of Proposition 79.10 for $CW$-complexes. This will allows in Proposition 120.20 to give a new proof of Proposition 79.10.

Examples.

(1) We consider the torus $T = S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ and we make the usual identification $H_1(T; \mathbb{Z}) = \mathbb{Z}^2$. We consider the cohomology classes in $H^1(T; \mathbb{Z}) = \text{Hom}(H_1(T), \mathbb{Z})$ that are given by

$$\phi: H_1(T; \mathbb{Z}) = \mathbb{Z}^2 \to \mathbb{Z} \quad \text{and} \quad \psi: H_1(T; \mathbb{Z}) = \mathbb{Z}^2 \to \mathbb{Z}$$

$$(m, n) \mapsto m \quad \text{and} \quad (m, n) \mapsto n.$$ 

These two cohomology classes are evidently realized by the projection $S^1 \times S^1 \to S^1$ onto the first, respectively the second factor. In Exercise 79.3 the goal will be to give an example of an explicit map $g: T \to S^1$ that realizes the homomorphism $\varphi: H_1(T; \mathbb{Z}) = \mathbb{Z}^2 \to \mathbb{Z}$ given by $\varphi(m, n) = 6m + 4n$.

(2) In Figure 1153 we consider the surface $\Sigma$ of genus 2. As we saw on page 1270 the oriented curves $x_1, y_1, x_2, y_2$ represent a basis for $H_1(\Sigma)$. We consider some random epimorphism $\phi: H_1(\Sigma) \to \mathbb{Z}$, e.g. we could consider the epimorphism $\phi: H_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0, \phi(y_1) = 1, \phi(x_2) = -2$ and $\phi(y_2) = 1$. By Proposition 79.10, we know that $\phi$ can be realized by some map $g: \Sigma \to S^1$. But can one “visualize” such a map? We will return to this question on page 2370.

\[\text{Figure 1153}\]

We break the proof of Proposition 79.10 into three parts.

**Proof of Proposition 79.10 (1).** Let $M$ be a connected smooth manifold. We first assume that $M$ has no boundary. We start out with the following definition. Let $\omega$ be a smooth differential 1-form on $M$ and let $\gamma: [a, b] \to M$ be a piecewise smooth path. We pick $a = t_0 < t_1 < \cdots < t_n = b$ such that the restriction of $\gamma$ to each subinterval $[t_i, t_{i+1}]$ is smooth. We define

$$\int_{[a,b]} \gamma^* \omega = \sum_{i=0}^{n-1} \int_{[t_i, t_{i+1}]} \gamma^* \omega.$$ 

It follows immediately from Proposition 78.2 (2) that this definition does not depend on the choice of the subdivision.
After this preparation we start with the actual proof of the proposition. We fix a base point \( P \in M \). Furthermore let \( \phi \in H^1(M; \mathbb{Z}) = \text{Hom}(\pi_1(M, P), \mathbb{Z}) \). We denote by \( u \) the natural isomorphism from de Rham cohomology to singular cohomology with real coefficients from Theorem 79.6. We pick a smooth closed differential 1-form \( \omega \) on \( M \) with \( u([\omega]) = \phi \).

**Claim.** Let \( \delta: [0, 1] \to M \) be a piecewise smooth loop in \( P \). Then

\[
\int_{[0,1]} \delta^* \omega = \phi([\delta]) \in \mathbb{R}.
\]

Let \( \delta: [0, 1] \to M \) be a piecewise-preserving smooth loop in \( P \). One can show easily that after possibly performing an orientation-preserving reparametrization we can write \( \delta = \delta_1 \cdots \delta_k \) as a product of smooth paths \( \delta_i: [0, 1] \to M, i = 1, \ldots, k \). As in the definition of the Hurewicz homomorphism we use the map \( t \mapsto (1-t, t) \) to make the identification \([0, 1] = \Delta^1\). Using this identification we view each \( \delta_i \) also as a smooth 1-simplex. In particular we have \( \delta_1 + \cdots + \delta_k \in C^\text{smooth}_1(M) \). Then

\[
\int_{[0,1]} \delta^* \omega = \int_{\delta_1 + \cdots + \delta_k} \omega = \phi([\delta_1 + \cdots + \delta_k]) = \phi([\delta]).
\]

We define

\[
g: M \to S^1 = \mathbb{R}/\mathbb{Z}
\]

\[
Q \mapsto \left\lbrack \int_{[0,1]} \gamma^* \omega \right\rbrack \quad \text{where } \gamma \text{ is a smooth path}^{1136} \text{ from } P \text{ to } Q.
\]

We claim that the map \( g \) has the required properties. It remains to prove the following four statements:

1. The map \( g \) is well-defined.
2. We have \( g(P) = [0] \in \mathbb{R}/\mathbb{Z} \).
3. The map \( g \) is smooth.
4. We have \( g_* = \phi: \pi_1(M, P) \to \pi_1(S^1, 1) = \mathbb{Z} \).

Now we turn to the proofs of the statements.

1. Let \( Q \) in \( M \). Suppose we are given two piecewise smooth paths \( \beta \) and \( \gamma \) from the base point \( P \) to \( Q \). (See the left of Figure 1154 for an illustration.) Then

\[
\int_{[0,1]} \beta^* \omega - \int_{[0,1]} \gamma^* \omega = \int_{[0,1]} (\beta * \gamma)^* \omega = \phi([\beta * \gamma]) \in \mathbb{Z}.
\]

This shows that \( g \) is indeed well-defined.

---

1136 By Lemma 8.30 (2) any two points on a connected smooth manifold, that do not lie on the boundary, can be connected by a smooth path. Here we again use that \( M \) has no boundary.
(2) We determine $g(P)$ by taking the constant path from $P$ to $P$. It follows immediately from the definition of $g$ that $g(P) = [0] \in \mathbb{R}/\mathbb{Z}$.

(3) Let $Q \in M$. We need to show that $g$ is smooth in an open neighborhood of $Q$. We pick a path $\gamma$ from $P$ to $Q$. We pick a chart $\Phi: U \to B_r(0)$ around $Q$ with $\Phi(Q) = 0$. Given a point $R \in U$ we denote by $\delta_R$ the piecewise smooth path that is given by the concatenation of the following two paths:

(a) the path $\gamma$ from $P$ to $Q$,

(b) the "radial path" from $Q$ to $R$ that corresponds, under the diffeomorphism $\Phi$, to the radial path from 0 to $\Phi(R) \in B_r(0)$.

(See the right of Figure 1154 for an illustration.) Using these paths $\delta_R$ it is now relatively straightforward to show that $g$ is smooth in $U$. We leave the verification of the details to the reader.

(4) Suppose we are given an element in $\pi_1(M, P)$. By Lemma 8.30 (1) we can represent this element by a smooth loop $\delta: [0, 1] \to M$. We have the following equality:

by Theorem 16.16

\[
g_*([\delta]) = \text{endpoint of the lift of } g \circ \delta: [0, 1] \to \mathbb{R} \text{ to the universal covering } \mathbb{R} \text{ of } \mathbb{R}/\mathbb{Z}
\]

\[
= \text{endpoint of the lift of the path } t \mapsto \int_{[0, t]} \delta^* \omega \text{ to the universal covering } \mathbb{R}
\]

\[
= \text{endpoint of the path } t \mapsto \int_{[0, t]} \delta^* \omega = \text{the point } \int_{[0, 1]} \delta^* \omega = \phi([\delta])
\]

by the above claim

We have thus shown that $g_* = \phi: \pi_1(M, P) \to \pi_1(S^1, 1) = \mathbb{Z}$.

This concludes the proof of the theorem in the case that $M$ has empty boundary.

Finally let $M$ be a smooth manifold with non-empty boundary. To deal with this case we consider $W := M \cup (\partial M \times [0, 1))$ where we make the obvious identification of $P = P \times \{0\}$ for $P \in \partial M$. Using the Collar Neighborhood Theorem 8.12 one can easily verify that $W$ is a smooth manifold such that $M$ is a submanifold and such that $W$ has no boundary. Evidently $M$ is a deformation retract of $W$. It follows from Lemma 18.14 and Proposition 18.16 (2) that the induced map $i_*: \pi_1(M, P) \to \pi_1(W, P)$ is an isomorphism. Now let $\phi \in \text{Hom}(\pi_1(M, P), \mathbb{Z})$. By the previously considered case we can realize $\phi \circ (i_*)^{-1}: \pi_1(W, P) \to \mathbb{Z}$ by a smooth map $g: W \to S^1$. The restriction of $g$ to $M$ has all the desired properties.

**Figure 1154**

**Proof of Proposition 79.10 (2).** We suppose that $\partial M = \emptyset$. In the following let $f, g: M \to S^1 = \mathbb{R}/\mathbb{Z}$ be two smooth maps with $g(P) = 1$, such that we have the equality
\[ f_\ast = g_\ast : \pi_1(M, P) \to \pi_1(S^1, 1) \]. We need to show that \( f \) and \( g \) are homotopic. Let \( \omega \) be the standard closed differential 1-form on \( S^1 = \mathbb{R}/\mathbb{Z} \). We set \( \alpha := f^\ast \omega \) and \( \beta := g^\ast \omega \).

**Claim.** There exists a closed differential 1-form \( \psi \) on \( M \times [0, 1] \) such that the restriction to \( M \times \{0\} = M \) equals \( \alpha \) and such that the restriction to \( M \times \{1\} = M \) equals \( \beta \).

First note that it follows from the fact that \( f_\ast = g_\ast \) and from the natural isomorphisms \( H^1_{\text{dR}}(M) = \text{Hom}(\pi_1(M, P), \mathbb{R}) = \text{Hom}(\pi_1(M, P), \mathbb{R}) \) that \([\alpha] = f^\ast (\omega) = g^\ast (\omega) = [\beta] \in H^1_{\text{dR}}(M)\).

By definition this means that there exists a 0-form \( \varphi \) on \( M \) with \( d \varphi = \alpha - \beta \). Next let \( p: M \times [0, 1] \to M \) and \( q: M \times [0, 1] \to [0, 1] \) be the obvious projection. Furthermore let \( h: [0, 1] \to [0, 1] \) be a map that is zero close to 0 and one close to 1. On \( M \times [0, 1] \) we consider the 1-form that given by \( \psi := p^\ast \alpha - d(q^\ast h \cdot \varphi) \). It follows from Proposition 78.2 that \( \psi \) is closed. We calculate that

\[
\psi = p^\ast \alpha - d(q^\ast h \cdot \varphi) = p^\ast \alpha - (q^\ast (dh) \cdot \varphi + q^\ast h \cdot d \varphi) = p^\ast \alpha - q^\ast (dh) \cdot \varphi - q^\ast h \cdot d \varphi.
\]

Next note that, as in the proof of Statement (1), the closed 1-form \( \psi \) gives rise to a map \( F: M \times [0, 1] \to S^1 \). It follows fairly easily from the definitions that \( F_0 = f \) and \( F_1 = g \). We leave it to the reader to fill in the details.

**Proof of Proposition 79.10 (3).** Let \( \phi \in H^1(M; \mathbb{Z}) \), let \( P \in \partial M \) and let \( f: \partial M \to S^1 \) be a smooth map that realizes \( \phi|_{\partial M} \). By the Collar Neighborhood Theorem 8.12 we can pick a collar neighborhood \( [0, 1] \times \partial M \). We set \( W := M \setminus ([0, 1) \times \partial M) \) and we equip it with the base point \((P, 1)\). By Corollary 8.14 we know that \( W \) is an \( n \)-dimensional smooth manifold with \( \partial W = \{1\} \times M \). By Proposition 79.10 (1) there exists a smooth map \( h: W \to S^1 \) which realizes \( \phi|_W \). It is now straightforward to see that under the obvious isomorphism \( \{0\} \times M \to \{1\} \times M \) the maps \( f_\ast : H_1(M; \mathbb{Z}) \to H_1(S^1; \mathbb{Z}) \) and \( h_\ast : H_1(M; \mathbb{Z}) \to H_1(S^1; \mathbb{Z}) \) agree. At this point we can conclude from Proposition 79.10 (2) that there exists a smooth map \( F: [0, 1] \times \partial M \to S^1 \) such that \( F_0 = f \) and \( F_1 = h|_{\{1\} \times M} \).

Note that by definition of a collar neighborhood and by Lemma 8.11 we know that \([0, 1] \times \partial M \) and \( W \) are closed subsets of \( M \). Thus we obtain from Lemma 2.33 (2) that the two maps \( F \) and \( g \) combine to a continuous map \( h: M \to S^1 \).

Since \( h \) is smooth on \([0, 1] \times \partial M \) we obtain from the Whitney Approximation Theorem 9.3 that \( h \) is homotopic rel \( \{0\} \times \partial M \) to a smooth map \( g: M \to S^1 \). This map now has all the desired properties.

Of course one can ask many variations on Question 79.9. Since arbitrary topological spaces can be quite weird we restrict ourselves in the following questions to CW-complexes.

**Question 79.11.** Let \( X \) be a connected CW-complex.

1. Let \( g \geq 1 \) and let \( \Sigma_g \) be the surface of genus \( g \geq 1 \). Can every homomorphism \( \pi_1(X) \to \pi_1(\Sigma_g) \) be realized by a map \( X \to \Sigma_g \)?
(2) Can every homomorphism $\pi_1(X) \to \pi_1\left(\bigvee_{i=1}^k S^1\right) = \langle x_1, \ldots, x_k \rangle$ be realized by a map $X \to \bigvee_{i=1}^k S^1$?

(3) Can every homomorphism $\pi_1(X) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}P^2)$ be realized by a map $X \to \mathbb{R}P^2$?

79.5. **Rewriting products** $M \times S^1 \ (\ast)$. Proposition 79.10 (1) has many consequences. For example in Proposition 98.4 we will use it to show that for a given compact orientable $n$-dimensional smooth manifold $M$ any class in $H_{n-1}(M; \mathbb{Z})$ can be represented by a submanifold. In this section we will give a different application, namely we will see that in many situations one can find interesting ways to rewrite a product $M \times S^1$ where $M$ is a closed connected smooth manifold.

To formulate that application it is convenient to recall the following definition from page 711.

**Definition.** Let $X$ be a topological space and let $f : X \to X$ be a map. We refer to

$$\text{Tor}(X, f) := \left( X \times [0, 1]\right) / \sim$$

where $(x, 0) \sim (f(x), 1)$ for all $x \in X$,

as the **mapping torus** of $(X, f)$. We refer to the map

$$q : \text{Tor}(X, f) = \left( X \times [0, 1]\right)/\sim (x, 0) \sim (f(x), 1) \quad S^1$$

as the natural projection onto $S^1$.

Throughout this section we also use the following notation.

**Notation.** We denote by $\Theta : H_1(S^1) \to \mathbb{Z}$ the isomorphism given by $\Theta([S^1]) = 1$.

Now we can state the main result of this section.

**Proposition 79.12.** Let $M$ be a closed connected manifold and let $\phi : H_1(M \times S^1; \mathbb{Z}) \to \mathbb{Z}$ be an epimorphism. We set $k = k(\phi) := \phi([\ast] \times S^1)$). If $k \neq 0$, then there exists a $|k|$-fold covering $p : \tilde{M} \to M$ and a deck transformation $f : \tilde{M} \to \tilde{M}$ together with a diffeomorphism $\Xi : \text{Tor}(\tilde{M}, f) \to M \times S^1$ such that the following diagram commutes:

$$\begin{array}{ccc}
H_1(\text{Tor}(\tilde{M}, f); \mathbb{Z}) & \xrightarrow{\text{Z}_x} & H_1(M \times S^1; \mathbb{Z}) \\
\Theta \circ q & \downarrow \phi & \\
& \mathbb{Z}, &
\end{array}$$

*Here the diagonal map to the left is induced by the natural projection.*

**Remark.**

(1) Proposition 79.12 can be viewed as a “manifold analogue” of the group-theoretic statement of Exercise 24.17.

(2) One mathematician once called products “slippery”. Indeed, as we will see in the examples below, Proposition 79.12 shows that many products have alternative descriptions.

\[\text{By Lemma 24.22 the mapping torus } \text{Tor}(\tilde{M}, f) \text{ naturally has the structure of a smooth manifold.}\]
Examples.

(1) Let $M$ be a closed connected non-empty smooth manifold and let $\psi: H_1(M; \mathbb{Z}) \to \mathbb{Z}$ be a homomorphism. We apply Proposition 79.12 to the epimorphism $\phi: H_1(M \times S^1; \mathbb{Z}) = H_1(M; \mathbb{Z}) \oplus H_1(S^1; \mathbb{Z}) \to \mathbb{Z}$, $(\sigma, n \cdot [S^1]) \mapsto \psi(\sigma) + n$.

Note that we have $k = k(\phi) = 1$. This implies that the map $p: \tilde{M} \to M$ is a covering of degree 1. By Proposition 29.8 we can assume that $\tilde{M} = M$ and that $p = \text{id}$. Note that the only deck transformation of the 1-fold covering $\tilde{M} \to M$ is the identity. Thus we obtain from Proposition 79.12 that there exists a diffeomorphism $\Xi: M \times S^1 \to M \times S^1$ such that the following diagram commutes

$$
\begin{array}{ccc}
H_1(M \times S^1; \mathbb{Z}) & \xrightarrow{\Xi_*} & H_1(M \times S^1; \mathbb{Z}) \\
\downarrow{\Theta \circ q_*} & & \downarrow{\phi} \\
\mathbb{Z} & & \mathbb{Z}
\end{array}
$$

where $q: M \times S^1 \to S^1$ denotes the natural projection. Note that if $\psi: H_1(M; \mathbb{Z}) \to \mathbb{Z}$ is non-zero, then $\Xi_*$ is not the identity. Summarizing, we have now shown that if $H^1(M; \mathbb{Z}) = \text{Hom}(H_1(M; \mathbb{Z}), \mathbb{Z}) \neq 0$, then $M \times S^1$ can be decomposed as a product in more than one way.

(2) Let $\Sigma$ be the surface of some genus $g \in \mathbb{N}_{\geq 2}$ and let $\phi: H_1(\Sigma \times S^1; \mathbb{Z}) \to \mathbb{Z}$ be an epimorphism such that $k = k(\phi) \neq 0$. It follows from Proposition 79.12 together with Proposition 31.6 (1) or alternatively with Lemma 55.9 that $\Sigma \times S^1$ is diffeomorphic to a mapping torus of the form $\text{Tor}(\tilde{\Sigma}, f)$ where $\tilde{\Sigma}$ is a surface of genus $|k| \cdot (g-1) + 1$. In particular we obtain the slightly mind-boggling statement that the product $\Sigma \times S^1$ can also be viewed as a mapping torus of a self-diffeomorphism of a surface of arbitrarily high genus.

Proof. First we pick points $* \in M$ and $* \in S^1$ and we denote by $j_1: M \xrightarrow{x \mapsto (x,*)} M \times S^1$ and $j_2: S^1 \xrightarrow{z \mapsto (*)z} M \times S^1$ the corresponding inclusions. Note that by Proposition 79.10 (1) there exists a smooth map $g: M \to S^1$ such that the map $H_1(M) \xrightarrow{g} H_1(S^1) \xrightarrow{\text{id}} \mathbb{Z}$ equals $\phi \circ j_1*: H_1(M) \to \mathbb{Z}$. Now let us consider the following pullback diagram:

$$
\begin{array}{ccc}
\tilde{M} := \{(x, z) \in M \times S^1 \mid g(x) = z^k\} & \xrightarrow{(x, z) \mapsto z} & S^1 \\
\downarrow{(x, z) \mapsto x} & & \downarrow{z \mapsto z^k} \\
M & \xrightarrow{g} & S^1.
\end{array}
$$

By Lemma 25.16 we know that $p: \tilde{M} \to M$ is a $k$-fold covering. The map

$$
\begin{align*}
f: \tilde{M} & \to \tilde{M} \\
(x, z) & \mapsto (x, e^{-2\pi i/k} \cdot z)
\end{align*}
$$
is evidently a deck transformation. Next we consider the following diagram:

\[
\begin{array}{ccc}
\widetilde{M} \times S^1 & \xrightarrow{((x,z),w)\mapsto((x,z),z^{-1}w)} & \widetilde{M} \times S^1 \\
((x,z),e^{2\pi it})\mapsto([(x,z),k\cdot t \mod \mathbb{Z}]) & & ((x,z),w)\mapsto(x,w) \\
\text{Tor}(\widetilde{M}, f) & \xrightarrow{[((x,z),t)\mapsto(x,z)^{-1}e^{2\pi it/k}]} & M \times S^1.
\end{array}
\]

We make the following observations:

1. One can easily verify that the bottom map is in fact well-defined and that the diagram commutes.
2. It is pretty clear that the top map is a diffeomorphism.
3. It is straightforward to show that the vertical maps are local diffeomorphisms and they are degree \( k \) coverings.

It follows from the above together with Exercise 17.3 that the bottom map is also a diffeomorphism. It remains to prove the following claim.

Claim. We have \( \phi \circ \Xi_* = \Theta \circ q_* : H_1(\text{Tor}(\widetilde{M}, f)) \to \mathbb{Z} \).

We consider the following diagram:

\[
\begin{array}{ccc}
H_1(\widetilde{M}) & H_1(M) \oplus H_1(S^1) & H_1(S^1) \oplus H_1(S^1) \\
\downarrow i^* & \pi_1^* \oplus \pi_2^* \cong & \pi_1^* \oplus \pi_2^* \cong \\
H_1(\text{Tor}(\widetilde{M}, f)) & H_1(M \times S^1) & H_1(S^1) \\
\downarrow q_* & \phi & \Theta \\
H_1(S^1) & \mathbb{Z} & \mathbb{Z}.
\end{array}
\]

We make the following clarifications and observations:

1. The map \( i^* : \widetilde{M} \to \text{Tor}(\widetilde{M}, f) \) is the natural inclusion given by \( x \mapsto [(x,0)] \).
2. The map \( \mu : S^1 \times S^1 \to S^1 \) is the multiplication map.
3. In both settings we denote by \( \pi_1 \) and \( \pi_2 \) the projection onto the first respectively second factor.
4. The map \( h : S^1 \to S^1 \) is given by \( z \mapsto z^k \). Note that by Lemma 45.10 we know that \( h_* : H_1(S^1) \to H_1(S^1) \) is given by multiplication by \( k \).
5. It follows from Exercise 52.5 or alternatively from the discussion on page 1965 that the vertical maps in the middle are isomorphisms and inverses of one another.
6. The upper left triangle commutes by the functoriality of homology groups.
7. The triangle to the right commutes by Exercise 52.4.
8. The big rectangle to the right commutes by the choice of \( g \) and \( h \).

The reader might note that the top map is the restriction of the map \((M \times S^1) \times S^1 \to (M \times S^1) \times S^1\) given by the same formula, which is clearly a diffeomorphism, to the submanifold \( M \times S^1 \) of \((M \times S^1) \times S^1\).
(9) It follows from (5), (6), (7) and (8) that the triangle at the bottom commutes.

(10) Recall that any point \((x, z) \in \hat{M}\) satisfies by definition \(g(x) = z^k\). It now follows immediately that the map \((g \times h) \circ \mu \circ \Xi \circ i: \hat{M} \to S^1\) is the constant map.

(11) It follows from (9) and (10) that \(\phi \circ \Xi \circ i_s: H_1(\hat{M}) \to \mathbb{Z}\) is the zero map.

(12) By Lemma [46.23] we know that the vertical sequence to the left is exact.

(13) It follows from (10) and (11) that the vertical map \(\Omega\) exists.

(14) We pick \((x, z) \in \hat{M}\). We use the homeomorphism from Lemma 24.25 to make the identification \(\text{Tor}(\hat{M}, f) = (\hat{M} \times \mathbb{R})/(w, t) \sim (f(w), t + 1)\). Now we consider the singular 1-cycle

\[
\sigma: \Delta^1 \to \text{Tor}(\hat{M}, f) = (\hat{M} \times \mathbb{R})/(w, t) \sim (f(w), t + 1)
\]

\[
(1 - t, t) \mapsto [(x, z), kt].
\]

It follows immediately from the definitions that \((\phi \circ \Xi)(([\sigma])) = k\) and \((\Theta \circ q_\ast)([\sigma]) = k\).

Thus we have \(\Omega(k) = k\). Since \(k \neq 0\) we see that \(\Omega = \text{id}\). ■

79.6. **The wedge product of differential forms** \((\ast)\). For a real vector space \(V\) we had already introduced on page 1916 the bilinear wedge product

\[
\wedge^k V^* \times \wedge^l V^* \to \wedge^{k+l} V^*.
\]

Given a smooth manifold \(M\) we can define this wedge product for each tangent space \(V = T_P M\). Using charts one can show that this wedge product sends smooth forms to smooth forms. More precisely, we have a bilinear map

\[
\wedge: C^k_{\text{dr}}(M) \times C^l_{\text{dr}}(M) \to C^{k+l}_{\text{dr}}(M).
\]

We refer [Tu11, p. 205] for details.

**Lemma 79.13.** Let \(M\) be a smooth manifold. For any \(k, l \in \mathbb{N}_0\) the map

\[
\wedge: H^k_{\text{dr}}(M) \times H^l_{\text{dr}}(M) \to H^{k+l}_{\text{dr}}(M)
\]

\[
([\omega], [\sigma]) \mapsto [\omega] \wedge [\sigma] := [\omega \wedge \sigma]
\]

is well-defined.

**Proof.** By [Tu11, Proposition 4.7] we know that for any smooth differential \(k\)-form \(\omega\) and any smooth differential \(l\)-form \(\sigma\) we have

\[
(\ast) \quad d(\omega \wedge \sigma) = d\omega \wedge \sigma + (-1)^k \cdot \omega \wedge d\sigma.
\]

Now let \(\omega \in C^k_{\text{dr}}(M)\) and \(\sigma \in C^l_{\text{dr}}(M)\) be smooth forms.

(1) It follows immediately from \((\ast)\) that \(\omega \wedge \sigma\) is again closed.

(2) If \(\omega' = \omega + d\tau\) is another representative of \([\omega]\), then

\[
\omega' \wedge \sigma - \omega \wedge \sigma = (\omega' - \omega) \wedge \sigma = d\tau \wedge \sigma = d(\tau \wedge \sigma).
\]

↑ since “\(\wedge\)” is bilinear

by \((\ast)\) and since \(d\sigma = 0\)

This shows that \(\omega \wedge \sigma\) and \(\omega' \wedge \sigma\) represent the same de Rham cohomology class, i.e. the wedge product does not depend on the choice of the representative of the de Rham cohomology class of the first entry.
(3) The proof that the wedge product does not depend on the choice of the representative of the second de Rham cohomology class is basically the same as the proof of (2).

At this point it is helpful to introduce the following definition.

**Definition.**

1. A graded ring is a ring $R$ together with a direct sum decomposition $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ into subgroups such that for any $m, n \in \mathbb{N}_0$ the multiplication map restricts to a map $R_m \times R_n \to R_{m+n}$.

2. A graded ring $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ such that for any two homogeneous elements $a$ and $b$ the equality $a \cdot b = (-1)^{\deg(a)\cdot\deg(b)} \cdot b \cdot a$ holds is called a superalgebra.

3. Let $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ and $S = \bigoplus_{n \in \mathbb{N}_0} S_n$ be two graded rings. A morphism between the two graded rings is a ring homomorphism $\varphi: R \to S$ such that for any $n \in \mathbb{N}_0$ we have $\varphi(R_n) \subset S_n$.

4. We define the category $\text{GrRing}$ of graded rings to be the category where the objects are graded rings and the morphisms are morphisms of graded rings. Similarly we define the category of graded superalgebras.

**Example.** We consider the polynomial ring $R = \mathbb{Q}[x]$. We can view this ring as a graded ring by defining $R_n := \mathbb{Q} \cdot x^n$ for $n \in \mathbb{N}_0$.

Recall that for a given smooth manifold $M$ we write

$$H^*_\text{dR}(M) = \bigoplus_{i=0}^{\infty} H^i_{\text{dR}}(M).$$

We consider the following map

$$\wedge: H^*_\text{dR}(M) \times H^*_\text{dR}(M) \to H^*_\text{dR}(M)$$

$$\left(\sum_{i=0}^{\infty} x_i, \sum_{i=0}^{\infty} y_i\right) \mapsto \sum_{i,j=0}^{\infty} x_i \wedge y_j,$$

where it is understood that each $x_i$ and $y_i$ is homogeneous of degree $i$.

The following proposition summarizes the key features of the wedge product on de Rham cohomology.

**Proposition 79.14.** The maps

$$M \mapsto (H^*_\text{dR}(M), \wedge)$$

$$(f: M \to N) \mapsto (f^*: H^*_\text{dR}(N) \to H^*_\text{dR}(M))$$
define a contravariant functor from the category of smooth manifolds to the category of graded superalgebras.

Proof.

(1) First note that it follows almost immediately from Lemma 78.1 that for a given smooth manifold $M$ the wedge product turns $H^*_{\text{dR}}(M)$ into a graded superalgebra. It follows immediately from the definitions that the multiplicatively neutral element in de Rham cohomology is hereby the 0-dimensional cohomology class that is represented by the constant function $f : M \to \mathbb{R}, x \mapsto 1$.

(2) If $f : M \to N$ is a smooth map between smooth manifolds, then it follows immediately from the definitions that for any choice of $\omega \in C^k_{\text{dR}}(N)$ and $\sigma \in C^l_{\text{dR}}(N)$ the following equality holds:

$$ (f^*\omega \wedge f^*\sigma) = f^*(\omega \wedge \sigma). $$

Therefore the smooth map $f$ induces a morphism $f^* : H^*_{\text{dR}}(N) \to H^*_{\text{dR}}(M)$ of graded rings. $\blacksquare$

Example. We consider the differential 1-forms $dx$ and $dy$ on $\mathbb{R}^2$ which are given by $dx(v, w) = v$ and $dy(v, w) = w$. Furthermore we identify the 2-torus $T$ with the quotient space $\mathbb{R}^2 / \mathbb{Z}^2$ and we denote the projection $\mathbb{R}^2 \to T = \mathbb{R}^2 / \mathbb{Z}^2$ by $p$. It is straightforward to see that $dx$ and $dy$ induce differential 1-forms on $T$. We denote these also by $dx$ and $dy$. The 1-forms $dx$ and $dy$ are closed, i.e. $d(dx) = d(dy) = 0$. Thus they define cohomology classes $[dx], [dy] \in H^1_{\text{dR}}(T)$. A straightforward calculation, see e.g. [Frie16a, p. 248], shows that if we integrate the 2-form $dx \wedge dy$ on $T$ with the standard orientation, then we obtain 1. It follows from Proposition 78.4 that $[dx \wedge dy] = [dx] \wedge [dy]$ is a non-trivial element in $H^2_{\text{dR}}(T)$.

From the fact that $H^*_{\text{dR}}(T)$ is a superalgebra we know that

$$ [dx] \wedge [dy] = (-1)^{1-1} \cdot [dy] \wedge [dx] = -[dy] \wedge [dx]. $$

Since this wedge product is non-zero we see that $(H^*_{\text{dR}}(T), \wedge)$ is a non-commutative ring.

This discovery of a ring structure on de Rham cohomology raises the question whether one can also define such a ring structure using singular cohomology and whether such a ring structure exists on singular cohomology for more general spaces. We will answer these questions in Chapter 80.

---

1142 As always we identify $T_P \mathbb{R}^2$ with $\mathbb{R}^2$.
1143 Details are given in [Frie16a, p. 248].
1144 More precisely, we showed that there exists a unique 1-form $dx$ on $T$ such that for each point $P \in \mathbb{R}^2$ and $v \in T_P \mathbb{R}^2$ we have $dx_P(v) = dx_p(p(v))$. Of course the same statement also holds for $dy$.
1145 This is clear for $dx$ and $dy$ viewed as differential 1-forms on $\mathbb{R}^2$. But the projection map $p : \mathbb{R}^2 \to T = \mathbb{R}^2 / \mathbb{Z}^2$ is a local diffeomorphism. Since the differential commutes with smooth maps, see Proposition 78.2 (6), we also see that $d(dx) = d(dy) = 0$ on $\mathbb{R}^2 / \mathbb{Z}^2$. 

Exercises for Chapter 79

Exercise 79.1. Let $\mathcal{H}^\ast$ be a smooth cohomology theory with $\mathcal{H}^n(\ast) = 0$ for $n \geq 1$. We denote by $f: S^1 \to S^1$ the map that is given by $(x, y) \mapsto (x, -y)$. Show, only using the axioms of a smooth cohomology theory, that $f^*: \mathcal{H}^1(S^1) \to \mathcal{H}^1(S^1)$ is given by multiplication by $-1$.

Exercise 79.2. Let $M$ be a smooth manifold. Show that if $A$ and $B$ are subsets of $M$ such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact.

Exercise 79.3. We make the usual identification $\pi_1(\mathbb{R}^2/\mathbb{Z}^2) = \mathbb{Z}^2$. We consider the homomorphism $\phi: \mathbb{Z}^2 = \pi_1(\mathbb{R}^2/\mathbb{Z}^2) \to \mathbb{Z}$ given by $\phi((1,0)) = 6$ and $\phi((0,1)) = 4$. Provide an explicit map $f: \mathbb{R}^2/\mathbb{Z}^2 \to S^1$ such that $f_* = \phi$.

Exercise 79.4. Let $M$ be a smooth manifold and let $\phi \in H^1(M; \mathbb{Z})$. Show that $\phi \cup \phi = 0$.

Exercise 79.5. Let $M$ be a smooth manifold and let $A$ be a union of components of $\partial M$. We define

$$C^k_{\text{dr}}(M, A) := \{ \varphi \in \Omega^k(M) \mid \text{there exists a neighborhood } U \text{ of } A \text{ such that } \varphi|_U \equiv 0 \}.$$  

(a) Show that the usual differential $d: C^k_{\text{dr}}(M) \to C^{k+1}_{\text{dr}}(M)$ restricts to a coboundary map $d: C^k_{\text{dr}}(M, A) \to C^{k+1}_{\text{dr}}(M, A)$. We refer to resulting cohomology groups by $H^k_{\text{dr}}(M, A)$.

(b) Show that there exists a natural connecting homomorphism $\delta: H^k_{\text{dr}}(A) \to H^{k+1}_{\text{dr}}(X, A)$ which gives rise to a long exact sequence

$$\ldots \longrightarrow H^k_{\text{dr}}(M, A) \longrightarrow H^k_{\text{dr}}(M) \longrightarrow H^k_{\text{dr}}(A) \overset{\delta}{\longrightarrow} H^{k+1}_{\text{dr}}(M, A) \longrightarrow \ldots$$

(c) Show that there exists a natural isomorphism $u: H_k(M, A) \to$ such that the following diagram commutes:

$$\begin{array}{cccccc}
\ldots & \longrightarrow & H^k(M, A; \mathbb{R}) & \longrightarrow & H^k(M; \mathbb{R}) & \longrightarrow & H^k(A; \mathbb{R}) \\
& \downarrow{\cong} & \downarrow{\cong} & \downarrow{\cong} & \downarrow{\cong} & \downarrow{\cong} & \\
& \ldots & \longrightarrow & H^k_{\text{dr}}(M, A) & \longrightarrow & H^k_{\text{dr}}(M) & \longrightarrow & H^k_{\text{dr}}(A) \\
\end{array}$$

(d) Let $\varphi \in H^1(M, A; \mathbb{Z})$. Show that there exists a smooth map $f: M \to S^1$ that vanishes on an open neighborhood of $U$ and which has the property that the induced map $f_*: H_1(M, A; \mathbb{Z}) \to H_1(S^1) = \mathbb{Z}$ equals the given cohomology class $\varphi \in H^1(M, A; \mathbb{Z}) = \text{Hom}(H_1(M, A; \mathbb{Z}), \mathbb{Z})$.

Remark. This statement is the analogue of Proposition 79.10(1).
80. The Eilenberg-Zilber theorem and the cross product

In Section 79.6 we saw that de Rham cohomology of a smooth manifold carries a product structure which turns de Rham cohomology into a ring. It is therefore natural to try to find such a product structure in singular homology and/or in singular cohomology.

The key to doing so will be the Eilenberg-Zilber Theorem 58.4 that we had stated before without providing a proof. In this chapter we will give a slightly more precise statement and we provide the proof. In this chapter and in Chapter 81 we will see how it can be used to find product structures on homology and cohomology groups.

80.1. The Eilenberg-Zilber theorem. We start out by recalling and introducing some definitions.

*Definition.*

1. Let $\mathcal{C} = (C_\ast, \partial)$ and $\mathcal{C}' = (C_\ast', \partial')$ be two chain complexes. On page 1433 we defined the tensor product $\mathcal{C} \otimes \mathcal{C}'$ of the chain complexes where the $n$-th chain group is defined as

\[ (\mathcal{C} \otimes \mathcal{C}')_n := \bigoplus_{p+q=n} C_p \otimes C'_q \]

and where the boundary homomorphisms are given by

\[ \partial : (\mathcal{C} \otimes \mathcal{C}')_n \rightarrow (\mathcal{C} \otimes \mathcal{C}')_{n-1} \]

\[ c_p \otimes c'_q \mapsto \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q. \]

2. Given a point $x$ in a topological space $X$ we denote by $x$ also the singular 0-simplex given by sending the unique point of $\Delta^0$ to $x$.

3. Given two topological spaces $X$ and $Y$ we refer to the maps

\[ C_0(X) \otimes C_0(Y) \rightarrow C_0(X \times Y) \]

\[ x \otimes y \mapsto (x, y) \]

and

\[ C_0(X \times Y) \rightarrow C_0(X) \otimes C_0(Y) \]

\[ (x, y) \mapsto x \otimes y \]

as the canonical maps. We refer to the identity maps on $C_0(X) \otimes C_0(Y)$ and on $C_0(X \times Y)$ also as the canonical maps.

The following theorem is a slightly more precise formulation of the original Eilenberg-Zilber Theorem 58.4.

**Theorem 80.1. (Eilenberg-Zilber)**

1. Given any topological spaces $X$ and $Y$ there exist natural chain maps

\[ \Upsilon : C_\ast(X) \otimes C_\ast(Y) \rightarrow C_\ast(X \times Y) \]

and

\[ \Theta : C_\ast(X \times Y) \rightarrow C_\ast(X) \otimes C_\ast(Y), \]

which on the 0-level are the above canonical maps.

2. The maps $\Upsilon$ and $\Theta$ are unique up to natural chain homotopies.

3. The maps $\Upsilon$ and $\Theta$ are naturally chain homotopy inverses of one another.
We refer to the maps $\Upsilon$ and $\Theta$ as Eilenberg-Zilber maps. In the notation and our discussions we will usually ignore the fact that these maps are well-defined only up to a natural homotopy. We will only work with the properties of $\Upsilon$ and $\Theta$ stated in the theorem, so a different choice of maps $\Upsilon$ and $\Theta$ does not affect anything we say afterwards.

80.2. Proof of the Eilenberg-Zilber Theorem 80.1 The proof of the Eilenberg-Zilber Theorem 80.1 breaks up into three parts: we first construct $\Upsilon$, then we construct $\Theta$ and finally we show that these maps are unique in the above sense and that they have the desired properties.

We start out with the following definition.

**Definition.** A topological space $X$ is called acyclic if $H_0(X; \mathbb{Z}) \cong \mathbb{Z}$ and if all higher homology groups are zero.

**Example.** In Corollary 42.8 we showed that every contractible topological space is acyclic. In particular every standard simplex $\Delta^n$ is contractible and thus acyclic. Furthermore, all products $\Delta^p \times \Delta^q$ of standard simplices are contractible and thus acyclic.

We also fix some notation.

**Notation.** Let $X$ be a topological space and let $x \in X$. If $\sigma: \Delta^n \to Y$ is a singular $n$-simplex in a topological space $Y$, then we denote by $x \times \sigma: \Delta^n \to X \times Y$ the singular $n$-simplex given by $v \mapsto (x, \sigma(v))$. We use the analogous notation for the roles of $X$ and $Y$ swapped.

Now we can formulate the following theorem.

**Theorem 80.2.** Given any two topological spaces $X$ and $Y$ and any $p, q \in \mathbb{N}_0$ there exists a homomorphism

$\Upsilon_{p,q}: C_p(X) \otimes C_q(Y) \to C_{p+q}(X \times Y)$

such that the following conditions are satisfied:

1. for $x \in X$ and $\sigma: \Delta^n \to Y$ we have $\Upsilon_{0,q}(x \otimes \sigma) = x \times \sigma$, the same statement also holds with the roles of $X$ and $Y$ swapped;
2. the map $\Upsilon_{p,q}$ is natural, i.e. if $f: X' \to X$ and $g: Y' \to Y$ are maps between topological spaces, then for any $a \in C_p(X')$ and any $b \in C_q(Y')$ we have

$$(f \times g)_*(\Upsilon_{p,q}(a \otimes b)) = \Upsilon_{p,q}(f_*(a) \otimes g_*(b)).$$

\[\text{Here "natural chain homotopy" means that given two such maps $\Upsilon$ and $\Upsilon'$ there exists a choice of chain homotopies $(C_*(X) \otimes C_*(Y))_k \to C_{k+1}(X \times Y)$, which is natural in $X$ and $Y$, between $\Upsilon$ and $\Upsilon'$.}

An analogous statement holds for maps $\Theta$ and $\Theta'$.

\[\text{Here "naturally" means that $\Upsilon \circ \Theta$ and $\Theta \circ \Upsilon$ are naturally homotopic to the identity maps, i.e. there exist natural chain homotopies from $\Upsilon \circ \Theta$ to the identity map and from $\Theta \circ \Upsilon$ to the identity map.}

\[\text{This can be seen in many ways, for example pick points $x \in \Delta^p$ and $y \in \Delta^q$, it is straightforward to show that there exists a deformation retraction $r$ from $\Delta^p$ to $\{x\}$ and that there exists a deformation retraction $s$ from $\Delta^q$ to $\{y\}$. But these two deformation retraction also define a deformation retraction from $\Delta^p \times \Delta^q$ to $(x, y)$.}
(3) the maps $\Upsilon_{p,q}$ form a chain map, i.e. for any $a \in C_p(X)$ and any $b \in C_q(Y)$ we have
\[ \partial(\Upsilon_{p,q}(a \otimes b)) = - \Upsilon_{p-1,q}(\partial a \otimes b) + (-1)^p \Upsilon_{p,q-1}(a \otimes \partial b). \]

**Proof.** We prove the existence of the maps $\Upsilon_{p,q}$ by induction on $p \cdot q$. For clarity we henceforth suppress the subscript from $\Upsilon_{p,q}$.

Clearly for $p = 0$ or $q = 0$ the maps from (1) have the properties (2) and (3). So now suppose that we are given $p, q \in \mathbb{N}_0$ with $p \cdot q > 0$ such that the maps $\Upsilon$ have been defined for all $p', q'$ with $p' \cdot q' < p \cdot q$.

Given any $n \in \mathbb{N}_0$ we denote by $\text{id}_n : \Delta^n \to \Delta^n$ the identity map. We first want to come up with a reasonable definition of $\Upsilon(\text{id}_p \otimes \text{id}_q)$. If we want (3) to be satisfied we have to define $\Upsilon(\text{id}_p \otimes \text{id}_q) = z$ where $z \in C_{p+q}(\Delta^p \times \Delta^q)$ satisfies

\[ \partial z = \Upsilon(\partial \text{id}_p \otimes \text{id}_q) + (-1)^p \cdot \Upsilon(\text{id}_p \otimes \partial \text{id}_q) \in C_{p+q-1}(\Delta^p \times \Delta^q). \]

As we pointed out on page 1957, the product $\Delta^p \times \Delta^q$ is acyclic, in particular we have $H_{p+q-1}(\Delta^p \times \Delta^q) = 0$, which means that every singular $(p + q - 1)$-chain that is a cycle is in fact the boundary of some $(p + q)$-chain $z$. So we have to show that the right-hand side of (3) is indeed a cycle. We compute that

\[
\begin{align*}
\partial(\Upsilon(\partial \text{id}_p \otimes \text{id}_q)) &= \Upsilon(\partial(\partial \text{id}_p \otimes \text{id}_q)) + (-1)^p \cdot \partial(\Upsilon(\text{id}_p \otimes \partial \text{id}_q)) \\
&= \Upsilon(\partial \text{id}_p \otimes \text{id}_q) + (-1)^p \cdot \Upsilon(\partial \text{id}_p \otimes \partial \text{id}_q) \\
&+ (-1)^p \cdot \Upsilon(\partial \text{id}_p \otimes \partial \text{id}_q) + (-1)^p \cdot (-1)^p \cdot \Upsilon(\text{id}_p \otimes \partial \partial \text{id}_q) = 0.
\end{align*}
\]

by our induction hypothesis we can apply the boundary formula (3) to $\Upsilon(\partial \text{id}_p \otimes \text{id}_q)$ and $\Upsilon(\text{id}_p \otimes \partial \text{id}_q)$

This discussion gives us the definition of $\Upsilon(\text{id}_p \otimes \text{id}_q) := z$.

Now let $X$ and $Y$ be topological spaces and let $\varphi : \Delta^p \to X$ and $\psi : \Delta^q \to Y$ be singular simplices. If we want (2) to be satisfied then we have to define

\[ \Upsilon(\varphi \otimes \psi) := (\varphi \times \psi)_*(\Upsilon(\text{id}_p \otimes \text{id}_q)) \in C_{p+q}(X \times Y). \]

We extend this map linearly to all of $C_p(X) \otimes C_q(Y)$. It follows almost immediately from the definition of $\Upsilon$ that the map $\Upsilon$ is natural in $X$ and $Y$.

It remains to prove (3). This property holds basically by definition. But for completeness’ sake we carry out the proof. So let $\varphi : \Delta^p \to X$ and $\psi : \Delta^q \to Y$ be singular simplices.
We then have the following equality in $C_{p+q-1}(X \times Y)$:

$$\partial(\Upsilon(\varphi \otimes \psi)) = \partial((\varphi \otimes \psi)_{*}(\Upsilon(\text{id}_p \otimes \text{id}_q))) = (\varphi \otimes \psi)_{*}(\partial(\Upsilon(\text{id}_p \otimes \text{id}_q)))$$

$$= (\varphi \otimes \psi)_{*}(\Upsilon(\partial \text{id}_p \otimes \text{id}_q)) + (-1)^p \cdot (\varphi \otimes \psi)_{*}(\Upsilon(\text{id}_p \otimes \partial \text{id}_q))$$

by definition of $z$ and the linearity of $(\varphi \otimes \psi)_{*}$

$$= (\Upsilon(\varphi_{*}(\partial \text{id}_p) \otimes \psi_{*}(\text{id}_q))) + (-1)^p \cdot (\Upsilon(\varphi_{*}(\text{id}_p) \otimes \psi_{*}(\partial \text{id}_q)))$$

by induction we can apply the naturality of $\Upsilon$

$$= \Upsilon(\partial(\varphi \otimes \psi)) + (-1)^p \cdot \Upsilon(\varphi \otimes \partial \psi)$$

since $\varphi_{*}$ and $\psi_{*}$ are chain maps and since $\varphi_{*}(\text{id}_p) = \varphi$ and $\psi_{*}(\text{id}_q) = \psi$.

Now we turn to the construction of the second map in the Eilenberg-Zilber Theorem [80.1].

**Theorem 80.3.** Given any two topological spaces $X$ and $Y$ and any $k \in \mathbb{N}_0$ there exists a homomorphism

$$\Theta_k : C_k(X \times Y) \to (C_{*}(X) \otimes C_{*}(Y))_k = \bigoplus_{p+q=k} C_p(X) \otimes C_q(Y)$$

such that the following conditions are satisfied:

1. the map $\Theta_0$ is the canonical map on the 0-level, i.e. for every $x \in X$ and $y \in Y$ we have $\Theta_0((x,y)) = x \otimes y$,
2. the map $\Theta_k$ is natural in $X$ and $Y$, i.e. for any two maps $f: X' \to X$ and $g: Y' \to Y$ of topological spaces and any $c \in C_k(X' \times Y')$ we have $\Theta_k((f \times g)_*(c)) = (f_{*} \otimes g_{*})(\Theta_k(c))$,
3. the maps $\Theta_*$ form a chain map, i.e. for any $k \in \mathbb{N}_0$ we have $\partial_{k}^{\otimes} \circ \Theta_k = \Theta_{k-1} \circ \partial_k$.

In the proof of Theorem [80.3] we will need the following lemma.

**Lemma 80.4.** Let $X$ and $Y$ be two acyclic topological spaces. For every $k \geq 1$ we have

$$H_k(C_{*}(X) \otimes C_{*}(Y)) = 0.$$ 

Furthermore we have an isomorphism

$$\epsilon : H_0(C_{*}(X) \otimes C_{*}(Y)) \xrightarrow{\cong} \mathbb{Z}$$

$$\sum_{i=1}^{k} a_i \cdot x_i \otimes y_i \mapsto \sum_{i=1}^{k} a_i.$$ 

**Proof.** The lemma is an immediate consequence of our hypotheses, Proposition [41.5] and the Künneth Theorem [58.7] for Chain Complexes. (Note that this Künneth Theorem is purely algebraic.)
Proof of Theorem 80.3. As we will see the idea behind the proof of Theorem 80.3 is very similar to the idea of the proof of Theorem 80.2. We start out with the outline of proof:

(a) We use (1) to define Θ₀,
(b) we suppose the map Θ₀, . . . , Θₖ₋₁ are defined, we then use (3) to make an educated guess for Θₖ(dₖ) where we consider
(i) the topological spaces X = Y = Δᵏ and
(ii) the singular k-simplex dₖ: Δᵏ → Δᵏ × Δᵏ that is given by the diagonal map
dₖ(x) = (x, x).
(c) we then use the naturality statement of (2) to define Θₖ for all topological spaces X and Y and all singular simplices in Cₛ(X × Y).

Now we carry out the above program. First of all, given a 0-simplex (x, y) in X × Y we define Θ₀((x, y)) = x ⊗ y. Then we extend this definition linearly to get the desired map Θ₀: C₀(X × Y) → C₀(X) ⊗ C₀(Y).

Now suppose we have already constructed the maps Θ₀, . . . , Θₖ₋₁. We want to define Θₖ and we start out by defining Θₖ(dₖ): Δₖ → Δₖ × Δₖ. Since we need (3) to be satisfied we need to define Θₖ(dₖ) := c where c ∈ (Cₛ(Δᵏ) ⊗ Cₛ(Δᵏ))ₖ satisfies ∂ᵦ(c) = Θₖ₋₁(∂dₖ).

In the chain complex Cₛ(Δᵏ) ⊗ Cₛ(Δᵏ) we calculate that

\[
\text{defined by induction} \quad \partial \otimes (\Theta₋₁(\partial dₖ)) = \Theta₋₂(\partial₋₁ \partial dₖ) = 0,
\]

i.e. the chain Θ₋₁(∂ dₖ) ∈ (Cₛ(Δᵏ) ⊗ Cₛ(Δᵏ))₋₁ is in fact a cycle. Since Δᵏ is acyclic it follows immediately from Lemma 80.4 that this cycle is null-homologous. (For k = 1 one easily verifies, using the explicit description of Θ₀, that the cycle lies in the kernel of the isomorphism : H₀(Cₛ(Δᵏ) ⊗ Cₛ(Δᵏ)) → Z.) This means that there exists a singular chain c ∈ (Cₛ(Δᵏ) ⊗ Cₛ(Δᵏ))ₖ with ∂ᵦ(c) = Θ₋₁(∂ dₖ). We define Θₖ(dₖ) := c.

Now we define Θₖ for arbitrary topological spaces X and Y and an arbitrary singular k-simplex σ: Δᵏ → X × Y. We denote by p: X × Y → X and q: X × Y → Y the obvious projection maps. Note that we have a commutative diagram

\[
\begin{array}{ccc}
Δᵏ & \xrightarrow{dₖ} & Δᵏ \times Δᵏ \\
\downarrow{σ} & & \downarrow{(p ∘ σ) \times (q ∘ σ)} \\
X \times Y,
\end{array}
\]

i.e. we have σ = ((p ∘ σ) × (q ∘ σ)) ∘ dₖ = ((p ∘ σ) × (q ∘ σ))ₖ(dₖ). For the naturality condition (2) to be satisfied we need to define

\[
Θₖ(σ) := ((p ∘ σ)ₖ \otimes (q ∘ σ)ₖ)(Θₖ(dₖ)) \in (Cₛ(X) \otimes Cₛ(Y))ₖ.
\]

With this definition one readily verifies that the map Θₖ is natural in X and Y.
Finally we have to show that $\Theta_k$ satisfies the boundary formula (3). So as before let $\sigma: \Delta^k \to X \times Y$ be a singular $k$-simplex. Then

$$
\text{by definition of } \Theta_k(\sigma)
$$

is a chain map by Lemma 80.3.

$$
\partial^\otimes \Theta_k(\sigma) = \partial^\otimes \left( ((p \circ \sigma)_* \otimes (q \circ \sigma)_*) (\Theta_k(d_k)) \right) \quad \downarrow
$$

by definition of $\Theta_k(d_k)$

$$
= (p \circ \sigma)_* \otimes (q \circ \sigma)_* (\Theta_{k-1}(\partial d_k)) \quad \uparrow
$$

by naturality of $\Theta_{k-1}$

$$
= \Theta_{k-1} \partial \left( ((p \circ \sigma) \times (q \circ \sigma))_*(d_k) \right) \quad \uparrow
$$

since $(p \circ \sigma) \times (q \circ \sigma)$ is a chain map

$$
\text{by definition of } \Theta_k(\sigma_*)
$$

$$
= \Theta_{k-1} \partial (p \circ \sigma_*) (q \circ \sigma_*) (d_k) = \Theta_{k-1} \partial \sigma.
$$

We have now verified that $\Theta_k$ has all the desired properties. \[\blacksquare\]

As we saw in the proofs of Theorem 80.2 and Theorem 80.3, the natural chain maps

$$
\Upsilon: C_*(X) \otimes C_*(Y) \to C_*(X \times Y)
$$

and

$$
\Theta: C_*(X \times Y) \to C_*(X) \otimes C_*(Y)
$$

depend on many choices. The next theorem says that different choices in the proofs lead to natural chain maps that are naturally homotopy equivalent to one another.

**Theorem 80.5.** Let $X$ and $Y$ be topological spaces. Any two natural chain maps

$$
C_*(X \times Y) \to C_*(X) \otimes C_*(Y)
$$

that are the canonical maps on the 0-level are in fact naturally chain homotopic. The same conclusion also holds for any two natural chain maps

$$
C_*(X) \otimes C_*(Y) \to C_*(X \times Y), \quad C_*(X \times Y) \to C_*(X) \otimes C_*(Y), \quad C_*(X) \otimes C_*(Y) \to C_*(X \times Y)
$$

that are the canonical maps on the 0-level.

**Proof.** The proof of this theorem is in many ways quite similar to the proofs of Theorem 80.2 and 80.3.

In the following we show the first statement. The proofs of the other three statements are very similar. So let

$$
F,G: C_*(X \times Y) \to C_*(X) \otimes C_*(Y)
$$

be two natural chain maps that are the canonical maps on the 0-chains, i.e. which satisfy $F((x,y)) = x \otimes y = G((x,y))$ for all $x \in X, y \in Y$. Given any $k \in \mathbb{Z}_{\geq -1}$ we have to define a map

$$
P_k: C_k(X \times Y) \to (C_*(X) \otimes C_*(Y))_{k+1}
$$

that satisfies the following three properties:

1. the map $P_{-1}$ is the zero map,
2. the map $P_k$ is natural in $X$ and $Y$,
3. we have $\partial^\otimes \circ P_k + P_{k-1} \circ \partial = F - G$.

So suppose we have already defined the maps $P_{-1}, \ldots, P_{k-1}$ with $k \geq 0$. As before we denote by $d_k: \Delta^k \to \Delta^k \times \Delta^k$ the singular $k$-simplex that is given by the diagonal map
\(d_k(x) := (x, x)\). We first want to define \(P_k(d_k) \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_{k+1}\). In the chain complex \(C_*(\Delta^k) \otimes C_*(\Delta^k)\) we calculate that
\[
\partial^\otimes((F - G - P_{k-1}\partial)(d_k)) = \partial^\otimes F(d_k) - \partial^\otimes G(d_k) - \partial^\otimes P_{k-1}(\partial d_k) = F(\partial d_k) - G(\partial d_k) - (F - G - P_{k-2}\partial)(\partial d_k) = P_{k-2}\partial \partial d_k = 0.
\]

It follows from Lemma 80.4 that there exists a \((k + 1)\)-chain \(c \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_{k+1}\) with \(\partial^\otimes(c) = (F - G - P_{k-1}\partial)(d_k)\). (For \(k = 0\) we need to show that \(\epsilon((F - G)(d_0)) = 0\), to conclude this we need to use that \(F\) and \(G\) agree on 0-simplices.) We define \(P_k(d_k) := c\).

Now let \(X\) and \(Y\) be two topological spaces and let \(\sigma \in C_k(X \times Y)\). As in the proof of Theorem 80.2 we denote by \(p: X \times Y \to X\) and \(q: X \times Y \to Y\) the obvious projection maps and we set
\[
P_k(\sigma) := ((p \circ \sigma)_* \otimes (q \circ \sigma)_*)(P_k(d_k)) \in (C_*(X) \otimes C_*(Y))_{k+1}.
\]

Basically by definition this map is natural in \(X\) and \(Y\). As in the proof of Theorem 80.2 one easily verifies that condition (3) is satisfied.

Now we can easily provide the proof of the Eilenberg-Zilber Theorem 80.1

**Proof of the Eilenberg-Zilber Theorem 80.1** We pick natural chain maps
\[
\Upsilon: C_*(X) \otimes C_*(Y) \to C_*(X \times Y)
\]
and
\[
\Theta: C_*(X \times Y) \to C_*(X) \otimes C_*(Y)
\]
as provided by Theorems 80.2 and 80.3. These maps are the canonical maps on the 0-level. By Theorem 80.5 the maps \(\Upsilon\) and \(\Theta\) are thus unique up to a natural chain homotopy.

It remains to show that the maps \(\Upsilon\) and \(\Theta\) are naturally chain homotopy inverses of one another. The map \(\Theta \circ \Upsilon: C_*(X) \otimes C_*(Y) \to C_*(X \times Y)\) is a natural chain map that is the canonical map on the 0-level. But this is also the case for the identity map. It follows from Theorem 80.5 that \(\Theta \circ \Upsilon\) is naturally chain homotopic to the identity. The same argument shows that \(\Upsilon \circ \Theta\) is naturally chain homotopic to the identity.

80.3. The relative Eilenberg–Zilber map \(\Upsilon\). In this short section we introduce a relative version of the Eilenberg–Zilber map \(\Upsilon\). We start out with the following elementary but essential remark.

**Remark.** Let \(X\) and \(Y\) be topological spaces and let \(A \subset X\) and \(B \subset Y\) be subsets. We denote by \(i: A \to X\) and \(j: B \to Y\) the inclusion maps. Then the diagram
\[
\begin{array}{ccc}
C_*(A) \otimes C_*(B) & \xrightarrow{(i \otimes j)_*} & C_*(X) \otimes C_*(Y) \\
\downarrow \Upsilon & & \downarrow \Upsilon \\
C_*(A \times B) & \xrightarrow{(i \times j)_*} & C_*(X \times Y)
\end{array}
\]
commutes by the naturality of \(\Upsilon\). In the following we do not explicitly mention the names of the various inclusion induced maps.
Proposition 80.6. Let $X$ and $Y$ be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) The Eilenberg-Zilber map $\Upsilon$ induces a natural chain homotopy equivalence

$$
\begin{array}{c}
\sum_{i=1}^{n} [c_i] \otimes [d_i] \rightarrow \sum_{i=1}^{n} [\Upsilon(c_i \otimes d_i)].
\end{array}
$$

(2) The Eilenberg-Zilber map $\Upsilon$ descends to a well-defined chain map

$$
\begin{array}{c}
\sum_{i=1}^{n} [c_i] \otimes [d_i] \rightarrow \sum_{i=1}^{n} [\Upsilon(c_i \otimes d_i)].
\end{array}
$$

Proof. Let $X$ and $Y$ be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) We consider the following diagram

$$
\begin{array}{ccc}
0 & \rightarrow & C_*(A) \otimes C_*(Y) \\
& & \Upsilon \\
0 & \rightarrow & C_*(A \times Y) \\
\downarrow & & \downarrow \\
0 & \rightarrow & C_*(X,Y) \\
\end{array}
$$

The top sequence is given by tensoring a short exact sequence by the free abelian groups $C_*(Y)$, Lemma 57.9 implies that the resulting sequence is again exact. The bottom sequence is exact by definition. The two left vertical maps are homotopy equivalences by Theorem 80.1 and the diagram commutes by the naturality of $\Upsilon$, as explained in the remark preceding the proposition. Finally note that it follows from Corollary 49.4 that the right vertical map is also a chain homotopy equivalence.

We consider the following diagram

$$
\begin{array}{c}
0 \rightarrow C_*(X,A) \otimes C_*(B) \rightarrow C_*(X,A) \otimes C_*(Y) \rightarrow C_*(X,A) \otimes C_*(Y,B) \rightarrow 0 \\
\downarrow & & \downarrow & & \downarrow \\
0 \rightarrow C_*(X \times B)/C_*(A \times B) \rightarrow C_*(X \times Y)/C_*(A \times Y) \rightarrow \frac{C_*(X \times Y)}{C_*(A \times Y) + C_*(X \times B)} \rightarrow 0.
\end{array}
$$

As above, it follows from the fact that each $C_*(X,A)$ is a free abelian group and Lemma 57.9 that the top sequence is exact. It follows easily from [1149] that the bottom sequence is also exact. The middle vertical map is a chain homotopy equivalence by the above discussion. Exactly the same argument also shows that the left vertical map is a chain homotopy equivalence. The diagram commutes by the naturality of $\Upsilon$. It follows from Corollary 49.4 that the right vertical map is also a homotopy equivalence.

---

[1149] Note that $C_*(A \times Y) + C_*(X \times B)$ is in fact a subcomplex of the chain complex $C_*(X \times Y)$, so the right-hand side is indeed a chain complex.

[1150] Why does this equality of chain complexes hold?
(2) The second statement follows immediately from (1) together with the observation that $C_*(A \times Y) + C_*(X \times B)$ is a subcomplex of $C_*(A \times Y \cup X \times B)$. ■

80.4. The cross product on homology. Recall that one of our goals is to find some type of product structure in homology or cohomology. We start our search for a product structure in homology, since we are more comfortable with homology groups.

The following definition already gives us some type of product structure on homology.

**Definition.** Let $(X, A)$ and $(Y, B)$ be two pairs of topological spaces. We refer to the map

$$\times : H_p(X, A) \otimes H_q(Y, B) \xrightarrow{\sigma \mapsto [c] \otimes [d]} H_{p+q}(X \times Y, A \times Y \cup X \times B).$$

as the cross product.

In the following lemma we summarize some elementary properties of the cross product.

**Lemma 80.7.**

1. Let $X$ and $Y$ be two topological spaces and let $x \in X$ be a point. We denote by $f : Y \to X \times Y$ the map that is given by $y \mapsto (x, y)$ and we denote by $[x] \in H_0(X)$ the homology class defined by $x$. Then for any $q \in \mathbb{N}_0$ the maps

$$H_q(Y) \xrightarrow{\sigma \mapsto [x] \times \sigma} H_q(X \times Y)$$

agree. The statement holds with the roles of $X$ and $Y$ reversed.

2. The cross product is natural, i.e. if $f : (X, A) \to (X', A')$ and $g : (Y, B) \to (Y', B')$ are maps between pairs of topological spaces, then for any $p, q \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
H_p(X, A) \otimes H_q(Y, B) & \xrightarrow{\times} & H_{p+q}(X \times Y, A \times Y \cup X \times B) \\
\downarrow f_* & & \downarrow (f \times g)_* \\
H_p(X', A') \otimes H_q(Y', B') & \xrightarrow{\times} & H_{p+q}(X' \times Y', A' \times Y' \cup X' \times B').
\end{array}
$$

**Proof.** The lemma follows immediately from the definitions and the properties of $\Upsilon$ given in Theorem 80.2 (1) and (2).

We have the following variation on the Künneth Theorem 58.8 for topological spaces.

**Theorem 80.8. (The Künneth Theorem)** Let $(X, A)$ and $(Y, B)$ be pairs of topological spaces. We assume that one of the following two statements holds:

1. $A$ and $B$ are open subsets (note that $A$ and $B$ can possibly be empty), or
2. $(X, A)$ and $(Y, B)$ are pairs of CW-complexes.

---

Note that the map is well-defined by Lemmas 58.6 and 80.6 (2) and it is independent of the choice of $\Upsilon$ by Theorem 80.1 (2).
Then for each \( n \in \mathbb{N} \) there exists a natural short exact sequence

\[
0 \rightarrow \bigoplus_{p+q=n} H_p(X, A) \otimes H_q(Y, B) \xrightarrow{\sim} H_n(X \times Y, A \times Y \cup X \times B) \rightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(X, A), H_q(Y, B)) \rightarrow 0.
\]

Furthermore the above short exact sequence splits.

Examples.

(1) Let \( M \) be an \( m \)-dimensional topological manifold and let \( N \) be an \( n \)-dimensional topological manifold. Let \( x \in M \setminus \partial M \) and let \( y \in N \setminus \partial N \). Then it follows from the relative Künneth Theorem 80.8 (2), Lemma 86.4 and Lemma 57.17 that the cross product defines an isomorphism

\[
H_m(M, M \setminus \{x\}) \otimes H_n(N, N \setminus \{y\}) \xrightarrow{\sim} H_{m+n}(M \times N, (M \setminus \{x\}) \times N \cup M \times (N \setminus \{y\})).
\]

(2) Let \( X \) and \( Y \) be path-connected topological spaces. Let \( x \in X \) and let \( y \in Y \). We denote by \( i : X \to X \times Y \) the inclusion map that is given by \( i(x) = (x, y) \) and similarly we denote by \( j : Y \to X \times Y \) the inclusion map that is given by \( j(y) = (x, y) \). It follows from Proposition 41.5, Lemma 80.7 (1) and the Künneth Theorem 80.8 that the map

\[
i_* \oplus j_* : H_1(X; \mathbb{Z}) \oplus H_1(Y; \mathbb{Z}) \to H_1(X \times Y; \mathbb{Z})
\]

is an isomorphism.\(^{1152}\) Let \( G \) be any abelian group. Furthermore note that it follows easily from the above, the naturality of the Universal Coefficient Theorem 57.19 and Lemma 57.17 (3) that the map

\[
i_* \oplus j_* : H_1(X; G) \oplus H_1(Y; G) \to H_1(X \times Y; G)
\]

is also an isomorphism.

Proof. We consider the following maps

\[
0 \to \bigoplus_{p+q=n} H_p(X, A) \otimes H_q(Y, B) \to H_n(C_\ast(X, A) \otimes C_\ast(Y, B)) \to \bigoplus_{p+q=n-1} \text{Tor}(H_p(X, A), H_q(Y, B)) \to 0.
\]

We first note that the top sequence is exact by the Künneth Theorem for Chain Complexes 58.7. (Here we use again that relative chain groups are free abelian groups.) Here

\(^{1152}\) We had given an alternative proof of this fact in Exercise 52.5.
the top vertical map is an isomorphism by Proposition 80.6. Recall that we assume that one of the following two statements holds:

(1) $A$ and $B$ are open subsets, or
(2) $(X, A)$ and $(Y, B)$ are pairs of CW-complexes.

We then know from Proposition 74.12 (4) respectively (6) that the inclusion induced map

$$C^*_{(A \times Y, X \times B)}(A \times Y \cup X \times B) \to C^*(A \times Y \cup X \times B)$$

is a chain homotopy equivalence. The same argument as in the proof of Corollary 43.18 shows that this piece of information implies that the second vertical map is indeed an isomorphism. It follows immediately from the definition of the cross product that the induced diagonal map

$$\bigoplus_{p+q=n} H_p(X, A) \otimes H_q(Y, B) \to H_n(X \times Y, A \times Y \cup X \times B)$$

is precisely the cross product. \hfill ■

80.5. **Product orientations of topological manifolds.** In this second to last section we want to consider products of (topological) smooth manifolds. We start out with the following, arguably slightly surprising proposition. It can be viewed as a generalization of Propositions 6.5, 6.51 and Proposition 44.2 (7).

**Proposition 80.9.**

(1) Let $M$ be an $m$-dimensional topological manifold and let $N$ be an $n$-dimensional topological manifold. The topological space $M \times N$ is an $(m+n)$-dimensional topological manifold where the boundary is given by

$$\partial(M \times N) = (\partial M \times N) \cup (M \times \partial N).$$

(2) Given any two smooth manifolds $M$ and $N$ we can equip $M \times N$ with a natural smooth structure such that the following conditions are satisfied:

(a) If $\partial M = \emptyset$ or $\partial N = \emptyset$, then the smooth structure on $M \times N$ is the obvious smooth structure given by taking products of charts.

(b) For any two smooth manifolds $M$ and $N$ the following statements hold:

(i) the inclusion map $\hat{M} \times \hat{N} \to M \times N$ is smooth.

(ii) for any $P \in M$ and $Q \in N$ the inclusion maps

$$M \to M \times N \quad \text{and} \quad N \to M \times N$$

$$x \mapsto (x, Q) \quad \text{and} \quad y \mapsto (P, y)$$

are smooth.

**Example.** Let $M = \mathbb{B}^2$ and $N = [0, 1]$, then $M \times N = \mathbb{B}^2 \times [0, 1]$ is the solid cylinder which is a 3-dimensional topological manifold with boundary

$$\partial(\mathbb{B}^2 \times [0, 1]) = (\partial \mathbb{B}^2 \times [0, 1]) \cup (\mathbb{B}^2 \times \partial([0, 1])) = (S^1 \times [0, 1]) \cup (\mathbb{B}^2 \times \{0, 1\}).$$

\[^{1153}\] Note that it follows from Proposition 44.2 that $\hat{M} = M \setminus \partial M$ and $\hat{N} = N \setminus \partial N$ do not have boundary. Hence the smooth structure on $\hat{M} \times \hat{N}$ is given by the products of charts.
We refer to Figure 1155 for an illustration.

\[ \overline{B^2} \times \partial([0, 1]) \]

**Figure 1155**

**Proof.** Let \( M \) be an \( m \)-dimensional topological manifold and let \( N \) be an \( n \)-dimensional topological manifold. We consider the topological space \( M \times N \). By Proposition 3.12 we remarked that the product of two Hausdorff spaces is again Hausdorff. Thus we see that \( M \times N \) is Hausdorff. It follows from Lemma 6.1 that \( M \times N \) is second-countable.

It remains to find charts for \( M \times N \). More precisely, we have to find a chart of type (i) for each point in \( (M \times N) \setminus (\partial M \times N \cup M \times \partial N) \) and we have to find a chart of type (ii) for each point in \( \partial M \times N \cup M \times \partial N \). So let \( (x, y) \in M \times N \). We distinguish three cases:

1. If \( x \in M \setminus \partial M \) and \( y \in N \setminus \partial N \) then taking “product charts” it is straightforward to find a chart of type (i) for \( (x, y) \in M \times N \).
2. If \( x \in M \setminus \partial M \) and \( y \in \partial N \) or if \( x \in \partial M \) and \( y \in N \setminus \partial N \) then it is equally straightforward to find a chart of type (ii) for \( (x, y) \in M \times N \).
3. Finally suppose that \( x \in \partial M \) and \( y \in \partial N \). We have to find a chart of type (ii) for \( (x, y) \in M \times N \). It is straightforward to see that there exists an open neighborhood \( U \) of \( (x, y) \in M \times N \) and a homeomorphism \( \Phi: U \to \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \). We then compose this homeomorphism with the homeomorphism

\[
\Psi: \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}^{m+n-2} \times \mathbb{R} \times \mathbb{R}_{\geq 0} \quad (x_1, \ldots, x_{m+n-2}, r \cos(\varphi), r \sin(\varphi)) \mapsto (x_1, \ldots, x_{m+n-2}, r \cos(2\varphi), r \sin(2\varphi)).
\]

It is straightforward to see that \( \Psi \circ \Phi \) is a chart of type (ii) around \( (x, y) \).

If we start out with a smooth atlas for \( M \) and \( N \) then one can easily verify that the atlas that we have just constructed is also smooth and that it has the properties stated in (a) and (b). The statement that the smooth structure on \( M \times N \) is natural is shown in [Wall16] Proposition 2.6.2.

**Figure 1156.** Illustration of the proof of Proposition 80.9

**Remark.** The approach in the proof of Proposition 80.9 for defining charts on \( \partial M \times \partial N \) is sometimes called rounding corners or smoothing corners.
The cross product now allows us to formulate the following proposition.

**Proposition 80.10.** Let $M$ be an $m$-dimensional topological manifold and let $N$ be an $n$-dimensional topological manifold. Suppose $M$ is equipped with an orientation $\{\mu_x\}_{x \in M \setminus \partial M}$ and that $N$ is equipped with an orientation $\{\nu_y\}_{y \in N \setminus \partial N}$.

1. Given $(x, y) \in (M \times N) \setminus \partial(M \times N)$ we denote by $\rho_{(x,y)}$ the image of $\mu_x \otimes \nu_y$ under the isomorphism

$$H_m(M, M \setminus \{x\}) \otimes H_n(N, N \setminus \{y\}) \xrightarrow{\sim} H_{m+n}(M \times N, (M \times N) \setminus \{(x, y)\})$$

from page 1965. Then these classes $\rho_{(x,y)}$ define an orientation on $M \times N$.

2. Suppose both $M$ and $N$ are compact and connected, then the map

$$H_m(M, \partial M) \otimes H_n(N, \partial N) \xrightarrow{\sim} H_{m+n}(M \times N, \partial(M \times N))$$

given by the cross product is an isomorphism and it has the property that

$$[M] \times [N] = [M \times N] \in H_{m+n}(M \times M, \partial(M \times N))$$

where $[M \times N]$ denotes the fundamental class of the compact topological manifold $M \times N$ equipped with the orientation defined in (1).

**Proof.** Let $M$ be an $m$-dimensional topological manifold and let $N$ be an $n$-dimensional topological manifold.

1. The first statement of the proposition is a straightforward consequence of the definitions and the naturality of the cross product, see Lemma [80.7]. For completeness’ sake we sketch the proof. To simplify the notation we assume that $\partial M = \partial N = \emptyset$. Now let $(x, y) \in M \times N$. We pick an open neighborhood $U$ of $x$ and a class $\mu_U \in H_m(M, M \setminus U)$ and an open neighborhood $V$ of $y$ and a class $\nu_V \in H_n(N, N \setminus V)$ as given by the definition on page 2101. By the naturality of the cross product we obtain the following commutative diagram

$$
\begin{array}{ccc}
H_m(M, M \setminus U) \times H_n(N, N \setminus V) & \xrightarrow{\times} & H_{m+n}(M \times N, (M \times N) \setminus (U \times V)) \\
\mu_U \mapsto \mu_x & & \downarrow \\
\nu_V \mapsto \nu_y \\
H_m(M, M \setminus \{x\}) \times H_n(N, N \setminus \{y\}) & \xrightarrow{\times} & H_{m+n}(M \times N, M \times N \setminus \{(x, y)\}).
\end{array}
$$

It is now straightforward to verify that $\phi_{U \times V} := \mu_U \times \nu_V$ has the properties desired by the definition on page 2101.

2. Now suppose that both $M$ and $N$ are compact. By Proposition 3.12 the product $M \times N$ is then also compact. Now let $x \in M \setminus \partial M$ and let $y \in N \setminus \partial N$. By Proposition 80.9 we have $(x, y) \in (M \times N) \setminus \partial(M \times N)$. Furthermore, by Lemma 80.7 we have the following commutative diagram

$$
\begin{array}{ccc}
H_m(M, \partial M) \otimes H_n(N, \partial N) & \xrightarrow{\times} & H_{m+n}(M \times N, \partial(M \times N)) \\
\downarrow & & \downarrow \\
H_m(M, M \setminus \{x\}) \otimes H_n(N, N \setminus \{y\}) & \xrightarrow{\times} & H_{m+n}(M \times N, M \times N \setminus \{(x, y)\}).
\end{array}
$$
The vertical maps are isomorphisms by Theorem 87.1. On page 1965 we saw that the bottom horizontal map is an isomorphism. It follows that, as claimed, the top horizontal map is also an isomorphism. The statement regarding the fundamental classes is an immediate consequence of the commutativity of the diagram and the definitions.

**Definition.** Let $M$ and $N$ be oriented topological manifolds. We refer to the orientation on $M \times N$ defined in Proposition [80.10] (1) as the product orientation.

**Remark.** Recall that given any open subset $U \subset \mathbb{R}^k$, $k \in \mathbb{N}_0$, we introduced on page 2106 the standard orientation for $U$ viewed as a topological manifold. (See also Figure [1157] for a reminder.) The following lemma says that the above definition of the product orientation gives us the “expected” answer when we deal with open subsets of $\mathbb{R}^k$'s.

![Diagram](image)

**Figure 1157**

**Proposition 80.11.** Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open non-empty subsets. We equip $U$ and $V$ with the standard orientation. Then the product orientation of $U \times V$, defined above, agrees with the standard orientation of $U \times V \subset \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$.

We postpone the proof of Proposition 80.11 to the next section.

**Examples.**

1. Let $M$ and $N$ be two oriented smooth manifolds such that at most one of them has non-empty boundary. We have the following diagram

   ![Diagram](image)

   **Figure 1158**

   It follows fairly easily from Proposition 80.11 that this diagram commutes.

2. We write $I = [-1, 1]$. We view $I$ as a 1-dimensional topological manifold and we equip $I$ with the orientation coming from $\mathbb{R}$. Given $k \in \mathbb{N}_0$ we write

   \[ \partial I^k := \{(x_1, \ldots, x_k) \mid \text{there exists an } i \text{ with } x_i = -1 \text{ or } x_i = 1 \}. \]

   Given any $m, n \in \mathbb{N}$ one sees easily that

   \[ \partial(I^m \times I^n) = (\partial I^m \times I^n) \cup (I^m \times \partial I^n) = \partial(I^{m+n}). \]

   (See also Figure [1158] for an illustration.) It follows from Proposition 80.9 and the above discussion that we can view each $I^k = I \times \cdots \times I$ as a $k$-dimensional topological manifold with boundary given by the above subset $\partial I^k$. We equip $I^k$ with the product orientation. It follows immediately from Proposition 80.11 that the orientation on
the open subset \( I^k \setminus \partial I^k \subset \mathbb{R}^k \) is the standard orientation. As usual we denote by \([I^k] \in H_k(I^k, \partial I^k; \mathbb{Z})\) the fundamental class.

Now let \( m, n \in \mathbb{N}_0 \). We get a cross product

\[
\begin{array}{c}
\mathbb{H}_m(I^m, \partial I^m) \otimes \mathbb{H}_n(I^n, \partial I^n) \\
\Rightarrow \mathbb{H}_{m+n}(I^{m+n}, \partial I^{m+n})
\end{array}
\]

which by Proposition 80.10 (2) has the property that

\[
[I^m] \times [I^n] = [I^{m+n}].
\]

Figure 1158

80.6. The shuffle product and the proof of Proposition 80.11 (*). In this section we will provide the proof of Proposition 80.11. The difficulty in the proof is that the definition of the cross product relies on the map \( \Upsilon \) from Theorem 80.2. We gave a non-constructive proof of the existence of the map \( \Upsilon \). In this section we give an explicit description of a map \( \nabla \) which has all the properties that we had asked for in Theorem 80.2. We will then use this map \( \nabla \) to prove Proposition 80.11.

First we recall some notation from page 1078.

Notation. For \( i = 0, \ldots, n \) we write

\[
v_i := (0, \ldots, 1, 0, \ldots, 0) \in \mathbb{R}^{n+1}.
\]

Furthermore for \( a_0, \ldots, a_k \in \Delta^n \) we consider the map

\[
[a_0, \ldots, a_k]: \Delta^k \rightarrow \Delta^n
\]

\[
\sum_{j=0}^k \lambda_j \cdot v_j \mapsto \sum_{j=0}^k \lambda_j \cdot a_j.
\]

The map \( [a_0, \ldots, a_k] \) thus sends the standard \( k \)-simplex \( \Delta^k \) to the simplex “spanned by \( a_0, \ldots, a_k \)” in \( \Delta^n \).

Definition. Let \( m, n \in \mathbb{N}_0 \).

1. An \((m, n)\)-shuffle is a pair \((\mu, \nu)\) of disjoint sets of integers

\[
1 \leq \mu_1 < \mu_2 < \cdots < \mu_m \leq m + n \quad \text{and} \quad 1 \leq \nu_1 < \nu_2 < \cdots < \nu_n \leq m + n.
\]

Note that the homeomorphism

\[
f: (I^k, \partial I^k) \rightarrow (B^k, S^{k-1})
\]

from Proposition 2.52 (2) has the property that the restriction to a dense open subset of \( I^k \setminus \partial I^k \rightarrow B^k \) is an orientation-preserving diffeomorphism. In particular this homeomorphism is thus an orientation-preserving homeomorphism from the oriented topological manifold \( I^k \) to the oriented topological manifold \( B^k \).
We denote by \( \text{sign}(\mu, \nu) \) the sign of the permutation \((\mu_1, \ldots, \mu_m, \nu_1, \ldots, \nu_n)\). We denote by \( \eta^\mu : \Delta^{m+n} \to \Delta^m \) the unique affine linear map which satisfies \( \eta^\mu(v_i) = v_j \) for \( \mu_j \leq i < \mu_{j+1} \). The same way we define \( \eta^\nu : \Delta^{m+n} \to \Delta^n \).

(2) Given two topological spaces \( X \) and \( Y \) we define
\[
\nabla_{mn} : C_m(X) \otimes C_n(Y) \to C_{m+n}(X \times Y)
\]

where we take the sum over all \((m,n)\)-shuffles.

**Examples.**

1. We consider the case \( X = Y = \mathbb{R} \) and \( m = n = 1 \). There exist two \((1,1)\)-shuffles, namely \( \{\mu_1 = 1, \nu_1 = 2\} \) and \( \{\mu_1 = 2, \nu_1 = 1\} \). Note that \( \eta^1 : \Delta^2 \to \Delta^1 \) equals the map \([v_0, v_1, v_2]\) and that \( \eta^2 : \Delta^2 \to \Delta^1 \) equals the map \([v_0, v_0, v_1]\). In Figure 1159 we illustrate \( \nabla_{11}(\sigma \otimes \tau) \) for two affine linear singular 1-simplices \( \sigma : \Delta^1 \to X = \mathbb{R} \) and \( \tau : \Delta^1 \to Y = \mathbb{R} \).

2. We consider the case \( X = Y = S^1 \) and \( m = n = 1 \). Furthermore we denote by \( \mu : \Delta^1 \to S^1 \) the singular 1-simplex that is given by \( \mu(1 - t, t) = e^{2\pi i t} \). On page 1714 we saw that \( \mu \) represents the fundamental class of \( S^1 \) with the standard orientation. Comparing Figures 1054 and 1159 we see that the shuffle \( \nabla(\mu \otimes \mu) \) is precisely the usual representative for the fundamental class of the 2-dimensional torus \( S^1 \times S^1 = ([0,1] \times [0,1]) \). 

**Proposition 80.12.** The maps \( \nabla \) that we had just defined have all the properties that we had mentioned in Theorem 80.2, i.e. the maps \( \nabla : C_*(X) \otimes C_*(Y) \to C_*(X \times Y) \) are natural chain maps that on the 0-level equal the canonical maps that we introduced on page 1956.

**Proof.** It follows immediately from the definition that the maps \( \nabla_{mn} \) are natural and that on the 0-level they agree with the canonical maps. It is elementary (albeit rather painful) to verify that these maps are chain maps. We refer to [Do56, p. 184] and [EM53] for details and proofs.

Now we can finally provide the proof of Proposition 80.11.

---

1155 Here we implicitly use that \( \mu_0 = 0 \) and \( \mu_{m+1} = m + n + 1 \).
Proof of Proposition 80.11. It suffices to prove the statement for $U = \mathbb{R}^m$ and for $V = \mathbb{R}^n$. Given any $k \in \mathbb{N}_0$ we consider the singular chain $\sigma_k = (-1)^k \cdot [v_0, \ldots, v_k, 0]$. (In plain English the singular simplex $[v_0, \ldots, v_k, 0] : \Delta^k \to \mathbb{R}^k$ is just given by the obvious projection.) We make the following observation:

(*) Let $z \in \mathbb{R}^k$ be any point that lies in the interior of the image of $\sigma_k$. It follows from the discussion on page 1991 that the chain $\sigma_k$ represents the standard generator of $H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{z\})$.

Next we consider the $(m, n)$-shuffle that is given by the sets $\mu_0 = \{1, \ldots, m\}$ and $\nu_0 = \{m + 1, \ldots, m + n\}$. It follows easily from the definitions that $\eta^{\mu_0} = [v_0, \ldots, v_m, \ldots, v_m] : \Delta^{m+n} \to \Delta^m$ and $\eta^{\nu_0} = [v_m, \ldots, v_m, \ldots, v_m] : \Delta^{m+n} \to \Delta^n$.

Also note that it is a straightforward consequence of the definitions that we have the following equality of singular $(m + n)$-chains in $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$:

$$(\sigma_m \circ \eta^{\mu_0}) \times (\sigma_n \circ \eta^{\nu_0}) = (-1)^m \cdot (-1)^n \cdot [v_0, \ldots, v_{m-1}, v_m, \ldots, v_{m+n-1}, 0] = \sigma_{m+n}.$$ 

We pick a point $(x, y) \in \mathbb{R}^m \times \mathbb{R}^n$ that lies in the interior of the image of $\sigma_{m+n}$. Note that $x$ lies in the interior of the image of $\sigma_m$ and that $y$ lies in the interior of the image of $\sigma_n$.

It follows from the observation (*), the definition of the product orientation on page 1969 and Proposition 80.6 (1) that it suffices to prove the following claim.

Claim. The following equality holds in $H_{m+n}(\mathbb{R}^{m+n}, \mathbb{R}^{m+n} \setminus \{(x, y)\})$:

$$[\sigma_m] \times [\sigma_n] = [\sigma_{m+n}].$$

We have

$$[\sigma_m] \times [\sigma_n] = \left[ \nabla_{mn}(\sigma_m \otimes \sigma_n) \right] \uparrow \left[ \sum_{(\mu, \nu)} \text{sign}(\mu, \nu) \cdot (\sigma_m \circ \eta^\mu \times \sigma_n \circ \eta^\nu) \right]$$

by definition

Proposition 80.12 and Theorem 80.5

for all other shuffles $(\mu, \nu)$ the point $(x, y)$ does not lie in the image of $\sigma_{m+n}$.

This concludes the proof of the claim and thus of the proposition.

80.7. The Acyclic Model Theorems. In this section we will prove two “Acyclic Model Theorems” which on many occasions will allow us to construct maps and homotopies. We start out with the following fairly Acyclic Model Theorem. We will need this particular Acyclic Model Theorem later on in Chapter 109 when we construct Steenrod operations.

Theorem 80.13. (Acyclic Model Theorem) Let $\text{Top}$ be the category of topological spaces and let $C$ be the category of generalized chain complexes. Let $G : \text{Top} \to C$ be a covariant functor. Furthermore let $S$ be a natural transformation from the functor $X \mapsto C_*(X)$ to the functor $X \mapsto G(X)$. If $H_i(G(\Delta^k)) = 0$ for any $k \in \mathbb{N}_0$ and any $i \in \mathbb{N}_0$, then there exists a natural chain homotopy $P$ from $S$ to the zero map. In other words, for any topological space $X$ and any $k \in \mathbb{N}$ there exists a natural map $P_X : C_k(X) \to G_{k+1}(X)$,
Since we assume that \( H \) we need to construct a suitable map \( X \)

**Sketch of proof.** The proof of this theorem is very similar to the “naturally chain homotopic statement” of Theorem 80.5. First recall that the fact that \( \partial \circ P_X + P_X \circ \partial = S_X : C_k(X) \rightarrow G_k(X) \).

Now we consider \( \text{id}_{\Delta^0} \in C_0(\Delta^0) \). It is a cycle in the chain complex \( C_\ast(\Delta^0) \). Since the above diagram commutes we see that \( S(\text{id}_{\Delta^0}) \) is also cycle in \( G_0(\Delta^0) \). Since we assume that \( H_0(G(\Delta^0)) = 0 \) we see that there exists some \( \mu_1 \in G_1(\Delta^0) \) with \( \partial_1(\mu_1) = S(\text{id}_{\Delta^0}) \).

Now, given any topological space \( X \) we define

\[
P_0 : C_0(X) \rightarrow G_1(X)
\]

\[
\sum_{i=1}^m a_i \cdot f_i \mapsto \sum_{i=1}^m a_i \cdot f_i(\mu_1).
\]

\[\text{map} \Delta^0 \rightarrow X\]

We iterate this procedure. Namely suppose that for \( i = 0, \ldots, k - 1 \) we have already constructed natural maps \( P_i : C_i(X) \rightarrow G_{i+1}(X) \) such that \( \partial \circ P_i + P_{i-1} \circ \partial = S_i \) for \( i = 0, \ldots, k - 1 \). For reference we consider the following diagram:

\[
\cdots \longrightarrow C_{k+1}(X) \xrightarrow{\partial_{k+1}} C_k(X) \xrightarrow{\partial_k} C_{k-1}(X) \longrightarrow \cdots
\]

\[
\cdots \longrightarrow G_{k+1}(X) \xleftarrow{\partial_{k+1}} G_k(X) \xrightarrow{\partial_k} G_{k-1}(X) \longrightarrow \cdots
\]

Next we need to construct a suitable map \( P_k \). We calculate that

\[
\partial_k((S_k - P_{k-1} \circ \partial)(\text{id}_{\Delta^k})) = \partial S_k(\text{id}_{\Delta^k}) - \partial P_{k-1}(\partial \text{id}_{\Delta^k})
\]

\[
= S_{k-1}(\partial \text{id}_{\Delta^k}) - (S_{k-1} - P_{k-2} \partial)(\partial \text{id}_{\Delta^k}) = (P_{k-2} \circ \partial \circ \partial)(\text{id}_{\Delta^k}) = 0
\]

since \( S \) is a chain map and since \( \partial \circ P_{k-1} + P_{k-2} \circ \partial = S_{k-1} \)

Since we assume that \( H_k(G(\Delta^k)) = 0 \) we see that there exists some \( \mu_{k+1} \in G_{k+1}(\Delta^k) \) with \( \partial_{k+1}(\mu_{k+1}) = (S_k - P_{k-1} \circ \partial)(\text{id}_{\Delta^k}) \). Now, given any topological space \( X \) we define

\[
P_k : C_k(X) \rightarrow G_{k+1}(X)
\]

\[
\sum_{i=1}^m a_i \cdot f_i \mapsto \sum_{i=1}^m a_i \cdot f_i(\mu_{k+1}).
\]

\[\text{map} \Delta^k \rightarrow X\]

Using the fact that \( S \) is natural one can easily verify that \( P_k \) has the desired properties. 

\[\text{Here “generalized” just means, see page 1086 that we also allow chain groups in negative degrees.}\]
The above version of the Acyclic Model Theorem will not work for the situations that we need to deal with in the near future. There are two problems with the above Acyclic Model Theorem:

(1) On several occasions we will be interested in natural transformations of the form \( C_*(X) \to C_*(X) \otimes C_*(X) \), but for \( X = \Delta^k \) the chain complexes to the right does not satisfy the condition that the homology groups for \( X = \Delta^k \) vanish in dimensions \( \geq 0 \).

(2) We will also need to deal with situations where to the left we have more complicated chain complexes, e.g. we might want to study natural transformations of the type \( C_*(X) \times C_*(X) \to C_*(X \times X) \).

To formulate a version of the Acyclic Model Theorem that deals with the above two issues we need a few more definitions.

**Definition.**

1. An augmented chain complex is a chain complex

   \[
   (C_*, \partial_*) = \cdots \to C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0
   \]

   together with an epimorphism \( \epsilon : C_0 \to \mathbb{Z} \) such that \( \epsilon \circ \partial_1 : C_1 \to \mathbb{Z} \) is the zero map.

2. We say that an augmented chain complex \( ((C_*, \partial_*), \epsilon : C_0 \to \mathbb{Z}) \) is acyclic if the generalized chain complex

   \[
   \cdots \to C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \xrightarrow{\epsilon} \mathbb{Z} \to 0
   \]

   is acyclic, i.e. if all homology groups are zero.

3. Let \( ((C_*, \partial_*), \epsilon) \) and \( ((C'_*, \partial'_*), \epsilon') \) be two augmented chain complexes. A chain map of augmented chain complexes is a chain map \( f_* : C_* \to C'_* \) such that the following diagram commutes:

   \[
   \begin{array}{ccc}
   C_0 & \xrightarrow{\epsilon} & \mathbb{Z} \\
   f_0 \downarrow & & \downarrow = \\
   C'_0 & \xrightarrow{\epsilon'} & \mathbb{Z}.
   \end{array}
   \]

4. We refer to the category \( \mathcal{A} \) with

   \[
   \text{Ob}(\mathcal{A}) = \text{ augmented chain complexes }
   \]

   \[
   \text{Mor}((C, \epsilon), (C', \epsilon')) = \text{ set of chain maps of augmented chain complexes from } (C, \epsilon) \text{ to } (C', \epsilon')
   \]

   as the category of augmented chain complexes.

**Examples.**

(1) Let \( X \) be a non-empty topological space. We denote by \( \epsilon_X : C_0(X) \to \mathbb{Z} \) the augmentation map that we introduced on page 1084, i.e. \( \epsilon_X \) is the map that sends each singular 0-simplex to 1. It follows from Lemma 41.4(1) that \( (C_*(X), \epsilon_X) \) is an augmented chain complex. If \( X \) is a contractible topological space, e.g. if \( X = \Delta^k \), then
it follows from Lemma $43.1$ (7) that the corresponding augmented chain complex is acyclic.

(2) If $(C_*, \mu)$ and $(D_*, \nu)$ are two augmented chain complexes then the tensor product $C_* \otimes D_*$ of chain complexes, as defined in Lemma $58.2$, together with the map

$$\mu \otimes \nu : (C_* \otimes D_*)_0 = C_0 \otimes D_0 \to \mathbb{Z}$$

$$\sum_{i=1}^k c_i \otimes d_i \mapsto \sum_{i=1}^k \mu(c_i) \cdot \nu(d_i)$$

is easily seen to be an augmented chain complex.$^{[1157]}$

**Definition.** We say a chain complex $C_*$ is almost acyclic if $H_i(C_*) = 0$ for $i \geq 1$ and if $H_0(C_*) \cong \mathbb{Z}$.

**Example.** If $X$ is a contractible topological space, then it follows from Corollary $42.8$ that $C_*(X)$ is almost acyclic.

**Proposition 80.14.** Let $C_*$ and $D_*$ be two chain complexes. If $C_*$ and $D_*$ are almost acyclic and if $C_*$ is free, i.e. if each chain group $C_n$ is a free abelian group, then $C_* \otimes D_*$ is also almost acyclic.

**Proof.** Let $n \in \mathbb{N}_0$. Since $C_*$ is free we can apply the Künneth Theorem for Chain Complexes $58.7$, which gives us the following short exact sequence:

$$0 \to \bigoplus_{p+q=n} H_p(C_*) \otimes H_q(D_*) \overset{\partial}{\to} H_n(C_* \otimes D_*) \to \bigoplus_{p+q=n-1} \text{Tor}(H_p(C_*), H_q(D_*)) \to 0.$$

The proposition is an immediate consequence of this short exact sequence and of some very elementary statements regarding tensor products and torsion groups, see Lemma $57.3$ and $57.17$.

The following lemma gives a convenient criterion for showing that augmented chain complexes are acyclic.

**Lemma 80.15.** Let $((C_*, \partial_*), \epsilon)$ be an augmented chain complex. If the chain complex $(C_*, \partial_*)$ is almost acyclic, then the augmented chain complex $((C_*, \partial_*, \epsilon)$ is acyclic.

**Proof (\#).** We denote by $\tilde{C}_*$ the generalized chain complex

$$\ldots \overset{\partial_3}{\to} C_2 \overset{\partial_2}{\to} C_1 \overset{\partial_1}{\to} C_0 \overset{\epsilon}{\to} \mathbb{Z} \to 0.$$

We need to show that this chain complex is acyclic. It is clear that for $i \geq 1$ we have $H_i(\tilde{C}_*) = H_i(C_*) = 0$. It remains to show that $H_0(\tilde{C}_*) = 0$. Since $\mathbb{Z}$ is a free abelian group

$^{[1157]}$Indeed, by definition $(C_* \otimes D_*)_1$ is generated by elements $c_1 \otimes d_0$ with $c_1 \in C_1$ and $d_0 \in D_0$ and by elements $c_0 \otimes d_1$ with $c_0 \in C_0$ and $d_1 \in D_1$. We calculate that

$$(\mu \otimes \nu) \circ \partial_1 (c_1 \otimes d_0) = (\mu \otimes \nu) (\partial c_1 \otimes d_0 + (-1)^1 c_1 \otimes \partial d_0) = (\mu \otimes \nu) (\partial c_1 \otimes d_0) = \mu(\partial c_1) \cdot \nu(d_0) = 0 \cdot \nu(d_0) = 0.$$

The same argument shows that $((\mu \otimes \nu) \circ \partial_1)(c_0 \otimes d_1) = 0$. 

and since $\epsilon: C_0 \to \mathbb{Z}$ is an epimorphism we can pick a map $s: \mathbb{Z} \to C_0$ with $\epsilon \circ s = \text{id}_\mathbb{Z}$. As in Lemma 43.1 (4) one can easily show that the map
\[ H_0(\tilde{C}_*) \oplus \mathbb{Z} \to H_0(C_*) \]
\[ [\sigma] \oplus n \mapsto [\sigma] + s(n) \]
is an isomorphism. Since $H_0(C_*) \cong \mathbb{Z}$ it follows from Exercise 19.3 (b) (see also more generally Proposition 19.10) that $H_0(\tilde{C}_*) = 0$. ■

**Definition.** Let $\mathcal{K}$ be a category (in all applications $\mathcal{K}$ will be the category of non-empty topological spaces or the category of tuples of non-empty topological spaces) and let $F: \mathcal{K} \to \mathcal{A}$ be a covariant functor from $\mathcal{K}$ to the category $\mathcal{A}$ of augmented chain complexes. Let $\mathcal{M}$ be a collection of objects of $\mathcal{K}$.

1. We say the functor $F$ is **acyclic relative to** $\mathcal{M}$ if given any $X \in \mathcal{M}$ the augmented chain complex $F(X)$ is acyclic.
2. We say the functor $F$ is **free relative to** $\mathcal{M}$ if for each $k \in \mathbb{N}_0$ there exists $\mathcal{M}_k \subset \mathcal{M}$ and if for each $M \in \mathcal{M}_k$ there exists an element $\sigma_M \in F_k(M)$ such that given any $X \in \mathcal{K}$ the following two statements hold:
   a. The set
   \[ \{ F(f)(\sigma_M) \in F_k(X) \mid M \in \mathcal{M}_k \text{ and } f \in \text{Mor}(M, X) \} \]
   the morphism $f: M \to X$ induces a homomorphism $F(f): F_k(M) \to F_k(X)$ is a basis for the abelian group $F_k(X)$.
   b. The description of the set in (a) has no double elements, much more precisely, for $(M, f) \neq (M', f')$ we have $F(f)(\sigma_M) \neq F(f')(\sigma_{M'})$.

**Remark.** The objects in a collection $\mathcal{M}$ as in the previous definition are often called **models**.

The definition of "free relative to $\mathcal{M}$" is arguably somewhat intimidating. The following example should convince the reader that in practice it is not that bad.

**Example.** Let $\mathcal{K}$ be the category of non-empty topological spaces and let $F$ be the covariant functor that assigns to each $X \in \mathcal{K}$ the augmented singular chain complex $(C_*(X), \epsilon_X)$. We consider
\[ \mathcal{M} := \{ \Delta^k \mid k \in \mathbb{N}_0 \} = \text{the set of all standard simplices.} \]
We claim that $F$ is acyclic and free relative to $\mathcal{M}$:

1. By Lemma 43.1 (7) we know that for every $k \in \mathbb{N}_0$ we have $\tilde{H}_k(\Delta^k) = 0$. But by Lemma 80.15 this just means that $\mathcal{M}$ is acyclic relative to $F$.

\[ F_k(M) \] is the $k$-chain group of the chain complex $F(M)$.
\[ F_k(M) \] is a free abelian group.

\[ F_k(M) \] is the $k$-chain group of the chain complex $F(M)$.\[ F_k(M) \] is a free abelian group.
80. THE EILENBERG-ZILBER THEOREM AND THE CROSS PRODUCT

(2) Let \( k \in \mathbb{N}_0 \). We set \( \mathcal{M}_k = \{ \Delta^k \} \) and we consider \( \sigma_k = \text{id}_{\Delta^k} \in C_k(\Delta^k) \). Now recall that given any topological space \( X \) and given any \( k \in \mathbb{N}_0 \) we have

by definition of \( C_k(X) \), see page 1077

\[
C_k(X) = \text{free abelian group generated by the set of singular } k\text{-simplices in } X
\]

by definition of a singular \( k \)-simplex, see page 1077

But this means that the set \( \{ f_\ast(id_{\Delta^k}) \} \) for \( f : \Delta^k \to X \) is a basis for \( C_k(X) \).

Now we can formulate the main theorem of this section.

**Theorem 80.16. (Acyclic Model Theorem)** Let \( K \) be a category with a collection of objects \( \mathcal{M} \). Furthermore let \( F, G : K \to A \) be two covariant functors from \( K \) to the category of augmented chain complexes. If \( F \) is free relative to \( \mathcal{M} \) and if \( G \) is acyclic relative to \( \mathcal{M} \), then the following statements hold:

1. There exists a natural transformation \( T_X \) from \( F(X) \to G(X) \) of augmented chain complexes such that for any morphism \( f : X \to Y \) in \( K \) the following diagram commutes:

\[
\begin{array}{ccc}
F(X) & \xrightarrow{F(f)} & F(Y) \\
T_X \downarrow & & \downarrow T_Y \\
G(X) & \xrightarrow{G(f)} & G(Y).
\end{array}
\]

2. Given two natural transformations \( S_X \) and \( T_X \) from \( F \to G \) there is a natural chain homotopy equivalence between \( S \) and \( T \).

**Proof.** The proof is, ultimately very much the same as the proof of Theorem 80.5. We decline to provide a proof and we follow the lead given by Munkres [Mun84, p. 185], namely like Munkres we assign the proof as an exercise to the reader. Alternatively the reader can find the proof in [Spa95, p. 169], [Vic94, Theorem 5.3] or [Dol80, p. 175].

As an example for the Acyclic Model Theorem 80.16 we will prove a statement that we will anyway need shortly. To formulate the application we need the following definition.

**Definition.** A diagonal approximation is a natural chain map

\[
\varphi : C_\ast(X) \to C_\ast(X) \otimes C_\ast(X)
\]

such that for each \( x \in X \), viewed as a singular 0-simplex, we have

\[
\varphi(x) = x \otimes x \in C_0(X) \otimes C_0(X).
\]

\[\ast(C_\ast(X) \otimes C_\ast(X))_0\]

**Proposition 80.17.** Given any two diagonal approximations \( \Phi \) and \( \Psi \) there exists a natural chain homotopy equivalence between \( \Phi \) and \( \Psi \).

\[\text{Note that the zero map is not a chain map of augmented chain complexes, since it does not respect the augmentation.}\]
Proof. We let $\mathcal{K}$ be the category of non-empty topological spaces. As on page 1976 we consider the collection

$$\mathcal{M} := \{\Delta^k \mid k \in \mathbb{N}_0\} = \text{the set of all standard simplices}.$$  

We consider the covariant functors

$$F : \mathcal{K} \rightarrow \mathcal{A} \quad \text{and} \quad G : \mathcal{K} \rightarrow \mathcal{A}$$

$$\begin{align*}
X & \mapsto (C_*(X), \epsilon_X) \quad \text{and} \quad X \mapsto (C_*(X) \otimes C_*(X), \epsilon_X \otimes \epsilon_X).
\end{align*}$$

Now let $\Phi, \Psi : C_*(X) \rightarrow C_*(X) \otimes C_*(X)$ be two diagonal approximations. By definition these are natural transformations from $F$ to $G$. The hypothesis that $\Phi$ and $\Psi$ are diagonal approximations implies that $\Phi$ and $\Psi$ define chain maps of augmented chain complexes.

By the Acyclic Model Theorem it remains to prove the following claim.

Claim.

(1) The functor $F$ is free relative to $\mathcal{M}$.
(2) The functor $G$ is acyclic relative to $\mathcal{M}$.

We prove these two statements:

(1) Conveniently enough we showed on page 1977 that $F$ is free relative to $\mathcal{M}$.
(2) We need to show that given any $k \in \mathbb{N}_0$ the corresponding augmented chain complex $(C_*(\Delta^k) \otimes C_*(\Delta^k), \epsilon_X \otimes \epsilon_X)$ is acyclic. By Lemma it suffices to show that the chain complex $C_*(\Delta^k) \otimes C_*(\Delta^k)$ is almost acyclic. But this is a consequence of the fact that $C_*(\Delta^k)$ is almost acyclic, see page 1975 and Proposition 80.14. ■

Exercises for Chapter 80

Exercise 80.1. Let $M$ and $N$ be topological manifolds and let $\varphi \in H_k(M)$ and $\psi \in H_l(N)$. If $\varphi$ is realized by a closed oriented $k$-dimensional submanifold $A$ and if $\psi$ is realized by a closed oriented $l$-dimensional submanifold $B$, then the cross product $\varphi \times \psi \in H_{k+l}(M \times N)$ is realized by the closed $(k+l)$-dimensional submanifold $A \times B$.

Exercise 80.2. Let $X$ and $Y$ be topological spaces. Show that for any $\sigma \in H_0(X)$ and $\tau \in H_0(Y)$ we have

$$\epsilon_X(\sigma) \cdot \epsilon_Y(\tau) = \epsilon_{X \times Y}(\sigma \times \tau).$$

Here the maps $\epsilon$ are as always the various augmentation maps.

Exercise 80.3. Let $M$ be the Möbius band. We consider the topological manifold $M \times [0,1]$.

(a) What is the homeomorphism type of $\partial(M \times [0,1])$?
(b) Is the topological manifold $M \times [0,1]$ orientable?

\text{It follows from the discussion on page 1975 that both $F$ and $G$ are indeed functors to the category of augmented chain complexes.}
81. The cup product

81.1. A first definition of the cup product. Let $X$ be a topological space. The cross product from page 1964 applied to the same topological spaces $X = Y$ gives us in particular the cross product \[\cup \colon H_p(C_\ast(X)) \otimes H_q(C_\ast(X)) \to H_{p+q}(C_\ast(X) \otimes C_\ast(X))\] from page 1964. Applied to the same topological spaces $\Theta$.

\[\text{Hom}((C \otimes D)_{p+q}, R) = \bigoplus_{i+j=p+q} C_i \otimes D_j \to C_p \otimes D_q\]

the obvious projection map.

(2) Let $R$ be a commutative ring. We denote by $\Xi$ the map

\[
(\varphi, \psi) \mapsto \left(\left(C_\ast \otimes D_\ast\right)_{p+q} \xrightarrow{\Pi_{p,q}} C_p \otimes D_q \xrightarrow{\varphi \otimes \psi} R \otimes R \xrightarrow{a \otimes b \mapsto a \cdot b}ight).
\]

Lemma 81.1. Let $C_\ast$ and $D_\ast$ be chain complexes. For any commutative ring $R$ the map

\[
H^p(C_\ast; R) \times H^q(D_\ast; R) \to H^{p+q}(C_\ast \otimes D_\ast; R)
\]

is well-defined.

Proof. We leave the verification of the lemma to the reader.

We return to topology. So let $X$ be a topological space. We consider the map

\[
\Xi \colon H^p(C_\ast(X); Z) \otimes H^q(C_\ast(X); Z) \to H^{p+q}(C_\ast(X) \otimes C_\ast(X); Z) \xrightarrow{\Theta^*} H^{p+q}(C_\ast(X \times X); Z).
\]

Summarizing we get a map

\[
H^p(X; Z) \otimes H^q(X; Z) \to H^{p+q}(X \times X; Z)
\]

This is very nice, but this construction does not give us a product on the homology groups of $X$ itself, since we end up in the homology of a different topological space.

Now we try our luck with cohomology groups. Before we can study maps on cohomology groups we need a little bit of algebraic preparation.

Definition. Let $C_\ast$ and $D_\ast$ be chain complexes.

(1) Given $p, q \in \mathbb{N}_0$ we denote by

\[
\Pi_{p,q} : (C_\ast \otimes D_\ast)_{p+q} = \bigoplus_{i+j=p+q} C_i \otimes D_j \to C_p \otimes D_q
\]

the obvious projection map.

(2) Let $R$ be a commutative ring. We denote by $\Xi$ the map

\[
(\varphi, \psi) \mapsto \left(\left(C_\ast \otimes D_\ast\right)_{p+q} \xrightarrow{\Pi_{p,q}} C_p \otimes D_q \xrightarrow{\varphi \otimes \psi} R \otimes R \xrightarrow{a \otimes b \mapsto a \cdot b}ight).
\]
which is sometimes called the cross product on cohomology. Again, this is nice, but exactly as in the case of the cross product on homology, we end up in the cohomology of \( X \times X \), but we really would like to end up in the cohomology of \( X \).

Now we have to find a way how to go back from the topological space \( X \times X \) to the original space \( X \). In general there does not exist an “interesting” map \( X \times X \rightarrow X \). But, as we saw before, there does exist an interesting map in the opposite direction, namely the diagonal map

\[
d: X \rightarrow X \times X
\]

\[
x \mapsto (x, x).
\]

This diagonal map \( d \) induces a map

\[
d_*: H_*(X; \mathbb{Z}) \rightarrow H_*(X \times X; \mathbb{Z})
\]

on homology, and, much more interesting in our context, it also induces a map

\[
d^*: H^*(X \times X; \mathbb{Z}) \rightarrow H^*(X; \mathbb{Z}).
\]

on cohomology groups that goes in the “opposite direction”. This discussion leads us to the following definition.

**Definition.** Let \( X \) be a topological space. We define the cup product \( \cup \) on the cohomology groups of \( X \) as the composition of the following maps:

\[
H^p(X; \mathbb{Z}) \times H^q(X; \mathbb{Z}) \rightarrow H^p(X; \mathbb{Z}) \otimes H^q(X; \mathbb{Z}) \xrightarrow{\Theta \circ \Xi} H^{p+q}(X \times X; \mathbb{Z}) \xrightarrow{d^*} H^{p+q}(X; \mathbb{Z}).
\]

For the resulting pairing we use the notation

\[
(a, b) \mapsto a \cup b
\]

and we refer to \( a \cup b \) as the cup product of \( a \) and \( b \).

### 81.2. An alternative definition of the cup product.

The definition of the cup product in the previous section was very natural and we could now develop the theory of the cup product using that definition. If one takes that route then one has to deal with the awkward fact that the Eilenberg-Zilber map \( \Theta \) is not very explicit.

Now we give an alternative definition of the cup product which is more ad hoc, but which works surprisingly well in practice.

**Definition.** Let \( X \) be a topological space and let \( R \) be a commutative ring. Furthermore let \( \varphi \in C^p(X; R) \) and \( \psi \in C^q(X; R) \) be cochains. We define the cup product of \( \varphi \) and \( \psi \)

\[
\varphi \cup \psi : H^r(X; R) \rightarrow H^{r+p+q}(X; R).
\]

The projection from \( X \times X \) onto one of the two factors does not count as “interesting”, since it does not “mix” the two factors. In fact in Exercise \[81.1\] we will see that the map

\[
H_*(X) \otimes H_*(X) \xrightarrow{\Theta} H_*(X \times X) \xrightarrow{p} H_*(X),
\]

where \( p: X \times X \rightarrow X \) denotes the projection on the first factor, is the zero map.

The name “cup product” comes from the notation “\( a \cup b \)” for the composition since \( \cup \) looks like a cup.
to be the singular cochain
\[ \varphi \cup \psi : C_{p+q}(X) \to R \]
that is given by
\[ (\sigma : \Delta^{p+q} \to X) \mapsto \left( \varphi(\sigma[v_0, \ldots, v_p]) \cdot \psi(\sigma[v_p, \ldots, v_{p+q}]) \right) \in R. \]

The cup product thus defines a map
\[ \cup : C^p(X; R) \times C^q(X; R) \to C^{p+q}(X; R). \]

**Remark.** The sign conventions for the cup product for cohomology classes \( \varphi \in H^p(X; R) \) and \( \psi \in H^q(X; R) \) differ in the literature. More precisely, given a topological space \( X \) and cochains \( \varphi \in C^p(X; R) \) and \( \psi \in C^q(X; R) \) the cup product \( \varphi \cup \psi \), applied to a singular \( (p+q) \)-simplex \( \sigma : \Delta^{p+q} \to X \) is defined as follows:

| (a) Hatcher [Hat02] p. 206 | \( \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |
| (b) Bredon [Bre93] p. 328 | \(( -1)^{pq} \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |
| (c) Dold [Dol56] p. 222 | \(( -1)^{pq} \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |
| (d) Spanier [Spa95] p. 251 | \( \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |
| (e) Munkres [Mun84] p. 288 | \( \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |
| (f) Greenberg-Harper [GH81] p. 195 | \( \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) |

So we see that our sign convention agrees with the conventions of Hatcher, Spanier, Munkres and Greenberg-Harper, but they differ by the sign \( ( -1)^{pq} \) from the conventions used in Bredon and Dold.

**Example.** Since the second definition of the cup product is initially strange and not very intuitive we consider an example in slightly more detail. In the following we consider the torus \( T = S^1 \times S^1 = ([0, 1] \times [0, 1])/\sim \) with the two singular 2-simplices \( \sigma_1 \) and \( \sigma_2 \) illustrated in Figure [161], which we already saw in Figure [1064]. We recall the following notation:

1. We denote by \( p \) respectively \( q \) the projection \( S^1 \times S^1 \to S^1 \) onto the first respectively second factor,

\[ \varphi \cup \psi : C_{p+q}(X) \to R \]

\[ (\sigma : \Delta^{p+q} \to X) \mapsto \left( \varphi(\sigma[v_0, \ldots, v_p]) \cdot \psi(\sigma[v_p, \ldots, v_{p+q}]) \right) \in R. \]

1. In the literature, given a singular \( n \)-simplex \( \sigma : \Delta^n \to X \) one often writes \( \sigma_p = \sigma[v_{n-p}, \ldots, v_n] \).

---

\(^{1166}\) Here, when we write \([v_0, \ldots, v_p] : \Delta^p \to \Delta^{p+q} \) and \([v_p, \ldots, v_{p+q}] : \Delta^q \to \Delta^{p+q} \), we use the notation from page 1970.

\(^{1167}\) In the literature, given a singular \( n \)-simplex \( \sigma : \Delta^n \to X \) one often writes \( \sigma_p = \sigma[v_{n-p}, \ldots, v_n] \).
(2) we denote by $\mu: \Delta^1 \to S^1$ the singular 1-simplex given by $\mu(1 - t, t) = e^{2\pi i t}$, 
(3) furthermore we denote by $\nu: \Delta^1 \to S^1$ the constant singular 1-simplex that is given
by $\nu(1 - t, t) = 1$.
(4) finally we recall that on page 1825 we introduced a cochain $\theta := \theta_z \in C_1(S^1, \mathbb{Z})$ and we
showed that $\theta(\mu) = 1$, also note that $\theta(\nu) = 0$.
We want to determine the values of $p^* (\theta) \cup q^* (\theta) \in C^2(T, \mathbb{Z}) = \text{Hom}(C_2(T), \mathbb{Z})$ on the
singular 2-simplices $\sigma_1$ and $\sigma_2$. We have

$$(p^* (\theta) \cup q^* (\theta))(\sigma_1) = p^* (\theta)((\sigma_1 \circ [v_0, v_1]) \cdot q^* (\theta)((\sigma_1 \circ [v_1, v_2]))
= \theta(p \circ \sigma_1 \circ [v_0, v_1]) \cdot \theta(q \circ \sigma_1 \circ [v_1, v_2]) = 0 \cdot 0 = 0.$$ 

Much more interestingly we have

$$(p^* (\theta) \cup q^* (\theta))(\sigma_2) = p^* (\theta)((\sigma_2 \circ [v_0, v_1]) \cdot q^* (\theta)((\sigma_2 \circ [v_1, v_2]))
= \theta(p \circ \sigma_2 \circ [v_0, v_1]) \cdot \theta(q \circ \sigma_2 \circ [v_1, v_2]) = 1 \cdot 1 = 1.$$ 

To aid the reader we also recall in Figure 1162 the notation that we had initially introduced
on page 1716 and that we use in Figure 1161.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure1161.png}
\caption{Figure 1161}
\end{figure}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure1162.png}
\caption{Figure 1162. Notation of the “dotted triangle”.
\end{figure}

The definition of the cup product on cochains might look strange and arbitrary. But
the following lemma shows that it behaves well with respect to coboundary maps.

**Lemma 81.2.** Let $X$ be a topological space and let $R$ be a commutative ring. Furthermore
let $\varphi \in C^p(X; R)$ and $\psi \in C^q(X; R)$. Then

$$\delta(\varphi \cup \psi) = \delta \varphi \cup \psi + (-1)^p \cdot \varphi \cup \delta \psi \in C^{p+q+1}(X; R).$$

**Remark.** Note that a similar looking statement holds for differential forms. More precisely,
given a smooth manifold $M$ and two differential forms $\omega \in \Omega^p(M)$ and $\eta \in \Omega^q(M)$ it follows
from Proposition 78.2 (5) that 
\[ d(\omega \wedge \eta) = d\omega \wedge \eta + (-1)^p \cdot \omega \wedge d\eta \in \Omega^{p+q+1}(M). \]

The (co-) boundary formula of Lemma 81.2 is of course also very similar to the definition of the boundary map in the tensor product of two chain complexes.

**Proof.** The lemma follows from an elementary, albeit slightly confusing, calculation. Indeed, let \( \varphi \in C^p(X; R) \) and \( \psi \in C^q(X; R) \) be cochains. We have to prove the following equality:

\[ \delta(\varphi \cup \psi) = \delta \varphi \cup \psi + (-1)^p \cdot \varphi \cup \delta \psi \in C^{p+q+1}(X; R) = \text{Hom}(C_{p+q+1}(X), R). \]

So let \( \sigma: \Delta^{p+q+1} \rightarrow X \) be a singular \((p+q+1)\)-simplex. We have the following three equalities in \( R \):

(a) \( \delta(\varphi \cup \psi)(\sigma) = (\varphi \cup \psi)\left( \sum_{j=0}^{p+q+1} \delta \varphi_j \cdot \sigma \circ \varphi_j \right) \)

\[ = (\varphi \cup \psi)\left( \sum_{j=0}^{p+q+1} \delta \varphi_j \cdot \sigma \circ \varphi_j \right) + (\varphi \cup \psi)\left( \sum_{j=p+1}^{p+q+1} \delta \varphi_j \cdot \sigma \circ \varphi_j \right) \]

\[ = \sum_{j=0}^{p+q+1} (-1)^j \cdot \varphi \circ (v_0, \ldots, v_{p+1} \circ \varphi_j) \cdot \psi(\sigma \circ [v_{p+1}, \ldots, v_{p+q+1}] \circ \varphi_j). \]

(b) \( \delta \varphi \cup \psi)(\sigma) = (\delta \varphi)(\sigma \circ [v_0, \ldots, v_{p+1}]) \cdot \psi(\sigma \circ [v_{p+1}, \ldots, v_{p+q+1}] \circ \varphi_j) \)

\[ = \varphi\left( \sum_{j=0}^{p+q+1} (-1)^j \cdot \sigma \circ [v_0, \ldots, v_{p+1} \circ \varphi_j] \right) \cdot \psi(\sigma \circ [v_{p+1}, \ldots, v_{p+q+1}] \circ \varphi_j). \]

(c) \( (-1)^p \cdot (\varphi \cup \delta \psi)(\sigma) = (-1)^p \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot (\delta \psi)(\sigma \circ [v_{p+1}, \ldots, v_{p+q+1}] \circ \varphi_j) \)

\[ = (-1)^p \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi\left( \sum_{k=0}^{q+1} (-1)^k \cdot \sigma \circ [v_{p+1}, \ldots, v_{p+q+1} \circ \varphi_j]. \right) \]

\[ = (-1)^p \cdot \sum_{k=0}^{q+1} (-1)^k \cdot \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_{p+1}, \ldots, v_{p+q+1} \circ \varphi_j]. \right) \]

Here in the argument we use on several occasions that for a singular \( n \)-cochain \( \phi \) and a singular \((n+1)\)-simplex \( \mu \) we have by definition

\[ (\delta \phi)(\mu) = \phi(\partial \mu) = \phi\left( \sum_{i=0}^{n+1} (-1)^i \cdot \mu \circ i_{n+1}^i \right). \]
Now we observe that if we take the sum of (b) and (c), then the \((j = p + 1)\)-summand in (b) cancels with the \((k = 0)\)-summand in (c). But after this observation it is obvious that the desired equality \((b)+(c)=(a)\) holds. ■

**Lemma 81.3.** Let \(X\) be a topological space and let \(R\) be a commutative ring. Then the map
\[
\cup : H^p(X; R) \times H^q(X; R) \to H^{p+q}(X; R)
\]
\([\varphi, [\psi]] \mapsto [\varphi] \cup [\psi] := [\varphi \cup \psi]
\]
is well-defined.

**Definition.** We refer to the pairing of Lemma 81.3 also as the *cup product*.

As we will see, the proof of Lemma 81.3 is basically identical to the proof of Lemma 79.13.

**Proof.** Let \(\varphi \in C^p(X; R)\) and \(\psi \in C^q(X; R)\) be cocycles.

1. It follows immediately from Lemma 81.2 that \(\varphi \cup \psi\) is again a cocycle.
2. If \(\varphi' = \varphi + \delta \tau\) is another representative of \([\varphi]\), then
\[
\varphi' \cup \psi - \varphi \cup \psi = (\varphi' - \varphi) \cup \psi = \delta \tau \cup \psi = \delta (\tau \cup \psi).
\]

This shows that \(\varphi \cup \psi\) and \(\varphi' \cup \psi\) represent the same cohomology class, i.e. the cup product does not depend on the choice of the representative of the cohomology class of the first entry.

3. The proof that the cup product does not depend on the choice of the representative of the second cohomology class is basically the same as the proof of (2). ■

The following proposition now says that the original definition of the cup product and the new definition actually agree.

**Proposition 81.4.** Let \(X\) be a topological space. Then for any \(\varphi \in H^p(X; \mathbb{Z})\) and any \(\psi \in H^q(X; \mathbb{Z})\) we have
\[
\varphi \bar{\cup} \psi = \varphi \cup \psi \in H^{p+q}(X; \mathbb{Z}).
\]

In the proof of Proposition 81.4 we need the following definition and the subsequent lemma.

**Definition.** A *diagonal approximation* consists of a natural chain map
\[
\Phi : C_*(X) \to C_*(X) \otimes C_*(X)
\]
for each topological space \(X\), such that for each \(x \in X\), viewed as a singular 0-simplex, the following equality holds in \((C_*(X) \otimes C_*(X))_0 = C_0(X) \otimes C_0(X)\):
\[
\Phi(x) = x \otimes x.
\]

**Example.** Given any topological space \(X\) we denote by \(d : X \to X \times X\) the diagonal map given by \(d(x) = (x, x)\). Then the induced chain maps
\[
\Theta \circ d_* : C_*(X) \xrightarrow{d_*} C_*(X \times X) \xrightarrow{\Theta} C_*(X) \otimes C_*(X)
\]
Eilenberg-Zilber map from Theorem 80.1.
form a diagonal approximation in the above sense.

The following lemma gives another diagonal approximation which will be very useful for doing actual calculations.

**Lemma 81.5.** Given any topological space $X$ we consider the map
\[ \Delta: C_*(X) \rightarrow C_*(X) \otimes C_*(X) \]
which for each singular $n$-simplex $\sigma: \Delta^n \rightarrow X$ is given by
\[ \sigma \mapsto \sum_{p=0}^{n} \sigma \circ [v_0, \ldots, v_p] \otimes \sigma \circ [v_p, \ldots, v_n]. \]

These maps form a diagonal approximation.

The diagonal approximation from Lemma 81.5 is called the *Alexander-Whitney diagonal approximation*.

**Proof.** It follows almost immediately from the definition that the maps $\Delta$ are natural. Furthermore it is obvious that on the 0-chains the maps are of the desired form. It remains to show that for a given topological space $X$ the maps actually form a chain map.

This follows from an elementary and uneventful calculation. For completeness’ sake we provide the argument. Let $\mu: \Delta^n \rightarrow X$ be a singular $n$-simplex. Given $i_1, \ldots, i_r$ we write $[i_1, \ldots, i_r] := \mu \circ [v_{i_1}, \ldots, v_{i_r}]$. We also use the convention that the empty singular simplex $[]$ is 0. We calculate that
\[
\Delta(\partial[0, \ldots, n]) = \Delta \left( \sum_{i=0}^{n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, n] \right)
= \sum_{0 \leq p < i \leq n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, n] + \sum_{0 \leq i < q \leq n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, q] \otimes [q, \ldots, n]
\]

in the second sum we secretly used the substitution $q = p + 1$

and
\[
\partial(\Delta[0, \ldots, n]) = \partial \left( \sum_{p=0}^{n} [0, \ldots, p] \otimes [p, \ldots, n] \right)
= \sum_{0 \leq i \leq p \leq n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, p] \otimes [p, \ldots, \hat{i}, \ldots, n] + \sum_{0 \leq p \leq i \leq n} (-1)^i \cdot [0, \ldots, p] \otimes [p, \ldots, \hat{i}, \ldots, n].
\]

here we use the sign convention for the boundary in a tensor product

We see that the difference between the two terms equals
\[
\sum_{i=p}^{n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, p] \otimes [p, \ldots, n] + \sum_{i=p}^{n} (-1)^i \cdot [0, \ldots, p] \otimes [p, \ldots, \hat{i}, \ldots, n]
\]
\[
= \sum_{i=1}^{n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, 0] \otimes [i, \ldots, n] + \sum_{i=0}^{n-1} (-1)^i \cdot [0, \ldots, i] \otimes [i+1, \ldots, n]
\]

here we use that $[\ ] = 0$

\[
= \sum_{i=1}^{n} (-1)^i \cdot [0, \ldots, \hat{i}, \ldots, 0] \otimes [i, \ldots, n] + \sum_{j=1}^{n} (-1)^{j-1} \cdot [0, \ldots, j-1] \otimes [j, \ldots, n] = 0.
\]
We have thus shown that $\Delta$ is indeed a chain map. \hfill ■

**Proposition 81.6.**

1. There exist diagonal approximations.
2. Given any two diagonal approximations $\Phi$ and $\Psi$ there exists a natural chain homotopy equivalence between $\Phi$ and $\Psi$.

**Proof.**

1. We had just given two examples of diagonal approximations.
2. The uniqueness statement was proved in Proposition 81.6. \hfill ■

Now we are ready to provide the proof of Proposition 81.4.

**Proof of Proposition 81.4.** We start out with the following claim.

**Claim.** For any two cochains $\varphi \in C^p(X; \mathbb{Z})$ and $\psi \in C^q(X; \mathbb{Z})$ we have $\varphi \cup \psi = (\varphi \otimes \psi) \circ \Pi_{p,q} \circ \Delta \in C^{p+q}(X; \mathbb{Z}) = \text{Hom}(C_{p+q}(X), \mathbb{Z})$.

We have to show that the two sides are the same maps $C_{p+q}(X) \to \mathbb{Z}$. Therefore let $\sigma : \Delta^{p+q} \to X$ be a singular $(p+q)$-simplex. We calculate that

\[
(\varphi \otimes \psi \circ \Pi_{p,q} \circ \Delta)(\sigma) = (\varphi \otimes \psi)\left(\Pi_{p,q}\left(\sum_{i+j=p+q} \sigma \circ [v_0, \ldots, v_i] \otimes \sigma \circ [v_i, \ldots, v_{p+q}]\right)\right)
\]

by definition of the Alexander-Whitney diagonalization

\[
eq (\varphi \otimes \psi)(\sigma \circ [v_0, \ldots, v_p] \otimes [v_q, \ldots, v_{p+q}])
\]

\[
= \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_q, \ldots, v_{p+q}])
\]

\[
= (\varphi \cup \psi)(\sigma).
\]

Now suppose that we are given cocycles $\varphi \in C^p(X; \mathbb{Z})$ and $\psi \in C^q(X; \mathbb{Z})$. We obtain the following equality in $H^{p+q}(X; \mathbb{Z})$.

\[
\varphi \cup \psi = (\varphi \otimes \psi)\circ \Pi_{p,q} \circ \Theta \circ d_* \Phi = \Delta^*\left(\left[(\varphi \otimes \psi)\circ \Pi_{p,q}\right]\right)
\]

by Proposition 81.6, the maps $\Theta \circ d_* \Delta : C_*(X) \to C_*(X) \otimes C_*(X)$ are chain homotopic by the claim so by Lemma 73.8 (3) they induce the same map on cohomology.

We have thus obtained the desired equality of cohomology classes. \hfill ■

Henceforth we will mostly work with the second definition of the cup product. In the following proposition we summarize some of the key properties of the cup product.

**Proposition 81.7.** Let $X$ be a topological space and let $R$ be a commutative ring.

1. The cup product on $H^*(X; R)$ is $R$-bilinear and associative.

---

1171 Here $\Delta : C_{p+q}(X) \to (C_* (X) \otimes C_* (X))_{p+q}$ denotes the above Alexander-Whitney diagonalization.
1172 Note that it follows from Lemma 81.1 that for two cocycles $\varphi$ and $\psi$ the composition $(\varphi \otimes \psi) \circ \Pi_{p,q}$ is indeed a cocycle, i.e. $(\varphi \otimes \psi) \circ \Pi_{p,q}$ defines an element in $H^{p+q}(C_*(X) \otimes C_*(X); \mathbb{Z})$. 
(2) The abelian group $H^*(X; R) = \bigoplus_{n \in \mathbb{N}_0} H^n(X; R)$ together with the map
\[
\cup : H^*(X; R) \times H^*(X; R) \to H^*(X; R)
\]
is a ring\(^{1173}\) where the multiplicatively neutral element is given by
\[
1_X := [\text{constant map } X \to R \text{ given by } x \mapsto 1] \in H^0(X; R).
\]

**Definition.** Given a topological space $X$ and a commutative ring $R$ we refer to $(H^*(X; R), \cup)$ as the $R$-cohomology ring of $X$.

**Proof.** Let $X$ be a topological space.

(1) It is clear from the second definition of the cup product that it is $R$-bilinear. It is also almost obvious, using the second definition, that the cup product is associative, but for completeness’ sake we carry out the argument. Thus let $\alpha \in C^p(X; R)$, $\beta \in C^q(X; R)$ and $\gamma \in C^r(X; R)$ be cochains and let $\sigma : \Delta^{p+q+r} \to X$ be a singular simplex. Then
\[
((\alpha \cup \beta) \cup \gamma)(\sigma) = (\alpha \cup \beta)(\sigma \circ [v_0, \ldots, v_{p+q}]) \cdot \gamma(\sigma \circ [v_{p+q}, \ldots, v_{p+q+r}])
\]
\[
= \alpha(\sigma \circ [v_0, \ldots, v_{p+q}]) \cdot \beta(\sigma \circ [v_{p+q}, \ldots, v_{p+q+r}]) \cdot \gamma(\sigma \circ [v_{p+q}, \ldots, v_{p+q+r}])
\]
\[
= (\alpha \cup (\beta \cup \gamma))(\sigma).
\]

Thus we see that the cup product is already associative for cochains, so it is in particular associative for cohomology classes.

(2) Let $\eta : X \to R$ be the map that assigns to each point in $X$ the value $1 \in R$. As usual we view $\eta$ as a singular 0-cochain. It follows from Proposition [73.11] that $\eta$ is a 0-cocycle and that we obtain an element $1_X := [\eta] \in H^0(X; R)$. It is clear from the definition that it is the neutral element with respect to the cup product. Together with (1) we have now shown that the cup product defines a ring structure on $H^*(X; R)$. \(\blacksquare\)

Now that we have shown that $(H^*(X; R), \cup)$ is a ring the question arises whether it is commutative or whether it is not commutative. It turns out that the answer, as for the wedge product on de Rham cohomology, lies somewhere in between. More precisely, we have the following proposition.

**Proposition 81.8.** Let $X$ be a topological space and let $R$ be a commutative ring. For any $a \in H^k(X; R)$ and $b \in H^l(X; R)$ we have
\[
a \cup b = (-1)^{kl} \cdot b \cup a.
\]

**Remark.**

(1) If $R = \mathbb{F}_2$, then we are in the pretty situation that $-1 = 1$, i.e. the cup product is commutative. Put differently, the $\mathbb{F}_2$-cohomology ring $H^*(X; \mathbb{F}_2)$ of a topological space $X$ is a commutative ring.

---

\(^{1173}\) Recall that on page 81 we stated that in the lecture notes a ring is understood to be associative and it is understood to have a multiplicatively neutral element. We do not demand that a ring is commutative.
(2) The proof for Proposition 81.8 that we provide below is based on the second definition of the cup product. It is elementary but unfortunately unpleasant to read. Later, in Exercise 84.1 we will provide a different, more conceptual proof based on the first definition of the cup product.

**Proof (⋆).** We give a proof of the proposition following [Hat02] p. 216-217. In Hatcher’s book more motivations for the steps in the proof are given.

So let \( \varphi \in C^k(X; R) \) and \( \psi \in C^l(X; R) \) be two cocycles. Given a singular \( n \)-simplex \( \sigma: \Delta^n \to X \) we denote by \( \hat{\sigma} \) the singular \( n \)-simplex obtained from \( \sigma \) by precomposing \( \sigma \) with the affine linear map \( [v_n, \ldots, v_0]: \Delta^n \to \Delta^n \) that reverses the order of the vertices. Furthermore we write \( \epsilon_n = (-1)^{(n+1)/2} \). We note that for any \( m, n \in \mathbb{N}_0 \) an elementary calculation shows that \( \epsilon_{m+n} = (-1)^{mn} \cdot \epsilon_m \epsilon_n \) and that \( \epsilon_1 = -1 \).

**Claim.** The maps

\[
\rho: C_n(X) \to C_n(X) \\
\sigma \mapsto \epsilon_n \cdot \hat{\sigma}
\]

form a chain map that is chain homotopic to the identity.

We first show that the claim actually implies the statement of the proposition. Thus let \([\varphi] \in H^k(X; R)\) and \([\psi] \in H^l(X, R)\). Since by the claim \( \rho \) is chain homotopic to the identity it follows from Lemma 73.8 that the induced map \( \rho^*: C^*(X; R) \to C^*(X; R) \) induces the identity on cohomology groups. So to deduce the statement of the proposition it suffices to show that

\[
\rho^*(\psi \cup \varphi) = (-1)^{kl} \cdot \rho^* \varphi \cup \rho^* \psi \in C^{k+l}(X; R).
\]

Now let \( \sigma \) be a \((k+l)\)-chain. Then

\[
(\rho^*(\psi \cup \varphi))(\sigma) = (\psi \cup \varphi)(\rho^*(\sigma)) = (\psi \cup \varphi)(\epsilon_{k+l} \cdot \sigma \circ [v_k, \ldots, v_l]) = \epsilon_{k+l} \cdot \psi(\sigma \circ [v_k, \ldots, v_l]) \cdot \varphi(\sigma \circ [v_k, \ldots, v_l]) = (-1)^{kl} \cdot \psi(\epsilon_k \cdot \sigma \circ [v_k, \ldots, v_l]) \cdot \varphi(\epsilon_l \cdot \sigma \circ [v_k, \ldots, v_l]) \quad \uparrow
\]

since \( \epsilon_{k+l} = (-1)^{kl} \cdot \epsilon_k \cdot \epsilon_l \) and since \( R \) is a commutative ring

\[
= (-1)^{kl} \cdot (\rho^* \varphi \cup \rho^* \psi)(\sigma).
\]

We have thus shown the statement of the proposition modulo the claim.

We turn to the proof of the claim. It is straightforward to verify that \( \rho \) is a chain map, indeed, for any singular \( n \)-simplex \( \sigma \) we have

\[
\partial \rho(\sigma) = \partial(\epsilon_n \cdot \sigma \circ [v_n, \ldots, v_0]) = \epsilon_n \cdot \sum_{i=0}^{n} (-1)^i \cdot \sigma \circ [v_n, \ldots, \hat{v}_{n-i}, \ldots, v_0],
\]

\[
\rho \partial(\sigma) = \rho(\sum_{i=0}^{n} (-1)^i \cdot \sigma \circ [v_0, \ldots, \hat{v}_i, \ldots, v_n]) = (\epsilon_{n-1}) \cdot \sum_{j=0}^{n} (-1)^{n-j} \cdot \sigma \circ [v_n, \ldots, \hat{v}_{n-j}, \ldots, v_0].
\]

The definition of \( \rho \) and substitution \( j = n - i \)

From \( \epsilon_n = (-1)^n \cdot \epsilon_{n-1} \) we now obtain that \( \partial \rho = \rho \partial \), i.e. we have shown that \( \rho \) is a chain map.

We still have to show that \( \rho \) is chain homotopic to the identity. We proceed with ideas similar to the ideas used in the proof of Proposition 42.5. As in that proof, given
\( i \in \{0, \ldots, n\} \) we write
\[
v_i := (0, \ldots, 1, 0, \ldots, 0) \times \{0\} \in \mathbb{R}^{n+1} \times \{0\},
\]
and
\[
w_i := (0, \ldots, 1, 0, \ldots, 0) \times \{1\} \in \mathbb{R}^{n+1} \times \{1\}.
\]
We justify the reassignment of \( v_i \) to a different point by saying that we identify \( \Delta^n \) with \( \Delta^n \times \{0\} \subseteq \mathbb{R}^{n+1} \times \mathbb{R} \). We denote by \( \pi: \Delta^n \times [0, 1] \to \Delta^n \) the projection map. We consider the map
\[
P: C_n(X) \to C_{n+1}(X),
\]
\[
\sigma \mapsto \sum_{i=0}^{n} (-1)^i \cdot \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, v_i, w_{n-i+1}, w_n, \ldots, w_i].
\]
Now we want to show that \( \partial P + P \partial = \rho - \text{id} \). We calculate
\[
(P \partial)(\sigma) = \sum_{i<j} (-1)^i (-1)^j \cdot \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, v_i, w_{n-i+1}, \ldots, w_j, \ldots, w_i]
\]
\[
+ \sum_{i>j} (-1)^{i-1} (-1)^j \cdot \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, \hat{v}_j, \ldots, v_i, w_{n-i+1}, \ldots, w_j, \ldots, w_i],
\]
On the other hand we have
\[
(\partial P)(\sigma) = \sum_{j \leq i} (-1)^i (-1)^j \cdot \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, \hat{v}_j, \ldots, v_i, w_{n-i+1}, \ldots, w_j, \ldots, w_i]
\]
\[
+ \sum_{j > i} (-1)^i (-1)^{i+1+n-j} \cdot \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, v_i, w_{n-i+1}, \ldots, \hat{w}_j, \ldots, w_i].
\]
Now using that \( \epsilon_{n-i} = (-1)^{n-i} \epsilon_{n-i-1} \) we see that the sum over the \( j \neq i \) terms agrees precisely with \( -P \partial \) calculated above (with the roles of \( i \) and \( j \) reversed). It remains to show that the sum over the \( i = j \) terms equals \( (\rho - \text{id})(\sigma) \). This is indeed the case since
\[
\text{sum of the } i = j \text{ summands in the above formula for } (\partial P)(\sigma)
\]
\[
= \epsilon_n \cdot (\sigma \circ \pi) \circ [w_n, \ldots, w_0] + \sum_{i=1}^{n-1} \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, v_{i-1}, w_{n-i}, \ldots, w_i]
\]
\[
+ \sum_{i=0}^{n-1} (-1)^{n+i} \epsilon_{n-i} \cdot (\sigma \circ \pi) \circ [v_0, \ldots, v_i, w_{n-i+1}, \ldots, w_i] - (\sigma \circ \pi) \circ [v_0, \ldots, v_n]
\]
\[
= \epsilon_n \cdot (\sigma \circ \pi) \circ [w_n, \ldots, w_0] - (\sigma \circ \pi) \circ [v_0, \ldots, v_n] = (\rho - \text{id})(\sigma).
\]
\[\uparrow\]
in the second sum we substitute \( j = i + 1 \), we obtain a new sign \( (-1)^{n+j} \epsilon_{n-j+1} = -\epsilon_{n-j} \),
thus we see that the two sums over \( i \) cancel
We have now completed the proof that \( \partial P + P \partial = \rho - \text{id} \), in particular we have shown the claim and thus also the proposition.

Let \( k \in \mathbb{N} \) be odd. It follows from Proposition \[81.8\] that given any topological space \( X \) and any \( \varphi \in H^k(X; \mathbb{Z}) \) we have \( \varphi \cup \varphi = -(1)^{kk} \cdot \varphi \cup \varphi \), put differently, we have \( 2 \cdot (\varphi \cup \varphi) = 0 \). Thus we see that \( \varphi \cup \varphi \) is 2-torsion. The next lemma makes the amusing observation that for \( k = 1 \) this “square” is in fact always zero.

**Lemma 81.9.** Let \( X \) be a topological space. For any \( \varphi \in H^1(X; \mathbb{Z}) \) we have \( \varphi \cup \varphi = 0 \).

**Remark.** Note that there is no higher-dimensional analogue of Lemma \[81.9\]. For example, on \[Hat02\] p. 403 it is shown that given any odd \( k \) with \( k \geq 3 \) there exists a cohomology class \( \gamma \in H^k(\mathbb{R}P^\infty \times \mathbb{R}P^\infty; \mathbb{Z}) \) with \( \gamma^m \neq 0 \) for all \( m \in \mathbb{N} \).
Proof. Let $X$ be a topological space and let $\varphi \in C^1(X;\mathbb{Z})$ be a cocycle. We need to show that $\varphi \cup \varphi \in C^2(X;\mathbb{Z})$ is a coboundary. We consider the 1-dimensional cochain

$$\mu : C_1(X) \to \mathbb{Z}$$

that is determined by

$$(\sigma : \Delta^1 \to X) \mapsto \frac{1}{2}(\varphi(\sigma) - \varphi(\sigma)^2).$$

It remains to prove the following claim.

Claim. We have $\varphi \cup \varphi = \delta \mu : C_2(X) \to \mathbb{Z}$.

We only need to prove this equality for singular 2-simplices. So suppose we are given $\tau : \Delta^2 \to X$. Given $j \in \{0, 1, 2\}$ we write $i_j = i_j^2 : \Delta^1 \to \Delta^2$. Note that

$$(\star) \quad \varphi(\tau \circ i_0) - \varphi(\tau \circ i_1) + \varphi(\tau \circ i_2) = \varphi(\partial \tau) = (\delta \varphi)(\tau) = 0.$$

$\uparrow$ definition of $\delta \varphi$ since $\varphi$ is a cocycle

Now we compute that

$$(\delta \mu)(\tau) = \mu(\partial \tau) = \mu((\tau \circ i_0) - (\tau \circ i_1) + (\tau \circ i_0))$$

$$= \frac{1}{2}(\varphi(\tau \circ i_0) - \varphi(\tau \circ i_1) + \varphi(\tau \circ i_2) + \varphi(\tau \circ i_0)^2 - \varphi(\tau \circ i_1)^2 + \varphi(\tau \circ i_2)^2)$$

$\uparrow$ by $(\star)$ we have $\varphi(\tau \circ i_1) = \varphi(\tau \circ i_0) + \varphi(\tau \circ i_2)$

$$= \varphi(\tau \circ i_1) \cdot \varphi(\tau \circ i_0) = (\varphi \cup \varphi)(\tau).$$

$\uparrow$ elementary algebra $\uparrow$ definition of the cup-product

This concludes the proof of the claim and thus of the lemma. $\blacksquare$

We continue with the following lemma that shows that the cup product behaves well under maps between topological spaces.

**Lemma 81.10.** Let $R$ be a commutative ring.

1. Let $f : X \to Y$ be a map between topological spaces. For any $c \in H^p(Y; R)$ and $d \in H^q(Y; R)$ we have

$$f^*(c) \cup f^*(d) = f^*(c \cup d).$$

In particular the map

$$f^* : H^*(Y; R) \to H^*(X; R)$$

is a homomorphism of graded rings which satisfies $f^*(1_Y) = 1_X$.

2. The maps

$$(X \mapsto (H^*(X; R), \cup))$$

$$(f : X \to Y) \mapsto (f^* : H^*(Y; R) \to H^*(X; R))$$

define a contravariant functor from the category Top of topological spaces to the category GrRing of graded rings.
The lemma follows basically immediately from the definitions. But for completeness’ sake we write down the proof. So let \( c = [\phi] \in H^p(Y; R) \) and let \( b = [\psi] \in H^q(Y; R) \). Furthermore let \( \sigma: \Delta^{p+q} \to X \) be a singular \((p+q)\)-chain. Then

\[
(f^* \phi \cup f^* \psi)(\sigma) = (f^* \phi)(\sigma \circ [v_0, \ldots, v_p]) \cdot (f^* \psi)(\sigma \circ [v_p, \ldots, v_{p+q}]) = \phi(f \circ (\sigma \circ [v_0, \ldots, v_p])) \cdot \psi(f \circ (\sigma \circ [v_p, \ldots, v_{p+q}]))) = \phi((f \circ \sigma) \circ [v_0, \ldots, v_p]) \cdot \psi((f \circ \sigma) \circ [v_p, \ldots, v_{p+q}]) = (\phi \cup \psi)(f \circ \sigma) = (f^*(\phi \cup \psi))(\sigma).
\]

Finally note that it follows immediately from the definitions of \( 1_X, 1_Y \) and \( f^* \) that we have the equality \( f^*(1_Y) = 1_X \). Statement (2) follows immediately from statement (1) and the fact that cohomology groups with \( R \)-coefficients form a contravariant functor of abelian groups.

We can use Lemma 81.10 to calculate the cup product of the wedge of finitely many spheres.

**Lemma 81.11.** For any wedge of finitely many spheres all cup products in degrees \( \geq 1 \) are zero.

**Proof.** Let \( S^{r_1} \vee \cdots \vee S^{r_k} \) be the wedge of finitely many spheres and let \( R \) be a commutative ring. For each \( i \in \{1, \ldots, k\} \) we denote by \( p_i: S^{r_i} \vee \cdots \vee S^{r_k} \to S^{r_i} \) the obvious projection map. By Proposition 74.17 we know that for every \( n \in \mathbb{N} \) the map

\[
p_i^* \oplus \cdots \oplus p_k^*: H^n(S^{r_1}; R) \oplus \cdots \oplus H^n(S^{r_k}; R) \xrightarrow{\cong} H^n(S^{r_1} \vee \cdots \vee S^{r_k}; R)
\]

is an isomorphism. It remains to show that for any choice of \( i, j \in \{1, \ldots, k\} \) with \( r_i > 0 \) and \( r_j > 0 \) we have \( p_i^*([S^{r_i}]^*) \cup p_j^*([S^{r_j}]^*) = 0 \). We prove the statement for \( i \neq j \). The proof of the statement for \( i = j \) is basically the same. So suppose that \( i \neq j \). We denote by \( g: S^{r_i} \vee \cdots \vee S^{r_j} \to S^{r_i} \vee S^{r_j} \) the obvious projection map and we denote by \( q_i: S^{r_i} \vee S^{r_j} \to S^{r_i} \) and \( q_j: S^{r_j} \vee S^{r_j} \to S^{r_j} \) the obvious projection maps. Then

\[
p_i^*([S^{r_i}]^*) \cup p_j^*([S^{r_j}]^*) = g^*(q_i^*([S^{r_i}]^*)) \cup g^*(q_j^*([S^{r_j}]^*)) = g^*(q_i^*([S^{r_i}]^*) \cup q_j^*([S^{r_j}]^*)) = 0.
\]

We have thus proved that all cup products in degrees \( \geq 1 \) are zero.

Later on, after we will have found methods for computing the cup product, we will often use the following corollary to show that certain topological spaces are not homotopy equivalent.

---

\[^{1174}\text{Recall that a graded ring is a ring } R \text{ together with a decomposition } R = \bigoplus_{n \in \mathbb{N}_0} R_n \text{ such that for any } m, n \in \mathbb{N}_0 \text{ the multiplication map restricts to a map } R_m \times R_n \to R_{m+n}. \text{ A homomorphism } f: R \to S \text{ between graded rings is a ring homomorphism with } f(R_n) \subset S_n \text{ for all } n \in \mathbb{N}_0.\]

Corollary 81.12. Let $X$ and $Y$ be topological spaces. If $X$ and $Y$ are homotopy equivalent, then for any commutative ring $R$ there exists an isomorphism

$$(H^*(Y; R), \cup) \xrightarrow{\simeq} (H^*(X; R), \cup)$$

of graded rings.

Proof. Let $f: X \to Y$ be a homotopy equivalence. In Lemma 73.13 we saw that the induced maps $f^*: H^n(Y; R) \to H^n(X; R)$ on cohomology groups are isomorphisms. But it follows from Lemma 81.10 that these isomorphisms preserve the ring structure, i.e. the map $f^*$ is in fact an isomorphism of graded rings. ■

81.3. The cup product of the torus. Evidently our goal now is to determine the cup product of some of our favorite different topological spaces. We start out with two elementary observations regarding the cup product.

Observation 81.13. Let $R$ be a commutative ring.

(1) Let $X$ be a path-connected topological space. It follows from Proposition 73.11 that $H^0(X; R) = R \cdot 1_X$. For any $r \cdot 1_X \in H^0(X; R)$ and $\varphi \in H^1(X; R)$ we have

$$(r \cdot 1_X) \cup \varphi = r \cdot (1_X \cup \varphi) = r \cdot \varphi = \varphi \cup (r \cdot 1_X).$$

since $\cup$ is $R$-bilinear

(2) If $M$ is an $m$-dimensional topological manifold, then for any $p, q$ with $p + q > m$ the cup product $H^p(M; R) \times H^q(M; R)$ is zero, since it takes values in the group $H^{p+q}(M; R)$, which is zero by Theorem 87.3.

(3) By Proposition 81.7 the cup product is $R$-bilinear, so it suffices to determine the cup product on a generating system.

In this section we want to determine the cup product on the torus $T = S^1 \times S^1$. By Observation 81.13 it remains to determine the cup product

$$\cup: H^1(T; \mathbb{Z}) \times H^1(T; \mathbb{Z}) \to H^2(T; \mathbb{Z}).$$

We first need to understand the cohomology groups $H^1(T; \mathbb{Z})$ and $H^2(T; \mathbb{Z})$ explicitly. We recall some notation and results from before:

(1) We denote by $p$ respectively $q$ the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor. Furthermore, we recall that on page 1825 we introduced a cochain $\theta := \theta_2 \in C^1(\mathbb{Z})$, we showed in Lemma 73.10 that $\theta$ is a cocycle and we showed on page 1848 that $\theta$ represents a generator of $H^1(S^1; \mathbb{Z})$.

(2) In Lemma 74.9 we showed that $H^1(T; \mathbb{Z}) \cong \mathbb{Z}^2$ and that the two cohomology classes $\alpha := p^*(\theta)$ and $\beta := q^*(\theta)$ form a basis for $H^1(S^1 \times S^1; \mathbb{Z})$.

(3) On page 1717 we showed that the cycle $-\sigma_1 + \sigma_2$, with the notation from Figure 1054 represents the fundamental class of $T$.

(4) In Lemma 74.9 and 75.16 we showed that

$$H^2(T; \mathbb{Z}) \to \mathbb{Z}$$

$$[\varphi] \mapsto \langle \varphi, [T] \rangle = \varphi(-\sigma_1 + \sigma_2)$$
is in fact an isomorphism. We will use this isomorphism to make the identification $H^2(T; \mathbb{Z}) = \mathbb{Z}$.

By Observation 81.13 (3) and the above discussion, it suffices to determine all entries in the following matrix

$$\begin{pmatrix} \langle \alpha \cup \alpha, [T] \rangle & \langle \alpha \cup \beta, [T] \rangle \\ \langle \beta \cup \alpha, [T] \rangle & \langle \beta \cup \beta, [T] \rangle \end{pmatrix}.$$ 

Now we determine these four entries separately.

1. We first consider the entry $\langle \alpha \cup \beta, [T] \rangle$. Fortunately we already did all the work on page 1982, more precisely, we have

$$\langle \alpha \cup \beta, [T] \rangle = (p^* \theta \cup q^* \theta)(-\sigma_1 + \sigma_2) = (p^* \theta \cup q^* \theta)(\sigma_2) = 0 + 1 = 1.$$

2. We could do the same argument as in (1) with $\alpha$ and $\beta$ reversed. But it is easier to apply Proposition 81.8 which gives us that $\beta \cup \alpha = (-1)^{11} \cdot \alpha \cup \beta = -\alpha \cup \beta = -1$.

3. There are many different ways for showing that $\alpha \cup \alpha = 0$:
   a. We could do the calculation as in (1), but that is the least efficient approach.
   b. We could use the symmetry from Proposition 81.8 to argue that $\alpha \cup \alpha = -\alpha \cup \alpha$, and hence $\alpha \cup \alpha = 0$ since $H^2(T; \mathbb{Z})$ is torsion-free.
   c. We could just use Lemma 81.9 and remove all the fun.
   d. We can also argue that

$$\langle \alpha \cup \alpha, [T] \rangle = \langle [p^* \theta] \cup [p^* \theta], [T] \rangle = \langle p^*([\theta] \cup [\theta]), [T] \rangle = 0.$$

   by Lemma 81.10 since $[\theta] \cup [\theta] \in H^2(S^1; \mathbb{Z}) = 0$

4. The same way as in (3) we see that $\beta \cup \beta = 0$.

Summarizing we have proved the following lemma.

**Lemma 81.14.** Let $T$ be the 2-dimensional torus. We use the above notation. The cup product $H^1(T; \mathbb{Z}) \times H^1(T; \mathbb{Z}) \to H^2(T; \mathbb{Z})$ with respect to the basis $\alpha, \beta$ of $H^1(T; \mathbb{Z})$ and the identification $H^2(T; \mathbb{Z}) = \mathbb{Z} \cdot [T]^*$ is given by the matrix

$$\begin{pmatrix} \alpha \cup \alpha & \alpha \cup \beta \\ \beta \cup \alpha & \beta \cup \beta \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Thus we have shown that the cup product on cohomology is in general non-zero and that it is in general not commutative.

**Remark.**

1. We have just shown that the 2-cocycle $p^*(\theta) \cup q^*(\theta) \in C^2(T; \mathbb{Z})$ represents a generator of $H^2(T; \mathbb{Z})$. We have thus answered Question 74.10.

2. We have now performed enough calculations to see that the cohomology rings contain more information than the homology or the cohomology groups. More precisely, it

\[ [T]^* \in H^2(T; \mathbb{Z}) \] denotes the dual fundamental class that we introduced on page 1873 it is uniquely determined by $\langle [T]^*, [T] \rangle = 1$. 

\[^{1175}\]
follows from Lemma 46.12 and Propositions 43.4 and 47.8 that for the 2-dimensional torus $S^1 \times S^1$ and for $S^1 \lor S^1 \lor S^2$ we have

$$H_i(S^1 \times S^1; \mathbb{Z}) \cong H_i(S^1 \lor S^1 \lor S^2; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, 2, \\ \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{if } i \geq 3. \end{cases}$$

We deduce from the Universal Coefficient Theorem 75.13 for Cohomology Groups that $S^1 \times S^1$ and $S^1 \lor S^1 \lor S^2$ also have isomorphic cohomology groups. In Lemma 81.14 we saw that the cup product on $H^1(S^1 \times S^1; \mathbb{Z})$ is non-zero, whereas we showed in Lemma 81.11 that the cup product on $H^1(S^1 \lor S^1 \lor S^2; \mathbb{Z})$ is zero.\footnote{1176}

In Exercise 81.2 we will use the above calculation of the cup product of the torus to prove the following slightly subtle lemma.

**Lemma 81.15.** Let $f: T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. If $f$ is orientation-preserving, then

$$\det \left( f_*: H_1(T; \mathbb{Z}) \to H_1(T; \mathbb{Z}) \right) = \det \left( f^*: H^1(T; \mathbb{Z}) \to H^1(T; \mathbb{Z}) \right) = +1.$$

Conversely, if $f$ is orientation-reversing, then both determinants equal $-1$.

### 81.4. The cup product of the surface of genus 2.

In this section we calculate the cup product for the surface $\Sigma$ of genus 2. By Observation 81.13 it remains to determine the cup product

$$H^1(\Sigma; \mathbb{Z}) \times H^1(\Sigma; \mathbb{Z}) \to H^2(\Sigma; \mathbb{Z})$$

on a basis of $H^1(\Sigma; \mathbb{Z})$. We recall that on page 1850 we introduced for $i = 1, 2$ a map $p_i: \Sigma \to T = S^1 \times S^1$. We refer to Figure 1163 on the right for a reminder of the definition of the maps. We denote by $\alpha, \beta \in H^1(T; \mathbb{Z})$ the basis from Lemma 74.9 that we had also

![fundamental class of \( \Sigma \)](image1)

![projections from \( \Sigma \) to the torus](image2)

**Figure 1163**

\footnotetext{1176}{Of course we do not need to use cup products to distinguish the torus $S^1 \times S^1$ and the wedge $S^1 \lor S^1 \lor S^2$, this can already be done using fundamental groups. Nonetheless it is encouraging to see that we found a new way to prove this statement.}
is an isomorphism. We deduce that a basis for $H^1(\Sigma; \mathbb{Z}) \cong \mathbb{Z}^4$ is given by $\alpha_i := p^*_i(\alpha)$, $\beta_i := p^*_i(\beta)$, $i = 1, 2$. Now we can use the definition of the cup product and the explicit description of a representative of the fundamental class $[\Sigma] \in H_2(\Sigma; \mathbb{Z})$ in Figure 1163 on the left (see also Figure 1055 for a more detailed discussion) to compute the cup product $H^1(\Sigma; \mathbb{Z}) \times H^1(\Sigma; \mathbb{Z}) \to H^2(\Sigma; \mathbb{Z}) = \mathbb{Z}$.

A not particularly exciting calculation leads us eventually to the following lemma.

**Lemma 81.16.** Let $\Sigma$ be the surface of genus 2. We use the above notation. The cup product $H^1(\Sigma; \mathbb{Z}) \times H^1(\Sigma; \mathbb{Z}) \to H^2(\Sigma; \mathbb{Z})$ with respect to the basis $\alpha_1, \beta_1, \alpha_2, \beta_2$ of $H^1(\Sigma; \mathbb{Z})$ and the identification $H^2(\Sigma; \mathbb{Z}) = \mathbb{Z} \cdot [\Sigma]^* = \mathbb{Z}$ is given by the matrix

\[
\begin{pmatrix}
\alpha_1 \cup \alpha_1 & \alpha_1 \cup \beta_1 & \alpha_1 \cup \alpha_2 & \alpha_1 \cup \beta_2 \\
\beta_1 \cup \alpha_1 & \beta_1 \cup \beta_1 & \beta_1 \cup \alpha_2 & \beta_1 \cup \beta_2 \\
\alpha_2 \cup \alpha_1 & \alpha_2 \cup \beta_1 & \alpha_2 \cup \alpha_2 & \alpha_2 \cup \beta_2 \\
\beta_2 \cup \alpha_1 & \beta_2 \cup \beta_1 & \beta_2 \cup \alpha_2 & \beta_2 \cup \beta_2
\end{pmatrix}
= \begin{pmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0
\end{pmatrix}
\]

An analogous statement holds for any surface of genus $g \geq 1$, i.e. the cup product on the first cohomology of the surface of genus $g \geq 1$ can be represented by a block diagonal matrix consisting of $g$ copies of

\[
\begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix}.
\]

**Remark.** In the next section we will obtain a more conceptual proof of Lemma 81.16.

Before we continue with more calculations of cup products we return to a question that we had asked earlier on.

**Question 69.13.**

(2) Let $g \geq 2$ and let $k \geq 2$. Does there exist a self-map $f: \Sigma_g \to \Sigma_g$ of degree $k$?

\[\text{Recall that if } f: M \to N \text{ is a map between two closed, oriented connected, non-empty } n\text{-dimensional topological manifolds, then the degree } \deg(f) \in \mathbb{Z} \text{ is defined as the unique integer } \deg(f) \text{ that satisfies } f_*(\lbrack M \rbrack) = \deg(f) \cdot \lbrack N \rbrack.\]

Now we have the tools to answer this question. In this context it is useful to introduce the following definition.

**Definition.** A closed oriented connected non-empty topological manifold $M$ is called flexible if given any $k \in \mathbb{Z}$ there exists a map $f: M \to M$ of degree $k$.

**Example.** In Lemma 45.10 we saw that $S^1$ is flexible. The combination of this fact with Lemma 45.12 shows that in fact any sphere $S^n$, $n \geq 1$ is flexible.

Now we can determine which closed oriented connected 2-dimensional smooth manifolds are flexible. More precisely, we have the following proposition which gives a negative answer to Question 69.13 (2).

\[\text{We have to evaluate the cup products of the explicit 1-cochains on the eight singular 2-simplices illustrated in Figure 1163. It is straightforward to see that all 16 cup products evaluate to zero on the four central singular 2-simplices. For the remaining cup products the calculation is almost the same as for the torus on page 1982.}\]
**Proposition 81.17.** Let \( g \geq 1 \). We denote by \( \Sigma_g \) the surface of genus \( g \).

1. The torus \( \Sigma_1 = S^1 \times S^1 \) is flexible.
2. For \( g \geq 2 \) the surface \( \Sigma_g \) is not flexible. In fact if \( k \neq -1, 0, 1 \), then there is no map \( \Sigma_g \to \Sigma_g \) of degree \( k \).

**Proof.**

(1) We first show that the torus \( S^1 \times S^1 \) is flexible. So let \( k \in \mathbb{Z} \). We consider the map \( f: S^1 \to S^1 \) that is given by \( z \mapsto z^k \). We claim that \( f \times \text{id}: S^1 \times S^1 \to S^1 \times S^1 \) has degree \( k \). By the naturality of the short exact sequence of the Künneth-Theorem 58.8 we have a commutative diagram

\[
\begin{array}{ccc}
H_1(S^1) \otimes H_1(S^1) & \xrightarrow{\Theta} & H_2(S^1 \times S^1) \\
\downarrow f_* \otimes \text{id} & & \downarrow (f \times \text{id})_* \\
H_1(S^1) \otimes H_1(S^1) & \xrightarrow{\Theta} & H_2(S^1 \times S^1)
\end{array}
\]

where the horizontal maps are isomorphisms. By Lemma 45.10 the map on the left is given by multiplication by \( k \). Hence the map on the right is also given by multiplication by \( k \).

(2) Now let \( g \geq 2 \) and let \( f: \Sigma_g \to \Sigma_g \) be a map of degree \( k \neq 0 \). We have to show that \( k \in \{ \pm 1 \} \). We write \( \pi := \pi_1(\Sigma_g) \). We start out with the following claim.

**Claim.** The map \( f_*: \pi \to \pi \) is an epimorphism.

First note that the argument in the proof of Proposition 69.9 shows that \( f_*(\pi) \) is a finite-index subgroup of \( \pi \). (Here we used that \( k \neq 0 \).) We denote by \( n \in \mathbb{N} \) the index of the subgroup \( f_*(\pi) \subset \pi \). In the proof of Proposition 31.17 we used the multiplicativity of the Euler characteristic under finite covers to show that the abelianization of \( f_*(\pi) \) is isomorphic to \( \mathbb{Z}^{2n-(g-1)+2} \). On the other hand the epimorphism \( \pi \to f_*(\pi) \) induces evidently an epimorphism of the abelianization of \( \pi \) onto the abelianization of \( f_*(\pi) \), i.e. we have an epimorphism from \( \mathbb{Z}^{2g} \) onto \( \mathbb{Z}^{2n-(g-1)+2} \). Since \( g \geq 2 \) this is only possible if \( n = 1 \).

**Claim.** The map \( f^*: H^1(\Sigma_g; \mathbb{Z}) \to H^1(\Sigma_g; \mathbb{Z}) \) is an isomorphism.

By the first claim we know that the map \( f_*: \pi \to \pi \) is an epimorphism. It follows from the naturality of the Hurewicz Isomorphism, see Propositions 52.3 and 52.2 (4), that the map \( f_*: H_1(\Sigma_g) \to H_1(\Sigma_g) \) is also an epimorphism. But any epimorphism from a finitely generated abelian group to itself is in fact an isomorphism, so we see that \( f_*: H_1(\Sigma_g; \mathbb{Z}) \to H_1(\Sigma_g; \mathbb{Z}) \) is in fact an isomorphism. By Proposition 75.18 the evaluation homomorphism \( \text{ev}: H^1(\Sigma_g; \mathbb{Z}) \cong \text{Hom}(H_1(\Sigma_g; \mathbb{Z}), \mathbb{Z}) \) is a...
natural isomorphism, i.e. we have a commutative diagram
\[
\begin{array}{c}
\text{H}^1(\Sigma_g; \mathbb{Z}) \\ \downarrow^{f^*} \\
\text{H}^1(\Sigma_g; \mathbb{Z})
\end{array} \cong \begin{array}{c}
\text{ev} \\ \text{ev}
\end{array} \cong \begin{array}{c}
\text{Hom}(\text{H}_1(\Sigma_g; \mathbb{Z}), \mathbb{Z}) \\ \text{Hom}(\text{H}_1(\Sigma_g; \mathbb{Z}), \mathbb{Z})
\end{array}.
\]

The right-hand map is an isomorphism, it follows from the commutative diagram that the left-hand map \( f^* : \text{H}^1(\Sigma_g; \mathbb{Z}) \to \text{H}^1(\Sigma_g; \mathbb{Z}) \) is also an isomorphism. \( \Box \)

By Lemma 81.16 we know that there exist \( a, b \in \text{H}^1(\Sigma_g; \mathbb{Z}) \) with \( a \cup b = [\Sigma_g]^* \).
Since \( f^* : \text{H}^1(\Sigma_g; \mathbb{Z}) \to \text{H}^1(\Sigma_g; \mathbb{Z}) \) is an isomorphism we can in particular find cohomology classes \( c, d \in \text{H}^1(\Sigma_g; \mathbb{Z}) \) with \( f^*(c) = a \) and \( f^*(d) = b \). Now we have

\[
[\Sigma_g]^* = a \cup b = f^*(c) \cup f^*(d) = f^*(c \cup d) = f^*(m \cdot [\Sigma_g]^*) = \deg(f) \cdot m \cdot [\Sigma_g]^*.
\]

Lemma 81.10 by Lemma 75.17 we have \( f^*([\Sigma_g]^*) = \deg(f) \cdot [\Sigma_g]^* \).

Evidently this is only possible if \( \deg(f) \in \{ \pm 1 \} \).

81.5. The cup product of the real projective plane \((*)\). Now we want to understand the cup product in the \( \mathbb{F}_2 \)-cohomology of the real projective plane \( \mathbb{R}P^2 \). Recall that on page 1845 we saw that \( \text{H}^i(\mathbb{R}P^2; \mathbb{F}_2) = \mathbb{F}_2 \) for \( i = 0, 1, 2 \) and that the \( \mathbb{F}_2 \)-cohomology vanishes in all other dimensions. By Observation 81.13 it remains to determine the cup product on the first cohomology.

To compute the cup product we need to get a good understanding of the cohomology groups. Recall that on page 1731 we had seen that \( (\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \text{C}_2(\mathbb{R}P^2; \mathbb{F}_2) \) is a representative of the \( \mathbb{F}_2 \)-fundamental class \( [\mathbb{R}P^2] \) of \( \mathbb{R}P^2 = \overline{\mathbb{B}^2} / \sim \). (See Figure 1164 for the definition of \( \sigma_1, \sigma_2, \tau_1 \) and \( \tau_2 \).) It follows from Proposition 75.19 and the above that the map

\[
\eta : \text{H}^2(\mathbb{R}P^2; \mathbb{F}_2) \to \mathbb{F}_2 \\
[\varphi \in \text{C}^2(\mathbb{R}P^2; \mathbb{F}_2)] \mapsto [\varphi(\sigma_1) + \varphi(\sigma_2) + \varphi(\tau_1) + \varphi(\tau_2)]
\]
is an isomorphism.

![projective plane \( \mathbb{R}P^2 = \overline{\mathbb{B}^2} / \sim \)]

The 2-cycle \( (\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in \text{C}_2(\mathbb{R}P^2; \mathbb{F}_2) \) represents the \( \mathbb{F}_2 \)-fundamental class of the real projective plane.

**Figure 1164**

\[\text{1179} \] Why is it safe to write \( \text{H}^i(\mathbb{R}P^2; \mathbb{F}_2) = \mathbb{F}_2 \)? Would it not be much more appropriate to write \( \text{H}^i(\mathbb{R}P^2; \mathbb{F}_2) \cong \mathbb{F}_2 ? \)

\[\text{1180} \] Here we use the identification \( \mathbb{R}P^2 = \overline{\mathbb{B}^2} / \sim \) from page 196.
Now we also need to find an explicit representative of \( x \in H^1(\mathbb{RP}^2; F_2) \). We will find such a representative in a similar fashion to the construction of the singular 1-cocycle \( \theta_z \in H^1(S^1; Z) \) on page 1826. More precisely, we consider the map

\[
    f : S^2 \to F_2,
\]

\[
    (x, y, z) \mapsto \begin{cases} 
        1, & \text{if } (z > 0) \text{ or } (z = 0 \text{ and } y > 0) \text{ or } (z = y = 0 \text{ and } x = 1), \\
        0, & \text{otherwise}.
    \end{cases}
\]

Note that for any point \( P \in S^2 \) we have \( f(-P) = 1 - f(P) \). For a singular 1-simplex \( \sigma : \Delta^1 \to \mathbb{RP}^2 \) we pick a lift \( \tilde{\sigma} : \Delta^1 \to S^2 \) of \( \sigma \) and we define

\[
    \varphi(\sigma) := f(\tilde{\sigma}(0,1)) - f(\tilde{\sigma}(1,0)) \in F_2.
\]

We refer to Figure 1165.

Note that \( \varphi \) is well-defined since the only other lift of \( \sigma \) is given by multiplying \( \tilde{\sigma} \) by \(-1\). But then it follows from \( f(-P) = 1 - f(P) \) that the difference of the evaluations at the endpoints does not change. (Here we use that we work with \( F_2 \)-coefficients instead of \( Z \)-coefficients.) The argument of Lemma 73.10 can easily be adapted to show that the singular 1-cochain \( \varphi : C_1(\mathbb{RP}^2) \to F_2 \) is a cocycle.

**Example.** We consider the map \( \mu : \Delta^1 \to \mathbb{RP}^2 = S^2/\sim \) given by \( \mu(1-t, t) = [e^{\pi i t}] \). Then \( \mu \in C_1(\mathbb{RP}^2) \). Thus we can apply the Kronecker pairing \( H^1(\mathbb{RP}^2; F_2) \times H_1(\mathbb{RP}^2) \to F_2 \) from Lemma 74.6 to \([\varphi] \in H^1(\mathbb{RP}^2; F_2)\) and \([\mu] \in H_1(\mathbb{RP}^2)\) and we calculate that

\[
    \langle [\varphi], [\mu] \rangle = \varphi(\mu) = f(e^{\pi i}) - f(e^0) = 1 \in F_2.
\]

Since this is non-zero we have now actually shown two statements at once: the cohomology class \([\varphi] \in H^1(\mathbb{RP}^2; F_2)\) is non-zero and we have also certified that the homology class \([\mu] \in H_1(\mathbb{RP}^2)\) is non-zero.

Now we have the tools to prove the following lemma.
Lemma 81.18. Under the identifications $H^i(\mathbb{RP}^2; \mathbb{F}_2) = \mathbb{F}_2$ the cup product

\[ \cup : H^1(\mathbb{RP}^2; \mathbb{F}_2) \times H^1(\mathbb{RP}^2; \mathbb{F}_2) \to H^2(\mathbb{RP}^2; \mathbb{F}_2) \]

is given by

\[ \mathbb{F}_2 \times \mathbb{F}_2 \to \mathbb{F}_2, \quad (a, b) \mapsto a \cdot b. \]

Remark. Note that the calculation in Lemma 81.18 that the statement of Lemma 81.9 does not hold for $\mathbb{F}_2$-coefficients.

Proof. By the discussion above it suffices to show that $\eta([\varphi] \cup [\varphi]) \neq 0$. Put differently, by definition of $\eta$ we need to show that

\[ (\varphi \cup \varphi)(\sigma_1) + (\varphi \cup \varphi)(\sigma_2) + (\varphi \cup \varphi)(\tau_1) + (\varphi \cup \varphi)(\tau_2) = 1 \in \mathbb{F}_2. \]

In Exercise 81.4 we will determine all four summands and we will see that the sum is indeed 1.

The above calculation of the cup product of the real projective plane $\mathbb{RP}^2$ is very explicit and hands on, but not very conceptual. Later on, in Proposition 90.16, we will give a very different calculation of the cup product on $\mathbb{F}_2$-cohomology of all real projective spaces $\mathbb{RP}^n$.

81.6. The cup product and the wedge product (*). As a reminder, we denote by $\text{SmMfd}$ the category of smooth manifolds. As we already saw, the maps

\[ M \mapsto (H^k_{\text{dR}}(M), \cup) \]

\[ (f : M \to N) \mapsto (f^* : H^k_{\text{dR}}(N) \to H^k_{\text{dR}}(M)) \]

define a contravariant functor from the category $\text{SmMfd}$ of smooth manifolds to the category of graded rings $\text{GrRing}$.

If we assign to a smooth manifold its $k$-th real cohomology groups, then we saw in Theorem 79.6 that it is naturally isomorphic to the $k$-th de Rham cohomology group. Now we can generalize Theorem 79.6.

Theorem 81.19. The natural isomorphisms $\nu$ from Theorem 79.6 are in fact ring homomorphisms, i.e. they define a natural isomorphism from the functor

\[ \text{SmMfd} \to \text{GrRing} \]

\[ M \mapsto (H^*_\text{dR}(M), \wedge) \]

to the functor

\[ \text{SmMfd} \to \text{GrRing} \]

\[ M \mapsto (H^*(M; \mathbb{R}), \cup). \]
**Example.** As usual we denote by $dt$ on $\mathbb{R}$ the 1-form that for every $v \in T_p \mathbb{R} = \mathbb{R}$ is
given by $dt(v) = v$. We denote by $\pi: \mathbb{R} \to \mathbb{R}/\mathbb{Z} = S^1$ the obvious projection map. The
closed 1-form $dt$ descends to a closed 1-form on $S^1$, i.e. there exists a unique 1-form $\overline{dt}$ on $\mathbb{R}/\mathbb{Z} = S^1$ whose pullback equals $dt$. Let $\sigma: \Delta^1 \to \mathbb{R}/\mathbb{Z} = S^1$ be a smooth singular
1-simplex. Since $\Delta^1$ is simply connected we can lift this singular 1-simplex, i.e. there exists a map (which is in fact smooth) $\tilde{\sigma}: \Delta^1 \to \mathbb{R}$ with $\pi \circ \tilde{\sigma} = \sigma$. We have
$$\int_\sigma \overline{dt} = - \int_0^1 \overline{dt}(\sigma(t, 1-t))ds = - \int_0^1 \tilde{\sigma}(t, 1-t)ds = -\tilde{\sigma}(1, 0) + \tilde{\sigma}(0, 1) = \theta_\mathbb{R}(\sigma).$$

This little calculation shows that under the natural isomorphisms from Theorem 79.6 the class $[\overline{dt}] \in H^1_{dR}(M)$ gets sent to our favorite generator $[\theta_\mathbb{R}] \in H^1(M; \mathbb{R})$, i.e. we have $u([\overline{dt}]) = [\theta_\mathbb{R}]$.

Next we consider the torus $M = S^1 \times S^1$. As before we denote $p: S^1 \times S^1 \to S^1$ respectively $q: S^1 \times S^1 \to S^1$ the projection onto the first, respectively the second factor. A
direct calculation shows that, with the usual product orientation on the torus $M = S^1 \times S^1$ we have
$$\int_{S^1 \times S^1} p^*(\overline{dt}) \wedge q^*(\overline{dt}) = +1.$$

On the other hand, by the naturality of $u$ we have $u(p^*([\overline{dt}])) = p^*(u([\overline{dt}])) = p^*([\theta_\mathbb{R}])$ and similarly we also have $u(q^*([\overline{dt}])) = q^*([\theta_\mathbb{R}])$. The calculation of the above integral is now consistent with the calculation in Lemma 81.14 where we had, implicitly, shown that $\langle p^*([\theta_\mathbb{R}]) \cup q^*([\theta_\mathbb{R}]), [S^1 \times S^1] \rangle = +1$.

**Proof.** It is shown in [Dup78 Theorem 2.4], through a rather lengthy calculation, that the
natural isomorphisms from Theorem 79.6 are ring homomorphisms. Unfortunately it
is rather difficult to make sure that all the different sign conventions match.\textsuperscript{1184} The above example gives us at least some confidence that the signs are right. We also refer to [War83]
Theorem 5.45 for a proof of the theorem.

---

**Exercises for Chapter 81**

**Exercise 81.1.** Let $X$ be a topological space. We consider the map
$$\Phi: H_*(X) \otimes H_*(X) \xrightarrow{\times} H_*(X \times X) \xrightarrow{p_*} H_*(X)$$
where $p: X \times X \to X$ denotes the projection on the first factor. Show that $\Phi$ is the trivial
map.

**Exercise 81.2.** Let $f: T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. Show that
if $f$ orientation-preserving, then the following two statements hold:
(a) $f_*: H_1(T; \mathbb{Z}) \to H_1(T; \mathbb{Z})$ has determinant one,

\textsuperscript{1184} For example, on [Dup78, p. 20] it says “let $\cup$ be the usual cup-product”, but as we had discussed on page 1981 it is not so clear what “usual cup-product” is supposed to mean.
(b) $f^*: H^1(T; \mathbb{Z}) \to H^1(T; \mathbb{Z})$ has determinant one.

**Exercise 81.3.**

(a) Use cup products to show that there is no map $f: S^1 \times S^1 \to S^2$ of degree one, i.e. there is no map that induces an isomorphism on second homology.
(b) Given $g \in \mathbb{N}_0$ we denote by $\Sigma_g$ the surface of genus $g$. Let $g < k$. Use cup product to show that there is no degree-one map from $\Sigma_g$ to $\Sigma_k$.

*Remark.* This exercise shows that cup products can also be used to answer Question 69.6.

**Exercise 81.4.** We consider $\mathbb{R}P^2 = S^2/\sim$ which we identify with $\mathbb{B}^2/\sim$ via the homeomorphism that is induced by the projection map $S^2 \to \mathbb{B}^2$. Let $\varphi \in C^1(\mathbb{R}P^2; \mathbb{F}_2)$ be the cocycle that we defined on page 1998. Determine each of the four summands in the sum

$$(\varphi \cup \varphi)(\sigma_1) + (\varphi \cup \varphi)(\sigma_2) + (\varphi \cup \varphi)(\tau_1) + (\varphi \cup \varphi)(\tau_2).$$

the 2-cycle $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in C_2(\mathbb{R}P^2; \mathbb{F}_2)$ represents the $\mathbb{F}_2$-fundamental class of the real projective plane

**Figure 1167**

**Exercise 81.5.** Let $K$ be the Klein bottle.

(a) Is the cup product $H^1(K; \mathbb{Z}) \times H^1(K; \mathbb{Z}) \to H^2(K; \mathbb{Z})$ is trivial?
(b) Show that the cup product $H^1(K; \mathbb{F}_2) \times H^1(K; \mathbb{F}_2) \to H^2(K; \mathbb{F}_2)$ is non-trivial.

**Exercise 81.6.** Let $k \in \mathbb{N}$. We denote by $N_k$ the non-orientable surface of genus $k$ as defined on page 206. For $i = 1, \ldots, k$ we denote by $p_i: N_k \to \mathbb{R}P^2$ the map that is illustrated in Figure 1168.

(a) Show that the map $p_1^* \oplus \cdots \oplus p_k^*: H^1(\mathbb{R}P^2; \mathbb{F}_2) \oplus \cdots \oplus H^1(\mathbb{R}P^2; \mathbb{F}_2) \to H^1(N_k; \mathbb{F}_2)$ is an isomorphism.

*Hint.* You could use cellular cohomology.

(b) Let $x \in H^1(\mathbb{R}P^2; \mathbb{F}_2)$ be the unique non-trivial element. For $i = 1, \ldots, k$ we write $y_i = p_i^*(x)$. Furthermore we denote by $[N_k]^* \in H^2(N_k; \mathbb{F}_2)$ the unique non-trivial element. Show that for any $i, j \in \{1, \ldots, k\}$ we have $y_i \cup y_j = \delta_{ij} \cdot [N_k]^*$.

(c) Let $\ g < k$. Use cup product to show that there is no map $f: N_g \to N_k$ that induces an isomorphism $f_*: H_2(N_g; \mathbb{F}_2) \to H_2(N_k; \mathbb{F}_2)$.

*Remark.* This statement is the non-orientable analogue of Exercise 81.3. Note that we had proved this statement in Exercise 69.7 using an alternative approach. Both are fun!
Exercise 81.7. Given a matrix $A \in M(n \times n, \mathbb{F}_2)$ we define the bilinear form
\[
\lambda(A) : \mathbb{F}_2^n \times \mathbb{F}_2^n \rightarrow \mathbb{F}_2,
\]
\[
(v, w) \mapsto v^T A w.
\]
We consider the two matrices $P = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $Q = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ over $\mathbb{F}_2$. Next we consider the torus $T = S^1 \times S^1$ and the Klein bottle $K = N_2$. By a slight variation on Lemma 81.14 and by Exercise 81.6 we know that the cup products $H^1(T; \mathbb{F}_2) \times H^1(T; \mathbb{F}_2) \rightarrow H^2(T; \mathbb{F}_2)$ and $H^1(K; \mathbb{F}_2) \times H^1(K; \mathbb{F}_2) \rightarrow H^2(K; \mathbb{F}_2)$ are isometric to $\lambda(P)$ respectively $\lambda(Q)$.

(a) Show that the forms $\lambda(P)$ and $\lambda(Q)$ are not isometric.
(b) Show that there is no map $f : T \rightarrow K$ such that the map $f_* : H_2(T; \mathbb{F}_2) \rightarrow H_2(K; \mathbb{F}_2)$ is an isomorphism.

Remark. This approach gives an alternative, and arguably more systematic solution, to Exercise 81.7.
82. **The Relative Cup Product**

Our goal in this chapter is to introduce a relative version of the cup product. More precisely, given an excisive triad \((X, A, B)\) and a commutative ring \(R\) we will introduce a cup product

\[
H^p(X, A; R) \times H^q(X, B; R) \xrightarrow{\cup} H^{p+q}(X, A \cup B; R)
\]

that is functorial in an appropriate sense and that equals the previous definition of the cup product for the special case that \(A = B = \emptyset\). This relative cup product will help us in determining the cup products of wedges of topological spaces and of the suspension of a topological space. Also it will help us to determine the mysterious sounding Lusternik-Schnirelmann category.

82.1. **Definition of the relative cup product.** In this section we will work a lot with relative cochains. Before we do so we recall the following convention from page 1829.

**Convention.**

1. Given an abelian group \(C\), a subgroup \(D\) and an abelian group \(G\) we have a natural isomorphism

\[
\text{Hom}(C/D, G) \xrightarrow{\cong} \{ f : C \to G \mid f \text{ vanishes on } D \}.
\]

We will use this isomorphism to identify the groups left and right.

2. In particular, given a pair of topological spaces \((X, A)\), a commutative ring \(R\) and \(n \in \mathbb{N}_0\) we make the identification

\[
C^n(X, A; R) \cong \{ f : C_n(X) \to R \mid f(\sigma) = 0 \text{ for all } \sigma : \Delta^n \to A \}.
\]

The definition of the relative cup product requires some preparation. We start out with the following definition.

**Definition.** Let \((X, A, B)\) be a triad of topological spaces. As in the definition on page 1851 we write

\[
C_n^{(A, B)}(A \cup B) := \left\{ \sum_{j=1}^k n_j \sigma_j \in C_n(A \cup B) \mid \text{for each } j \text{ the image of } \sigma_j \text{ lies in } A \text{ or it lies in } B \right\}
\]

The usual boundary map on the groups \(C_*(A \cup B)\) restricts to a boundary map on the groups \(C_*^{(A, B)}(A \cup B)\). Given a commutative ring \(R\) we consider

\[
C^n(X, \{A, B\}; R) := \ker \left( C^n(X; R) \to \text{Hom}(C_n^{(A, B)}(A \cup B), R) \right).
\]

This is again a cochain complex and we denote the corresponding cohomology groups by \(H^*(X, \{A, B\}; R)\).

**Remark.** With the above notation we could write that

\[
C^n(X, \{A, B\}; R) = \{ \varphi : C_n(X) \to R \mid \varphi(\sigma) = 0 \text{ for any } \sigma : \Delta^n \to A \text{ and any } \sigma : \Delta^n \to B \}.
\]

The definition of \(C^n(X, \{A, B\}; R)\) is illustrated in Figure 1169.
**Lemma 82.1.** Let \((X, A, B)\) be an excisive triad of topological spaces. Given any commutative ring \(R\) the natural map
\[
C^*(X, A∪B; R) \rightarrow C^*(X, \{A, B\}; R)
\]
induces for every \(n \in \mathbb{N}_0\) an isomorphism
\[
H^n(X, A∪B; R) \cong H^n(X, \{A, B\}; R).
\]

**Proof.** We have the following commutative diagram of short exact sequences of chain complexes
\[
\begin{array}{ccccccccc}
0 & \rightarrow & C_*^{(A,B)}(A∪B) & \rightarrow & C_* (X) & \rightarrow & C_*^{(A,B)}(A∪B) & \rightarrow & 0 \\
& & \downarrow & & \downarrow{=\text{id}} & & \downarrow & & \\
0 & \rightarrow & C_* (A∪B) & \rightarrow & C_* (X) & \rightarrow & C_* (X, A∪B) & \rightarrow & 0.
\end{array}
\]

By our hypothesis the triad \((X, A, B)\) is excisive. By definition this means that the left vertical map is a chain homotopy equivalence. The middle vertical map is the identity. It now follows from Corollary 49.4 that the right vertical map is also a chain homotopy equivalence.

Recall that by the convention on page 2003 we have an identification
\[
\text{Hom} \left( \frac{C_n(X)}{C_n^{(A,B)}(A∪B)}, R \right) = C^n(X, \{A, B\}; R).
\]
The lemma follows from the above vertical chain homotopy equivalence, the above observation and Lemma 73.8.

The following lemma is the motivation for introducing the rather technical cohomology modules \(H^*(X; \{A, B\}; R)\).

**Lemma 82.2.** Let \((X, A, B)\) be a triad of topological spaces and let \(R\) be a commutative ring. Then the map
\[
C^p(X, A; R) \times C^q(X, B; R) \rightarrow C^{p+q}(X, \{A, B\}; R)
\]
\[(\varphi, \psi) \mapsto \left[ C_{p+q}(X) \rightarrow R \sigma \mapsto \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \right].
\]
is well-defined and it induces an \(R\)-bilinear map
\[
\cup: H^p(X, A; R) \times H^q(X, B; R) \rightarrow H^{p+q}(X, \{A, B\}; R).
\]
82. THE RELATIVE CUP PRODUCT

**Proof.** The lemma follows easily from the following claim.

**Claim.** Given \( \varphi \in C^p(X, A; R) \) and \( \psi \in C^q(X, B; R) \) the homomorphism

\[
C^p+q(X) \rightarrow R \\
(\sigma: \Delta^{p+q} \rightarrow X) \mapsto \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])
\]

lies actually in \( C^{p+q}(X, \{A, B\}) \).

By the remark on page 2003 we have to show that the above cochain vanishes on all singular \((p + q)\)-simplices that lie entirely in \( A \) or that lie entirely in \( B \). But this is clear:

1. given \( \sigma: \Delta^{p+q} \rightarrow A \) the first factor \( \varphi(\sigma \circ [v_0, \ldots, v_p]) \) is necessarily zero since we have \( \varphi \in C^p(X, A; R) \), and similarly,
2. given \( \sigma: \Delta^{p+q} \rightarrow B \) the second factor \( \psi(\sigma \circ [v_p, \ldots, v_{p+q}]) \) is necessarily zero since we have \( \psi \in C^q(X, B; R) \).

This concludes the proof of the claim and thus also of the lemma.

**Definition.** Let \((X, A, B)\) be an excisive triad of topological spaces and let \( R \) be a commutative ring. We refer to the composition

\[
H^p(X, A; R) \times H^q(X, B; R) \xrightarrow{(c,d)\mapsto c \cdot d} H^{p+q}(X, \{A, B\}; R) \xrightarrow{\sim} H^{p+q}(X, A \cup B; R)
\]

again as a **cup product** (or sometimes as a **relative cup product**) and we denote it as usual by the “\( \cup \)”-symbol.

**Remark.** Let \( X \) be a topological space, let \( A, B \subset X \) be subsets and let \( R \) be a commutative ring. Suppose that \( C^*(A,B)(A \cup B) = C_*(A \cup B) \). (This is for example the case if \( A = B = \emptyset \) or more generally, if \( A \) is a subset of \( B \) or if \( B \) is a subset of \( A \).) Then the above definition of the cup product is just the “naive” definition given by

\[
C^p(X, A; R) \times C^q(X, B; R) \rightarrow C^{p+q}(X, A \cup B; R) \\
(\varphi, \psi) \mapsto \left( C^{p+q}(X, A \cup B) \rightarrow R \right) \\
\sigma \mapsto \varphi(\sigma \circ [v_0, \ldots, v_p]) \cdot \psi(\sigma \circ [v_p, \ldots, v_{p+q}])
\]

In the following we summarize a few properties of the relative cup product. We start out with the obvious generalization of Proposition 81.8.

**Proposition 82.3.** Let \((X, A, B)\) be an excisive triad of topological spaces and let \( R \) be a commutative ring. For every \( \varphi \in H^k(X, A; R) \) and \( \psi \in H^l(X, B; R) \) we have

\[
\varphi \cup \psi = (-1)^{kl} \cdot \psi \cup \varphi \in H^{k+l}(X, A \cup B; R).
\]

**Proof.** In Exercise 82.1 we will see that a modification of the proof of Proposition 81.8 provides us with a proof of Proposition 82.3.

Note that the first part of following proposition is a generalization of Lemma 81.10.
**Proposition 82.4.**

(1) Let \((X, A, B)\) and \((Y, C, D)\) be two excisive triads and let \(R\) be a commutative ring. Let \(f: (X, A, B) \to (Y, C, D)\) be a map. Then for all \(p, q \in \mathbb{N}_0\) the following diagram commutes:

\[
\begin{array}{ccc}
\mathbb{H}^p(Y, C; R) \times \mathbb{H}^q(Y, D; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(Y, C \cup D; R) \\
\downarrow f^* \times f^* & & \downarrow f^* \\
\mathbb{H}^p(X, A; R) \times \mathbb{H}^q(X, B; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(X, A \cup B; R).
\end{array}
\]

Proof. (1) It follows easily from the definitions that the following diagram commutes:

\[
\begin{array}{ccc}
\mathbb{H}^p(Y, C; R) \times \mathbb{H}^q(Y, D; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(Y, \{C, D\}; R) \xleftarrow{\cong} \mathbb{H}^{p+q}(Y, C \cup D; R) \\
\downarrow f^* \times f^* & & \downarrow f^* \\
\mathbb{H}^p(X, A; R) \times \mathbb{H}^q(X, B; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(X, \{A, B\}; R) \xleftarrow{\cong} \mathbb{H}^{p+q}(X, A \cup B; R).
\end{array}
\]

The desired statement follows immediately from this observation.

(2) This statement follows, similar to (1), basically immediately from the definitions. \(\square\)

We record a particularly useful special case of Proposition 82.4 (1) as a corollary.

**Corollary 82.5.** Let \((X, A, B)\) be an excisive triad and let \(R\) be a commutative ring. Then the following diagram commutes:

\[
\begin{array}{ccc}
\mathbb{H}^p(X, A; R) \times \mathbb{H}^q(X, B; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(X, A \cup B; R) \\
\downarrow & & \downarrow \\
\mathbb{H}^p(X; R) \times \mathbb{H}^q(X; R) & \xrightarrow{\cup} & \mathbb{H}^{p+q}(X; R).
\end{array}
\]

In particular, if \(\alpha \in \mathbb{H}^p(X; R)\) lies in the image of \(\mathbb{H}^p(X, A; R)\) and if \(\beta \in \mathbb{H}^q(X; R)\) lies in the image of \(\mathbb{H}^q(X, B; R)\) and if \(A \cup B = X\), then \(\alpha \cup \beta = 0\).

Proof. The first part of the corollary follows immediately from Proposition 82.4 (1) applied to the obvious map \(f: (X, \emptyset, \emptyset) \to (X, A, B)\) of excisive triads.

We turn to the proof of the second part. We denote by \(\sigma: \mathbb{H}^p(X, A; R) \to \mathbb{H}^p(X; R)\), \(\tau: \mathbb{H}^p(X, B; R) \to \mathbb{H}^p(X; R)\) and by \(\nu: \mathbb{H}^{p+q}(X, A \cup B; R) \to \mathbb{H}^{p+q}(X; R)\) the obvious maps. Let \(\hat{\alpha} \in \mathbb{H}^p(X, A; R)\) and \(\hat{\beta} \in \mathbb{H}^q(X, B; R)\). We write \(\alpha = \sigma(\hat{\alpha})\) and \(\beta = \tau(\hat{\beta})\). We
suppose that \( A \cup B = X \). Then
\[
\alpha \cup \beta = \sigma(\hat{\alpha}) \cup \tau(\hat{\beta}) = \nu(\hat{\alpha} \cup \hat{\beta}) = \nu(0) = 0.
\]
by the commutative diagram since \( \hat{\alpha} \cup \hat{\beta} \) lies in the group
\[
H^{p+q}(X, A \cup B; R) = H^{p+q}(X, X; R) = 0.
\]

Before we state the next lemma we introduce one more convention.

**Convention.** Let \( A, B, C, D, X \) and \( Y \) be sets, let \( f: C \to A \), \( g: B \to D \) and \( \mu: X \to Y \) be maps and let \( \varphi: A \times B \to X \) and \( \psi: C \times D \to Y \) be maps. We say that the diagram
\[
\begin{array}{ccc}
A \times B & \xrightarrow{\varphi} & X \\
\uparrow f & & \downarrow \mu \\
C \times D & \xrightarrow{\psi} & Y
\end{array}
\]
commutes, if for all \( c \in C \) and \( b \in B \) we have
\[
\psi(c, g(b)) = \mu(\varphi(f(c), b)).
\]
A similar convention holds with the directions of \( f \) and \( g \) reversed. Furthermore, if we are dealing with group homomorphisms, then there is an obvious notion of “commutes up to a given sign”.

Using this convention we can now formulate our next lemma.

**Lemma 82.6.** Let \((X, A)\) be a pair of topological spaces and let \( R \) be a commutative ring. We denote by \( i: A \to X \) the inclusion map and we denote by \( \delta \) the connecting homomorphisms in the long exact sequence in cohomology corresponding to the pair \((X, A)\). For any \( p, q \in \mathbb{N}_0 \) the following diagram commutes:
\[
\begin{array}{ccc}
H^q(A; R) \times H^p(A; R) & \xrightarrow{\cup} & H^{p+q}(A; R) \\
\downarrow & & \downarrow \\
H^{q+1}(X, A; R) \times H^p(X; R) & \xrightarrow{\cup} & H^{p+q+1}(X, A; R)
\end{array}
\]
and the following diagram commutes
\[
\begin{array}{ccc}
H^p(A; R) \times H^q(A; R) & \xrightarrow{\cup} & H^{p+q}(A; R) \\
\uparrow i^* & & \uparrow i^* \\
H^p(X; R) \times H^{q+1}(X, A; R) & \xrightarrow{\cup} & H^{p+q+1}(X, A; R)
\end{array}
\]
up to the sign \((-1)^p\).

**Remark.** In Lemma \[100.18\] we will formulate a generalization of Lemma \[82.6\].

**Proof (\(\ast\)).** For no particular reason we prove the second statement. The first statement can either be proved the same way or it can be deduced from the second statement using Proposition \[82.3\]. We pick cocycles \( \varphi \in C^p(X; R) \) and \( \psi \in C^q(A; R) \). In the following we denote by \( \psi: C^q(X) \to R \) the extension of \( \psi \) that is defined to be zero on all singular
$k$-simplices that do not lie in the subset $A$. We have the following equalities:

by the discussion of the connecting homomorphism in the remark on page 1833 and since $\varphi \cup \psi$ is the trivial extension of $i^* \varphi \cup \psi : C_{p+q}(A) \to R$ to a homomorphism $C_{p+q}(X) \to R$,

$$
\delta([i^* \varphi] \cup [\psi]) = \delta([i^* \varphi \cup \psi]) = \delta(\varphi \cup \tilde{\psi}) = [\delta(\varphi \cup \tilde{\psi}) + (-1)^p \cdot (\varphi \cup \delta \tilde{\psi})]
$$

Lemma 81.2

$$
= (-1)^p \cdot [\varphi \cup \delta \tilde{\psi}] = (-1)^p \cdot ([\varphi] \cup [\delta \tilde{\psi}]) = (-1)^p \cdot ([\varphi] \cup [\delta \psi]).
$$

This equality implies that the diagram commutes up to the sign $(-1)^p$.

Finally, recall that on page 1903 we introduced cohomology with compact support $H^*_c(X; \mathbb{Z})$. For the insatiable reader we also provide the definition of the cup product on cohomology with compact support.

**Definition.** Let $X$ be a topological space, let $\varphi \in H^k(X; \mathbb{Z})$ and let $\psi \in H^l_c(X; \mathbb{Z})$. Recall that by Lemma 77.2 there exists a compact subset $K \subset X$ and a cohomology class $\tilde{\varphi} \in H^k(X, X \setminus K; \mathbb{Z})$ such that the image of $\tilde{\varphi}$ in $H^k(X; \mathbb{Z})$ equals $\varphi$. Analogously we find a compact set $L$ and $\tilde{\psi} \in H^l(X, X \setminus L; \mathbb{Z})$. We define

$$
\varphi \cup \psi := \text{the image of } \varphi \cup \psi \in H^{k+l}(X, X \setminus (K \cup L)) \text{ in } H_{c}^{k+l}(X; \mathbb{Z}).
$$

It follows easily from Corollary 82.5 that this definition does not depend on any of the choices. We refer to $\varphi \cup \psi$ as the **cup product in cohomology with compact support**.

The cup product on cohomology with compact support can be very useful for tackling non-compact topological spaces. For example in Exercise 82.5 we will make use of the cup product on cohomology with compact support to show that the topological manifold $W = \mathbb{R}^2 \setminus \{(n, 0) \mid n \in \mathbb{Z}\}$ is not homeomorphic to the surface $X$ of infinite genus that is shown in Figure 1170. On a more theoretical side we will make of the above definition in Theorem 95.9 when we will learn how to compute cup products on topological manifolds by “intersecting cycles”.

![Figure 1170](image)

**Figure 1170**

82.2. **Calculations using the relative cup product.** In this section we will use Proposition 82.1 (1) to calculate cup products of several topological spaces. We start out with the suspension $\Sigma(X) = (X \times [-1, 1])/\sim$ of a topological space $X$. We refer to page 694 for the precise definition and we refer to Figure 1171 for a reminder.

The following lemma shows that the cup product of the suspension of a topological space is quite dull.
Lemma 82.7. Let $X$ be a path-connected topological space and let $R$ be a commutative ring.

1. We have

$$H^k(\Sigma(X); R) \cong \begin{cases} R, & \text{if } k = 0, \\ 0, & \text{if } k = 1, \\ H^{k-1}(X; R), & \text{if } k \geq 2. \end{cases}$$

2. For any $k, l \geq 1$ the cup product

$$H^k(\Sigma(X); R) \times H^l(\Sigma(X); R) \to H^{k+l}(\Sigma(X); R)$$

is the zero map.

Proof. We denote by $p: X \times [-1, 1] \to \Sigma(X)$ the obvious projection map. We denote by $N := [X \times \{1\}]$ the “North Pole” and we denote by $S := [X \times \{-1\}]$ the South Pole. We refer to Figure 1171 for an illustration. We write $U = \Sigma(X) \setminus \{S\}$ and $V = \Sigma(X) \setminus \{N\}$. By the same argument as in Lemma 24.1 that $U$ admits deformation retraction from $U$ to the North Pole $N$. This shows that $U$ is contractible. The same argument shows that $V$ is contractible.

1. Note that $U$ and $V$ are open subsets of $\Sigma(X)$. It follows from Proposition 74.12 (4) that $(\Sigma(X), U, V)$ is excisive. Therefore we can apply the Mayer–Vietoris Theorem 74.15 for Cohomology Groups and we obtain the following long exact sequence

$$\ldots \to H^i(\Sigma(X); R) \to H^i(U; R) \oplus H^i(V; R) \to H^i(U \cap V; R) \to H^{i+1}(\Sigma(X); R) \to \ldots$$

The desired isomorphism now follows easily from the above long exact sequence and the following:

(a) above we had observed that $U$ and $V$ are contractible,

(b) the intersection $U \cap V$ is homeomorphic to $X \times (-1, 1)$, in particular it is homotopy equivalent to $X$,

(c) Lemmas 73.14 and 73.12 and the discussion of induced maps on 0-th cohomology on page 1330.

2. Now let $k, l \geq 1$. It follows immediately from the long exact sequence of cohomology groups corresponding to the pair $(\Sigma(X), U)$, the fact that $U$ is homotopy equivalent to a point (together with Lemmas 73.12 and 73.13) that the inclusion induced map

Why is that?
\[ H^k(\Sigma(X), U; R) \rightarrow H^k(\Sigma(X); R) \] is an isomorphism. Evidently the same also holds if we replace \( U \) by \( V \).

By Corollary 82.5, and the fact that \((\Sigma(X), U, V)\) is excisive, we have the following commutative diagram

\[
\begin{array}{ccc}
H^k(\Sigma(X), U; R) \times H^l(\Sigma(X), V; R) & \rightarrow & H^{k+l}(\Sigma(X), U \cup V; R) \\
\downarrow \cong & & \downarrow \\
H^k(\Sigma(X); R) \times H^l(\Sigma(X); R) & \rightarrow & H^{k+l}(\Sigma(X); R).
\end{array}
\]

Since \( U \cup V = \Sigma(X) \) we see that the cohomology group on the top-right is zero. Furthermore, since the vertical map on the left is an isomorphism we see that the cup product on the bottom is zero.

Let \( X \) and \( Y \) be two topological spaces and let \( x \in X \) and \( y \in Y \) be good points. (See page 604 for the definition of a good point.) We use these points to define the wedge \( X \vee Y \) of \( X \) and \( Y \). Furthermore let \( R \) be a commutative ring. We denote by \( p: X \vee Y \rightarrow X \) and \( q: X \vee Y \rightarrow Y \) the obvious projection maps. By Proposition 74.17 we know that for every \( n \in \mathbb{N} \) the map

\[ p^* \oplus q^*: H^n(X; R) \oplus H^n(Y; R) \cong H^n(X \vee Y; R) \]

is an isomorphism. The following lemma determines the cup product of \( X \vee Y \) in terms of the cup products of \( X \) and \( Y \). It can be viewed as a generalization of Lemma 81.11.

**Lemma 82.8.** We continue with the above notation. Then for any \( \alpha, \beta \in H^*(X; R) \) and \( \varphi, \psi \in H^*(Y; R) \) in degrees \( \geq 1 \) the following statements hold in \( H^*(X \vee Y; R) \):

<table>
<thead>
<tr>
<th></th>
<th>( p^*(\beta) )</th>
<th>( q^*(\psi) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p^*(\alpha) )</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>( q^*(\varphi) )</td>
<td>0</td>
<td>( q^*(\varphi \cup \psi) )</td>
</tr>
</tbody>
</table>

**Proof (\( \ast \)).** The statement regarding the “diagonal” terms of the table follows immediately from Lemma 81.11. It remains to prove that the off-diagonal terms are zero. We show that the top-right entry is zero. The proof that the bottom-left entry is zero is basically identical.

Thus let \( \alpha \in H^k(X; R) \) and \( \psi \in H^l(Y; R) \) with \( k, l \geq 1 \). We view \( X \) and \( Y \) as subsets of \( X \vee Y \). We denote by \( f: (X \vee Y, \emptyset) \rightarrow (X \vee Y, X) \) and \( g: (X \vee Y, \emptyset) \rightarrow (X \vee Y, Y) \) the two inclusion maps of pairs of topological spaces.

**Claim.** There exist \( \tilde{\alpha} \in H^k(X \vee Y, Y; R) \) with \( g^*(\tilde{\alpha}) = p^*(\alpha) \) and \( \tilde{\psi} \in H^l(X \vee Y, X; R) \) with \( f^*(\tilde{\psi}) = q^*(\psi) \).
To prove the claim we consider the following two diagrams:\footnote{Recall that in \( X \lor Y \) the points \( x \) and \( y \) get identified, so we can view \( x \) as an element in \( Y \) and we can view \( y \) as an element in \( X \).}

\[
\begin{array}{c}
\xymatrix{
H^k(X \lor Y; R) \ar[r]^{g^*} \ar[d]_{p^*} & H^k(X \lor Y, Y; R) \ar[d] \quad \text{and} \quad H^i(X \lor Y; R) \ar[r]^{f^*} \ar[d]_{q^*} & H^i(X \lor Y, X; R) \ar[d] \\
H^k(X; R) \ar[r] & H^k(X, \{x\}; R) & H^i(Y; R) \ar[r] & H^i(Y, \{y\}; R).}
\end{array}
\]

Here the maps that are unlabeled are induced by the obvious inclusions. It is easy to verify that the diagrams commute. It follows easily from the long exact sequence in cohomology of a pair of topological spaces that the two bottom horizontal maps are isomorphisms. Recall that in Lemma \[74.16\] we showed that the triad \((X \lor Y, X, Y)\) is excisive. Therefore it follows from Lemma \[74.13\] that the vertical maps on the right are isomorphisms. The claim is an immediate consequence of these observations.

Since, as we had just seen, the triad \((X \lor Y, X, Y)\) is excisive we can apply Corollary \[82.5\] and we obtain that

\[
p^*(\alpha) \cup q^*(\psi) = g^*(\tilde{\alpha}) \cup f^*(\tilde{\psi}) = 0.
\]

by Corollary \[82.3\] since \( X \lor Y = X \lor Y \)

\[\tag*{\Box}\]

\[\text{Figure 1172. Illustration for the proof of Lemma \[82.8\].}\]

\textbf{Example.} Now we can also give a new proof of Lemma \[81.16\] more precisely, we can give a new and somewhat more conceptual proof of the calculation of the cup product of the surface \( \Sigma \) of genus 2. First we recall that on page 1850 we introduced two projection maps \( p_i: \Sigma \to T_i = S^1 \times S^1 \) for \( i = 1, 2 \). It follows easily from Lemma \[72.3\] that these projection maps are degree-one maps, i.e. they send the fundamental class \([\Sigma]\) to the fundamental class \([T_i]\). In Lemma \[74.11\] we saw that the map

\[
p_1^* \oplus p_2^*: H^1(T_1; \mathbb{Z}) \oplus H^1(T_2; \mathbb{Z}) \to H^1(\Sigma; \mathbb{Z})
\]

is an isomorphism. We make the following observations:

1. Let \( \varphi, \psi \in H^1(T_i; \mathbb{Z}) \), \( i = 1, 2 \). Then

\[
\langle \varphi \cup \psi, [T_i] \rangle_{T_i} = \langle \varphi \cup \psi, p_i^*([\Sigma]) \rangle_{T_i} = \langle p_i^*(\varphi) \cup p_i^*(\psi), [\Sigma] \rangle_{T_i} = \langle p_i^*(\varphi) \cup p_i^*(\psi), [\Sigma] \rangle_{\Sigma}.
\]

since \( p_i \) is of degree one \quad Lemma \[74.6\] (3) \quad Lemma \[81.10\]

2. We denote by \( q_i: T_i \lor T_2 \to T_i \), \( i = 1, 2 \) the obvious projections. The two projection maps \( p_1, p_2 \) give rise to a map \( p_1 \lor p_2: \Sigma \to T_1 \lor T_2 \) which has the property that
\( q_i \circ (p_1 \lor p_2) = p_i, \ i = 1, 2. \) (See Figure 1173 for an illustration.) Now let \( \varphi_1 \in H^1(T_1; \mathbb{Z}) \) and \( \varphi_2 \in H^1(T_2; \mathbb{Z}). \) Then
\[
p_1^*(\varphi_1) \lor p_2^*(\varphi_2) = (p_1 \lor p_2)^*(q_1^*(\varphi_1) \lor q_2^*(\varphi_2)) = (p_1 \lor p_2)^*(0) = 0.
\]

Precisely the same proof shows also that \( p_2^*(\varphi_2) \lor p_1^*(\varphi_1) = 0. \)

These two claims, together with the previous calculation of the cup product on the torus \( T = S^1 \times S^1, \) see Lemma 81.14, give a new proof of Lemma 81.16.

82.3. The Lusternik-Schnirelmann category. We start out with the following definition.

**Definition.** Let \( M \) be an \( m \)-dimensional smooth manifold.

1. A parametrization for \( M \) is a smooth map \( \Psi: V \to M \) with the following properties:
   a. the domain \( V \) is either an open ball in \( \mathbb{R}^m \), or an open rectangle, or all of \( \mathbb{R}^m \); and
   b. the map \( \Psi \) is a diffeomorphism onto its image.
2. We say a family \( \{ \Psi_i: V_i \to M \}_{i \in I} \) of parametrizations covers \( M \) if \( \bigcup_{i \in I} \Psi_i(V_i) = M. \)

The following slightly vague question arises:

**Question 82.9.** For a given smooth manifold \( M \), how many parametrizations do we need to cover all of \( M? \)

**Examples.**

1. Let \( N = (0, \ldots, 0, 1) \) be the North Pole and let \( S = (0, \ldots, 0, -1) \) be the South Pole of the \( n \)-dimensional sphere \( S^n \). We can cover \( S^n \) by the two open subsets \( S^n \setminus \{ N \} \) and \( S^n \setminus \{ S \} \). Stereographic projection, see Figure 30, gives rise to two diffeomorphisms \( \Phi_1: S^n \setminus \{ N \} \to \mathbb{R}^n \) and \( \Phi_2: S^n \setminus \{ S \} \to \mathbb{R}^n \). The inverses of these two maps define parametrizations that cover \( S^n \).

Since \( S^n \) is not diffeomorphic to any of the admissible domains of a parametrization we see that the above collection of parametrizations is optimal in the sense that we cannot parametrize \( S^n \) with fewer parametrizations.

---

1188 The condition on \( V \) sounds slightly arbitrary, and it is, but it is reasonable that for practical purposes one prefers domains that are “easy to describe.”
(2) We consider the \(n\)-torus \((S^1)^n = \mathbb{R}^n / \mathbb{Z}^n\). We denote by \(p : \mathbb{R}^n \to \mathbb{R}^n / \mathbb{Z}^n\) the projection map. We pick real numbers \(0 < s_1 < s_2 < \cdots < s_{n+1} < 1\). For \(i = 1, \ldots, n+1\) we consider the map

\[
\Psi_i : (s_i, s_i + 1) \times \cdots \times (s_i, s_i + 1) \to \mathbb{R}^n / \mathbb{Z}^n \\
(t_1, \ldots, t_n) \mapsto p(t_1, \ldots, t_n).
\]

For \(i = 1, \ldots, n+1\) we write \(U_i = \Psi_i(V_i)\). It is straightforward to see that the maps \(\Psi_1, \ldots, \Psi_{n+1}\) are parametrizations that cover \(\mathbb{R}^n / \mathbb{Z}^n\). We illustrate the images of the parametrizations for the 2-torus in Figure 1174.

![Figure 1174](image.png)

For \(i = 1, \ldots, n+1\) we consider the map

\[
\Psi_i : \mathbb{R}^n \to \mathbb{R}P^n = (\mathbb{R}^{n+1} \setminus \{0\}) / \sim \\
(x_1, \ldots, x_n) \mapsto [x_1 : \ldots : x_{i-1} : 1 : x_i : \ldots : x_n],
\]

point in \(\mathbb{R}P^n\) represented by \((x_1, \ldots, x_{i-1}, 1, x_i, \ldots, x_n)\).

It is straightforward to see that the maps \(\Psi_1, \ldots, \Psi_{n+1}\) are parametrizations that cover the real projective space \(\mathbb{R}P^n\).

(4) Almost the same construction as in (3) shows that we can cover the complex projective space \(\mathbb{C}P^n = (\mathbb{C}^{n+1} \setminus \{0\}) / \sim\) by \(n + 1\) parametrizations such that the domain of each parametrization is diffeomorphic to \(\mathbb{C}^n \cong \mathbb{R}^{2n}\).

The following question is now a more precise version of Question 82.9.

**Question 82.10.**

1. Can we cover \((S^1)^n\) by fewer than \(n + 1\) parametrizations?
2. Can we cover \(\mathbb{R}P^n\) by fewer than \(n + 1\) parametrizations?
3. Can we cover \(\mathbb{C}P^n\) by fewer than \(n + 1\) parametrizations?

In the remainder of this chapter we will study a generalization of these questions and we will see how cup products can be used to approach this question and its generalizations. We will eventually answer Question 82.10 in Corollary 84.23 and Proposition 90.18.

Now we will generalize this discussion to arbitrary topological spaces by introducing the following definition.

**Definition.**

1. We say that a map \(f : Y \to X\) between topological spaces is *null-homotopic* if it is homotopic to a constant map.
(2) The Lusternik-Schnirelmann category $\text{cat}(X)$ of a topological space $X$ is defined as the smallest $n \in \mathbb{N}_0$ such that there exists an open cover $U_1, \ldots, U_{n+1}$ of $X$ such that each inclusion map $U_i \to X$ is null-homotopic. If no such $n$ exists, then we define $\text{cat}(X) = \infty$.

Remark.

(1) Suppose that a given smooth manifold $M$ can be covered by $n + 1$ parametrizations. Since the domain of a parametrization is contractible and since a parametrization is a diffeomorphism onto its image we see that $\text{cat}(M) \leq n$.

(2) The sets $U_i$ in the definition of the Lusternik-Schnirelmann category do not have to be contractible, for example if $X$ itself is contractible, then for any subset $U \subset X$ the inclusion map $U \to X$ is null-homotopic.

(3) The Lusternik-Schnirelmann category plays an important role in topological robotics, see e.g. [Far08] for more details.

Examples.

(1) For a non-empty topological space $X$ we have $\text{cat}(X) = 0$ if and only if $\text{id}: X \to X$ is null-homotopic, i.e. if $X$ is contractible.

(2) The above discussion of parametrizations of $S^n$ together with statement (1) shows that $\text{cat}(S^n) = 1$.

(3) (a) In Figure 1175 we consider the wedge $X$ of $n \geq 1$ circles together with two open covers $X = U_1 \cup U_2$ and also $X = V_1 \cup V_2$. Note that all the inclusion maps $U_i \to X$ and also $V_i \to X$ are null-homotopic. So this gives us two separate proofs that $\text{cat}(X) \leq 1$. Together with Statement (1) this shows that we have $\text{cat}(X) = 1$.

(b) Using the obvious generalization of the sets $V_1$ and $V_2$ shown in Figure 1175 one can easily show that the Lusternik-Schnirelmann category of any non-empty wedge of spheres has Lusternik-Schnirelmann category equal to 1.

![Figure 1175](image)

(4) The discussion preceding Question 82.10 gives us the inequalities $\text{cat}((S^1)^n) \leq n$, $\text{cat}(\mathbb{R}P^n) \leq n$ and also $\text{cat}(\mathbb{C}P^n) \leq n$.

(5) For any $g \geq 2$ the surface $\Sigma$ of genus $g$ satisfies $\text{cat}(\Sigma) \leq 2$, see Figure 1176 for an illustration in the case $g = 2$.

---

1100 The word “category” with its modern meaning was first used by Eilenberg-Maclane [EM45] in 1945. On the other hand the term “Lusternik-Schnirelmann category” was already established by 1941, see [Fox41].

1101 Note the fairly well-hidden “+1” in the subscript of $U_{n+1}$. Sometimes, especially in the older literature the Lusternik-Schnirelmann category is defined without the adjustment given by the “+1”.

1102 Hmm, why is the image of a parametrization an open subset of the smooth manifold?
To obtain lower bounds on the Lusternik-Schnirelmann category we introduce the following definition.

**Definition.** Given a topological space $X$ we define its *cup length* $\text{cl}(X) \in \mathbb{N}_0 \cup \{\infty\}$ as follows:

$$\text{cl}(X) := \max \left\{ n \in \mathbb{N}_0 \mid \right. \text{there exists a commutative ring } R \text{ and } R\text{-cohomology classes } x_1, \ldots, x_n \text{ in degrees } \geq 1 \text{ with } x_1 \cup \cdots \cup x_n \neq 0 \left. \right\}.$$ 

**Examples.**

1. If $X$ is an $n$-dimensional CW-complex, then it follows immediately from Proposition [74.4] that $\text{cl}(X) \leq n$.

2. In Lemma [81.14] and Lemma [81.16] we saw that for any surface $\Sigma$ of genus $g \geq 1$ there exist $x, y \in H^1(\Sigma; \mathbb{Z})$ with $x \cup y \neq 0$, which together with (1) shows that $\text{cl}(\Sigma) = 2$.

3. In Lemma [81.18] we saw that there exists an $x \in H_1(\mathbb{R}P^2; \mathbb{Z}_2)$ with $x \cup x \neq 0$, which shows that $\text{cl}(\mathbb{R}P^2) = 2$.

The following proposition shows that the cup length is a lower bound on the Lusternik-Schnirelmann category.

---

\[1139\] I do not know whether the case of 4-dimensional topological manifolds is known.
Proposition 82.11. For every topological space $X$ we have \[ \text{cl}(X) \leq \text{cat}(X). \]

Example. It follows immediately from Proposition 82.11 and the above examples that \[ \text{cat}(S^1 \times S^1) = \text{cat}((\text{surface of genus } g \geq 2)) = \text{cat}(\mathbb{R}P^2) = 2. \]

Proof. Let $X$ be a topological space, let $R$ be a commutative ring and let $x_j \in H^s(X; R)$, $j = 1, \ldots, n$ be cohomology classes in dimensions $s_j \geq 1$ such that $x_1 \cup x_2 \cup \cdots \cup x_n \neq 0$.

We have to show that $\text{cat}(X) \geq n$.

Thus let $k \leq n$ and let $U_1, \ldots, U_k$ be open subsets in $X$ with $U_1 \cup \cdots \cup U_k = X$ such that each inclusion map $U_i \rightarrow X$ is null-homotopic. We have to show that $U_1 \cup \cdots \cup U_k$ is a proper subset of $X$.

Claim. For any $j \in \{1, \ldots, k\}$ the obvious map $\rho_j : H^s(X, U_j; R) \rightarrow H^s(X; R)$ is in fact an isomorphism.

By our hypothesis the inclusion map $i_j : U_j \rightarrow X$ is null-homotopic, it follows that the restriction map $i_j^* : H^s(X; R) \rightarrow H^s(U_j; R)$ is the zero map for $k \geq 1$ and an epimorphism for $k = 0$. We deduce from this observation, the long exact sequence of cohomology groups corresponding to the pair $(X, U_j)$ and the fact that $s_j \geq 1$ that the obvious map $\rho_j : H^s(X, U_j; R) \rightarrow H^s(X; R)$ is in fact an isomorphism.

Given $j \in \{1, \ldots, k\}$ we write $y_j := \rho_j^{-1}(x_j) \in H^s(X, U_j; R)$ and we set $s = s_1 + \cdots + s_k$.

By Corollary 82.11 we have the following commutative diagram
\[
\begin{array}{ccc}
H^1(X, U_1; R) \times \cdots \times H^{s_k}(X, U_k; R) & \rightarrow & H^s(X, U_1 \cup \cdots \cup U_k; R) \\
\downarrow (y_1, \ldots, y_k) & & \downarrow \\
H^1(X; R) \times \cdots \times H^{s_k}(X; R) & \rightarrow & H^s(X; R).
\end{array}
\]

By our hypotheses the cup product $x_1 \cup \cdots \cup x_k$ is non-zero, which then implies, by the commutativity of the diagram, that the cup product $y_1 \cup \cdots \cup y_k$ is also non-zero. But this implies that the group $H^s(X, U_1 \cup \cdots \cup U_k; R)$ is non-zero, which in turn implies that $U_1 \cup \cdots \cup U_k$ is a proper subset of $X$.

Proposition 82.11 gives us a tool to attack Question 82.10. In fact we saw right after Proposition 82.11 that we can now answer the question for the 2-dimensional torus $(S^1)^2$ and the real projective plane $\mathbb{R}P^2$.

The following questions naturally arise:

Question 82.12.

\footnote{This can be seen as follows: the map $i_j : U_j \rightarrow X$ is homotopic to a constant map that takes the value $P_j \in X$. We denote by $c_j : U_j \rightarrow \{P_j\}$ the constant map and we denote by $k_j : \{P_j\} \rightarrow X$ the inclusion map. We statement now follows from $i_j^* = (k_j \circ c_j)^* = c_j^* \circ k_j^*$ and Lemmas 73.13 and 73.12.}

\footnote{Strictly speaking Corollary 82.5 was formulated for the cup product of two terms, but one can easily reduce the general case of $k$ terms to the special case of 2 terms.}
(1) What is the $\mathbb{Z}$-cohomology ring of $(S^1)^n$?
(2) What is the $\mathbb{F}_2$-cohomology ring of $\mathbb{R}P^n$?
(3) What is the $\mathbb{Z}$-cohomology ring of $\mathbb{C}P^n$?

We will answer these questions in Propositions \textbf{84.22}, \textbf{90.16} and \textbf{90.7}.

There are many other questions that we cannot answer in these notes, in fact which are still open. As an example we conclude this introduction to the Lusternik-Schnirelmann category of a topological space with the following conjecture which is formulated as a question in [Rudy17], Question 1.1.

\textbf{Conjecture 82.13. (Rudyak Conjecture)} Let $M$ and $N$ be two closed oriented connected $n$-dimensional topological manifolds. If there exists a map $f : M \to N$ of degree one, then $\text{cat}(M) \geq \text{cat}(N)$.

\section*{Exercises for Chapter 82}

\textbf{Exercise 82.1.} Let $(X, A, B)$ be an excisive triad of topological spaces and let $R$ be a commutative ring. Show that for every $\varphi \in H^k(X, A; R)$ and $\psi \in H^l(X, B; R)$ the following equality holds:

$$\varphi \cup \psi = (-1)^{kl} \cdot \psi \cup \varphi \in H^{k+l}(X, A \cup B; R).$$

\textit{Hint.} Evidently you should study the proof of Proposition \textbf{81.8} carefully.

\textbf{Exercise 82.2.} Let $M$ be the torus minus one open disk. Show that the cup product $H^1(M, \partial M; \mathbb{Z}) \times H^1(M, \partial M; \mathbb{Z}) \to H^2(M, \partial M; \mathbb{Z})$ is non-trivial.

\textit{Hint.} Reduce this statement to the calculation of the cup product of the torus.

\textbf{Exercise 82.3.} Let $N$ be the disk $\overline{B^2}$ minus two open disks.

(a) Show that the two homology classes $\alpha, \beta \in H_1(N, \partial N; \mathbb{Z})$ shown in Figure \textbf{1177} are a basis for $H_1(N, \partial N; \mathbb{Z}) \cong \mathbb{Z}^2$.

(b) We denote by $\varphi, \psi \in H^1(N, \partial N; \mathbb{Z}) = \text{Hom}(H_1(N, \partial N; \mathbb{Z}), \mathbb{Z})$ the basis dual to $\alpha, \beta$. Show that $\alpha \cup \beta = 0 \in H^2(N, \partial N; \mathbb{Z})$.

\textit{Hint.} Show that there exist open subsets $A$ and $B$ with the following properties:

(i) $\partial N \subset A$ and $\partial N \subset B$.

(ii) $A \cup B = N$.

(iii) $\varphi$ lies in the image of $H^1(N, A; \mathbb{Z}) \to H^1(N, \partial N; \mathbb{Z})$ and $\psi$ lies in the image of $H^1(N, B; \mathbb{Z}) \to H^1(N, \partial N; \mathbb{Z})$.

(c) Show that the cup product $H^1(N, \partial N; \mathbb{Z}) \times H^1(N, \partial N; \mathbb{Z}) \to H^2(N, \partial N; \mathbb{Z})$ is the zero map.

  \caption{Illustration for Exercise 82.3}
\end{figure}
**Exercise 82.4.** Let $M$ be the torus minus one open disk and let $N$ be the disk $\overline{B}^2$ minus two open disks. Use the calculations from Exercise 82.2 and 82.3 to show that there is no degree one map $g: N \to M$.

*Remark.* This gives an alternative solution to Exercise 69.6 (b).

**Exercise 82.5.** As in Exercise 82.5 we consider $W = \mathbb{R}^2 \setminus \{(n, 0) \mid n \in \mathbb{Z}\}$ and we consider the surface $X$ of infinite genus that is shown in Figure 1178.

(a) Show that the cup product $H_1^c(W; \mathbb{Z}) \times H_1^c(W; \mathbb{Z}) \to H_2^c(W; \mathbb{Z})$, that we defined on page 2008 is the zero map.

(b) Show that the cup product $H_1^c(X; \mathbb{Z}) \times H_1^c(X; \mathbb{Z}) \to H_2^c(X; \mathbb{Z})$ is non-zero.

*Hint.* You could use the pairing $H_1^2(X; \mathbb{Z}) \times H_1^1(X) \to \mathbb{Z}$ from Exercise 87.5 to detect that an element in $H_2^c(X; \mathbb{Z})$ is non-zero.

(c) Show that $X$ and $W$ are not homeomorphic.

(d) Does this argument imply that $X$ and $W$ are not homotopy equivalent?

*Remark.* In Exercise 23.14 we showed the weaker statement that $W$ and $X$, viewed as 2-dimensional smooth manifolds, are not diffeomorphic.

![Illustration of Exercise 82.5](image)

**Figure 1178.** Illustration of Exercise 82.5

**Exercise 82.6.** Let $X$ and $Y$ be non-empty topological spaces. Show that we have the following lower bound on the cup length of $X \times Y$:

\[
\text{cl}(X \times Y) \geq \max\{\text{cl}(X), \text{cl}(Y)\}.
\]

**Exercise 82.7.** Let $X$ and $Y$ be topological spaces. Show that if $X$ and $Y$ are homotopy equivalent, then the cup lengths of $X$ and $Y$ agree, i.e. we have $\text{cl}(X) = \text{cl}(Y)$.

**Exercise 82.8.** Determine the Lusternik-Schnirelmann category for all compact (not necessarily connected) 2-dimensional smooth manifolds.
83. THE CAP PRODUCT

In this chapter we introduce the cap product that relates the homology and the cohomology groups. It can be viewed as a generalization of the Kronecker pairing. Initially it might not be clear that the cap product is good for, but later on we will see that it plays an essential role in many calculations and in the formulation of the Poincaré Duality Theorem.

83.1. The definition of the cap product and calculations. We start out by introducing a convention that simplifies our notation later on.

**Convention.** Let $R$ be a commutative ring and let $S$ be a non-empty set. We consider $R(S) := \text{all maps from } S \text{ to } R \text{ which are non-zero for only finitely many } s \in S$ with the obvious $R$-module structure. We refer to $R(S)$ as the free $R$-module generated by $S$. We use the same convention as on page 580 to identify elements in $R(S)$ with finite formal linear combinations $r_1 s_1 + \cdots + r_k s_k$ where $r_1, \ldots, r_k \in R$ and $s_1, \ldots, s_k \in S$. By Lemma 57.3 the map $\mathbb{Z}(S) \otimes R \rightarrow R(S) \ni \sum_{i=1}^n r_i s_i \otimes r_i \mapsto \sum_{i=1}^n r_i s_i$ is an isomorphism. We use this isomorphism to identify the left-hand side with the right-hand side. In particular, given a topological space $X$ and given $k \in \mathbb{N}_0$ we write

$$C_k(X; R) := \mathbb{Z}^{S_k(X)} \otimes R = R^{S_k(X)} = \left\{ \sum_{i=1}^n r_i \sigma_i \bigm| r_1, \ldots, r_n \in R \text{ and } \sigma_i : \Delta^k \rightarrow X \right\},$$

where $S_k(X)$ denotes the set of singular $k$ simplices in $X$.

The following definition is inspired by the second definition of the cup product that we gave on page 1970.

**Definition.** Let $X$ be a topological space and let $R$ be a commutative ring. Given a singular cochain $\varphi \in C^k(X; R)$ and a singular simplex $\sigma : \Delta^l \rightarrow X$ with $k \leq l$ we define the cap product as

$$\varphi \cap \sigma := \left( \varphi \circ [v_0, \ldots, v_k] \right) \cdot \sigma \circ [v_k, \ldots, v_l].$$

We extend this definition to singular $R$-chains and we obtain the cap product

$$\cap : C^k(X; R) \times C_l(X; R) \rightarrow C_{l-k}(X; R) \quad \varphi \cap r \sigma \mapsto r \cdot \left( \varphi \cap \sigma \right).$$

For $k > l$ we define the cap product to be the zero map.
As for the cup product, the first thing we want to verify is that this map on the cochain and chain level defines a map on the level of cohomology groups and homology groups. The key to doing so is the following elementary lemma.

**Lemma 83.1.** Let $X$ be a topological space and let $R$ be a commutative ring. Furthermore let $\varphi \in C^k(X;R)$ and let $\sigma \in C_l(X;R)$. Then

$$\partial(\varphi \cap \sigma) = (-1)^k \cdot (-\delta \varphi \cap \sigma + \varphi \cap \partial \sigma) \in C_{l-k-1}(X;R).$$

In particular this implies that $\varphi \cap \partial \sigma$ and $\delta \varphi \cap \sigma$ are homologous.

**Proof.** For $k > l$ the statement is trivial. So assume that $k \leq l$. Clearly it suffices to prove the equality for the case that $\sigma : \Delta^l \to X$ is a singular $l$-simplex. This case follows from an elementary calculation. Indeed, we have

$$\varphi \cap \partial \sigma = \sum_{i=0}^k (-1)^i \cdot \varphi(\sigma_0 [v_0, \ldots, \hat{v}_i, \ldots, v_k]) \cdot \sigma_0 [v_{k+1}, \ldots, v_l] + \sum_{i=k+1}^l (-1)^i \cdot \varphi(\sigma_0 [v_0, \ldots, v_k]) \cdot \sigma_0 [v_{k+1}, \ldots, \hat{v}_i, \ldots, v_l]$$

$$\delta \varphi \cap \sigma = \sum_{i=0}^{k+1} (-1)^i \cdot \varphi(\sigma_0 [v_0, \ldots, \hat{v}_i, \ldots, v_{k+1}]) \cdot \sigma_0 [v_{k+1}, \ldots, v_l]$$

$$(-1)^k \cdot \partial(\varphi \cap \sigma) = \sum_{i=k}^l (-1)^i \cdot \varphi(\sigma_0 [v_0, \ldots, v_k]) \cdot \sigma_0 [v_{k}, \ldots, \hat{v}_i, \ldots, v_l].$$

Note that the summand of (b) corresponding to $i = k + 1$ equals minus the summand of (c) corresponding to $i = k$. Adding (b) and (c) and comparing it to (a) we see that

$$\varphi \cap \partial \sigma = \delta \varphi \cap \sigma + (-1)^k \cdot \partial(\varphi \cap \sigma)$$

which gives the desired equality.

The following lemma says that “$\cap$” descends to a map on homology and cohomology.

**Lemma 83.2.** Let $X$ be a topological space and let $R$ be a commutative ring. Then for any $k, l \in \mathbb{N}_0$ the map

$$H^k(X;R) \times H_l(X;R) \to H_{l-k}(X;R)$$

$$([\varphi], [\sigma]) \mapsto [\varphi \cap \sigma]$$

is well-defined and $R$-bilinear.

We refer to the pairing from Lemma 83.2 as the *cap product*.\(^{1197}\)

**Proof.** For $k > l$ the statement is trivial. So assume that $k \leq l$. The statement now follows easily from Lemma 83.1. Indeed, let $\varphi \in C^k(X;R)$ be a cocycle and let $\sigma \in C_l(X;R)$ be a cycle.

(1) It follows from Lemma 83.1 that $\varphi \cap \sigma$ is a cycle, i.e. it represents a homology class.

---

\(^{1197}\)The name “cap product” comes from the notation “$a \cap b$” for the composition since $\cap$ looks like, just a little bit, like the “a” in cap. The other reason is that the cup product was first introduced, and mathematicians needed a different name for a somewhat related object. Also mathematicians are well-known for their great sense of humor.
(2) If \( \sigma' = \sigma + \partial \tau \) is another representative of \([\sigma]\), then
\[
\varphi \cap \sigma - \varphi \cap \sigma' = \varphi \cap (\sigma - \sigma') = \varphi \cap \partial \tau = \pm \partial (\varphi \cap \tau).
\]
by Lemma 83.1 and since \( \delta \varphi = 0 \)

This shows that \( \varphi \cap \sigma \) and \( \varphi \cap \sigma' \) represent the same homology class, i.e. the cap product does not depend on the choice of the representative of the homology class.

(3) The proof that the cap product does not depend on the choice of representative of the cohomology class is basically the same as the proof of (2).

This shows that the map is well-defined. It is clear that the map is indeed \( R \)-bilinear. □

**Remark.** We already saw on page 1981 that the definition of the cup product in the literature is not uniform. Rather depressingly, the situation is even worse for the cap product, there is an endless variety of definitions of the cap product in the literature. More precisely, given a cochain \( \varphi \in C^k(X; R) \) and a singular simplex \( \sigma: \Delta^l \to X \) the following definitions of \( \varphi \cap \sigma \) can be found in the literature:

| (a) | Hatcher [Hat02] p. 239 | \( \varphi(\sigma \circ [v_0, \ldots, v_l]) \cdot \sigma \circ [v_k, \ldots, v_l] \) |
| (b) | Bredon [Bre93] p. 335 | \((-1)^{k(l-k)} \cdot \varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, v_l] \) |
| (c) | Dold [Dol56] p. 335 | \((-1)^{k(l-k)} \cdot \sigma \circ [v_0, \ldots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \ldots, v_l]) \) |
| (d) | Spanier [Spa95] p. 254 | \( \sigma \circ [v_0, \ldots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \ldots, v_l]) \) |
| (e) | Munkres [Mun84] p. 389 | \( \sigma \circ [v_0, \ldots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \ldots, v_l]) \) |

To the best of my understanding, see [Spa95, p. 250], the singular chains

\[
\varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, v_l] \quad \text{and} \quad \varphi(\sigma \circ [v_0, \ldots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \ldots, v_l])
\]

are homologous. This shows that on the level of homology and cohomology groups the definition (a), which is also our definition, agrees with (c), but that the sign differs for (b), (d) and (e). For the most part this is not an issue, but one needs to be careful when one cites formulas from the literature. For example, as we had already mentioned on page 1821 Bredon [Bre93] defined the coboundary map as

\[
\delta^B_k := (-1)^{k+1} \cdot \partial^*_k = (-1)^{k+1} \cdot \delta_k
\]

and as we saw above, the cap product is also defined differently. Thus our Lemma 83.1 which says that for \( \varphi \in C^k(X; R) \) and \( \sigma: \Delta^l \to X \) we have

\[
\partial (\varphi \cap \sigma) = (-1)^k \cdot (\varphi \cap \partial \sigma - \delta \varphi \cap \sigma)
\]

becomes the following equality in [Bre93] Proposition VI.5.1:

\[
\partial (\varphi \cap \sigma) = (-1)^k \cdot \varphi \cap \partial \sigma + \delta^B (\varphi) \cap \sigma.
\]

---

\[\text{The definition of the cap product given by Greenberg-Harper in [GH81] p. 205 agrees with our definition, except, that they use a different notation, namely they cap a homology class with a cohomology class instead of capping a cohomology class with a homology class. In other words, in our setting they write } \sigma \cap \varphi \text{ instead of } \varphi \cap \sigma.\]

\[\text{The lesson you should draw is that if you ever have to write algebraic topology lectures notes, stick to a single book and do not try to mix books.}\]
The following lemma follows immediately from the definitions.

**Lemma 83.3.** Let $X$ be a topological space and let $R$ be a commutative ring. Then for any $\sigma \in H_k(X; R)$ we have

$$1_X \cap \sigma = \sigma.$$  

For future applications we state the special case $k = l$ in the cap product in the following lemma.

**Lemma 83.4.** Let $X$ be a topological space and let $R$ be a commutative ring.

1. The composition

$$H^k(X; R) \times H_k(X; R) \xrightarrow{\text{augmentation}} H_0(X; R) \xrightarrow{\text{from page 401}} R$$

is precisely the Kronecker pairing from pages 1847 and 1874.

2. If $X$ is path-connected, and if we make the usual identification $H_0(X; R) = R$ given by the augmentation map, see Proposition 41.5 then for any $\varphi \in H^k(X; R)$ and $\sigma \in H_k(X; R)$ we have

$$\varphi \cap \sigma = \langle \varphi, \sigma \rangle \in R.$$  

**Proof.** Both statements follow immediately from recalling all the relevant definitions. ■

**Example.** We consider some examples of the cap product in detail to get some feeling for what it does.

1. Let $T = S^1 \times S^1 = ([0, 1] \times [0, 1])/ \sim$ be the torus. We recall the following notations and results that we have by now used on many occasions. (We refer to Figure 1179 for some of the notation.)

   a. We denote by $\sigma_1, \sigma_2$ the singular 2-simplices from Figure 1179. As we pointed out on page 1717, the singular 2-chain $-\sigma_1 + \sigma_2$ is a representative of the fundamental class $[T]$.

   b. We denote by $p$ respectively $q$ the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor.

   c. We denote by $\theta := \theta \in C^1; \mathbb{Z})$ the singular 1-cocycle that we introduced on page 1825.

   d. As before we denote by $\mu: \Delta^1 \to S^1$ the singular 1-simplex that is given by $\mu(1-t, t) = e^{2\pi i t}$. By the discussion on page 1714 we know that $\mu$ represents the fundamental class $[S^1]$ of $S^1$ equipped with the standard orientation. By a slight abuse of notation we also denote by $[1 \times S^1]$ the image of the fundamental class under the monomorphism $H_1(1 \times S^1; \mathbb{Z}) \to H_1(S^1 \times S^1; \mathbb{Z})$.

We calculate that

$$p^*(\theta) \cap \sigma_1 = p^*(\theta)(\sigma_1 \circ [v_0, v_1]) \cdot \sigma_1 \circ [v_1, v_2] = 0$$

and similarly we calculate that

$$p^*(\theta) \cap \sigma_2 = p^*(\theta)(\sigma_2 \circ [v_0, v_1]) \cdot \sigma_2 \circ [v_1, v_2] = \sigma_2 \circ [v_1, v_2] = 1 \times \mu.$$
Putting these calculations together we obtain that
\[ [p^*(\theta)] \cap [T] = [q^*(\theta) \cap (-\sigma_1 + \sigma_2)] = [1 \times S^1]. \]

Basically the same calculation shows that
\[ [q^*(\theta)] \cap [T] = [q^*(\theta) \cap (-\sigma_1 + \sigma_2)] = -[S^1 \times 1]. \]

So we see that the map
\[ \cap [T] : H^1(T; \mathbb{Z}) \rightarrow H_1(T; \mathbb{Z}) \]

is non-trivial, in fact we have just shown that this map satisfies
\[ [p^*(\theta)] \mapsto [1 \times S^1] \]
\[ [q^*(\theta)] \mapsto -[S^1 \times 1] \]

which shows that “capping with the fundamental class” is in this case an isomorphism.

(2) In Exercise 83.2 we will deal with the surface \( \Sigma \) of genus 2 and there we will also see that the map
\[ \cap [\Sigma] : H^1(\Sigma; \mathbb{Z}) \rightarrow H_1(\Sigma; \mathbb{Z}) \]

is an isomorphism.

(3) Finally we consider again the real projective plane \( \mathbb{R}P^2 = \overline{B^2}/\sim \). We introduce the following notation:

(a) We denote by \( \varphi \in C^1(\mathbb{R}P^2; \mathbb{F}_2) \) the cocycle that we introduced on page 1998.

(b) We denote by \( \gamma : \Delta^1 \rightarrow \mathbb{R}P^2 = \overline{B^2}/\sim \) the singular 1-simplex that is given by \( \gamma(t, 1-t) = [e^{\pi i t}] \). Note that \( \gamma \) is a cycle in \( C_1(\mathbb{R}P^2) \) and note that \( \varphi(\gamma) = 1 \).

(c) In Figure 1064 we already saw a representative for the \( \mathbb{F}_2 \)-fundamental class, but we will work with a different one that is “smaller” and that is shown in Figure 1180. In Figure 1180 we see the singular 2-simplex \( \sigma \) that sends the face \([v_0, v_2]\) to a point \( P \) and the singular 2-simplex \( \tau \) that sends all points on \( \Delta^2 \) to \( P \). It is straightforward to see that \((\sigma + \tau) \otimes 1 \in C_2(\mathbb{R}P^2; \mathbb{F}_2)\) is a cycle. Using Proposition 68.18 we see that it represents the \( \mathbb{F}_2 \)-fundamental class of \( \mathbb{R}P^2 \).

It is straightforward to see that
\[ [\varphi] \cap [\mathbb{R}P^2] = [\varphi] \cap [(\sigma + \tau) \otimes 1] = \left[ \varphi \cap \sigma \otimes 1 + \varphi \cap \tau \otimes 1 \right] = [\gamma \otimes 1] \]
We saw on page 1998 that $[\gamma \otimes 1]$ is the unique non-trivial element of $H_1(\mathbb{R}P^2; F_2)$. Thus in this case we see that the map

$\wedge [\mathbb{R}P^2]: H^1(\mathbb{R}P^2; F_2) \to H_1(\mathbb{R}P^2; F_2)$

is also an isomorphism.

Remark. In the last three examples we saw for the closed 2-dimensional smooth manifolds $F = S^1 \times S^1$, $F = \Sigma$, $F = \mathbb{R}P^2$ and for $R = \mathbb{Z}$ respectively $R = \mathbb{F}_2$ that the map

$- \cap [F]_R: H^1(F; R) \to H_1(F; R)$

is an isomorphism. In Chapter 88 we will see that it is not a coincidence. More precisely we will see that this observation can be generalized to all closed topological manifolds.

83.2. The relative cap product and more properties of the cap product. After considering the various examples of the cap product we continue with developing the theory.

Similar to the case of the cup product, we intend to extend the notion of cap product to relative homology and cohomology groups. As in the case of the cup product it requires some delicate footwork to get to the right notion of a relative cap product. We start out with the following rather technical definition.

**Definition.** Let $(X, A, B)$ be a triad of topological spaces and let $R$ be a commutative ring. We write

$C_n(X, \{A, B\}; R) := \frac{C_n(X) \otimes R}{C_n\{A, B\}(A \cup B) \otimes R}.$

The boundary map on $C_\ast(X; R)$ descends to a boundary map on $C_\ast(X, \{A, B\}; R)$ which we can thus view as a chain complex. We denote the corresponding homology groups by $H_\ast(X, \{A, B\}; R)$.

This technical definition allows us to define a first version of a relative cap product.

**Lemma 83.5.** Let $(X, A, B)$ be a triad of topological spaces, let $k \leq l$ and let $R$ be a commutative ring. Then the map

$\cap: C^k(X; A; R) \times C_l(X, \{A, B\}; R) \to C_{l-k}(X, B; R)

(\varphi, [\sigma: \Delta^l \to X]) \mapsto [\varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_k, \ldots, v_l]]_{\in R}$

for $\varphi \in C^k(X; A; R)$ and $[\sigma: \Delta^l \to X] \in C_l(X, \{A, B\}; R)$.
is well-defined and it descends to a map
\[ \cap : H^k(X, A; R) \times H_\ell(X, \{A, B\}; R) \to H_{\ell-k}(X, B; R) \]
that is \( R \)-bilinear.

**Proof.** We first show that the cap product on (co-)chains is well-defined. By definition of
\[ C_n(X, \{A, B\}; R) := \frac{C_n(X) \otimes R}{C_n^{(A,B)}(A \cup B) \otimes R} = \frac{C_n(X) \otimes R}{C_n(A) \otimes R + C_n(B) \otimes R} \]
we have to show that if we are given a singular \( l \)-simplex \( \sigma : \Delta^l \to X \) such that

1. the image of \( \sigma \) lies in \( A \), or
2. the image of \( \sigma \) lies in \( B \),

then the product \( \varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_0, \ldots, v_k] \) is zero in \( C_{\ell-k}(X, B; R) \). But this is indeed the case:

1. first, if the image of \( \sigma \) lies in \( A \), then it follows immediately from the hypothesis that
   \( \varphi \) lies in \( C_k(X, A; R) \) that \( \varphi(\sigma \circ [v_0, \ldots, v_k]) = 0 \), and
2. if the image of \( \sigma \) lies in \( B \), then the image of \( \sigma \circ [v_0, \ldots, v_k] \) also lies in \( B \). Hence the term is zero in \( C_{\ell-k}(X, B; R) \).

This concludes the proof of the first part of the lemma.

The argument that the map on (co-)chain complexes descends to a map on the level of homology and cohomology groups is the same as in the proof of Lemma 83.2. It is obvious that the map \( \cap \) is \( R \)-bilinear. ■

Evidently we are not very interested in the group \( H_n(X, \{A, B\}; R) \). The following lemma allows us to replace this group by the much more agreeable group \( H_n(X, A \cup B; R) \), at least for reasonable triads.

**Lemma 83.6.** If \( (X, A, B) \) is an excisive triad of topological spaces, then given any commutative ring \( R \) the obvious map
\[ C_*(X, \{A, B\}; R) \to C_*(X, A \cup B; R) \]
induces for every \( n \in \mathbb{N}_0 \) an isomorphism
\[ H_*(X, \{A, B\}; R) \xrightarrow{\cong} H_*(X, A \cup B; R). \]

**Proof.** In the proof of Lemma 82.1 we already showed that the map
\[ C_*(X, \{A, B\}; \mathbb{Z}) \to C_*(X, A \cup B; \mathbb{Z}) \]
on chain complexes is a chain homotopy equivalence. By tensoring all maps and chain homotopies with \( R \) we see that the map
\[ C_*(X, \{A, B\}; R) \to C_*(X, A \cup B; R) \]
is also a chain homotopy equivalence. The second statement is then an immediate consequence of Corollary 42.3. ■

Lemma 83.6 leads to the following definition.
**Definition.** Let \((X, A, B)\) be an excisive triad of topological spaces, let \(k \leq l\) and let \(R\) again be a commutative ring. We refer to the map

\[
H^k(X; R) \times H_l(X, A; R) \xrightarrow{\sim} H^k(X, A; R) \times H_l(X, \{A, B\}; R) \xrightarrow{\sim} H_{l-k}(X, B; R)
\]

as the *cap product* (sometimes we refer to it as the *relative cap product*) that we also denote by “\(\cap\)”. For \(k > l\) we define the cap product to be the zero map.

**Remark.** In many examples, e.g. if \(A = \emptyset\), or \(B = \emptyset\) or \(A = B\), then the slightly mysterious first map in the definition of the cap product is just the identity. In particular, for any subset \(A\) of \(X\) we obtain cap products

\[
H^k(X; R) \times H_l(X, A; R) \xrightarrow{\cap} H_{l-k}(X, A; R)
\]

and

\[
H^k(X, A; R) \times H_l(X, A; R) \xrightarrow{\cap} H_{l-k}(X; R)
\]

and both of them are induced, on the (co-)chain level, by the formula

\[
(\varphi, \sigma: \Delta^l \to X) \mapsto \varphi(\sigma|_{[v_0, \ldots, v_k]} \cdot \sigma|_{[v_k, \ldots, v_l]}).
\]

This observation also shows that we can easily generalize Lemma [83.4] to the relative case in the obvious way. For example, if \(X\) is path-connected, and if we make the usual identification \(H_0(X; \mathbb{Z}) = \mathbb{Z}\) given by the augmentation map, see Proposition [41.5] then for any \(\varphi \in H^k(X, A; \mathbb{Z})\) and \(\sigma \in H_k(X, A; \mathbb{Z})\) we have

\[
\varphi \cap \sigma = \langle \varphi, \sigma \rangle \in \mathbb{Z}.
\]

For the record we point out that it follows from this observation and Lemma [75.16] that if \(M\) is a compact oriented path-connected \(n\)-dimensional topological manifold, then for any point \(P \in M\) we have

\[
[M]^* \cap [M] = [P]
\]

and \([M]^*\) is the only element in \(H^n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}\) that has that property.

**Example.** Let \(X = S^1 \times [0, 1]\) be the annulus. In Figure [1181] we show two singular 2-simplices \(\sigma_1, \sigma_2\). It follows easily from Proposition [68.4] that \(-\sigma_1 + \sigma_2\) represents the fundamental class \([X] \in H_2(X, \partial X; \mathbb{Z})\) of the annulus \(X\) with the usual orientation. We denote by \(p: X \to [0, 1]\) the projection map. As on page [1830] we consider the function

\[
f: [0, 1] \to \mathbb{Z}
\]

\[
x \mapsto \begin{cases} 
0, & \text{if } x \in [0, \frac{1}{2}) \\
1, & \text{otherwise}
\end{cases}
\]

which we use to define the singular 1-cochain

\[
\rho: C_1([0, 1]) \to \mathbb{Z}
\]

\[
(\sigma: \Delta^1 \to [0, 1]) \mapsto f(\sigma(0)) - f(\sigma(1)).
\]
It follows from the discussion on page 1830 that $p^*(\rho) \in C^1(X, \partial X; \mathbb{Z})$ is a cochain, thus it represents an element in $H^1(X, \partial X; \mathbb{Z})$. We calculate that

$$[p^*(\rho)] \cap \sigma_1 = p^*(\sigma_1 \circ [v_0, v_1]) \cdot \sigma_1 \circ [v_1, v_2] = [S^1 \times 1]$$

$$[p^*(\rho)] \cap \sigma_2 = p^*(\sigma_2 \circ [v_0, v_1]) \cdot \sigma_2 \circ [v_1, v_2] = 0.$$ 

Adding up we see that

$$[p^*(\rho)] \cap [X] = [p^*(\rho) \cap (-\sigma_1 + \sigma_2)] = -[S^1 \times 1].$$

Since the inclusion $S^1 \times 1 \to X$ is a homotopy equivalence we see that $H_1(X; \mathbb{Z}) \cong \mathbb{Z}$ and that $[S^1 \times 1]$ is a generator. A straightforward argument, e.g. using the long exact sequence of the pair $(X, \partial X)$, shows that $H^1(X, \partial X; \mathbb{Z}) \cong \mathbb{Z}$. The above calculation thus shows that the map

$$H^1(X, \partial X; \mathbb{Z}) \to H_1(X; \mathbb{Z})$$

$$\varphi \mapsto \varphi \cap [X]$$

is an epimorphism. Since both groups are isomorphic to $\mathbb{Z}$ we see that the map is in fact an isomorphism and as a bonus we obtain that $[\rho] \in H^1(X, \partial X; \mathbb{Z})$ is a generator. In Exercise 83.3 we will show that the map

$$H^1(X; \mathbb{Z}) \to H_1(X, \partial X; \mathbb{Z})$$

$$\varphi \mapsto \varphi \cap [X]$$

is also an isomorphism.

![Figure 1181](image-url)

The following lemma relates the cup product to the cap product.

**Lemma 83.7.** Let $X$ be a topological space and let $R$ be a commutative ring.

1. Let $\varphi \in C^k(X; R)$, $\psi \in C^l(X; R)$ and let $\sigma \in C_n(X; R)$. Then

$$\varphi \cap (\psi \cap \sigma) = (\psi \cup \varphi) \cap \sigma \in C_{n-k-l}(X; R).$$

2. If $A \subset X$ is a subset and $C, D \in \{\emptyset, A\}$ we have for any $\varphi \in H^k(X, C; R)$, any $\psi \in H^l(X, D; R)$ and any $\sigma \in H_n(X, C \cup D; R)$ that

$$\varphi \cap (\psi \cap \sigma) = (\psi \cup \varphi) \cap \sigma \in H_{n-k-l}(X; R).$$
(3) If \( A \subset X \) is a subset and \( C, D \in \{\emptyset, A\} \) we have for any \( \varphi \in H^k(X, C; R) \), any \( \psi \in H^l(X, D; R) \) and any \( \sigma \in H_{k+l}(X, C \cup D; R) \) that
\[
\langle \varphi, \psi \cap \sigma \rangle = \langle \psi \cup \varphi, \sigma \rangle \in R.
\]

**Proof.** The case \( k + l > n \) is trivial. So suppose that \( k + l \leq n \).

(1) So let \( \varphi \in C^k(X; R) \), \( \psi \in C^l(X; R) \). It suffices to consider the case that \( \sigma: \Delta^n \to X \)
is a singular \( n \)-simplex. We have
\[
\varphi \cap (\psi \cap \sigma) = \varphi \cap (\psi(\sigma \circ [v_0, \ldots, v_l]) \cdot \sigma \circ [v_l, \ldots, v_n]) = \psi(\sigma \circ [v_0, \ldots, v_l]) \cdot \varphi \cap (\sigma \circ [v_l, \ldots, v_n]) = (\psi \cup \varphi)(\sigma \circ [v_l, \ldots, v_{l+k}]) \cdot \sigma \circ [v_{l+k}, \ldots, v_n] = (\psi \cup \varphi) \cap \sigma.
\]

(2) The statement regarding the (co-) homology classes follows almost immediately from the above result on (co-) chains obtained in (1).

(3) This statement follows immediately from (2) together with Lemma 83.4.

Now suppose we are given a map of excisive triads of topological spaces. We get induced maps on homology and cohomology and the following lemma tells us the relationship of these induced maps and the cap product.

**Lemma 83.8.** Let \( R \) be a commutative ring.

(1) If \( f: (X, A, B) \to (\tilde{X}, \tilde{A}, \tilde{B}) \) is a map between two excisive triads, then for any \( k, l \in \mathbb{N}_0 \) the following diagram commutes:
\[
\begin{array}{ccc}
H^k(X, A; R) \times H_l(X, A \cup B; R) & \xrightarrow{f^* \times \text{id}} & H_l(X, B; R) \\
\downarrow f^* & & \downarrow f^*
\end{array}
\]

\( i.e. \) for any \( \varphi \in H^k(\tilde{X}, \tilde{A}; R) \) and any \( \sigma \in H_l(X, A \cup B; R) \) we have
\[
\varphi \cap f_*(\sigma) = f_*(f^*(\varphi) \cap \sigma) \in H_{l-k}(\tilde{X}, \tilde{B}; R).
\]

(2) Let \( X \) and \( \tilde{X} \) be path-connected topological spaces and let \( B \subset X \) and \( \tilde{B} \subset \tilde{X} \) be subsets. If \( f: (X, B) \to (\tilde{X}, \tilde{B}) \) is a map, then for any \( \varphi \in H^k(\tilde{X}, \tilde{B}; R) \) and any

\[\text{Note that on the right-hand side it says } (\psi \cup \varphi) \cap \sigma \text{ instead of } (\varphi \cup \psi) \cap \sigma. \text{ In fact if one picks a different sign convention for the cap product this sign goes away. For example with the sign conventions used by Bredon, see [Bre93, Chapter 5], the equation becomes}
\]
\[\varphi \cap (\psi \cap \sigma) = (\varphi \cup \psi) \cap \sigma
\]

which looks much more appealing. Once we consider (co-) homology classes we obtain from Proposition 81.8 that the difference between these two expressions \((\psi \cup \varphi) \cap \sigma\) and \((\varphi \cup \psi) \cap \sigma\) is just a factor of \((-1)^{kl}.\)
\[ \sigma \in H_k(X, B; R) \text{ we have} \]
\[ \varphi \cap f_*(\sigma) = f^*(\varphi) \cap \sigma \in H_0(X; R) = R = H_0(\tilde{X}; R). \]

**Remark.** Note that by Lemma 83.4 (1) we can view the above as a generalization of Lemma 74.6 (3).

**Proof.** The first statement follows immediately from the definitions. We leave the details to the skeptical reader. The second statement is an immediate consequence of the first statement. ■

The next lemma says that cup and cap products behave in the obvious way with respect to the path-components. The statements in the lemma follow easily from the definitions. Therefore we leave the proof of the lemma to the reader.

**Lemma 83.9.** Let \( \ast \) denote the path-components of \( X \). By Lemmas 41.14 and 73.14 the inclusion maps \( \iota_j : X_j \to X \), \( j \in J \), induce for any \( n \in \mathbb{N}_0 \) isomorphisms
\[
\Phi := \bigoplus_{j \in J} \iota_j^* : \bigoplus_{j \in J} H_n(X_j; G) \xrightarrow{\cong} H_n(X; G)
\]
and
\[
\Psi := \prod_{j \in J} \iota_j^* : \prod_{j \in J} H^n(X_j; G) \xrightarrow{\cong} \prod_{j \in J} H^n(X_j; G).
\]

Then the following two statements hold:

1. For any \( i \neq j \) and any \( \alpha \in H^m(X_i; R) \) and \( \beta \in H^n(X_j; R) \) we have
\[
\Psi^{-1}(\alpha) \cup \Psi^{-1}(\beta) = 0.
\]
2. For any \( i \neq j \) and any \( \alpha \in H^m(X_i; R) \) and \( \beta \in H_n(X_j; R) \) we have
\[
\Psi^{-1}(\alpha) \cap \Phi(\beta) = 0.
\]

The same type of statements hold for cup and cap products on relative (co-) homology groups.

In the next lemma of the chapter we relate the relative cap product to (co-) boundary maps on (co-) homology. More precisely, we have the following lemma which is similar in spirit to Lemma 82.6.

\[ \text{Here “the diagram commutes” is understood in the sense of the convention from page 2007.} \]
Lemma 83.10. Let $R$ be a commutative ring.

(1) Let $(X, B, A)$ be a triple of topological spaces. For any $n, k \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
H^k(B, A; R) \times H_{n-1}(B, A; R) & \xrightarrow{\cap} & H_{n-k-1}(B; R) \\
\downarrow \delta & & \downarrow i_* \\
H^{k+1}(X, B; R) \times H_n(X, B; R) & \xrightarrow{\cap} & H_{n-k-1}(X; R).
\end{array}
$$

Here $i : B \to X$ denotes the inclusion map and $\delta$ and $\partial$ denote the connecting homomorphisms in the long exact sequences in (co-)homology corresponding to the triple $(X, B, A)$.

(2) Let $(X, A, B)$ be an excisive triad and let $n \in \mathbb{N}_0$. Note that by Lemma 74.13 the map $j : H_{n-1}(B, A \cap B; R) \to H_{n-1}(A \cup B, A; R)$ is an isomorphism. For any $k \in \mathbb{N}_0$ the following diagram commutes up to the sign $(-1)^{k+1}$:

$$
\begin{array}{ccc}
H^k(X, A; R) \times H_n(X, A \cup B; R) & \xrightarrow{\cap} & H_{n-k}(X, B; R) \\
\downarrow i^* & & \downarrow \partial \\
H^k(A \cup B, A; R) \times H_{n-1}(A \cup B, A; R) & \xrightarrow{\cap} & H_{n-k-1}(B, A \cap B; R) \\
\downarrow j^* \cong & & \downarrow (j_*)^{-1} \cong \\
H^k(B, A \cap B; R) \times H_{n-1}(B, A \cap B; R) & \xrightarrow{\cap} & H_{n-k-1}(B; R).
\end{array}
$$

Here $i : (A \cup B, A) \to (X, A)$ and $j : (B, A \cap B) \to (A \cup B, A)$ denote the inclusion maps and $\partial$ denotes the connecting homomorphisms in the long exact sequences in homology corresponding to the triple $(X, A \cup B, A)$ respectively the pair $(X, B)$.

**Proof (**)**

1. We pick $\psi \in H^k(B, A; R)$ and $\tau \in H_n(B, A; R)$. We make the following observations:

   a. We can find $\sigma \in C_n(B; R)$ such that the image of $\sigma$ in $C_n(B, A; R)$ is a cycle that represents $\tau$.

   b. We can pick a singular cochain $\varphi \in C^k(B; R) = \text{Hom}(C_k(B), R)$ that vanishes on $C_k(A)$ and such that the corresponding element in $C^k(B, A; R)$ represents $\psi$.

   We denote by $\tilde{\varphi} : C_k(X) \to R$ the extension of $\varphi$ that is defined to be zero on all singular $k$-simplices that do not lie in $B$.

   We have the following equalities:

   $$
   \delta \psi \cap \tau = [\delta \tilde{\varphi} \cap [\delta \varphi \cap \sigma] = [\tilde{\varphi} \cap \partial \sigma] = [\varphi \cap \partial \sigma] = [\varphi \cap [\partial \sigma] = \psi \cap \partial \tau.
   $$

   See Lemma 83.13 and the discussion on page 1833 for the classes $\delta \varphi \cap \sigma$ and $\varphi \cap \partial \sigma$ are homologous.

   This equality implies that the diagram commutes.\textsuperscript{1202}

\textsuperscript{1202}With the various quotient groups, lifts, extensions, inclusions and so on it is admittedly quite tricky to figure out in between where any of the equalities hold.
(2) We pick $\psi \in \text{H}^k(X, A; R)$ and $\tau \in \text{H}_n(X, A \cup B; R)$. We make the following observations:

(a) It follows immediately from our hypothesis that the triad $(X, A, B)$ is excisive together with Lemma 83.6 that we can find $\sigma \in \text{C}_n(X; R)$ such that $\partial \sigma = \alpha + \beta$ with $\alpha \in \text{C}_{n-1}(A; R)$ and $\beta \in \text{C}_{n-1}(B; R)$ and such that the image of $\sigma$ in $\text{C}_n(X, A \cup B; R)$ is a cycle that represents $\tau$.

(b) As on page 2031 we make the identification

$$
C^k(X, A; R) \xrightarrow{\sim} \text{all homomorphisms } C_k(X) \rightarrow R \text{ that vanish on } C_k(A).
$$

We can pick a singular cochain $\varphi \in C^k(X; R) = \text{Hom}(C_k(X), R)$ that vanishes on $C_k(A)$ and such that the corresponding element in $C^k(X, A; R)$ is a cocycle that represents $\psi$. Note that $\delta \varphi = 0$.

We have the following equalities:

\[
\begin{align*}
\partial(\psi \cap \tau) &= \partial([\varphi \cap \sigma]) = [\partial(\varphi \cap \sigma)] \\
&= (-1)^k \cdot [\varphi \cap \alpha + \varphi \cap \beta] \\
&= (-1)^k \cdot [(j^*i^*\varphi) \cap j_*^{-1}(\partial[\sigma])].
\end{align*}
\]

This equality implies that the diagram commutes. ■

As we had mentioned before, a frequently used trick in the study of topological manifolds is to replace a topological manifold with non-empty boundary by its double. When doing this trick the following lemma can at times be useful.

\textbf{Lemma 83.11.} Let $M$ be a topological manifold. We denote by $r: DM \rightarrow M$ the folding map from page 1164 and given $l \in \mathbb{N}_0$ we denote by $D: \text{H}_l(M, \partial M; \mathbb{Z}) \rightarrow \text{H}_l(DM; \mathbb{Z})$ the doubling homomorphism that we introduced in Lemma 44.16. Then for any $\phi \in \text{H}^k(M; \mathbb{Z})$ and any $\sigma \in \text{H}_l(M, \partial M; \mathbb{Z})$ we have

$$
r^* \phi \cap D(\sigma) = D(\phi \cap \sigma) \in \text{H}_{l-k}(DM; \mathbb{Z}).
$$

\textbf{Proof.} We will show that the desired equality actually holds already on the (co-) chain level. So let $\phi \in C^k(M; \mathbb{Z})$ and let $\sigma: \Delta^l \rightarrow M$ be a singular $l$-simplex. If $k > l$, then both sides of the lemma are trivially zero. Hence we can assume that $k \leq l$. For $i = 1, 2$ we
denote by \( j_i : M \to M \times \{i\} \subset DM \) the obvious map. Then

\[
\text{by definition of } D(\sigma) \quad \text{since } \cap \text{ is bilinear} \\
\]

\[
r^* \phi \cap D(\sigma) = r^* \phi \cap (j_1 \circ \sigma - j_2 \circ \sigma) = r^* \phi \cap j_1 \circ \sigma - r^* \phi \cap j_2 \circ \sigma \\
= \phi((r \circ j_1 \circ \sigma \circ [v_0, \ldots, v_k]) \circ [v_k, \ldots, v_l]) - \phi((r \circ j_2 \circ \sigma \circ [v_0, \ldots, v_k]) \circ j_2 \circ \sigma \circ [v_k, \ldots, v_l]) \\
\]

\[
\text{definition of cap product and definition of } r^* \phi \\
= \phi(\sigma \circ [v_0, \ldots, v_k]) \circ j_1 \circ (\sigma \circ [v_k, \ldots, v_l]) - \phi(\sigma \circ [v_0, \ldots, v_k]) \circ j_2 \circ (\sigma \circ [v_k, \ldots, v_l]) \\
\]

\[
= j_{1*}(\phi \cap \sigma) - j_{2*}(\phi \cap \sigma) = D(\phi \cap \sigma). \\
\]

\[
\text{definition of } j_{1*}, j_{2*} \text{ and the cap product} 
\]

---

**Exercises for Chapter 83**

**Exercise 83.1.** Let \( X = S^1 \vee S^2 \). We denote by \( p : X \to S^1 \) and \( q : X \to S^2 \) the obvious projection maps and we denote by \( i : S^1 \to X \) and \( j : S^2 \to X \) the obvious inclusion maps. Determine \( p^*([\theta_2]) \cap j_*([S^2]) \).

**Exercise 83.2.** We denote by \( \Sigma \) the surface of genus two. Furthermore we denote by \( p_1, p_2 : \Sigma \to T = S^1 \times S^1 \) the two projection maps and we denote by \( p, q : S^1 \times S^1 \to S^1 \) the projection onto the first respectively the second factor. As usual we write \( \alpha = p^*(\theta) \) and \( \beta = q^*(\theta) \). We saw that \( [p_1^*(\alpha)], [p_1^*(\beta)], [p_2^*(\alpha)], [p_2^*(\beta)] \) form a basis for \( H_1(\Sigma; \mathbb{Z}) \). Furthermore we denote by \( x_0, y_1, x_2, y_2 \in H_1(\Sigma; \mathbb{Z}) \) the standard basis. For each of the four basis elements of \( H_1(\Sigma; \mathbb{Z}) \) determine the cap product with \( [\Sigma] \) in terms of the basis for \( H_1(\Sigma; \mathbb{Z}) \).

**Remark.** This exercise is not as bad as it might sound initially.

**Exercise 83.3.** We consider the annulus \( X = S^1 \times [0, 1] \). Determine the following map:

\[
H^1(X; \mathbb{Z}) \to H_1(X, \partial X; \mathbb{Z}) \\
\varphi \mapsto \varphi \cap [X] \\
\]

More precisely, give a basis for \( H^1(X; \mathbb{Z}) \) and \( H_1(X, \partial X; \mathbb{Z}) \) and express the map \( - \cap [X] \) in terms of that basis.

**Exercise 83.4.** Let \( X \) be a topological space and let \( k, l \in \mathbb{N}_0 \). We consider the cohomology with compact support group \( H^k_c(X; \mathbb{Z}) \) and as in Exercise 87.5 we consider the group

\[
\tilde{H}_l(X; \mathbb{Z}) := \lim_{\to} H_n(X, X \setminus K; G), \\
\]

\[
\cap : H^k_c(X; \mathbb{Z}) \times \tilde{H}_l(X; \mathbb{Z}) \to H_{l-k}(X; \mathbb{Z}) \\
\]

that equals the usual cap product if \( X \) is compact.

**Remark.** Use the description of cohomology with compact support that is provided by Proposition 77.4.
84. The Product Theorem and the Künneth Theorem for Cohomology

In this chapter we will deal with the cup and cap product of product topological spaces. In particular at the end of the chapter we will have determined the cup product of the product $S^n \times S^n$ of two spheres and of the $n$-dimensional torus $(S^1)^n$. Furthermore we will have determined the Lusternik-Schnirelmann category of the $n$-dimensional torus.

84.1. The Product Theorem. The following theorem relates the cross product to the cap product and the cup product.

**Theorem 84.1. (Product Theorem)** Let $(X, A)$ and $(Y, B)$ be two pairs of topological spaces such that the triad $(X \times Y, A \times Y, X \times B)$ is excisive. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the obvious projection maps. Furthermore let $A_1, A_2 \in \{\emptyset, A\}$ and let $B_1, B_2 \in \{\emptyset, B\}$. Then for any $\alpha \in H^k(X, A_1; \mathbb{Z})$, $\mu \in H_m(X, A_1 \cup A_2; \mathbb{Z})$, $\beta \in H^l(Y, B_1; \mathbb{Z})$ and $\nu \in H_n(Y, B_1 \cup B_2; \mathbb{Z})$ we have the equality

$$(p^*\alpha \cup q^*\beta) \cap (\mu \times \nu) = (-1)^{\deg(\alpha) \cdot \deg(\beta) + \deg(\beta) \cdot \deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu)$$

in $H_{m+n-k-l}(X \times Y, X \times B_2 \cup A_2 \times Y; \mathbb{Z})$.

**Remark.** Even though the equality in the Product Theorem 84.1 is easy to write down, it is much harder to figure out in which (co-) homology groups the various objects actually live. In fact the equality is understood as follows:

$$\left\langle \begin{array}{c}
p^*\alpha \\
q^*\beta \\
\mu \\
\nu \\
\end{array} \right\rangle \cap \left\langle \begin{array}{c}X \\
X \times Y \\
X \\
X \times Y \\
\end{array} \right\rangle = (-1)^{\deg(\alpha) \cdot \deg(\beta) + \deg(\beta) \cdot \deg(\mu)} \cdot \left\langle \begin{array}{c}
\alpha \cap \mu \\
\beta \cap \nu \\
X \times Y \\
X \times Y \\
\end{array} \right\rangle$$

in $H_{m+n-k-l}(X \times Y, X \times B_2 \cup A_2 \times Y; \mathbb{Z})$.

In this formula we have to ensure that all products are in fact defined. This follows easily from Proposition 74.12 our hypothesis that $A_1, A_2 \in \{\emptyset, A\}$ and $B_1, B_2 \in \{\emptyset, B\}$ and our hypothesis that the triad $(X \times Y, A \times Y, X \times B)$ is excisive.

**Remark.**

1. The condition in the Product Theorem 84.1 that the triad $(X \times Y, A \times Y, X \times B)$ needs to be excisive is arguably a little awkward. By Proposition 74.12 this condition is satisfied if we are in one of the following situations:
   (a) $A = \emptyset$ or $B = \emptyset$,
   (b) $(X, A)$ and $(Y, B)$ are pairs of CW-complexes.

---

1203 By $A_1, A_2 \in \{\emptyset, A\}$ we mean that $A_1 = \emptyset$ or $A_1 = A$ and that $A_2 = \emptyset$ or $A_2 = A$.

1204 Here, and throughout this section, we denote by $p$ also the map of pairs $(X \times Y, A \times Y) \to (X, A)$ given by projection onto the first factor and we denote by $q$ the map of pairs $(X \times Y, X \times B) \to (Y, B)$ given by projection onto the second factor.
(c) \((X,A) = (X,\partial X)\) and \((Y,B) = (Y,\partial Y)\) where \(X\) and \(Y\) are topological manifolds. \(\textcolor{red}{1204}\)

(d) \(A\) and \(B\) are open subsets of \(X\) respectively \(Y\).

(2) In fact a more general statement of the Product Theorem 84.1 holds if we deal with excisive triads \((X, A_1, A_2)\) and \((Y, B_1, B_2)\) and \((\co-\text{homology classes} \; \alpha \in H^k(X;A_1;\mathbb{Z}), \mu \in H_m(X;A_2;\mathbb{Z})\), \(\beta \in H^l(Y;B_1;\mathbb{Z})\) and \(\nu \in H_n(Y;B_2;\mathbb{Z})\). But some care needs to be taken to see which other triads need to be excisive to ensure that all the cap and cup products are defined. We will not attempt to formulate this more general statement and we will not make use of it. (See also \textcolor{red}{Bre93} p. 240 and p. 244\) for a few more details.)

(3) The cross product is defined the same way in all of the usual text books in algebraic topology. But we saw on pages \textcolor{red}{1981} and \textcolor{red}{2021} that in the literature different sign conventions are used for the cup product and the cap product. These also lead to different formulations of the Product Theorem 84.1. More precisely, given topological spaces \(X\) and \(Y\) and \(\alpha \in H^k(X;\mathbb{Z})\), \(\mu \in H_m(X;\mathbb{Z})\), \(\beta \in H^l(Y;\mathbb{Z})\) and \(\nu \in H_n(Y;\mathbb{Z})\) the following equations can be found in the literature:

\[
\begin{align*}
&\text{[Bre93] p. 337} \quad (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\beta) \cdot \deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu) \\
&\text{[Do56] p. 240} \quad (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\beta) \cdot \deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu) \\
&\text{[Spa95] p. 255} \quad (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\alpha) \cdot (\deg(\nu) - \deg(\beta))} \cdot (\alpha \cap \mu) \times (\beta \cap \nu).
\end{align*}
\]

With the aforementioned sign conventions the formulas of Dold and Spanier are consistent with our formula, whereas the formula of Bredon differs from the formula of Dold and Spanier by the term \((-1)^{\deg(\alpha) \cdot \deg(\nu) + \deg(\beta) \cdot \deg(\mu)}\). \(\textcolor{red}{1205}\)

(4) The conclusion of the Product Theorem 84.1 also holds, with verbatim the same proof, if throughout we replace \(\mathbb{Z}\)-coefficients by \(\mathbb{F}_2\)-coefficients.

The proof of the Product Theorem 84.1 is somewhat lengthy and technical. Therefore we first discuss some consequences of Theorem 84.1 which will then hopefully convince us that it is worth the effort to prove Theorem 84.1.

The following is one of the key calculations of the cup product and the cap product. As we will see later, many other calculations can be reduced to this calculation.

\textbf{Proposition 84.2.} Let \(X\) be a compact oriented connected \(m\)-dimensional topological manifold and let \(Y\) be a compact oriented connected \(n\)-dimensional topological manifold.

\(\textcolor{red}{1205}\)Let \(X\) be an \(m\)-dimensional topological manifold and let \(Y\) be an \(n\)-dimensional smooth manifold. It follows from Propositions 80.9 and 44.2 that \(W := \partial(X \times Y) = \partial X \times Y \cup X \times \partial Y\) is an \((m+n-1)\)-dimensional topological manifold. It is straightforward to verify that \(\partial X \times Y\) and \(X \times \partial Y\) are submanifolds of \(W\) such that

\[
(\partial X \times Y) \cap (X \times \partial Y) = \partial X \times \partial Y = \partial(\partial X \times Y) = \partial(X \times \partial Y).
\]

Therefore it follows from Proposition 74.12(5) that the triad \((X \times Y, \partial X \times Y, X \times \partial Y)\) is excisive. \(\textcolor{red}{1206}\) Mathematicians with a long experience of teaching cohomology group sidestep all issues with signs by working with \(\mathbb{F}_2\)-coefficients, see \textcolor{red}{Hau14}.

\(\textcolor{red}{1207}\)We leave it to the never-flagging enthusiasm of the reader to figure out whether the formulas agree with the one given by Greenberg-Harper \textcolor{red}{[CH81]} p. 262.]
We denote by \( p: X \times Y \to X \) and \( q: X \times Y \to Y \) the obvious projection maps. Then the following two statements hold:

\[
\begin{align*}
(1) & \quad p^*([X]^*) \cup q^*([Y]^*) = [X \times Y]^*.
\end{align*}
\]

\[
\begin{align*}
(2) & \quad \text{If } P \in X \text{ and } Q \in Y \text{ are points, then }\n\end{align*}
\]

\[
\begin{align*}
& \quad p^*([X]^*) \cap [X \times Y] = ([P] \times Y)
\end{align*}
\]

\[
\begin{align*}
& \quad q^*([Y]^*) \cap [X \times Y] = (-1)^{mn} \cdot [X \times \{Q\}].
\end{align*}
\]

Remark. As we pointed out above, the conclusion of the Product Theorem also holds if we work with \( \mathbb{F}_2 \)-coefficients. It follows easily that there is also an \( \mathbb{F}_2 \)-coefficient analogue of Proposition 84.2.

Example. If we apply Proposition 84.2 (2) to \( X = S^1 \) and \( Y = S^1 \) we see that

\[
p^*([S^1]^*) \cap [S^1 \times S^1] = [1 \times S^1] \quad \text{and} \quad q^*([S^1]^*) \cap [S^1 \times S^1] = -[S^1 \times 1].
\]

This matches our down-to-earth calculation from page 2023.

Proof. Let \( X \) be a compact oriented connected \( m \)-dimensional topological manifold and let \( Y \) be a compact oriented connected \( n \)-dimensional topological manifold. Furthermore let \( P \) be a point in \( X \) and let \( Q \) be a point in \( Y \). We start out with the following two observations:

(a) For any compact oriented connected \( k \)-dimensional topological manifold \( M \) and any point \( R \in M \) we obtain from the discussion on page 2026 that \([M]^* \cap [M] = [R]\)

and that \([M]^*\) is the unique element in \( H^k(M, \partial M; \mathbb{Z}) \cong \mathbb{Z} \) with \([M]^* \cap [M] = [R]\) in \( H_0(M; \mathbb{Z}) = \mathbb{Z} \cdot [R] \).

(b) By Proposition 80.10 we have \([X \times Y] = [X] \times [Y]\).

\[\text{\footnotesize\cite{1206}}\]

Here we use the following suggestive notation: We can view \( \{P\} \times Y \) as a submanifold of \( X \times Y \). It is canonically homeomorphic to \( Y \), thus we can view \( \{P\} \times Y \) as a compact oriented topological manifold. We denote by \([\{P\} \times Y]\) its fundamental class, and by a slight abuse of notation we also denote by \([\{P\} \times Y]\) the image of the fundamental class under the inclusion \( \{P\} \times Y \to X \times Y \).
Now we turn to the actual proof of the two statements.

(1) We perform the following calculation in $H_0(X \times Y; \mathbb{Z})$:

$$
(p^*([X]^*) \cup q^*([Y]^*)) \cap ([X \times Y]) = (p^*([X]^*) \cup q^*([Y]^*)) \cap ([X] \times [Y])
$$

observation (b)

$$
= (-1)^{mn+mn} \cdot ([X]^* \cap [X]) \times ([Y]^* \cap [Y]) = [P] \times [Q] = ([P, Q])
$$

by Theorem 84.1 applied to $(X, A_1, A_2) = (X, \partial X, \partial X)$

and $(Y, B_1, B_2) = (Y, \partial Y, \partial Y)$

This implies, by observation (a), that $p^*([X]^*) \cup q^*([Y]^*) = [X \times Y]^*$.

(2) Let $P \in X$. Then

$$p^*([X]^*) \cap ([X \times Y]) = (p^*([X]^*) \cup q^*([1_Y])) \cap ([X] \times [Y])
$$

by Proposition 82.4 (1) we have $q^*([1_Y]) = [X \times Y]$ and by observation (b) we have $[X \times Y] = [X] \times [Y]$

$$= ([X]^* \cap [X]) \times (1_Y \cap [Y]) = [P] \times [Y] = ([P] \times [Y])
$$

by Lemma 80.7 (2) and observation (a)

This proves the first equality of (2). Now let $Q \in Y$. Then, very similar to the above, we have

$$q^*([Y]^*) \cap ([X \times Y]) = (p^*([1_X] \cup q^*([Y]^*))) \cap ([X] \times [Y])
$$

$$= (-1)^{mn} \cdot (1_X \cap [X]) \times ([Y]^* \cap [Y])
$$

$$= (-1)^{mn} \cdot [X] \times [Q] = (-1)^{mn} \cdot [X \times \{Q\}].$$

Using Proposition 84.2 (1) we can now easily compute the cup product of the product $S^m \times S^n$ of two spheres.

**Lemma 84.3.** Let $m, n \in \mathbb{N}$. We denote by $p: S^m \times S^n \to S^m$ and by $q: S^m \times S^n \to S^n$ the two obvious projection maps. Let $1 \in H^0(S^m \times S^n; \mathbb{Z})$ be the neutral element from Proposition 81.7.

(1) The cohomology of $S^m \times S^n$ is given as follows:

$$H^*(S^m \times S^n; \mathbb{Z}) = \mathbb{Z} \cdot 1 \oplus \mathbb{Z} \cdot p^*([S^m]^*) \oplus \mathbb{Z} \cdot q^*([S^n]^*) \oplus \mathbb{Z} \cdot [S^m \times S^n]^*.$$

(2) The multiplication table for the cup product is given by

<table>
<thead>
<tr>
<th>\</th>
<th>$p^<em>([S^m]^</em>)$</th>
<th>$q^<em>([S^n]^</em>)$</th>
<th>$[S^m \times S^n]^*$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1$</td>
<td>$p^<em>([S^m]^</em>)$</td>
<td>$q^<em>([S^n]^</em>)$</td>
<td>$[S^m \times S^n]^*$</td>
</tr>
<tr>
<td>$p^<em>([S^m]^</em>)$</td>
<td>$[S^m \times S^n]^*$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
<tr>
<td>$q^<em>([S^n]^</em>)$</td>
<td>$[S^m \times S^n]^*$</td>
<td>$(-1)^{mn} \cdot [S^m \times S^n]^*$</td>
<td>$0$</td>
</tr>
<tr>
<td>$[S^m \times S^n]^*$</td>
<td>$[S^m \times S^n]^*$</td>
<td>$0$</td>
<td>$0$</td>
</tr>
</tbody>
</table>

Here the table shows the cup product of the term in the first column with the term in the first row (and not the other way round).

**Remark.**
(1) For $m = n = 1$, i.e. for the torus $S^1 \times S^1$ we had calculated the cup product in Lemma 81.14.

(2) If we use Proposition 84.2 (1) with $\mathbb{F}_2$-coefficients then we can also determine the cup product on $H^*(S^m \times S^n; \mathbb{F}_2)$ and we obtain basically the same result.

**Proof.**

(1) Using Proposition 43.4 the Künneth Theorem 58.8 for topological spaces and the Universal Coefficient Theorem 75.13 for Cohomology Groups one can easily determine the isomorphism type of $H^*(S^m \times S^n; \mathbb{Z})$. Furthermore, using Lemma 74.7 and the homology classes given by the fundamental classes of $S^m$, $S^n$ and $S^m \times S^n$ it is straightforward to verify that the given cohomology classes do indeed form a basis for $H^*(S^m \times S^n; \mathbb{Z})$.

(2) By Observation 81.13 it remains to show that the red-colored and the blue-colored entries are correct.

(a) First we consider the red-colored entries. We have

$$ p^*([S^m]^*) \cup p^*([S^n]^*) = p^*([S^m]^* \cup [S^n]^*) = p^*(0) = 0. $$

The same argument also shows that $q^*([S^n]^*) \cup q^*([S^n]^*) = 0$.

(b) We turn to the blue-colored entries. We calculate that

$$ (-1)^{mn} \cdot q^*([S^n]^*) \cup p^*([S^m]^*) = p^*([S^m]^* \cup q^*([S^n]^*) = [S^m \times S^n]^*. $$

**Figure 1183**

The following lemma is much deeper than the above discussions.

---

1209 How can you prove rigorously that given any point $Q \in S^2 \times S^2$ the complement $S^2 \times S^2 \setminus \{Q\}$ is still path-connected?
Lemma 84.4. The topological spaces $S^2 \lor S^2 \lor S^4$ and $S^2 \times S^2$ are not even homotopy equivalent.

Proof. We had just seen in Lemma 84.3 that there exist cohomology classes $\alpha$ and $\beta$ in $H^2(S^2 \times S^2; \mathbb{Z})$ with $\alpha \cup \beta \neq 0$. On the other hand in Lemma 81.11 we saw that the cup product
\[ \cup : H^2(S^2 \lor S^2 \lor S^4; \mathbb{Z}) \times H^2(S^2 \lor S^2 \lor S^4; \mathbb{Z}) \to H^4(S^2 \lor S^2 \lor S^4; \mathbb{Z}) \]
is the zero-map. It follows from Corollary 81.12 that the topological spaces $S^2 \lor S^2 \lor S^4$ and $S^2 \times S^2$ are not homotopy equivalent. ■

In Proposition 69.3 we saw that there exists a degree-one map from $S^2 \times S^2$ onto the 4-dimensional sphere $S^4$. In Question 69.11 we had asked whether there exists a degree-one map from the 4-dimensional sphere $S^4$ to $S^2 \times S^2$. Now we can answer this question in the negative.

Lemma 84.5. There is no map $f : S^4 \to S^2 \times S^2$ of non-zero degree.

Proof. Let $f : S^4 \to S^2 \times S^2$ be a map. We have to show that $\deg(f) = 0$. By Lemma 75.17 it suffices to show that $f^*([S^2 \times S^2]^*) = 0$. In Lemma 84.3 we showed that there exist cohomology classes $a, b \in H^2(S^2 \times S^2; \mathbb{Z})$ such that $a \cup b = [S^2 \times S^2]^* \in H^4(S^2 \times S^2; \mathbb{Z})$. It follows that
\[ f^*([S^2 \times S^2]^*) = f^*(a \cup b) = f^*(a) \cup f^*(b) = 0 \cup 0 = 0. \]
Since $[S^2 \times S^2]^* = a \cup b$ Lemma 81.10 since $f^*(a), f^*(b) \in H^2(S^4; \mathbb{Z}) = 0$ ■

84.2. Proof of the Product Theorem 84.1. Now that we are fully convinced of the value of Theorem 84.1 it is time to actually provide a proof thereof.

Initially we introduced only the tensor product $C_\ast \otimes D_\ast$ of two chain complexes $C_\ast$ and $D_\ast$. The definition of the boundary map in the tensor product $C_\ast \otimes D_\ast$ is not symmetric in the two terms. But it is straightforward to see that the tensor product of chain complexes is associative. More precisely, given chain complexes $C_\ast^1, \ldots, C_\ast^k$ the boundary map on the tensor product $C_\ast^1 \otimes \cdots \otimes C_\ast^k$ is always determined by
\[ \partial(c_1 \otimes c_2 \otimes \cdots \otimes c_k) = \sum_{i=1}^k (-1)^{\deg(c_1) + \cdots + \deg(c_{i-1})} \cdot c_1 \otimes \cdots \otimes \partial c_i \otimes \cdots \otimes c_k, \]
regardless of the way how one breaks the tensor product into the tensor product of pairs of two chain complexes.

The following lemma is basically the same as Lemma 58.3, but we state it here for the convenience of the reader.
Lemma 84.6. Let $f_i : C^i_* \to D^i_*$, $i = 1, \ldots, k$ be chain maps between chain complexes. Then the map
\[
f_1 \otimes \cdots \otimes f_k : C_*^1 \otimes \cdots \otimes C_*^k \to D_*^1 \otimes \cdots \otimes D_*^k
\]
that is determined by
\[
c_1 \otimes \cdots \otimes c_k \mapsto f(c_1) \otimes \cdots \otimes f(c_k)
\]
is also a chain map.

Remark. Even the definition of $f_1 \otimes \cdots \otimes f_k$ is, oddly enough, not the same everywhere. For example [Bre93, p. 315] adds a sign to the map.

Proof. Since in the proof of the Product Theorem 84.1, there are lots of steps later on which can make us nervous, let us convince ourselves that the statement is indeed correct.

We have
\[
\partial((f_1 \otimes \cdots \otimes f_k)(c_1 \otimes \cdots \otimes c_k)) = \partial(f_1(c_1) \otimes \cdots \otimes f_k(c_k)) = \sum_{i=1}^k (-1)^{\deg(f_i(c_1)) + \cdots + \deg(f_i(c_k))} f_i(c_1) \otimes \cdots \otimes f_i(c_k)
\]
since $\deg(f_i(c_i)) = \deg(c_i)$
\[
= (f_1 \otimes \cdots \otimes f_k)(\sum_{i=1}^k (-1)^{\deg(c_1)+\cdots+\deg(c_{i-1})} c_1 \otimes \cdots \otimes \partial c_i \otimes \cdots \otimes c_k)
\]
Note though that the naive swapping of two factors in the tensor product of two chain complexes is not necessarily a chain map. But we have the following lemma.

Lemma 84.7. Let $A_*$ and $B_*$ be chain complexes. The unique map
\[
\tau : A_* \otimes B_* \to B_* \otimes A_*
\]
that for $a \in A_k$ and $b \in B_l$ is given by
\[
a \otimes b \mapsto (-1)^{kl} \cdot b \otimes a
\]
is a chain map.

Remark. In Exercise 84.1, we will see that we can use Lemma 84.7 to give a new proof of Proposition 81.8, i.e. we can give a new proof that the cup product is (anti-) commutative.

Proof. The difficult bit about the lemma is coming up with the statement. The verification is now almost trivial. So let $a \in A_k$ and $b \in B_l$. Then we have
\[
\tau(\partial(a \otimes b)) = \tau(\partial a \otimes b + (-1)^{k} \cdot a \otimes \partial b) = \tau(\partial a \otimes b) + (-1)^{k} \cdot \tau(a \otimes \partial b) = (-1)^{(k-1)} \cdot b \otimes \partial a + (-1)^{k+l(t-1)} \cdot \partial b \otimes a = (-1)^{kl} \cdot \partial b \otimes a + (-1)^{l+kl} \cdot b \otimes \partial a = \partial((-1)^{kl} \cdot b \otimes a) = \partial(\tau(a \otimes b)).
\]

Now we have to introduce a plethora of new definitions and notations.

Notation.
(1) We denote by $\mathbb{Z}$ also the chain complex given by the group $\mathbb{Z}$ in degree zero and where all other chain groups are zero.
(2) Given a chain complex $C_*$ and $k \in \mathbb{N}_0$ we denote by $C_*[k]$ the chain complex which is the result of “shifting $C_*$ by $k$ to the left”, i.e. it is the chain complex for which the
$m$-th chain groups $(C_*[k])_m$ is given by $C_{m-k}$ for example, $\mathbb{Z}[3]$ is the following chain complex:

$$\ldots \rightarrow 0 \rightarrow \mathbb{Z} \rightarrow 0 \rightarrow 0 \rightarrow 0.$$  

(3) If $\alpha : C_* \rightarrow D_*$ is a chain map, then for any $k \in \mathbb{N}_0$ we denote by $\alpha[k] : C_* \rightarrow D_*[k]$ the obvious shift of the chain map. Evidently this is again a chain map.

(4) Let $C_*$ be a chain complex and let $k \in \mathbb{N}_0$.

(a) Given a cocycle $\varphi : C_k \rightarrow \mathbb{Z}$ we denote by $\Pi_k(\varphi) : C_* \rightarrow \mathbb{Z}[k]$ the map that is given by $\varphi$ on $C_n$ and zero on all other chain groups.

(b) Conversely, given a chain map $\psi : C_* \rightarrow \mathbb{Z}[k]$ we denote by $\psi_k : C_k \rightarrow \mathbb{Z}$ the map that is the $k$-th map of the chain map.

**Lemma 84.8.** Let $C_*$ be a chain complex and let $k \in \mathbb{N}_0$. The following statements hold:

1. Let $\varphi : C_k \rightarrow \mathbb{Z}$ be a cocycle. The map $\Pi_k(\varphi) : C_* \rightarrow \mathbb{Z}[k]$ is a chain map.

2. Let $\psi : C_* \rightarrow \mathbb{Z}[k]$ be a chain map. The map $\psi_k : C_k \rightarrow \mathbb{Z}$ is a cocycle.

3. Let $\alpha, \beta : C_* \rightarrow \mathbb{Z}[k]$ be chain maps. If $\alpha$ and $\beta$ are chain homotopic, then $\alpha_k$ and $\beta_k$ are cohomologous.

**Proof.**

1. Let $\varphi : C_k \rightarrow \mathbb{Z}$ be a cocycle. We consider the following diagram:

$$\ldots \rightarrow C_{k+1} \xrightarrow{\partial} C_k \xrightarrow{\partial} C_{k-1} \rightarrow \ldots$$

$$\downarrow \quad \downarrow \quad \downarrow$$

$$0 \quad \mathbb{Z} \quad 0 \rightarrow \ldots$$

The hypothesis that $\varphi$ is a cocycle means that $\delta \varphi = \varphi \circ \partial = 0$, which implies immediately that $\Pi_k(\varphi)$ is a chain map.

2. The proof of statement (2) is almost the same as the proof of statement (1).

3. Let $\alpha, \beta : C_* \rightarrow \mathbb{Z}[k]$ be chain maps and let $\{P_m : C_m \rightarrow \mathbb{Z}[k]_{m+1}\}_{m \in \mathbb{N}_0}$ be a chain homotopy between $\alpha$ and $\beta$. We summarize all relevant maps in the following diagram:

$$\ldots \rightarrow C_{k+1} \xrightarrow{\partial} C_k \xrightarrow{\partial} C_{k-1} \rightarrow \ldots$$

$$\downarrow \quad \downarrow \quad \downarrow$$

$$0 \quad \mathbb{Z} \quad 0 \rightarrow \ldots$$

$$\alpha_k - \beta_k \quad P_{k-1} \quad \partial$$

$$\alpha_k - \beta_k \quad P_{k-1} \quad \partial$$

By definition of a chain homotopy we obtain that $\alpha_k - \beta_k = P_{k-1} \circ \partial$. But this means that $\alpha_k - \beta_k = \delta P_{k-1}$, i.e. $\alpha_k$ and $\beta_k$ are cohomologous. 

---

1210 Once again, conventions in the literature differ. It is fairly common to define the boundary maps on $C_*[k]$ to be the boundary maps of $C_*$ multiplied by $(-1)^{k}$, see e.g. [Weib94] p. 10].
**Lemma 84.9.** Let $C_*$ be a chain complex and let $k \in \mathbb{Z}$. The maps

$$
\eta_m : (\mathbb{Z}[k] \otimes C_*)_m = \mathbb{Z} \otimes C_{m-k} \rightarrow (C_*[k])_m = C_{m-k}
$$

form an isomorphism

$$
\eta : \mathbb{Z}[k] \otimes C_* \xrightarrow{\cong} C_*[k]
$$
of chain complexes.

**Example.** Let $k, l \in \mathbb{N}_0$. The chain map

$$
\eta : \mathbb{Z}[k] \otimes \mathbb{Z}[l] \rightarrow \mathbb{Z}[k+l]
$$
is determined by the fact that for $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and $b \in (\mathbb{Z}[l])_l = \mathbb{Z}$ we have

$$
\eta(a \otimes b) = (-1)^{kl} \cdot a \cdot b.
$$

**Proof.** It follows from Lemma 57.3(3) that each $\eta_m$ is an isomorphism. But we still need to verify that the maps $\eta_m$ form a chain map $\eta : \mathbb{Z}[k] \otimes C_* \rightarrow C_*[k]$. Thus let $k \in \mathbb{N}_0$, let $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and let $c_{m-k} \in C_{m-k}$. Then

since $a$ is of degree $k$ and since $\partial a = 0$ since $\partial c_{m-k}$ is of degree $m - k - 1$

$$
\eta_{m-1}(\partial(a \otimes c_{m-k})) = \eta_{m-1}((-1)^k \cdot a \otimes \partial c_{m-k}) = (-1)^k \cdot (-1)^{(m-1-k)} \cdot a \cdot \partial c_{m-k}
$$

$$
= \partial((-1)^{k(m-k)} \cdot a \cdot c_{m-k}) = \partial(\eta_m(a \otimes c_{m-k})).
$$

It follows immediately that the maps $\eta_m$ form a chain map. 

**Notation.**

(1) Given topological spaces $X$ and $Y$ we denote by $Y : C_*(X) \otimes C_*(Y) \rightarrow C_*(X \times Y)$ and $\Theta : C_*(X \times Y) \rightarrow C_*(X) \otimes C_*(Y)$ the chain maps from the Eilenberg-Zilber Theorem 80.1.

(2) Given a topological space $W$ we denote by $\Delta_W : C_*(W) \rightarrow C_*(W) \otimes C_*(W)$ the Alexander-Whitney diagonalization from page 1985. Recall that $\Delta_W$ is also a chain map.

In the following two lemmas we will reinterpret the cup product and the cap product as chain maps.

**Lemma 84.10.** Let $W$ be a topological space and let $\alpha \in C^k(W; \mathbb{Z})$ and $\beta \in C^l(W; \mathbb{Z})$ be cocycles. Then we have the following equality of chain maps:

$$
(-1)^{kl} \cdot \Pi_{k+l}(\alpha \cup \beta) = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Delta_W : C_*(W) \rightarrow \mathbb{Z}[k+l].
$$

cocycle in $C^{k+l}(W; \mathbb{Z})$

**Proof.** We introduce the following notation:

(1) We denote by $\mu : \mathbb{Z} \otimes \mathbb{Z} \rightarrow \mathbb{Z}$ the obvious isomorphism of abelian groups given by

$$
\mu(a \otimes b) = a \cdot b.
$$

(2) We denote by $\Pi_{k,l} : (C_*(W) \otimes C_*(W))_{k+l} \rightarrow C_k(W) \otimes C_l(W)$ the obvious projection map.
In the proof of Proposition \[81.4\] on page \[1986\] we showed that
\[
\alpha \cup \beta = \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Delta_W : C_{k+l}(W) \to \mathbb{Z}.
\]
The lemma follows immediately from this equality and the following claim.

**Claim.** \[1211\]
\[
(-1)^{kl} \cdot \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} = (\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)))_{k+l} : (C_*(W) \otimes C_*(W))_{k+l} \to \mathbb{Z}.
\]

The restriction to the \((k+l)\)-th chain group of the chain map \(C_*(W) \otimes C_*(W) \to \mathbb{Z}[k] \otimes \mathbb{Z}[l] \to \mathbb{Z}[k+l]\)
\[
a \circ b \mapsto (-1)^{kl} \cdot ab
\]

Let \(\sigma_i \in C_i(W)\) and \(\sigma_j \in C_j(W)\) with \(i + j = k + l\). If \((i,j) \neq (k,l)\), then both maps are zero. So now suppose that \((i, j) = (k, l)\). Then it is clear that both maps send \(\sigma_k \otimes \sigma_l\) to \((-1)^{kl} \cdot \alpha(\sigma_k) \otimes \beta(\sigma_l)\). (Note that the sign \((-1)^{kl}\) for the map on the right-hand side stems from the definition of the chain map \(\eta\).)

Given a topological space \(W\) and given \(\varphi \in C^k(W; \mathbb{Z})\) we obtain for each \(m \in \mathbb{N}_0\) a map
\[
\varphi \cap - : C_m(W) \to C_{m-k}(W) = (C_*(W)[k])_m
\]
\[
\sigma \mapsto \varphi \cap \sigma.
\]

Unfortunately in general these maps do not form a chain map from the chain complex \(C_*(W)\) to the chain complex \(C_*(W)[k]\). This motivates introducing the following slight variation on the cap product.

**Definition.** Let \(W\) be a topological space. Given \(\varphi \in C^m(W; \mathbb{Z})\) and given \(\sigma \in C_n(W)\) we define\[1212\]
\[
\varphi \tilde{\cap} \sigma := (-1)^{m(n-m)} \cdot \varphi \cap \sigma.
\]

In particular for \(m = n\) we have \(\varphi \tilde{\cap} \sigma = \varphi \cap \sigma\).

**Lemma 84.11.** Let \(W\) be a topological space.

1. If \(\varphi \in C^m(W; \mathbb{Z})\) is a cocycle, then the map
\[
\varphi \tilde{\cap} - : C_*(W) \to C_*(W)[m]
\]
\[
\sigma \mapsto \varphi \tilde{\cap} \sigma
\]
is a chain map.

2. If \(\varphi, \psi \in C^m(W; \mathbb{Z})\) are cohomologous cocycles, then the chain maps \(\varphi \tilde{\cap} -\) and \(\psi \tilde{\cap} -\) are chain homotopic.

**Proof.** Let \(W\) be a topological space. We start out with the following claim.

**Claim.** For any cochain \(\tau \in C^l(W; \mathbb{Z})\) and any chain \(\mu \in C_n(W; \mathbb{Z})\) we have
\[
\partial(\tau \tilde{\cap} \mu) = (-1)^{l+n} \cdot \delta \tau \tilde{\cap} \mu + \tau \tilde{\cap} \partial \mu.
\]

\[1211\] Here, given two chain complexes \(C_*\) and \(D_*\) the map \(\Pi_{k,l} : C_* \otimes D_* \to C_k \otimes D_l\) is the obvious projection map that we introduced on page \[1979\].

\[1212\] If we compare this definition with the discussion on page \[2021\] we see that the definition of \(\tilde{\cap}\) is precisely the definition of the cap product in Bredon [Bre93] and Dold [Dol56].
The claim is an immediate consequence of Lemma 83.1. Since we are worried about signs we write down the detailed calculation. We have

\[
\partial(\tau \curvearrowright \mu) = (-1)^{l(n-l)} \cdot \partial(\tau \cap \mu) = (-1)^{l(n-l)} \cdot (-1)^l \cdot (\tau \cap \mu + \partial \cap \mu)
\]

definition of \(\tau \curvearrowright \mu\) \[Lemma 83.1\]

\[
= (-1)^{l(n-l)+l} \cdot \delta \tau \curvearrowright \mu + (-1)^{l(n-l-1)} \cdot \tau \curvearrowright \partial \mu
\]

Now we turn to the actual proof of the two statements.

1. Let \(\varphi \in C^m(W; \mathbb{Z})\) be a cocycle. Furthermore let \(\sigma \in C_n(W)\). By the definition of the cap product and by definition of the shifting of chain complexes we have \(\varphi \cap \sigma \in C_{n-m}(W) = (C_*(W)[m])_n\). This shows that \(\varphi \curvearrowright\) preserves degrees. It remains to show that the map \(\varphi \curvearrowright\) commutes with the boundary maps. But this is an immediate consequence of the above claim and the fact that \(\varphi\) is a cocycle.

2. So let \(\varphi, \psi \in C^m(W; \mathbb{Z})\) be cocycles. We assume they are cohomologous which means that there exists a \(\tau \in C^{m-1}(W; \mathbb{Z})\) such that \(\varphi = \psi + \delta \tau\). For any \(k \in \mathbb{N}_0\) we consider the map

\[
P_k: C_k(W) \rightarrow (C_*(W)[m])_{k+1} = C_{k-m+1}(W)
\]

\[
\sigma \mapsto (-1)^{m+k} \cdot \tau \curvearrowright \sigma.
\]

We calculate that for any \(\sigma \in C_k(W)\) we have

\[
\varphi \curvearrowright \sigma - \psi \curvearrowright \sigma = \delta \tau \curvearrowright \sigma \downarrow
\]

by the claim

\[
= (-1)^{m+k} \cdot \partial(\tau \curvearrowright \sigma) + (-1)^{m+k-1} \cdot \tau \curvearrowright \partial \sigma
\]

\[
= (\partial \circ P_k)(\sigma) + (P_{k-1} \circ \partial)(\sigma).
\]

This shows that the maps \(\{P_k\}_{k \in \mathbb{N}_0}\) form a chain homotopy between the chain maps \(\varphi \curvearrowright\) and \(\psi \curvearrowright\).

In the proof of Theorem 84.1 we will also need the following reformulation of the cap product.

**Proposition 84.12.** Let \(W\) be a topological space and let \(\varphi \in C^m(W; \mathbb{Z})\) be a cocycle. Then we have the following equality of chain maps

\[
\varphi \curvearrowright = \eta \circ (\Pi_m(\varphi) \otimes \text{id}) \circ \Delta_W: C_*(W) \rightarrow C_*(W)[m].
\]
Proof. Let $W$ be a topological space, let $\varphi \in C^m(W)$ be a cocycle and let $\sigma: \Delta^n \to W$ be a singular $n$-simplex. We have the following equalities in $C_*(W)[m]_n = C_{n-m}(W)$:

\[ (\eta \circ (\Pi_m(\varphi) \otimes \text{id}) \circ \Delta_W)(\sigma) = \eta(\varphi(\sigma \circ [v_0, \ldots, v_m]) \otimes [v_m, \ldots, v_n]) \]

by definition of the chain map $\Pi_m(\varphi) \otimes \text{id} : C_*(W) \otimes C_*(W) \to \mathbb{Z}[m] \otimes C_*(W)$

\[ = (-1)^m (\varphi \circ [v_0, \ldots, v_m] \cdot \sigma \circ [v_m, \ldots, v_n]) = \varphi \cap \sigma. \]

We have thus verified that the desired equality holds.

The following statement is just the definition of the cross product.

**Tautology 84.13.** Let $X$ and $Y$ two topological spaces. For any $[\mu] \in H_n(X; \mathbb{Z})$ and $[\nu] \in H_n(Y; \mathbb{Z})$ we have

\[ [\mu] \times [\nu] = [\varphi(\mu \otimes \nu)]. \]

We need one more slightly delicate chain map before we can finally turn to the proof of the Product Theorem 84.1.

**Lemma 84.14.** Let $C_*$ and $D_*$ be chain complexes and let $k, l \in \mathbb{N}_0$. The map

\[ \Psi_{k,l}: C_*[k] \otimes D_*[l] \to (C_* \otimes D_*)[k+l] \]

which is defined by the property that for $c_m \in C_m$ and $d_n \in D_n$ we have

\[ c_m \otimes d_n \mapsto (-1)^{k(l+n)} \cdot c_m \otimes d_n. \]

is an isomorphism of chain complexes.

Proof. First note that it is clear that $\Psi_{k,l}$ preserves degrees and that on each degree it is an isomorphism. It remains to show that the map $\Psi_{k,l}$ is a chain map. Let $c_m \in C_m$ and $d_n \in D_n$. We calculate that

\[ \Psi_{k,l}(\partial(c_m \otimes d_n)) = \Psi_{k,l}(\partial c_m \otimes d_n + (-1)^{m+k} \cdot c_m \otimes \partial d_n) \]

since $c_m$ has degree $m+k$ in $C_*[k]$

\[ = (-1)^{k(l+n)} \cdot \partial c_m \otimes d_n + (-1)^{m+k} \cdot (-1)^{k(l+n-1)} \cdot c_m \otimes \partial d_n \]

\[ = (-1)^{k(l+n)} \cdot (\partial c_m \otimes d_n + (-1)^m \cdot c_m \otimes \partial d_n) = (-1)^{k(l+n)} \cdot \partial (c_m \otimes d_n). \]

This calculation implies that $\Psi_{k,l}$ is a chain map.

The following theorem is the main technical result of this section. As we will see shortly, the Product Theorem 84.1 is a straightforward consequence of Theorem 84.15.
Theorem 84.15. Let $X$ and $Y$ be topological spaces. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the projection maps. Let $\alpha \in C^k(X; \mathbb{Z})$ and $\beta \in C^l(Y; \mathbb{Z})$ be cocycles. Then the chain maps

$$(-1)^{kl} \cdot ((p^* \alpha \cup q^* \beta) \circ \eta) \circ \Upsilon$$

and

$$\Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \otimes \beta) \circ \eta$$

from $C_* (X) \otimes C_* (Y)$ to $C_* (X \times Y) [k+l]$ are chain homotopic.

Proof. Let $X$ and $Y$ be topological spaces and let $\alpha \in C^k(X; \mathbb{Z})$ and $\beta \in C^l(Y; \mathbb{Z})$ be cocycles. We consider the following diagram of chain maps

$$
\begin{array}{c}
C_* \times C_* Y \xrightarrow{\gamma} C_* (X \times Y) \xrightarrow{\Delta X \times Y} C_* (X \times Y) \otimes C_* (X \times Y) \\
\downarrow\Delta X \otimes \Delta Y \quad \downarrow\Theta \otimes \text{id} \\
C_* \times C_* Y \otimes C_* Y \xrightarrow{\text{id} \otimes \text{sd}} C_* \times C_* Y \otimes C_* X \times C_* Y \xrightarrow{\text{id} \otimes \text{id} \otimes \Upsilon} C_* \times C_* Y \otimes C_* (X \times Y) \\
\downarrow\Pi_k(\alpha) \otimes \Pi_l(\beta) \otimes \text{id} \quad \downarrow\Pi_k(\alpha) \otimes \Pi_l(\beta) \otimes \text{id} \\
Z[k] \otimes C_* X \otimes Z[l] \otimes C_* Y \xrightarrow{\text{id} \otimes \tau \otimes \text{id}} Z[k] \otimes Z[l] \otimes C_* X \otimes C_* Y \xrightarrow{\text{id} \otimes \text{id} \otimes \Upsilon} Z[k] \otimes Z[l] \otimes C_* (X \times Y) \\
\downarrow\eta \otimes \text{id} \otimes \text{id} \quad \downarrow\eta \otimes \text{id} \otimes \text{id} \\
C_* X[k] \otimes C_* Y[l] \xrightarrow{\Psi_{k,l}} (C_* X \otimes C_* Y)[k+l] \xrightarrow{\Upsilon[k+l]} C_* (X \times Y) [k+l].
\end{array}
$$

Claim. The above diagram commutes up to chain homotopies.

To prove the claim we consider the various smaller squares and rectangles.

1. The two paths along the top rectangle from the top-left corner to the bottom-right corner are both natural chain maps. Furthermore, both have the property that for $x \in X$ and $y \in Y$ the element $x \otimes y \in C_*(X) \otimes C_*(Y)$ gets sent to $x \otimes y \otimes (x, y)$ in $C_*(X \times Y) \otimes C_*(X \times Y)$. In particular both paths agree on the 0-level.

It follows from Acyclic Model Theorem [80.16] (2) that the rectangle commutes up to a chain homotopy. More precisely, we apply the Acyclic Model Theorem [80.16] as follows:

(a) We take $\mathcal{C}$ to be the category of tuples $(X, Y)$ of topological spaces.

(b) We consider the two functors $F: (X, Y) \mapsto (C_*(X) \otimes C_*(Y), \epsilon_X \otimes \epsilon_Y)$ and $G: (X, Y) \mapsto (C_*(X \times Y), \epsilon_{X \times Y})$.

(c) We take $\mathcal{M} = \{\Delta^k \times \Delta^l\}_{k,l \in \mathbb{N}_0}$.

(d) We consider the two natural transformations that are given by the two extremal paths in the diagram (shifted downward in degrees).

2. It is clear that the two squares between the second and the third row commute.

3. It is straightforward to verify that the two squares at the bottom right commute.

4. It remains to consider the big square to the bottom left of the diagram. Starting with $a \in (Z[k])_k = \mathbb{Z}$, $b \in C_m(X)$, $c \in (Z[l])_l = \mathbb{Z}$ and $d \in C_n(Y)$ and keeping in mind...
the sign conventions of Lemmas 84.7, 84.9 and 84.14 we get the following results for $a \otimes b \otimes c \otimes d$:

(a) going down-right gives $(-1)^{km} \cdot (-1)^{ln} \cdot (-1)^{k(l+n)} \cdot ac \cdot (b \otimes d)$,

(b) going right-down-down gives $(-1)^{md} \cdot (-1)^{kl} \cdot (-1)^{(k+l)(m+n)} \cdot ac \cdot (b \otimes d)$.

One easily verifies that the signs agree. So we see that the bottom left square also commutes.

In light of the previous claim it suffices to prove the following claim.

**Claim.**

(1) the “left-bottom route” equals the chain map $\Upsilon[k + l] \circ \Psi_{k,l} \circ ((\alpha \widetilde{\otimes} -) \otimes (\beta \widetilde{\otimes} -))$,

(2) the “top-right route” is chain homotopic to $(-1)^{kl} \cdot ((p^* \alpha \cup q^* \beta) \widetilde{\otimes} -) \circ \Upsilon$.

We start out with the proof of statement (1). First we note that

\[
(\alpha \widetilde{\otimes} -) \otimes (\beta \widetilde{\otimes} -) = (\eta \circ (\Pi_k(\alpha) \otimes \text{id}) \circ \Delta_X) \otimes (\eta \circ (\Pi_l(\beta) \otimes \text{id}) \circ \Delta_Y)
\]

by Proposition 84.12.

\[
\begin{align*}
&= (\eta \otimes \eta) \circ ((\Pi_k(\alpha) \otimes \text{id} \otimes \Pi_l(\beta) \otimes \text{id})) \circ (\Delta_X \otimes \Delta_Y).
\end{align*}
\]

follows from the observation that for chain maps $a, b, c$ and $d$ we have $(a \circ b) \otimes (c \circ d) = (a \otimes b) \circ (c \otimes d)$.

If we compose this equality with $\Upsilon[k + l] \circ \Psi_{k,l}$ then we obtain the “bottom left route” in the above diagram. This concludes the proof of statement (1).

We continue with the proof of statement (2). In that proof we will make use of the following subclaim.

**Subclaim.** The two cocycles $\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta) \circ \Theta))_{k+l}$ and $(-1)^{kl} \cdot p^*(\alpha) \cup q^*(\beta)$ in $C^{k+l}(X \times Y; Z)$ are cohomologous.

We consider the following diagram

\[
\begin{array}{ccc}
C_{k+l}(X \times Y) & \xrightarrow{\Delta_{X \times Y}} & C_s(X \times Y) \\
\downarrow & & \downarrow \theta \circ \Delta_{X \times Y} \\
C_s(X \times Y) \otimes C_s(X \times Y) & \xrightarrow{\Pi_k(p^*(\alpha)) \otimes \Pi_l(q^*(\beta))} & Z[k] \otimes Z[l] \\
\end{array}
\]

Note that by the above discussion all maps except for the top left map are chain maps. It follows immediately from the definitions that the bottom triangle of chain maps commutes “on the nose”. The top triangle of chain maps commutes, up to a chain homotopy, by Theorem 80.5. It follows from Lemma 84.8(3) that the restrictions of these two chain

\[\text{maps \ are \ cohomologous.}\]

\[\text{Recall \ that \ } \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta) \circ \Theta) \text{ \ is \ a \ chain \ map } C_s(X \times Y) \to Z[k + l]. \text{ \ Furthermore \ recall \ that \ the \ map } (\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta) \circ \Theta))_{k+l} : C_{k+l}(X \times Y) \to (Z[k + l])_{k+l} = Z \text{ \ is \ the \ } (k + l)\text{-th \ map \ of \ the \ chain \ map.}\]

\[\text{More \ precisely, \ given \ } x \in X \\text{ \ and } y \in Y \text{ \ both \ routes \ along \ the \ triangle \ send } (x, y) \text{ \ to } x \otimes y. \text{ \ Furthermore \ both \ routes \ are \ natural \ chain \ maps. \ Thus \ we \ can \ apply \ Theorem 80.5.}\]
maps to maps $C_{k+l}(X \times Y) \to \mathbb{Z} = \mathbb{Z}[k+l]$ are cohomologous cochains. But the restriction of the “top route” equals evidently the left-hand side of the subclaim. On the other hand, by Lemma [84.10] the restriction of the “bottom route” equals the right-hand side of the subclaim. This concludes the proof of the subclaim.

Now we see that

the above subclaim and Lemma [84.11] (2)

\[ (-1)^{kl} \cdot (p^*\alpha \cup q^*\beta) \sim \circ \mathcal{Y} \quad \downarrow \quad \mathcal{Y} \]

\[ = \eta \circ (\Pi_{k+l}(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l}) \otimes id) \circ \Delta_{X \times Y} \circ \mathcal{Y} \]

Proposition [84.12] applied to the $(k+l)$-cocycle $\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \mathcal{Y}_{k+l}$

\[ = \eta \circ (\Pi_{k+l}(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \otimes \Theta \otimes id) \circ \Delta_{X \times Y} \circ \mathcal{Y} \]

since for every chain map $\Omega: C_*(X) \times C_*(Y) \to \mathbb{Z}[k+l]$ we have $\Pi_{k+l}(\Omega \otimes \Theta)_{k+l} = \Pi_{k+l}((\Omega \otimes \Theta))_{k+l}$ as maps $C_*(X \times Y) \to \mathbb{Z}[k+l]$, applies this observation to $\Omega = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta))$

\[ = \eta \circ ((\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \otimes \Theta) \otimes id) \circ \Delta_{X \times Y} \circ \mathcal{Y} \]

here we use the equality of chain maps

\[ \Pi_{k+l}(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta))_{k+l}) = \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)): C_*(X) \otimes C_*(Y) \to \mathbb{Z}[k+l] \]

which is obvious once one unravels the definitions

\[ \uparrow \]

are the “top right route” in the above diagram.

\[ \uparrow \]

follows from $(f \otimes id) \circ (g \otimes id) = (g \circ f) \otimes id$

This concludes the proof of the claim and thus also of the theorem.

\[ \square \]

Now we can finally provide the proof of Theorem [84.1]

**Proof of Theorem [84.1]** To simplify the notation we only consider the special case that $A = B = \emptyset$. For the general case one needs to take more care, we refer to [Dol56] p. 240 and p. 244 for details. So let $X$ and $Y$ be two topological spaces. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the projection maps. Let $[\alpha] \in H^k(X; \mathbb{Z})$, $[\beta] \in H^l(Y; \mathbb{Z})$ and let $[\mu] \in H_m(X; \mathbb{Z})$ and $[\nu] \in H_n(Y; \mathbb{Z})$. We have to show that

\[
\left( [p^*(\alpha)] \cup [q^*(\beta)] \right) \cap \left( [\mu] \times [\nu] \right) = (-1)^{kl+mn} \cdot \left( [\alpha] \cap [\mu] \right) \times \left( [\beta] \cap [\nu] \right)
\]
We have the following equality in \( H_{m+n-k-l}(X \times Y) \):

\[
\text{Tautology 84.13 and the definition of } \widetilde{\cap}, \text{ see page 2042}
\]

\[
(p^*([\alpha]) \cup q^*([\beta])) \cap ([\mu] \times [\nu]) = (-1)^{(k+l)(m+n-k-l)} \cdot ([p^*\alpha \cup q^*\beta]) \cap (Y(\mu \otimes \nu))
\]

\[
= (-1)^{(k+l)(m+n-k-l)} \cdot ((p^*\alpha \cup q^*\beta) \cap \alpha) \circ \gamma, ([\mu] \otimes [\nu])
\]

\[
= (-1)^{(k+l)(m+n-k-l)} \cdot ((-1)^{kl} \cdot \gamma[k+l] \circ \Psi_{k,l} \circ (\alpha \cap \mu \otimes \beta \cap \nu))([\mu] \otimes [\nu])
\]

by Theorem 84.15 and the fact that chain homotopic maps induce the same map on homology groups.

\[
= (-1)^{(k+l)(m+n-k-l)} \cdot (-1)^{kl} \cdot [\gamma[k+l] \circ \Psi_{k,l} \circ \left( \begin{array}{c}
\alpha \cap \mu \\
\otimes \\
\beta \cap \nu
\end{array} \right) = (-1)^{k(m-k)} \cdot \alpha \cap \mu \\
\otimes \\
\beta \cap \nu
\]

\[
= (-1)^{(k+l)(m+n-k-l)} \cdot (-1)^{kl} \cdot (-1)^{kl+n-l} \cdot (-1)^{k(m-k)} \cdot (-1)^{l(n-l)} \cdot \left( Y(\alpha \cap \mu \otimes \beta \cap \nu) \right)
\]

definition of \( \Psi_{k,l} \), see page 2014 and of the shifting from \( \gamma \) to \( \gamma[k+l] \)

\[
= (-1)^{kl+lm} \cdot [\alpha \cap \mu \times \beta \cap \nu] = (-1)^{kl+lm} \cdot (\ [[\alpha] \cap [\mu] \times [\beta] \cap [\nu] )
\]

\[
\text{cleaning up signs and Tautology 84.13}
\]

84.3. The \textbf{Künneth Theorem for cohomology groups}. Given two topological spaces \( X \) and \( Y \) the Künneth Theorem [80.8] for topological spaces determines the homology groups of \( X \times Y \) in terms of the homology groups of \( X \) and \( Y \). The following proposition gives us, under some mild hypothesis, a similar answer for cohomology groups.

**Theorem 84.16. (The Künneth Theorem for cohomology groups)** Let \( X \) and \( Y \) be two topological spaces. We denote by \( p \colon X \times Y \to X \) and \( q \colon X \times Y \to Y \) the obvious projection maps. If all the homology groups of \( X \) are finitely generated\(^{1215}\), then given any \( n \in \mathbb{N}_0 \) there exists a short exact sequence

\[
0 \to \bigoplus_{k+l=n} H^k(X; \mathbb{Z}) \otimes H^l(Y; \mathbb{Z}) \to H^n(X \times Y; \mathbb{Z}) \to \bigoplus_{k+l=n+1} \text{Tor}(H^k(X; \mathbb{Z}), H^l(Y; \mathbb{Z})) \to 0
\]

which is natural with respect to the topological spaces \( X \) and \( Y \). If all the homology groups of \( Y \) are also finitely generated, then the short exact sequence splits (albeit not naturally).

**Remark.** Let \( X \) and \( Y \) be two topological spaces. In the literature the map

\[
H^k(X; \mathbb{Z}) \times H^l(Y; \mathbb{Z}) \to H^{k+l}(X \times Y; \mathbb{Z})
\]

\[
(\varphi, \psi) \mapsto p^*\varphi \cup q^*\psi
\]

is often referred to as the cohomology cross product and it is written as \( \varphi \times \psi := p^*\varphi \cup q^*\psi \). We will not make use of this notation.

The proof of the theorem rests on a purely algebraic theorem that, given two chain complexes \( C \) and \( C' \), relates the cohomology groups of \( C \) and \( C' \) to the cohomology groups of \( C \otimes C' \). Before we can state the theorem we need to introduce one more definition, which is closely related to the definitions introduced on page 1979.

\(^{1215}\)By this we mean that for every \( k \in \mathbb{N}_0 \) the abelian group \( H_k(X; \mathbb{Z}) \) is finitely generated.
**Definition.** Let $C$ and $C'$ be two chain complexes and let $p, q \in \mathbb{N}_0$.

1. We denote by
   \[ \Pi_{p,q} : (C \otimes C')_{p+q} = \bigoplus_{i+j=p+q} C_i \otimes C'_j \rightarrow C_p \otimes C'_q \]
   the obvious projection map.

2. We denote by $\mu : \mathbb{Z} \otimes \mathbb{Z} \rightarrow \mathbb{Z}$ the obvious isomorphism given by $\mu(a \otimes b) = ab$.

3. We consider the map:
   \[ \Xi_{p,q} : \text{Hom}(C_p, \mathbb{Z}) \otimes \text{Hom}(C'_q, \mathbb{Z}) \rightarrow \text{Hom}(C \otimes C', \mathbb{Z}) \]
   \[ \varphi_p \otimes \varphi'_q \mapsto \left( \bigoplus_{i+j=p+q} C_i \otimes C'_j \rightarrow C_p \otimes C'_q \rightarrow \mathbb{Z} \otimes \mathbb{Z} \mu \right). \]

4. It is straightforward to verify that the map $\Xi_{p,q}$ induces a well-defined map on cohomology groups, i.e. that the map
   \[ \Xi_{p,q} : H^p(C; \mathbb{Z}) \otimes H^q(C'; \mathbb{Z}) \rightarrow H^{p+q}(C \otimes C'; \mathbb{Z}) \]
   \[ ([\varphi_p] \otimes [\varphi'_q]) \mapsto [\Xi_{p,q}(\varphi_p \otimes \varphi'_q)] \]
   is well-defined. Furthermore it follows immediately from the definition that $\Xi_{p,q}$ is natural with respect to $C$ and $C'$.

Now we can state the promised purely algebraic theorem.

**Theorem 84.17. (The Künneth Theorem for cochain complexes)** Let $C$ and $C'$ be chain complexes. If $C$ is a free chain complex and if all homology groups of $C$ are finitely generated, then for every $n \in \mathbb{N}_0$ there exists a short exact sequence

\[
0 \rightarrow \bigoplus_{p+q=n} H^p(C; \mathbb{Z}) \otimes H^q(C'; \mathbb{Z}) \xrightarrow{\Xi_{p,q}} H^n(C \otimes C'; \mathbb{Z}) \rightarrow \bigoplus_{p+q=n+1} \text{Tor}(H^p(C; \mathbb{Z}), H^q(C; \mathbb{Z})) \rightarrow 0
\]

which is natural with respect to $C$ and $C'$. If all the chain groups of $C'$ are also free abelian and all the homology groups of $C'$ are also finitely generated, then the short exact sequence splits (albeit not naturally).

In the proof of the Künneth Theorem for cochain complexes we need one technical lemma. To state the lemma we recall that on page 1433 we introduced the tensor product of two chain complexes. Basically the same definition also allows us to define the tensor product of two cochain complexes. With this preamble we can formulate the next lemma.

---

In this case this means that for chain maps $f : C \rightarrow D$ and $f' : C' \rightarrow D'$ the following diagram commutes:

\[
\begin{array}{ccc}
H^p(D; \mathbb{Z}) \otimes H^q(D'; \mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & H^{p+q}(D \otimes D'; \mathbb{Z}) \\
(f \otimes f')^* & & (f \otimes f')^*
\end{array}
\]

\[
\begin{array}{ccc}
H^p(C; \mathbb{Z}) \otimes H^q(C'; \mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & H^{p+q}(C \otimes C'; \mathbb{Z}) \\
(f \otimes f')^* & & (f \otimes f')^*
\end{array}
\]
Lemma 84.18. Let $C_*$ and $C'_*$ be two chain complexes. We assume that all chain groups of $C$ are finitely generated free abelian groups. Then the map
\[
\Omega: \text{Hom}(C_*, Z) \otimes \text{Hom}(C'_*, Z) \to \text{Hom}(C_\otimes C'_*, Z)
\]
\[
(\varphi_p: C_p \to Z) \otimes (\varphi'_q: C'_q \to Z) \mapsto (\mu \circ (\varphi_p \otimes \varphi'_q) \circ \Pi_{p,q}: (C_\otimes C'_*)_{p+q} \to Z)
\]
is an isomorphism of cochain complexes.

Proof (\(*\)). We start out the proof of the lemma with the following elementary well-known observation:

\((\ast)\) For finitely many abelian groups $A_1, \ldots, A_k$ we have a canonical isomorphism
\[
\text{Hom}(A_1 \oplus \cdots \oplus A_k, Z) = \text{Hom}(A_1, Z) \oplus \cdots \oplus \text{Hom}(A_k, Z).
\]

Now we turn to the actual proof of the lemma. It is elementary to verify that the map $\Omega$ is in fact a cochain map. So it remains to show that for every $n \in \mathbb{N}_0$ the map
\[
\bigoplus_{p+q=n} \text{Hom}(C_p, Z) \otimes \text{Hom}(C'_q, Z) \to \text{Hom}\left( \bigoplus_{p+q=n} C_p \otimes C'_q, Z \right)
\]
\[
\varphi_p \otimes \varphi'_q \mapsto \mu \circ (\varphi_p \otimes \varphi'_q) \circ \Pi_{p,q}
\]
is an isomorphism. Applying (\(*\)) to the right-hand side we see that it suffices to prove the following claim.

Claim. For every choice of $p, q \in \mathbb{N}_0$ the map
\[
\text{Hom}(C_p, Z) \otimes \text{Hom}(C'_q, Z) \to \text{Hom}(C_p \otimes C'_q, Z)
\]
\[
\varphi_p \otimes \varphi'_q \mapsto \mu \circ (\varphi_p \otimes \varphi'_q)
\]
is an isomorphism.

Let $p, q \in \mathbb{N}_0$. By our hypothesis on $C_*$ the chain group $C_p$ is a finitely generated free abelian group. Therefore we can find a basis $a_1, \ldots, a_k$ for $C_p$. We denote by $\widehat{a}_1, \ldots, \widehat{a}_k$ the dual basis of $\text{Hom}(C_p, Z)$. We can thus write
\[
\text{Hom}(C_p, Z) = \bigoplus_{i=1}^k \mathbb{Z} \cdot \widehat{a}_i \quad \text{and} \quad C_p \otimes C'_q = \bigoplus_{i=1}^k \mathbb{Z} \cdot a_i \otimes C'_q.
\]
Applying (\(*\)) to the above decompositions and both sides of the claim one sees easily that the given homomorphism is an isomorphism. This concludes the proof. \[\Box\]

Now we can finally prove the Künneth Theorem 84.17 for cochain complexes.

Proof of the Künneth Theorem 84.17 for cochain complexes. We only provide an outline of the proof. Let $C = (C_*, c_*)$ and $C' = (C'_*, c'_*)$ be chain complexes such that all the chain groups $C_n$ are free abelian groups and such that all the homology groups $H_k(C; Z)$ are finitely generated.

The idea is that one can turn any cochain complex into a chain complex by reversing the signs in the degrees. Thus one can try to reduce the theorem to the Künneth Theorem 58.7. Towards the end of the proof we need to insert Lemma 84.18 to make everything work.
The proof proceeds in three steps:

(1) Since $\mathcal{C}$ is a free chain complex and since all homology groups of $\mathcal{C}$ are finitely generated we can use Lemma 49.6 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups.

(2) Given $n \in \mathbb{Z}_{\leq 0}$ we write $E_n := \text{Hom}(C_{-n}, \mathbb{Z})$, $e_n := \partial_{-n+1}^* : E_n \to E_{n-1}$ and similarly we write $E'_n := \text{Hom}(C'_{-n}, \mathbb{Z})$ and $e'_n := \partial_{-n+1}^* : E'_n \to E'_{n-1}$. It follows immediately from the definitions that $\mathcal{E}_* := (E_*, e_*)$ and $\mathcal{E}'_* := (E'_*, e'_*)$ form chain complexes in negative degrees. (We defined chain complexes to be given by chain groups indexed by $n \in \mathbb{N}_0$ but evidently the same theory also works for chain groups indexed by $\mathbb{Z}$ and $\mathbb{Z}_{\leq 0}$.) Since the groups $E_n$ are free abelian we can apply the Künneth Theorem 58.7 (which also applies to chain complexes in non-positive degrees) to obtain for each $n \in \mathbb{Z}_{\leq 0}$ a natural short exact sequence

$$0 \to \bigoplus_{p+q=n} H_p(\mathcal{E}) \otimes H_q(\mathcal{E}') \to H_n(\mathcal{E} \otimes \mathcal{E}') \to \bigoplus_{p+q=n-1} \text{Tor}(H_p(\mathcal{E}), H_q(\mathcal{E}')) \to 0.$$

Put differently, for each $n \in \mathbb{N}_0$ we have a natural short exact sequence

$$0 \to \bigoplus_{-p-q=n} H_{-p}(\mathcal{E}) \otimes H_{-q}(\mathcal{E}') \to H_{-n}(\mathcal{E} \otimes \mathcal{E}') \to \bigoplus_{-p-q=n+1} \text{Tor}(H_{-p}(\mathcal{E}), H_{-q}(\mathcal{E}')) \to 0.$$

(3) For each $n \in \mathbb{N}_0$ we have isomorphisms

$$H_{-n}(\mathcal{E}_* \otimes \mathcal{E}'_*) = H^n(\mathcal{E}_* \otimes \mathcal{E}'_*) = H^n(\text{Hom}(C_*, \mathbb{Z}) \otimes \text{Hom}(C'_*, \mathbb{Z})) \overset{\Omega}{\to} H^n(C_* \otimes C'_*; \mathbb{Z}).$$

by definition

We use this isomorphism to replace the middle term of the second short exact sequence in (2) and we obtain the desired short exact sequence.

Finally suppose that all the chain groups of $\mathcal{C}'$ are also free abelian and that all the homology groups of $\mathcal{C}'$ are also finitely generated. As in (1) we can use Lemma 49.6 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups. It follows that $\mathcal{E}_*$ is a free chain complex which implies, by the last statement of the Künneth Theorem 58.7, that the short exact sequence splits.

Now we are in a position to prove the Künneth Theorem 84.16 for cohomology groups.

**Proof of the Künneth Theorem 84.16 for cohomology groups (\*)**. Let $X$ and $Y$ be two topological spaces such that all the homology groups of $X$ are finitely generated. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the obvious projection maps. Throughout the proof we use all the definitions that we introduced in Section 84.2.

It follows from the Eilenberg-Zilber Theorem 80.1 together with comparing the conclusion of the Künneth Theorem 84.17 for cochain complexes with the desired statement of the Künneth Theorem 84.16 for cohomology groups, that it remains to prove the following claim.
Claim. For any $k, l \in \mathbb{N}_0$ the map

$$H^k(X; \mathbb{Z}) \otimes H^l(Y; \mathbb{Z}) \to H^{k+l}(X \times Y; \mathbb{Z})$$

agrees with the map that is given by

$$[\alpha] \otimes [\beta] \mapsto [(\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Theta].$$

Let $\alpha \in C^k(X; \mathbb{Z})$ and $\beta \in C^l(Y; \mathbb{Z})$ be cocycles. We have to show that the two cocycles

$$p^*\alpha \otimes q^*\beta$$

and

$$(\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Theta$$

are cohomologous.

As usual, given a topological space $W$ we denote by $\epsilon_W : C_0(W) \to \mathbb{Z}$ the augmentation map. Clearly $\epsilon_W$ is a cocycle so by Lemma 84.8 (2) we can extend $\epsilon_W$ to a chain map $C_*(W) \to \mathbb{Z}$ which, by a slight abuse of notation, we also denote by $\epsilon_W$. It follows from the Eilenberg-Zilber Theorem 80.1, Theorem 84.15 and Lemma 84.8 (2) that the maps

$$(−1)^{kl} \cdot \epsilon_{X \times Y}[k+l] \circ ((p^*\alpha \otimes q^*\beta)\bar{\sim}) : C_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

and

$$\epsilon_{X \times Y}[k+l] \circ \Psi_{k,l} \circ (\alpha \bar{\sim} \otimes \beta \bar{\sim}) \circ \Theta : C_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

are cocycles that are cohomologous. It remains to prove the following two subclaims.

Subclaim. We have

$$\mathfrak{N}' = (-1)^{kl} \cdot \mathfrak{N} : C_{k+l}(X \times Y) \to \mathbb{Z}.$$ 

Let $\sigma \in C_{k+l}(X \times Y)$. Then

$$\mathfrak{N}'(\sigma) = (-1)^{kl} \cdot \epsilon_{X \times Y}((p^*\alpha \otimes q^*\beta)\bar{\sim}\sigma) = (-1)^{kl} \cdot (p^*\alpha \otimes q^*\beta)(\sigma) = (-1)^{kl} \cdot \mathfrak{N}(\sigma).$$

under the identification $\mathbb{Z}[k+l] = \mathbb{Z}$ we have $\epsilon_{X \times Y}[k+l] = \epsilon_{X \times Y}$ by definition of $\bar{\sim}$, see page 2042 together with Lemma 83.4 (1)

This concludes the proof of the subclaim.

Subclaim. We have

$$\mathfrak{Z}' = (-1)^{kl} \cdot \mathfrak{Z} : (C_*(X) \otimes C_*(Y))_{k+l} \to \mathbb{Z}.$$ 

We have to show that both sides take the same value on any tensor product of the form $\sigma_i \otimes \sigma_j$ with $i + j = k + l$ and $\sigma_i \in C_i(X)$ and $\sigma_j \in C_j(Y)$. It follows easily from the definition that both sides are zero for $\sigma_i \otimes \sigma_j$ with $(i, j) \neq (k, l)$. So let $\sigma_k \in C_k(X)$ and
let $\sigma_i \in C_i(Y)$. Then

$$\mathfrak{z}'(\sigma_k \otimes \sigma_l) = \uparrow (\epsilon_{X \times Y} \circ \Upsilon)[k + l] \circ \Psi_{k,l} \circ (\alpha \otimes \sigma_k \otimes \beta \otimes \sigma_l)$$

since $\epsilon_{X \times Y}[k + l] \circ \Upsilon[k + l] = (\epsilon_{X \times Y} \circ \Upsilon)[k + l]$

$$= (-1)^{kl} \cdot (\epsilon_X \otimes \epsilon_Y) \circ (\alpha \otimes \sigma_k \otimes \beta \otimes \sigma_l) \quad \uparrow$$

we use $\epsilon_{X \times Y} \circ \Upsilon = \epsilon_X \otimes \epsilon_Y : (C_\ast(X) \otimes C_\ast(Y))_0 \to \mathbb{Z} \otimes \mathbb{Z} = \mathbb{Z}$,

the definition of $\Psi_{k,l}$ in Lemma 84.14 and the definition of $\otimes$ on page 2042

$$\Rightarrow = (-1)^{kl} \cdot ((\alpha \otimes \beta) \circ \Pi_{k,l})(\sigma_k \otimes \sigma_l) \quad \uparrow$$

by Lemma 83.3

$$\Rightarrow = (-1)^{kl} \cdot \mathfrak{z}(\sigma_k \otimes \sigma_l).$$

This concludes the proof of the second subclaim, thus also of the claim and therefore also of the theorem. \qed

84.4. The cohomology ring of product topological spaces. In this section we will determine the cohomology ring of the $m$-dimensional torus $(S^1)^m$ and more generally, under some mild technical hypothesis, we will determine the cohomology ring of a product $X \times Y$ of topological spaces in terms of the cohomology rings of $X$ and $Y$.

We recall the following definition.

**Definition.**

1. A graded ring is a ring $R$ together with a decomposition $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ such that for any $m, n \in \mathbb{N}_0$ the multiplication map restricts to a map $R_m \times R_n \to R_{m+n}$. We say that an element $r$ of $R$ that lies in some $R_n$ is homogeneous and we refer to $\deg(r) := n$ as the degree of $r$.

2. A homomorphism $\varphi : A \to B$ between graded rings is a ring homomorphism that preserves the gradings, i.e. that satisfies $\varphi(A_n) \subseteq B_n$ for all $n \in \mathbb{N}_0$.

3. A graded ring $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ such that for any two homogeneous elements $a$ and $b$ the equality $a \cdot b = (-1)^{\deg(a) \cdot \deg(b)} \cdot b \cdot a$ holds is called a superalgebra.

**Examples.**

1. Proposition 81.8 says in particular that for any topological space $X$ the cohomology ring $(H^\ast(X; \mathbb{Z}), \cup)$ is a superalgebra. Furthermore Lemma 81.10 implies that for any map $f : X \to Y$ the induced map $f^\ast : H^\ast(Y; \mathbb{Z}) \to H^\ast(X; \mathbb{Z})$ is a homomorphism of superalgebras.

2. The polynomial ring $\mathbb{F}_2[a] = \bigoplus_{i \in \mathbb{N}_0} \mathbb{F}_2 \cdot a^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(a^i) := i$.

3. The polynomial ring $\mathbb{Z}[x] = \bigoplus_{i \in \mathbb{N}_0} \mathbb{Z} \cdot x^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(x^i) := 2i$.

4. More generally, the polynomial ring $\mathbb{Z}[x_1, \ldots, x_k]$ in $k$ variables $x_1, \ldots, x_k$ can be viewed as a superalgebra by setting $\deg(x_1^{r_1} \cdots x_k^{r_k}) = 2(r_1 + \cdots + r_k)$.

5. The ring $\mathbb{Z}[x]/(x^2)$ is a superalgebra by viewing elements in $\mathbb{Z}$ as elements of degree 0 and by viewing elements in $\mathbb{Z} \cdot x$ as elements of degree 1. Note that the
map
\[ \mathbb{Z}[x]/(x^2) \to H^*(S^1; \mathbb{Z}) \]
\[ a \cdot 1 + b \cdot x \mapsto a \cdot 1_\mathbb{S} + b \cdot [S^1]^* \]
is an isomorphism of superalgebras.

(6) We consider the ring
\[ \Lambda[x_1, \ldots, x_k] := \mathbb{Z}[x_1, \ldots, x_k]/\text{ideal generated by } x_1^2, \ldots, x_k^2, \{x_ix_j + x_jx_i\}_{i,j=1,\ldots,k}. \]
In this ring we use the symbol “\( \land \)” for multiplication instead of “\( \cdot \)”. For example for any \( i, j \in \{1, \ldots, k\} \) we have \( x_i \land x_i = 0 \) and \( x_i \land x_j = -x_j \land x_i \). This ring can be viewed in a unique way as a superalgebra such that \( \deg(x_j) = 1 \) for \( j = 1, \ldots, k \). The ring \( \Lambda[x_1, \ldots, x_k] \) is often referred to as the exterior algebra on generators \( x_1, \ldots, x_k \), see e.g. [Hat02, p. 217] and [Mac75, p. 183]. We leave it as an amusing exercise to verify that \( \Lambda[x_1, \ldots, x_k] \) is a free abelian group of rank \( 2^k \) where a basis is given by
\[ \{x_{n_1} \land \cdots \land x_{n_l} \mid n_1 < \cdots < n_l\}. \]

In Exercise 75.2 we saw that any sequence \( \{A_n\}_{n \geq 1} \) of finitely generated abelian groups, with \( A_1 \) torsion-free, can appear as the sequence of cohomology groups \( H^*(X; \mathbb{Z}) \) of some CW-complex. It is natural to ask whether any superalgebra structure can be realized as the cohomology ring of a topological space. More precisely, we have the following question, to which we will return later with Proposition 110.6.

**Question 84.19.** Let \( R = \bigoplus_{n \in \mathbb{N}_0} R_n \) be superalgebra such that \( 0 \cong \mathbb{Z} \), \( R_1 \) is torsion-free and such that all \( R_n \) are finitely generated. Does there exist a topological space \( X \) such that \( (H^*(X; \mathbb{Z}), \cup) \) is isomorphic to \( R \)?

Since there is not much to say right now about this question we continue with the next definition.

**Definition.** The tensor product of two superalgebras \( A = \bigoplus_{n \in \mathbb{N}_0} A_n \) and \( B = \bigoplus_{n \in \mathbb{N}_0} B_n \) is defined as the graded abelian group
\[ A \otimes B := \bigoplus_{n \in \mathbb{N}_0} \bigoplus_{p+q=n} A_p \otimes B_q \]
where for \( a_k \in A_k, a_l \in A_l, b_m \in B_m \) and \( b_n \in B_n \) the multiplication is given by
\[ (a_k \otimes b_l) \cdot (a_m \otimes b_n) = (-1)^{lm} \cdot a_k \cdot a_m \otimes b_l \cdot b_n. \]

\(^{1217}\)If we replace the \( \mathbb{Z} \)-coefficients by \( \mathbb{R} \)-coefficients we obtain a ring that we denote by \( \Lambda_{\mathbb{R}}[x_1, \ldots, x_k] \). This ring is isomorphic to the ring \( \land^*(\mathbb{R}^k)^* = \bigoplus_{j=0}^{k} \land^j(\mathbb{R}^k)^* \) of alternating forms on \( \mathbb{R}^k \), where the ring structure on \( \land^*(\mathbb{R}^k)^* \) is given by the wedge product of alternating forms. More precisely a ring isomorphism is given by
\[ \Lambda_{\mathbb{R}}[x_1, \ldots, x_k] \to \land^*(\mathbb{R}^k)^* \]
\[ x_i \land \cdots \land x_i \to dy_1 \land \cdots \land dy_i \]
where \( dy_i : \mathbb{R}^k \to \mathbb{R} \) is the projection onto the \( i \)-th coordinate.
Lemma 84.20. 

(1) The tensor product of two superalgebras is again a superalgebra. 

(2) The tensor product of superalgebras is associative, i.e. for any three superalgebras $A, B$ and $C$ the map

$$(A \otimes B) \otimes C \rightarrow A \otimes (B \otimes C)$$

that is induced by

$$(a \otimes b) \otimes c \mapsto a \otimes (b \otimes c)$$

is an isomorphism of superalgebras.

It follows immediately from Lemma 84.20 (2) that we can ignore parentheses when we consider the tensor product of several superalgebras.

Proof (*). Let $A, B$ and $C$ be superalgebras and let $a_k \in A_k, a_l \in A_l, b_m \in B_m$ and $b_n \in B_n$.

(1) We have the following equalities:

$$(a_k \otimes b_l) \cdot (a_m \otimes b_n) = (-1)^{lm} \cdot a_k \cdot a_m \otimes b_l \cdot b_n = (-1)^{lm+km+ln} \cdot a_m \cdot a_k \otimes b_n \cdot b_l$$

$$= (-1)^{lm+km+ln+kn} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l)$$

$$= (-1)^{(m+n)(l+r)} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l)$$

$$= (-1)^{\deg(a_m \otimes b_n) \cdot \deg(a_k \otimes b_l)} \cdot (a_m \otimes b_n) \cdot (a_k \otimes b_l).$$

It follows immediately that $A \otimes B$ is again a superalgebra.

(2) It suffices to show that the indicated map is a homomorphism of superalgebras. Thus let $c_r \in C_r$ and $c_s \in C_s$. Then

$$((a_k \otimes b_l) \otimes c_r) \cdot ((a_m \otimes b_n) \otimes c_s) = (-1)^{r(m+n)} \cdot ((a_k \otimes b_l) \cdot (a_m \otimes b_n)) \otimes (c_r \cdot c_s)$$

$$= (-1)^{r(m+n)+lm} \cdot (a_k \cdot a_m \otimes b_l \cdot b_n \otimes c_r \cdot c_s)$$

$$= (-1)^{r(l+r)} \cdot (a_k \cdot a_m \otimes (b_l \otimes c_r) \cdot (b_n \otimes c_s))$$

$$= (a_k \otimes (b_l \otimes c_r)) \cdot (a_m \otimes (b_n \otimes c_s)).$$

Examples.

(1) As above we view the polynomial rings $\mathbb{F}_2[a]$ and $\mathbb{F}_2[b]$ as superalgebras by setting $\deg(a^i) = \deg(b^i) = i$. We consider the map

$$\mathbb{F}_2[a] \otimes \mathbb{F}_2[b] \rightarrow \mathbb{F}_2[a, b]$$

$$a^r \otimes b^s \mapsto a^r \cdot b^s.$$

Using Lemma 57.3 (1) it is straightforward to show that this map is an isomorphism of abelian groups. One can easily verify that the map is a homomorphism of superalgebras. Summarizing we have convinced ourselves that this map is in fact an isomorphism of superalgebras.

(2) As before we view the polynomial rings $\mathbb{Z}[x_j], \ j = 1, \ldots, k$ as superalgebras with $\deg(x_j) = 2i$. We consider the map

$$\mathbb{Z}[x_1] \otimes \cdots \otimes \mathbb{Z}[x_k] \rightarrow \mathbb{Z}[x_1, \ldots, x_k]$$

$$x_1^{r_1} \otimes \cdots \otimes x_k^{r_k} \mapsto x_1^{r_1} \cdots x_k^{r_k}.$$

The same argument as in (1) shows that this map is an isomorphism of superalgebras.
(3) As above we view the rings \( \mathbb{Z}[x_j]/(x_j^2) \) as superalgebras with \( \text{deg}(x_j) = 1 \). We leave it as an amusing exercise to verify that the map
\[
\begin{align*}
\mathbb{Z}[x_1]/(x_1^2) \otimes \cdots \otimes \mathbb{Z}[x_k]/(x_k^2) & \rightarrow \Lambda[x_1, \ldots, x_k] \\
x_1^i \otimes \cdots \otimes x_k^j & \mapsto x_1^{i_1} \wedge \cdots \wedge x_k^{i_k}
\end{align*}
\]
is an isomorphism of superalgebras.

The following proposition explains our sudden interest in tensor products of superalgebras.

**Proposition 84.21.** Let \( X \) and \( Y \) be two topological spaces. We denote by \( p: X \times Y \rightarrow X \) and \( q: X \times Y \rightarrow Y \) the obvious projection maps.

1. The map
\[
\Phi: H^*(X; \mathbb{Z}) \otimes H^*(Y; \mathbb{Z}) \rightarrow H^*(X \times Y; \mathbb{Z}) \\
\varphi \otimes \psi \mapsto p^* \varphi \cup q^* \psi
\]
is a homomorphism of superalgebras.

2. If all the homology groups of \( X \) are finitely generated and torsion-free, then the homomorphism from (1) is in fact an isomorphism.

**Proof.** Let \( X \) and \( Y \) be two topological spaces.

1. Let \( \varphi_k \in H^k(X; \mathbb{Z}) \), \( \psi_l \in H^l(Y; \mathbb{Z}) \), \( \varphi_m \in H^m(X; \mathbb{Z}) \) and \( \psi_n \in H^n(Y; \mathbb{Z}) \). Then
\[
\Phi(\varphi_k \otimes \psi_l) = (-1)^{lm} \cdot (\varphi_k \cup \varphi_m) \otimes (\psi_l \cup \psi_n) = (-1)^{lm} \cdot p^*(\varphi_k \cup \varphi_m) \cup q^*(\psi_l \cup \psi_n) = p^* \varphi \cup q^* \psi
\]

2. Now suppose that all the homology groups of \( X \) are finitely generated and torsion-free. This hypothesis allows us to apply the Künneth Theorem [84.16] for cohomology groups and we obtain the following short exact sequence:
\[
0 \rightarrow \bigoplus_{k+l=n} H^k(X; \mathbb{Z}) \otimes H^l(Y; \mathbb{Z}) \rightarrow H^n(X \times Y; \mathbb{Z}) \rightarrow \bigoplus_{k+l=n+1} \text{Tor}(H^k(X; \mathbb{Z}), H^l(Y; \mathbb{Z})) \rightarrow 0.
\]

Since the homology groups of \( X \) are torsion-free we obtain from the Universal Coefficient Theorem [75.13] for Cohomology Groups that the cohomology groups \( H^k(X; \mathbb{Z}) \) are also torsion-free. But by Lemma [57.17] this implies that all the Tor-terms on the right-hand side of the short exact sequence vanish.

The following proposition in particular provides an answer to Question 82.12 (1).

**Proposition 84.22.** Let \( n \in \mathbb{N}_0 \). We denote by \( T = (S^1)^n \) the \( n \)-dimensional torus. For \( i = 1, \ldots, n \) we denote by \( p_i: T \rightarrow S^1 \) the projection onto the \( i \)-th factor. Then there exists
a unique isomorphism
\[ \psi: \Lambda[x_1, \ldots, x_n] \rightarrow \mathbb{H}^*(T; \mathbb{Z}) \]
of superalgebras which has the property that for each \( i \in \{1, \ldots, n\} \) we have
\[ \psi(x_i) = p_i^*([S^1]^*) \].

**Proof.** We consider the following isomorphism of superalgebras
\[
\Lambda[x_1, \ldots, x_n] \xrightarrow{\cong} \mathbb{Z}[x_1] / (x_1^2) \otimes \cdots \otimes \mathbb{Z}[x_k] / (x_k^2) \xrightarrow{\cong} \mathbb{H}^*(S^1; \mathbb{Z}) \otimes \cdots \otimes \mathbb{H}^*(S^1; \mathbb{Z}) \xrightarrow{\cong} \mathbb{H}^*((S^1)^n; \mathbb{Z}).
\]

It is clear from the definitions of the various maps that the map from left to right sends each \( x_i \) to \( p_i^*([S^1]^*) \). The composition of the isomorphisms thus gives us the desired isomorphism. The uniqueness follows immediately from the fact that the \( x_i \) generate \( \Lambda[x_1, \ldots, x_n] \) as a ring.

The following corollary gives in particular a negative answer to Question 82.10.

**Corollary 84.23.** For the \( n \)-dimensional torus \( T = (S^1)^n \) the Lusternik-Schnirelmann category \( \text{cat}(T) \) equals \( n \).

**Proof.** Given any \( n \in \mathbb{N}_0 \) we have
\[
\begin{align*}
n \geq \text{Lusternik-Schnirelmann category} \quad & \geq \text{cup length} \quad \geq n.
\end{align*}
\]

by Proposition 82.11

by Proposition 84.22, there exists an isomorphism \( \psi: \Lambda[x_1, \ldots, x_n] \rightarrow \mathbb{H}^*((S^1)^n; \mathbb{Z}) \) of graded rings,

furthermore by the discussion on page 2054 we know that \( x_1 \wedge \cdots \wedge x_n \neq 0 \),

since \( \psi \) is an isomorphism we deduce that \( \psi(x_1) \cup \cdots \cup \psi(x_n) \neq 0 \), i.e. \( \text{cl}((S^1)^n) \geq n \)

We conclude this chapter with the following variation on Proposition 84.21.

**Proposition 84.24.** Let \( X \) and \( Y \) be two topological spaces. We denote by \( p: X \times Y \rightarrow X \) and \( q: X \times Y \rightarrow Y \) the obvious projection maps. If all the homology groups of \( X \) are finitely generated, then the map
\[
\Phi: \mathbb{H}^*(X; \mathbb{F}_2) \otimes \mathbb{H}^*(Y; \mathbb{F}_2) \rightarrow \mathbb{H}^*(X \times Y; \mathbb{F}_2)
\]

\( \varphi \otimes \psi \mapsto p^* \varphi \cup q^* \psi \)

is an isomorphism of superalgebras.

In the proof of Proposition 84.24 we will need the following theorem which is a variation on the Künneth Theorem 84.17 for cochain complexes.

**Theorem 84.25.** Let \( C \) and \( C' \) be chain complexes. If \( C \) is a free chain complex and if all homology groups of \( C \) are finitely generated, then for every \( n \in \mathbb{N}_0 \) there exists a natural isomorphism
\[
\bigoplus_{k+l=n} \mathbb{H}^k(C; \mathbb{F}_2) \otimes \mathbb{H}^l(C'; \mathbb{F}_2) \xrightarrow{\cong} \mathbb{H}^n(C \otimes C'; \mathbb{F}_2).
\]

The proof of Theorem 84.25 is evidently very similar to the proof of the Künneth Theorem 84.17 for cochain complexes. We refer to [Mun84] Theorem 60.6 for a proof.
Proof of Proposition 84.24. The proof is almost the same as the proof of Proposition 84.21. More precisely, we first note that if in the proof of the Künneth Theorem 84.16 for cohomology groups we replace the Künneth Theorem 84.17 for cochain complexes by Theorem 84.25 we obtain that the map

$$\bigoplus_{k+l=n} H^k(X; \mathbb{F}_2) \otimes H^l(Y; \mathbb{F}_2) \rightarrow H^n(X \times Y; \mathbb{F}_2)$$

$$\varphi \otimes \psi \mapsto p^*\varphi \cup q^*\psi$$

is an isomorphism. But the same argument as in the proof of Proposition 84.21 shows that this map is in fact a homomorphism of superalgebras.

Exercises for Chapter 84

Exercise 84.1. Let $X$ be a topological space. Recall that Proposition 81.8 says that for any $a \in H^k(X; \mathbb{Z})$ and $b \in H^l(X; \mathbb{Z})$ we have

$$a \cup b = (-1)^{kl} \cdot b \cup a.$$ Provide a proof of this statement using the original definition of the cup product from page 1980 and using Lemma 84.7.

Exercise 84.2. Let $g \in \mathbb{N}$ and denote by $\Sigma_g$ the surface of genus $g$. Show that the Lusternik-Schnirelmann category of $S^1 \times \Sigma_g$ is greater or equal than three.

Exercise 84.3. Let $\Sigma$ be the surface of genus 2, let $q: \Sigma \times S^1 \rightarrow \Sigma$ be the projection map and let $p: \Sigma \rightarrow S^1$ be the map shown in Figure 1184. Determine the cap product

$$q(p^*([S^1])) \cap [\Sigma \times S^1] \in H_2(\Sigma \times S^1; \mathbb{Z})$$

up to sign.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1184.png}
\caption{Figure 1184}
\end{figure}

Exercise 84.4. Let $n \in \mathbb{N}_0$. We write $T := (S^1)^n$. Let $\varphi: T \rightarrow T$ be map. We pick a basis for $H_1(T) \cong \mathbb{Z}^n$ and we denote by $A$ the $(n \times n)$-matrix that represents the map $\varphi_*: H_1(T) \rightarrow H_1(T)$ with respect to the given basis. Show that

$$\sum_{k=0}^{n} (-1)^k \cdot \text{tr}(\varphi_*: H_k(T) \rightarrow H_k(T)) = \det(\text{id} - A).$$

\textit{Hint.} Use the cohomological reformulation of the Lefschetz number given in Exercise 75.12 and use Proposition 84.22.

\textit{Remark.} It follows from this calculation together with the Lefschetz Fixed Point Theorem 65.9 that unless 1 is an eigenvalue of $A$ the map $\varphi$ has a fixed point.
Exercise 84.5. Let \( n \in \mathbb{N} \) and let \( W \) be a compact orientable \((n+1)\)-dimensional topological manifold such that \( \partial W \) is homeomorphic to the \( n \)-torus \((S^1)^n\). Show that the inclusion induced map \( H_1(\partial W; \mathbb{Z}) \to H_1(W; \mathbb{Z}) \) is not an injection.

*Hint.* Consider the cup product on \((S^1)^n\) and consider the interplay of the fundamental classes of \( \partial W \) and \( W \).

Exercise 84.6. Given \( n \in \mathbb{N} \) we denote by \( p: S^n \times S^n \to S^n \) and \( q: S^n \times S^n \to S^n \) the two obvious projections. Let \( \varphi \in H^n(S^n; \mathbb{Z}) \) be a generator. We know, for example by Proposition 84.21, that \( p^*(\varphi) \) and \( q^*(\varphi) \) form a basis for \( H^n(S^n \times S^n; \mathbb{Z}) \). Given a map \( f: S^n \times S^n \to S^n \times S^n \) we denote by \( A(f) \) the matrix representing the automorphism \( f^* \) of \( H^n(S^n \times S^n; \mathbb{Z}) \) with respect to the basis \( p^*(\varphi) \) and \( q^*(\varphi) \).

(a) Let \( B \in SL(2, \mathbb{Z}) \). Show that there exists a homeomorphism \( f: S^1 \times S^1 \to S^1 \times S^1 \) with \( A(f) = B \).

*Hint.* Use Lemma 52.7.

(b) Now let \( f: S^n \times S^n \to S^n \times S^n \) be a homeomorphism. Show that if \( n \) is even, then \( A(f) \) is given by one of the following eight matrices

\[
\begin{pmatrix}
\pm 1 & 0 \\
0 & \pm 1
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
0 & \pm 1 \\
\pm 1 & 0
\end{pmatrix}.
\]

Poincaré Duality
85. Borsuk’s Theorem, ENRs and ANRs

In this chapter we will state and prove Borsuk’s Theorem\footnote{So far, in Chapter 65 we only proved the Lefschetz Fixed Point Theorem for simplicial complexes and smooth manifolds.} which will give us many goodies:

1. We can prove the Lefschetz Fixed Point Theorem also for CW-complexes and topological manifolds.\footnote{Note that Lemma 18.12 says that a topological space $X$ is contractible if and only if the identity map is homotopic to a constant map.}

2. We can get some control over the invariants of compact topological manifolds, for example we will be able to show that the homology groups of a compact topological manifold are finitely generated and that the fundamental groups are finitely presented.

85.1. Neighborhood retracts. We recall two definitions from pages 547 and 138 and we introduce two related definitions.

**Definition.** Let $X$ be a topological space.

1. We say $X$ is contractible if $X$ is homotopy equivalent to a point.

2. We say $X$ is locally contractible if given any $Q \subseteq X$ and given any open neighborhood $U$ of $Q$ there exists an open neighborhood $V$ of $Q$ that is contained in $U$ and that is contractible.

3. We say that a subset $U$ of $X$ is contractible in $X$ if the inclusion map $U \to X$ is homotopic to a constant map.\footnote{What we call a “weakly locally contractible” topological space is referred to in many books, see e.g. [Bor67, Saka13], as a “locally contractible” topological space. Since on page 138 we defined once and for all what it means that a topological space is “locally $P$” we stick with our more cumbersome name.}

4. We say $X$ is weakly locally contractible if given any $Q \subseteq X$ and given any open neighborhood $U$ of $Q$ there exists an open neighborhood $V$ of $Q$ that is contained in $U$ and that is contractible in $U$. We illustrate this definition in Figure 1186.

---

**Figure 1185.**

\[ X \] is contractible in $X$.

\[ U \text{ is not contractible, but it is contractible in } X \]

---

**Figure 1186.**

\[ X \]

\[ Q \]

\[ V \text{ is contractible in } U \]

\[ X \text{ is weakly locally contractible} \]
(2) By Lemma 6.9 (1) every topological manifold is locally homeomorphic to some non-empty convex subset of \( \mathbb{R}^n \). Since non-empty convex subsets are contractible we see that every topological manifold is locally contractible.

(3) In Proposition 36.10 (6) we showed that CW-complexes are locally contractible. In particular topological graphs are locally contractible. (Note that we had also shown in Exercise 29.1 that topological graphs are locally contractible.)

(4) It is easy to show that \( \mathbb{R}^2 \setminus \{ \frac{1}{n} \mid n \in \mathbb{N} \} \) is not weakly locally contractible.

(5) It is an amusing exercise to show that the topologist’s sine curve

\[
\{(0, y) \mid y \in [-1, 1]\} \cup \{(x, \sin(\frac{1}{x})) \mid x \in (0, \pi]\} \subset \mathbb{R}^2,
\]

which we had initially introduced on page 131, is not weakly locally contractible.

(6) It is an equally amusing (but not entirely trivial) exercise to come up with a topological space that is weakly locally contractible but not locally contractible.

\[\text{Figure 1187}\]

Next we recall the following definition from page 484.

**Definition.** Let \( X \) be a topological space. We say a subset \( A \subset X \) is a *retract of \( X \) if there exists a map \( r: X \to A \) with \( r(a) = a \) for all \( a \in A \).

In our discussions of retracts the following two basically trivial observations will at times be helpful.

**Observation 85.1.** Let \( Z \) be a topological space and let \( K \) be a subset.

1. Let \( K \subset U \subset V \subset Z \) be subsets. If \( K \) is a retract of \( V \), then \( K \) is also a retract of \( U \).
2. If \( K \) is a retract of a neighborhood, then it is also a retract of an open neighborhood.

**Proof.** The first statement follows from the observation that the restriction of any retraction \( r: V \to K \) to \( U \) is again a retraction. The second statement follows immediately from the first statement.

\[\text{ Definition. Let } Y \text{ be a topological space and let } X \text{ be a subset. We say } X \text{ is a neighborhood retract in } Y \text{ if there exists an open neighborhood } N \text{ of } X \text{ in } Y \text{ such that } X \text{ is a retract of } N.\]

\[\text{End of Definition.}\]

\[\text{Observation 85.1 (2) this definition is equivalent to asking that there exists any neighborhood (not necessarily closed) that admits a retract to } X \text{. This formulation is often the definition of a neighborhood retract that is used in the literature. For our discussion it is convenient to already assume that the neighborhood is open.}\]
Examples.

(1) Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem \[8.24\] we know that there exists a tubular neighborhood $B^2 \times K$ of $K$ in $S^3$. Since $K = \{0\} \times K$ is evidently a retract of $B^2 \times K$ we see that $K$ is a neighborhood retract in $S^3$.

(2) Later on we will generalize (1) as follows. It is a consequence of the Regular Neighborhood Theorem \[10.3\] which is a fairly immediate consequence of the General Tubular Neighborhood Theorem \[10.5\] that every compact proper submanifold $X$ of a given smooth manifold $M$ is a neighborhood retract in $M$.

(3) We will see in Exercise \[85.2\] that $X = \{0\} \cup \{\frac{1}{n} | n \in \mathbb{N}\}$, viewed as a subset of $Y = \mathbb{R}$, is not a neighborhood retract.

We continue with the following fairly elementary lemma.

**Lemma 85.2.** Let $n \in \mathbb{N}_0$ and let $X$ be a subset of $\mathbb{R}^n$. If $X$ is a neighborhood retract in $\mathbb{R}^n$, then the topological space $X$ is weakly locally contractible.

**Proof** (*). Let $W$ be a neighborhood of $X$ that admits a retraction $r: W \to X$. Let $Q \in X$ and let $U$ be a neighborhood of $Q$ in $X$. Since $W$ is a neighborhood of $X$ there exists an $s > 0$ such that $B^a_s(Q) \subset r^{-1}(U)$. We denote by $F: B^a_s(Q) \times [0, 1] \to B^a_s(Q)$ the obvious homotopy from the identity to the constant map. Finally we consider the map

$$(B^a_s(Q) \cap X) \times [0, 1] \to U$$

$$\begin{array}{cccc}
\quad & (x, t) & \mapsto & r\left( F(x, t) \right) \\
& & & \quad \in B^a_s(Q) \cap r^{-1}(U)
\end{array}$$

Evidently this map is a homotopy from the identity to a constant map. In particular $V := B^a_s(Q) \cap X$ is contractible in $U$. \hfill \blacksquare

![Diagram](image1.png)  

**Figure 1189.** Illustration of the proof of Lemma \[85.2\]

It is rather stunning that for closed subsets of $\mathbb{R}^n$ the converse to Lemma \[85.2\] holds. More precisely, the following theorem was proved by Karol Borsuk \[Bor32\] in 1932.
**Theorem 85.3. (Borsuk’s Theorem)** Let \( n \in \mathbb{N}_0 \) and let \( X \) be a closed subset of \( \mathbb{R}^n \). If the topological space \( X \) is weakly locally contractible, then \( X \) is a neighborhood retract in \( \mathbb{R}^n \).

\( ^* \)Is it perhaps worth stressing that the proposition does not claim that \( X \) is a deformation retract of a neighborhood of \( X \).

**Remark.** Proofs of Borsuk’s Theorem 85.3 are also given in [Bre93, Theorem E.3] and [Hat02, Theorem A.7].

**Example.** We define a wild knot to be the image of an embedding \( \gamma: S^1 \to \mathbb{R}^3 \). If the embedding is smooth, then we obtain the usual notion of a knot in \( \mathbb{R}^3 \). But once we drop smoothness one can get weird examples. For example using Proposition 2.43 (3) it is not difficult to show that the example shown in Figure 1190 is indeed a wild knot.  

![Wild Knot](wild_knot.png)  

**Figure 1190**

Evidently \( S^1 \) is locally contractible and by Lemma 2.40 together with Lemma 2.17 we know that \( \gamma(S^1) \) is a closed subset of \( \mathbb{R}^3 \). Thus it follows from Borsuk’s Theorem 85.3 that every wild knot is a neighborhood retract in \( \mathbb{R}^3 \). It is a fantastic exercise to try to visualize a neighborhood of the above wild knot together with a retraction to \( \gamma(S^1) \).

85.2. **Proof of the Borsuk’s Theorem 85.3** Before we provide the proof of Borsuk’s Theorem 85.3 it is convenient to introduce one definition and to prove one lemma.

**Definition.** Let \( k \in \mathbb{N}_0 \) and let \( n \in \mathbb{N} \). A \( \frac{1}{2^k} \)-cube is a subset \( C \) of \( \mathbb{R}^n \) of the form

\[
C = \left[ a_1 \frac{1}{2^k}, a_1 + \frac{1}{2^k} \right] \times \cdots \times \left[ a_n \frac{1}{2^k}, a_n + \frac{1}{2^k} \right] \quad \text{with} \quad a_1, \ldots, a_n \in \mathbb{Z}.
\]

Put differently, a \( \frac{1}{2^k} \)-cube is a cube in \( \mathbb{R}^n \) with side length \( \frac{1}{2^k} \) and where the coordinates of all vertices lie in \( \frac{1}{2^k} \cdot \mathbb{Z} \).

**Lemma 85.4.** Let \( x \in \mathbb{R}^n \) and let \( r > 0 \). If \( k \in \mathbb{N}_0 \) is chosen such that \( \frac{1}{2^k} < \frac{1}{3 \sqrt{n}} \cdot r \), then there exist finitely many \( \frac{1}{2^k} \)-cubes \( W_1, \ldots, W_m \) such that

\[
x \in \text{interior of } (W_1 \cup \cdots \cup W_m) \subset W_1 \cup \cdots \cup W_m \subset B^n_r(x).
\]

**Proof (\(*\)).** Let \( x = (x_1, \ldots, x_n) \in \mathbb{R}^n \) and let \( r > 0 \). Furthermore let \( k \in \mathbb{N}_0 \) such that \( \frac{1}{2^k} < \frac{1}{3 \sqrt{n}} \cdot r \). We write \( \epsilon = \frac{1}{2^k} \). For \( i = 1, \ldots, n \) we denote by \( y_i \) the result of rounding \( x_i \) down to the closest number in \( \mathbb{Z} \cdot \epsilon \). Clearly we have

\[
(x_1, \ldots, x_n) \in \left[ y_1, y_1 + \epsilon \right] \times \cdots \times \left[ y_n, y_n + \epsilon \right] \subset \text{interior of } \left[ y_1 - \epsilon, y_1 + 2\epsilon \right] \times \cdots \times \left[ y_n - \epsilon, y_n + 2\epsilon \right].
\]

\( ^{1222} \)It is also not difficult, but rather pointless, to write down such an embedding explicitly.
Since $V$ is the union of finitely many $\epsilon$-cubes it suffices to show that $V$ is contained in $B_r^n(x)$. Thus let $y \in V$. We have

$$d(y, x) \leq \text{diameter of } V = \sqrt{n} \cdot 3\epsilon = \sqrt{n} \cdot \frac{3}{2\epsilon} < r$$

since $x \in V$ up, see page 1341 up, choice of $k$.

which means by definition that $y \in B_r^n(x)$. Thus we have shown that $V \subset B_r^n(x)$.

\begin{figure}
\centering
\includegraphics[width=0.8\textwidth]{figure1191.png}
\caption{Illustration of the proof of Lemma 85.4}
\end{figure}

Now we turn to the actual proof of Borsuk’s Theorem 85.3.

Proof of Borsuk’s Theorem 85.3 Let $X$ be a closed, weakly locally contractible subset of $\mathbb{R}^n$. By Observation 85.1 (2) it suffices to show that there exists a neighborhood $W$ of $X$ in $\mathbb{R}^n$ that admits a retraction $W \to X$. Evidently we only have to consider the case that $X$ is non-empty. We introduce the following notation.

1. We define $C_1$ to be the union of all 1-cubes that do not intersect $X$.
2. We define $C_2$ to be the union of all $\frac{1}{2}$-cubes that do not intersect $C_1$ and that do not intersect $X$.
3. We iterate this process, i.e. for any $k \geq 3$ we define $C_k$ to be the union of all $\frac{1}{2^k}$-cubes that do not intersect the interior of $C_1 \cup \cdots \cup C_{k-1}$ and that do not intersect $X$.

\begin{figure}
\centering
\includegraphics[width=0.8\textwidth]{figure1192.png}
\caption{Figure 1192}
\end{figure}

Claim.

1. We have $\bigcup_{k \in \mathbb{N}} C_k = \mathbb{R}^n \setminus X$.
2. Given any $x_0 \in \mathbb{R} \setminus X$ there exists an open neighborhood $U$ that intersects only finitely many cubes of $C_1, C_2, \ldots$.

To prove the claim, let $x_0 \in \mathbb{R}^n \setminus X$. Since $X$ is closed we know that $\mathbb{R}^n \setminus X$ is open. This means that there exists an $r > 0$ such that $B_r^n(x_0) \subset \mathbb{R}^n \setminus X$. We pick $k \in \mathbb{N}_0$ such
that \( \frac{\sqrt{n}}{3^{2/3}} < r \). By Lemma 85.4 there exist finitely many \( \frac{1}{2^k} \)-cubes \( W_1, \ldots, W_m \) such that 
\[
x_0 \in \text{interior of } W_1 \cup \cdots \cup W_m \subset B^n_r(x). 
\]
This implies in particular that \( x_0 \) is contained in \( C_n \) or it is contained already in one of \( C_1, \ldots, C_{k-1} \). Furthermore it is fairly easy to see that if \( U \) intersects a \( \frac{1}{2^k} \)-cube with \( m \geq k \) it already intersects a \( \frac{1}{2^k} \)-cube. It follows from this observation and the iterative definition of the \( C_i \) that \( U \) intersects only finitely many cubes of \( C_1, C_2, \ldots \). \( \square \)

We view each \( C_i \) as a CW-complex in the obvious way: the \( n \)-cells correspond precisely to the cubes and the lower dimensional cells correspond precisely to the faces of the cubes. For each \( k \) the union \( C_1 \cup \cdots \cup C_n \) is also a CW-complex in an obvious way and finally we can also view the union \( C := \bigcup_{k \in \mathbb{N}} C_k = \mathbb{R}^n \setminus X \) as a CW-complex. We leave it to the reader to verify, using statement (2) of the claim and using Lemma 2.6 (2), that the topology on this CW-complex, given by the weak topology defined on page 941 agrees with the usual subspace topology on \( \mathbb{R}^n \setminus X \).

We continue with the following definition: given a cell \( \sigma \) of \( C \) and a map \( f: \sigma \to X \) we define
\[
\rho(f) := \max\{d(z, f(z)) \mid z \in \sigma\}. 
\]
We start with the iterative definition of a subset of \( \mathbb{R}^n \) together with a map to \( X \).

(a) We denote by \( A_0 \) the 0-skeleton of \( C \). Next we define a map \( r_0: A_0 \to X \). Let \( a \in A_0 \). Since \( X \) is a closed subset of \( \mathbb{R}^n \) it follows from Corollary 3.19 (1) that we can find a point \( r_0(a) \in X \) with \( d(a, r_0(a)) = d(a, X) \).

(b) Now suppose inductively that we have defined a map \( r_i: A_i \to X \) on a union \( A_i \) of some of the \( i \)-cells of \( C \). We define the next set \( A_{i+1} \) and the corresponding map \( r_{i+1}: A_{i+1} \to X \) as follows:

\( (b_1) \) Let \( \sigma \) be an \( (i+1) \)-cell of \( C \) for which \( r_i \) is defined on \( \partial \sigma \). Suppose that \( r_i \) can be extended to a map \( g: \sigma \to X \) that agrees with \( r_i \) on \( \partial \sigma \). Then we pick a map \( r_{i+1}: \sigma \to X \) with \( r_{i+1}|_{\partial \sigma} = r_i|_{\partial \sigma} \) such that
\[
\rho(r_{i+1}) \leq 2 \inf\{\rho(g) \mid g: \sigma \to X \text{ is a map with } g|_{\partial \sigma} = r_i|_{\partial \sigma}\}. 
\]
\[
\geq d(\sigma, X) \text{ which in turn is } > 0 \text{ by Corollary 3.19 (2), here we use again that } X \subset \mathbb{R}^n \text{ is closed.}
\]

\( (b_2) \) We denote by \( A_{i+1} \) the union of all \( (i+1) \)-cells as in \( (b_1) \) and we define \( r_{i+1} \) on \( A_{i+1} \) as in \( (b_1) \).

(c) We set \( A := \bigcup_{i \in \mathbb{N}} A_i \cup X \) and we define \( r: A \to X \) to be the unique map that equals \( r_i \) on each \( A_i \) and that is the identity on \( X \).

We refer to Figure 1193 for an illustration. It remains to show that the set \( A \) is a neighborhood of \( X \) and that the map \( r: A \to X \) is continuous. Both statements follow from the following claim.

\footnote{1223 Given \( a, b \in \mathbb{R}^n \) we denote by \( d(a, b) = \|a - b\| \) the usual Euclidean distance.}

\footnote{1224 Note that \( \sigma \) is compact, hence the maximum exists by Lemma 2.40 (2).}
Claim. Given any \( x \in X \) and any \( \epsilon_0 > 0 \) there exists an open neighborhood \( U \) of \( x \) that is contained in \( A \) and such that \( \| r(x) - r(y) \| < \epsilon_0 \) for all \( y \in U \), i.e. such that \( r(U) \subset B^n_{\epsilon_0}(x) \).

So let \( x \in X \) and let \( \epsilon_0 > 0 \). We adopt the following notation: given \( \mu > 0 \) we write \( W(\mu) = X \cap B^n_{\mu}(x) \).

Subclaim. We can find \( \epsilon_1, \ldots, \epsilon_{2n} \) with the following two properties:

1. for each \( i \in \{0, \ldots, 2n - 1\} \) we have \( \epsilon_{i+1} < \frac{1}{3} \cdot \epsilon_i \),
2. for every \( i = 1, \ldots, 2n \) the subset \( W(\epsilon_i) \) is contractible in \( W(\epsilon_{i-1}) \).

So suppose that we have already found \( \epsilon_0, \ldots, \epsilon_i \) for some \( i \in \{0, \ldots, 2n - 1\} \) with the desired properties. Since \( X \) is weakly locally contractible we can find an open neighborhood \( U \) of \( x \) in \( X \) that is contained in \( W(\epsilon_i) \) and that is contractible in \( W(\epsilon_i) \). Since \( U \) is open there exists an \( \epsilon_{i+1} < \frac{1}{3} \epsilon_i \) such that \( W(\epsilon_{i+1}) \subset U \). Since \( U \) is contractible in \( W(\epsilon_i) \) the subset \( W(\epsilon_{i+1}) \) is also contractible in \( W(\epsilon_i) \). We refer to Figure 1194 for an illustration. This concludes the proof of the subclaim.

Subclaim 1. For each \( i = 0, \ldots, n \) the map \( r \) is defined for each \( i \)-cell \( \sigma \) of the CW-complex \( C \) that lies in \( U \) and for each such \( \sigma \) we have \( r(\sigma) \subset W(\epsilon_{2n-2i}) \).

Subclaim 2. The union of \( X \) with all cells of \( C \) that lie in \( U \) is a neighborhood of \( x \).

First we prove Subclaim 1. We prove Subclaim 1 iteratively for \( i = 0, 1, \ldots, n \). We start out with \( i = 0 \). Thus we have to show that \( r(U \cap A_0) \subset W(\epsilon_{2n}) \). Therefore let \( y \in U \cap A_0 \).
Then we have

\[ d(x, r(y)) \leq d(x, y) + d(y, r_0(y)) \leq d(x, y) + d(y, x) = 2d(x, y) \leq 2 \cdot \frac{1}{4} \cdot \epsilon_{2n} = \frac{1}{2} \cdot \epsilon_{2n}. \]

triangle inequality and \( r(y) = r_0(y) \) by (a) since \( x \in X \) since \( y \in U = B^n_{\frac{3}{4} \epsilon_{2n}}(x) \)

But since \( r(y) \in X \) this means precisely that \( r(y) \in W(\epsilon_{2n}) = X \cap B^n_{\epsilon_{2n}}(x) \). This shows that Subclaim 1 holds for \( i = 0 \).

Now suppose that Subclaim 1 holds for some \( i \in \{0, \ldots, n-1\} \). Let \( \sigma \) be an \((i+1)\)-cell of the CW-complex \( C \) inside \( U \). Since \( r(\partial \sigma) \subset W(\epsilon_{2n-2i}) \) and since \( W(\epsilon_{2n-2i}) \) is contractible in \( W_{2n-2i-1} \) it follows from Proposition 2.52 and Proposition 10.7 (3) that we can extend \( r|_{\partial \sigma} = r_i|_{\partial \sigma} \) to a map \( s: \sigma \to W(\epsilon_{2n-2i-1}) \). By definition of \( A_{i+1} \) this implies that \( \sigma \subset A_{i+1} \).

In particular \( r \) is defined on \( \sigma \). It remains to show that \( r(\sigma) \subset W(\epsilon_{2n-2i-2}) \). Thus let \( y \in \sigma \).

We have

\[ d(x, r(y)) \leq d(x, y) + d(y, r_{i+1}(y)) \leq \frac{1}{4} \epsilon_{2n} + \rho(r_{i+1}) \leq \frac{1}{4} \epsilon_{2n} + 2 \cdot \inf \left\{ \rho(g) \mid g: \sigma \to X \text{ with } g|_{\partial \sigma} = r_i|_{\partial \sigma} \right\}. \]

by the triangle inequality since \( y \in \sigma \subset U = B^n_{\frac{3}{4} \epsilon_{2n}}(x) \) by (b1)

and since \( r(y) = r_{i+1}(y) \) and by definition of \( \rho(r_{i+1}) \)

\[ \leq \frac{1}{4} \epsilon_{2n} + 2 \cdot \max \{ d(z, s(z)) \mid z \in \sigma \} \leq \frac{1}{4} \epsilon_{2n} + 2 \cdot \max \{ d(z, x) + d(x, s(z)) \mid z \in \sigma \} \]

since \( s \) is such a map \( = \rho(s) \) triangle inequality

\[ \leq \frac{1}{4} \epsilon_{2n} + 2 \left( \frac{1}{4} \epsilon_{2n} + \epsilon_{2n-2i-1} \right) = \frac{3}{4} \epsilon_{2n} + 2 \epsilon_{2n-2i-1} \leq \frac{1}{12} \epsilon_{2n-2i-2} + \frac{2}{3} \epsilon_{2n-2i-2} \leq \epsilon_{2n-2i-2}. \]

since \( \sigma \subset U = B^n_{\frac{3}{4} \epsilon_{2n}}(x) \) and since for each \( z \in \sigma \) we have \( s(z) \in W(\epsilon_{2n-2i-1}) \subset B^n_{\epsilon_{2n-2i-1}}(x) \)

This concludes the proof that \( r(\sigma) \subset W(\epsilon_{2n-2i-2}) \). In particular this concludes the proof of Subclaim 1.

Finally it remains to prove Subclaim 2. We set \( s = \frac{1}{4} \epsilon_{2n} \). As a reminder, we have to show that the union of \( X \) with all cells of \( C \) that lie in \( B^n_s(x) \) is a neighborhood of \( x \). Let \( W \) be a \( \frac{1}{2n} \)-cube with \( W \cap B^n_s(x) \neq \emptyset \) and \( W \cap (\mathbb{R}^n \setminus B^n_s(x)) \neq \emptyset \). It follows that the diameter of \( W \) is at least \( \frac{s}{2} \) which in turn implies that \( \frac{s}{2} \geq \frac{s}{2} \). We set \( k_0 = \lfloor \ln(\frac{2 \sqrt{n}}{s}) \rfloor \).
We see that

\[ \text{union of } X \text{ with all cells of } C \text{ that lie in } B^n_s(x) \]
\[ \implies \text{union of } X \text{ with all cubes of } C \text{ that lie in } B^n_s(x) \]
\[ \implies B^n_s(x) \setminus \text{union of all cubes of } C \text{ that are not completely contained in } B^n_s(x) \]
\[ \uparrow \]

since \( \mathbb{R}^n \setminus X = C \)
\[ = B^n_s(x) \setminus \text{union of all cubes of } C \text{ that are not completely contained in } B^n_s(x) \]
\[ \implies B^n_s(x) \setminus \text{union of all } \frac{1}{2^n}-\text{cubes with } k \leq k_0 \text{ of } C \text{ that are not contained in } B^n_s(x) \]
\[ \uparrow \]

definition of \( k_0 \)

finite union of cubes, hence a closed subset

The last set is clearly an (open) neighborhood of \( x \). But then the first set is also a neighborhood of \( x \). This concludes the proof of Subclaim 2. \( \blacksquare \)

\[ \text{Figure 1196. Illustration for the proof of Theorem 85.3} \]

85.3. **Euclidean Neighborhood Retracts.** Borsuk’s Theorem 85.3 has many applications. For example, much later, it will be a key ingredient in the proof of the Generalized Alexander Duality Theorem 92.10.

In this section we will discuss several fairly direct consequences of Borsuk’s Theorem 85.3. For the following discussion it is convenient to introduce the following definition.

**Definition.** A topological space \( X \) is called a **euclidean neighborhood retract** (or short ENR) if there exists an embedding \( f : X \to \mathbb{R}^n \) and an open neighborhood \( U \) of \( f(X) \) such that \( f(X) \) is a retract of \( U \).

**Remark.** Let \( i : X \to \mathbb{R}^n \) be an embedding of a topological space. The property of \( X \) being a retract of an open neighborhood, rather surprisingly, does not depend on the choice of the embedding. More precisely, [TD08] Proposition 1.4.1 says the following. If \( X \) is an ENR, then given any embedding \( f : X \to Y \) into a metric space \( Y \) there exists an open neighborhood \( U \) of \( f(X) \) such that \( X \) is a retract of \( U \). We will not make use of this pretty statement.

In the following we will mostly work with the following slight reformulation of Borsuk’s Theorem.

**Theorem 85.5. (Borsuk’s Theorem)** Let \( X \) be a topological space which is weakly locally contractible and which admits an embedding \( f : X \to \mathbb{R}^n \).

1. If \( f(X) \) is closed, then \( X \) is an ENR.
(2) If \( X \) is regionally compact (e.g. if \( X \) is compact), then \( X \) is an ENR.

**Proof.**

(1) This statement follows immediately from Borsuk’s Theorem [85.5].

(2) Now assume that \( X \) is regionally compact. If \( X \) is compact, then we know of course by Lemma 2.17 (2) that \( f(X) \) is compact and we can apply (1). Slightly more interestingly, if \( X \) is regionally compact, then we know by Exercise [85.6] that there exists an embedding \( g: X \rightarrow \mathbb{R}^{n+1} \) such that \( g(X) \) is a closed subset of \( \mathbb{R}^{n+1} \). Thus we obtain again from (1) that \( X \) is an ENR.

---

**Definition.** Let \( X \) be a topological space and let \( C \) be a class of topological spaces (e.g. \( C \) could be the class of CW-complexes). We say \( X \) is a retract of an element in \( C \) if there exists a topological space \( Y \in C \), a map \( i: X \rightarrow Y \) and a map \( r: Y \rightarrow X \) with \( r \circ i = \text{id}_X \).

In this chapter our key interest in ENR and thus in Borsuk’s Theorem [85.3] stems from the following fairly simple proposition.

**Proposition 85.6.**

(1) If \( K \subset \mathbb{R}^n \) is a compact neighborhood retract, then \( K \) is the retract of a finite \( n \)-dimensional simplicial complex.

(2) Every compact ENR is a retract of a finite simplicial complex.

**Proof.**

(1) Let \( K \) be a compact subset of \( \mathbb{R}^n \) which is a retract of some open neighborhood \( V \). The idea is to define a simplicial complex \( X \) to be the union of finitely many sufficiently small cubes. To do so we set \( r := d(K, \mathbb{R}^n \setminus V) \). Since \( K \) is compact and since \( \mathbb{R}^n \setminus V \) is closed it follows from Corollary [3.19] that \( r > 0 \). We pick \( k \in \mathbb{N}_0 \) such that \( \frac{1}{2k} < \frac{1}{\sqrt{n}} \cdot r \). We denote by \( X \) the union of all \( \frac{1}{2k} \)-cubes that intersect \( K \).
(See page [2065] for the definition of a \( \frac{1}{2k} \)-cube.) Since \( K \) is compact we see that \( X \) is the union of finitely many \( \frac{1}{2k} \) cubes. The same argument as in the proof of Lemma [85.4] shows, by our choice of \( k \), that each \( \frac{1}{2k} \)-cube is contained in \( V \).

We equip each cube with the canonical simplicial structure that we introduced on page [1503]. As in Lemma [61.17] we see that the union of the cubes \( X \) also admits a simplicial structure. It follows from Observation [85.1] (1) that \( K \) is a retract of the finite simplicial complex \( X \).

(2) This statement follows immediately from (1).

The statement of the following proposition is quite similar to the statement of Proposition [85.6], it just replaces simplicial complexes by smooth manifolds. We will not make much use of Proposition [85.7] except that it will come in handy at one occasion later on.

---

Note that Exercise [2.42] implies that such a map \( i: X \rightarrow Y \) is necessarily an embedding.

Why is that? Why do we need only finitely many such cubes?
Proposition 85.7. (*)

(1) If $K \subset \mathbb{R}^n$ is a compact neighborhood retract, then $K$ is the retract of a compact $n$-dimensional smooth submanifold of $\mathbb{R}^n$.

(2) Every compact ENR is a retract of a compact smooth manifold.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1198.png}
\caption{Illustration of Proposition 85.7.}
\end{figure}

Proof (*).

(1) Let $K$ be a compact subset of $\mathbb{R}^n$ that is a retract of some open neighborhood $V$. Since $V$ is an open subset of $\mathbb{R}^n$ it is in particular an $n$-dimensional smooth manifold. Therefore we can apply the Proposition 6.64 and we obtain a sequence $M_1, M_2, \ldots$ of subsets of $V$ with the following three properties:

(a) the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $M_i \subset M_{i+1}$,

(b) each $M_i$ is a compact $n$-dimensional smooth submanifold of $V$,

(c) we have $\bigcup_{i \in \mathbb{N}} M_i = V$ where $\check{M}_i := M_i \setminus \partial M_i$.

We make the following observations:

(i) By Lemma 89.1 (3) each $\check{M}_i$ is an open subset of $V$ and thus also of $\mathbb{R}^n$.

(ii) It follows from (a), (c) and (i), the hypothesis that $K$ is compact and Lemma 2.41 that there exists an $i \in \mathbb{N}$ such that $f(K) \subset M_i$.

(iii) Since $V$ is an open subset of $\mathbb{R}^n$ every smooth submanifold of $V$ is in fact also a smooth submanifold of $\mathbb{R}^n$.

It follows from this discussion and property (2) and Observation 85.1 (1) that the smooth manifold $M := M_i$ has all the desired properties.

(2) This statement follows immediately from (1).

The following proposition shows that many of our favorite topological spaces are ENRs.

Proposition 85.8.

(1) Every topological manifold is an ENR.

(2) Every countable CW-complex that is regionally compact and finite-dimensional is an ENR.

Remark.
(1) By Corollary 36.15 we know that a finite CW-complex is compact, in particular regionally compact. Thus Proposition 85.8 (2) implies that every finite CW-complex is an ENR.

(2) By Exercise 36.8 we know that a CW-complex is regionally compact if and only if it is locally finite.

The proof of Proposition 85.8 (2) relies very much on the following lemma which is perhaps interesting in its own right.

**Lemma 85.9.** Let $X$ be a CW-complex. If $X$ is countable, regionally compact and finite-dimensional, then $X$ admits an embedding into some $\mathbb{R}^n$.

**Remark.** The special case of Lemma 85.9 provided by finite CW-complexes is precisely the content of Exercise 36.11.

**Proof of Lemma 85.9.** The theorem in its full generality is proved in [FrPi90, Theorem A]. In the discussion below we will only deal with the much simpler case that $X$ is actually a finite CW-complex. We prove this case by induction on the dimension of the CW-complex $X$. The case $\dim(X) = -1$ is of course trivial. So suppose we already know the statement for all finite CW-complexes of dimension $\leq m - 1$. Now let $X$ be a finite $m$-dimensional CW-complex. As usual we denote by $X^{m-1}$ the $m$-skeleton of $X$. We denote by $\varphi_1, \ldots, \varphi_k : S^{m-1} \to X^{m-1}$ the attaching maps of the $m$-cells of $X$. By induction there exists an $n \in \mathbb{N}_0$ and an embedding $f : X^{m-1} \to \mathbb{R}^n$. We consider the map

$$
\left( \frac{X^{m-1} \cup \bigcup_{i=1}^k \overline{B}_i^m}{\sim} \right) \to \mathbb{R}^n \times \mathbb{R}^{m+1} \times \cdots \times \mathbb{R}^{m+1}
$$

$$
[x] \mapsto \begin{cases} 
(f(x), 0, \ldots, 0), & \text{if } x \in X^{m-1}, \\
(r \cdot f(\varphi_i(v)), 0, \ldots, r v \cdot (1-r), 1-r, \ldots, 0), & \text{if } x = r \cdot v \in \overline{B}_i^m \text{ where } r \in [0, 1] \text{ and } v \in S^{m-1}.
\end{cases}
$$

It follows from Lemma 3.25 (2) that the somewhat risqué notation for points in $\overline{B}_i^m$ actually leads to a meaningful and continuous map on each $\overline{B}_i^m$. Note that from Lemma 36.7 (4) we obtain that the overall map is continuous. Our hypothesis that $X$ is a finite CW-complex implies by Corollary 36.15 that $X$ is compact. Finally it is elementary to verify that the map is actually injective. Thus, in summary, we can appeal to everybody’s best friend, i.e. Proposition 2.43 (2), to conclude the proof that this map is in fact an embedding. ■

![Figure 1199. Illustration for the proof of Lemma 85.9](image)

Now we can provide the proof of Proposition 85.8.

**Proof of Proposition 85.8.**
(1) Just for fun we first give a separate, more down to earth argument, for the case of a closed smooth manifold \( M \). By Proposition 9.1 (1) and Proposition 8.1 we can view \( M \) as a closed submanifold of some \( \mathbb{R}^n \). Now we apply Proposition 8.25 to conclude that \( M \subset \mathbb{R}^n \) admits an open neighborhood that retracts to \( M \).

Now we turn to the general case. Thus let \( M \) be a topological manifold. By Proposition 9.1 we know that there exists an embedding \( f: M \to \mathbb{R}^n \) such that \( f(M) \) is a closed subset of \( \mathbb{R}^n \). As we discussed on page 2063 every topological manifold is weakly locally contractible. Thus we can apply Borsuk’s Theorem 85.5 to deduce that \( M \) is indeed an ENR.

(2) Let \( X \) be a CW-complex that is countable, regionally compact and finite-dimensional. By Lemma 85.9 we know that there exists an embedding \( f: X \to \mathbb{R}^n \). Furthermore, as we discussed on page 2063 it follows almost immediately from Proposition 36.10 (6) that the CW-complex \( X \) is weakly locally contractible. Thus we can once again apply Borsuk’s Theorem 85.5 (2) to conclude that \( X \) is an ENR.

Recall that in Theorem 65.9 and 65.10 we formulated and proved the Lefschetz Fixed Point Theorem in the realm of finite simplicial complexes and compact smooth manifolds. Our aim now is to extend the Lefschetz Fixed Point Theorem to compact ENRs. To do so we first need to convince ourselves that in this setting the Lefschetz number is actually defined. This follows from the following lemma.

**Lemma 85.10.** If \( X \) is a compact ENR, then for every field \( \mathbb{F} \) the homology of \( X \) is \( \mathbb{F} \)-finite.

**Proof.** Let \( X \) be a compact ENR and let \( \mathbb{F} \) be a field. It follows from Propositions 85.6 that \( X \) is a retract of a finite simplicial complex \( Y \). Recall that this means that there exists a map \( i: X \to Y \) and a map \( r: Y \to X \) with \( r \circ i = \text{id}_X \).

(1) It follows from Lemma 61.24 together with Proposition 48.5 and the discussion on page 1402 that the homology of \( Y \) is \( \mathbb{F} \)-finite.

(2) It follows from the functoriality of homology groups and the fact that \( r \circ i = \text{id}_X \) that for every \( k \in \mathbb{N} \) the map \( r_*: H_k(Y; \mathbb{F}) \to H_k(X; \mathbb{F}) \) is an epimorphism.

It follows immediately from (1) and (2) that the homology of \( X \) is \( \mathbb{F} \)-finite.

Now that we know that the Lefschetz number of every self-map of a compact ENR is defined we can now formulate the following theorem.

**Theorem 85.11. (Lefschetz Fixed Point Theorem III)** Let \( X \) be a compact ENR (e.g. \( X \) could be a compact topological manifold or a finite CW-complex) and let \( \varphi: X \to X \) be a map. If the \( \mathbb{F} \)-Lefschetz number \( \Lambda(\varphi, \mathbb{F}) \) is non-zero for some field \( \mathbb{F} \), then \( \varphi \) has a fixed point.

**Remark.**

(1) The above Lefschetz Fixed Point Theorem 85.11 together with Proposition 85.8 also gives a different, now totally self-contained, proof of the Lefschetz Fixed Point Theorem 65.10 for compact smooth manifolds.
(2) For compact orientable topological manifolds we will provide a generalization of the above Lefschetz Fixed Point Theorem \[85.11\] in the Lefschetz-Hopf Theorem \[96.9\].

**Proof.** Let \( X \) be a compact ENR. By Proposition \[85.6\] we know that \( X \) is a retract of a finite simplicial complex \( Y \). Recall that this means that there exists a map \( i: X \to Y \) and a map \( r: Y \to X \) with \( r \circ i = \text{id}_{X} \). By the very harmless Exercise \[2.42\] we know that \( i \) is an embedding. Thus in the following we will view \( X \) as a subspace of \( Y \). Now let \( \varphi: X \to X \) be a map. We consider the map \( i \circ \varphi \circ r: Y \to Y \).

**Claim.** We have \( \Lambda(i \circ \varphi \circ r, \mathbb{F}) = \Lambda(\varphi, \mathbb{F}) \).

Let \( k \in \mathbb{N}_{0} \). We consider the following sequence of maps

\[
0 \longrightarrow \ker(r_{*}) \longrightarrow H_{k}(Y; \mathbb{F}) \xrightarrow{r_{*}} H_{k}(X; \mathbb{F}) \xrightarrow{i_{*}} H_{k}(Y; \mathbb{F}) \longrightarrow 0.
\]

Note that we have the equality \( r_{*} \circ i_{*} = (r \circ i)_{*} = \text{id}_{*} = \text{id}_{H_{k}(X; \mathbb{F})} \). This observation implies that the horizontal sequence is exact and that it splits. As in Splitting Lemma \[46.2\] we see that this implies that we can write \( H_{k}(Y; \mathbb{F}) = i_{*}(H_{k}(X; \mathbb{F})) \oplus \ker(r_{*}) \). With slightly suggestive notation we see that

\[
\text{tr} \left( H_{k}(Y; \mathbb{F}) \xrightarrow{i_{*} \circ \varphi \circ r_{*}} H_{k}(Y; \mathbb{F}) \right) = \text{tr} \left( \begin{pmatrix} \text{id} & 0 \\ 0 & \text{id} \end{pmatrix} \right) = \text{tr} \left( H_{k}(X; \mathbb{F}) \xrightarrow{\varphi_{*}} H_{k}(X; \mathbb{F}) \right).
\]

The desired formula for the Lefschetz numbers follows immediately from this claim.

From our hypothesis, the claim and the Lefschetz Fixed Point Theorem \[65.9\] for simplicial complexes we obtain that \( i \circ \varphi \circ r: Y \to Y \) admits a fixed point \( y \in Y \). This fixed point \( y \) lies necessarily in the image of the last map, i.e., it lies in \( i(X) = X \). It is clear that the point \( y \) is also a fixed point for \( \varphi \).

**Remark.** In the possibly unlikely event that the reader wants to know more about ENRs we refer to \[Dol80\], Chapter IV.8 for more information.

85.4. **Invariants of compact topological manifolds.** There are several ways how one can get a grip on the topology of a (compact) smooth manifold \( M \):

(a) In Corollary \[63.37\] we used the fact that (compact) smooth manifolds admit good (finite) covers together with the Nerve Theorem \[63.32\] to show that \( M \) is weakly homotopy equivalent to a finite simplicial complex.
(b) In Theorem 64.5 we used the fact that $M$ is diffeomorphic to a smooth submanifold of some $\mathbb{R}^n$ to show that $M$ actually admits a (finite) smooth simplicial structure.

(c) Later on, in Propositions 104.12 and 105.8, we will use “Morse theory” to show that $M$ is homotopy equivalent to a (finite) CW-complex $X$ with $\dim(X) \leq \dim(M)$.

These results, together with basic facts about invariants of finite CW-complexes, see Proposition 37.13 (3) and Proposition 48.5 (2), imply the following excerpt of Proposition 64.6.

**Proposition 64.6.** Let $M$ be a 0-connected smooth manifold.

1. For any $k > n$ we have $H_k(M) = 0$ and for every abelian group $G$ we also have $H_k(M; G) = 0$.
2. The higher homotopy groups of $M$ are countable.

Furthermore, if $M$ is compact, then the following statements hold:

3. The fundamental group of $M$ is finitely presented.
4. All homology groups of $M$ are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $H_k(M; \mathbb{F})$ are finite-dimensional.

To the best of the author’s understanding none of the above approaches (a), (b) and (c) can be carried over to topological manifolds.

It seems like the only tool we have for handling “the size” of invariants of compact topological manifolds is the following theorem, which is an immediate consequence of Proposition 85.8 together with Proposition 85.6.

**Theorem 85.12.** Every compact topological manifold is a retract of a finite simplicial complex.

Fortunately this is enough to extend most of the results of Proposition 64.6.

**Proposition 85.13.** Let $M$ be a compact 0-connected topological manifold. The following statement holds:

1. There exists an $l \in \mathbb{N}_0$ such that for every $k > l$ we have $H_k(M) = 0$ and such that for every abelian group $G$ we have $H_k(M; G) = 0$.
2. The higher homotopy groups of $M$ are countable.
3. The fundamental group of $M$ is finitely presented.
4. All homology groups $H_k(M)$ are finitely generated abelian groups. Furthermore, given any field $\mathbb{F}$ the homology groups $H_k(M; \mathbb{F})$ are finite-dimensional.

**Remark.**

1. Let $M$ be an $n$-dimensional topological manifold.
   a. In Theorem 87.3 we will see that in (1) we can take $l = \dim(M)$.
   b. If $M$ is in fact a smooth manifold, then Theorem 66.6 allows us to compute the homology group $H_n(M)$. In Theorem 87.3 we will prove the analogous result without the hypothesis that $M$ is smooth.
2. Proposition 85.13 together with Lemma 64.7 often allows us to control the “size” of relative homology groups of a compact topological manifold. For example for a compact topological manifold $M$ all relative homology groups $H_k(M, \partial M)$ are finitely generated.
3. We will deal with non-compact topological manifolds in Theorem 85.17 below.
Proof of Proposition 85.13. Let $M$ be a compact 0-connected topological manifold, let $F$ be a field, let $G$ be an abelian group and let $n \in \mathbb{N}$. We pick a base point $x_0 \in M$. It follows from Propositions 85.6 and 85.8 (1) that $M$ is a retract of a finite simplicial complex $Y$. Recall that this means that there exists a map $i: M \to Y$ and a map $r: Y \to M$ with $r \circ i = \text{id}_M$. We write $y_0 = i(x_0)$. Furthermore we denote the dimension of the simplicial complex by $l$. We make the following observations:

(a) By Proposition 62.9 we know that $\pi_n(Y, y_0)$ is countable.

(b) It follows from Lemma 61.24 together with Proposition 37.13 that $\pi_1(Y, y_0)$ is finitely presented.

(c) It follows from Lemma 61.24 together with Proposition 48.5 and the discussion on page 1402 that the homology groups $H_k(Y)$ are finitely generated, that the homology groups $H_k(Y; F)$ are finite dimensional and that $H_k(Y) = 0$ and $H_k(Y; G) = 0$ for $k > l$.

Now we turn to the invariants of $M$.

(1) Let $k \in \mathbb{N}_0$. It follows from the functoriality of homology groups and the fact that $r \circ i = \text{id}_M$ that the maps $r_*: H_k(Y) \to H_k(M)$ and $H_k(Y; G) \to H_k(M; G)$ are epimorphisms. In particular if the groups to the left vanish, then do the groups to the right. This observation together with (c) implies (1).

(4) The argument in (1) also shows that if $H_k(Y)$ is finitely generated, then so is $H_k(M)$. Similarly, if $H_k(Y; F)$ is finite-dimensional, then so is $H_k(M; F)$. Thus we see that (c) implies (4).

(2) As in (1) we see $r_*: \pi_n(Y, y_0) \to \pi_n(M, x_0)$ is an epimorphism. It follows from (a) and Lemma 1.7 that $\pi_n(M, x_0)$ is also countable.

(3) The logic of (1), (2) and (4) shows immediately that $\pi_1(M, x_0)$ is finitely generated. The statement that $\pi_1(M, x_0)$ is finitely presented requires a little more thought. More precisely, by the functoriality of fundamental groups we know that $\pi_1(M, x_0)$ is a retract of $\pi_1(Y, y_0)$. By (b) we know that the group $\pi_1(Y, y_0)$ is finitely presented. Thus we obtain from the purely group-theoretic Lemma 21.16 that $\pi_1(M, x_0)$ is also finitely presented. ■

85.5. ANRs and the homotopy type of topological manifolds. In this section we will see in particular that all topological manifolds are homotopy equivalent to locally finite simplicial complexes, in particular, they are homotopy equivalent to CW-complexes. In contrast to the previous sections we will not attempt to prove the statements of this section, instead we try our best to give a good overview of the literature.

We start out with the following definition.

**Definition.** We say that a topological space $X$ is dominated by a topological space $Y$ if there exist maps $i: X \to Y$ and $r: Y \to X$ such that $r \circ i$ is homotopic to the identity $\text{id}_X$.

**Example.**

1227 The argument below is quite similar to the proof of Lemma 85.10.
(1) If a topological space $X$ is a retract of some topological space $Y$, then evidently $X$ is dominated by $Y$.

(2) It follows from Proposition 85.6 together with Proposition 85.8 that every compact topological manifold and every finite CW-complex is dominated by a finite simplicial complex.

The following proposition is the most powerful result on dominations that we actually prove in these notes.

**Proposition 119.12.** Let $X$ be a topological space. If $X$ is dominated by a CW-complex, then $X$ is homotopy equivalent to a CW-complex.

**Remark.** Suppose a topological space $X$ is a retract of some CW-complex $Y$. By Proposition 119.12 we now know that $X$ is homotopy equivalent to a CW-complex. One might hope that $X$ should actually admit the structure of a CW-complex. But in Exercise 85.5 we will see that in general this is not the case.

**Proof.** We will prove Proposition 119.12 in Section 119.4 using the Whitehead Theorem 119.9. Alternatively see the proofs of Theorems 85.17, 85.20 and 85.21 for alternative proofs.

It turns out that there exist several powerful generalizations of Proposition 119.12. To formulate these generalizations it is helpful to introduce the following definition.

**Definition.** A topological space $X$ is called an *absolute neighborhood retract* (or short *ANR*) if $X$ is metrizable and if the following condition is satisfied: whenever $f : X \to Y$ is an embedding into a metric space $Y$ such that $f(X)$ is a closed subset of $Y$, then $f(X)$ is a neighborhood retract in $Y$.

![Figure 1201](image)

**Remark.**

(1) Like in many other settings in the literature there exist various equivalent approaches to defining an ANR, see e.g. [MaS82, Chaper I.3.1(ii)] and [FrP90a, Proposition A.6.2]. The definition above is the one given in [FrP90a, p. 281].

(2) Let $X$ be an ANR. If $X$ admits a closed embedding into some $\mathbb{R}^n$, then it follows immediately from the definitions that $X$ is an ENR. Nonetheless, not every ANR is an ENR. For example we will see shortly that the disjoint union $X = \bigsqcup_{k \in \mathbb{N}} B^n_k$ is an ANR, but it follows easily from the Topological Invariance of Domain Theorem 50.6 that $X$ does not admit an embedding into any $\mathbb{R}^n$.

(3) Some references use a definition of an ANR which differs slightly from ours. More precisely, in [Han51, p. 390] and [Mih59, p. 272] an ANR is supposed to satisfy the extra condition that it is separable, i.e. that it contains a countable subset that
is dense. Note that in Exercise 6.4 we saw that a metrizable topological space is separable if and only if it is second-countable. Thus, since in these notes we are more familiar with the concept of second-countable topological spaces we will use that notion in the remainder of our discussion of ANRs.

4. The theory of ANRs is developed in great detail in [Hu65, Bor67, Chig96].

We will soon see what ANRs are good for. But first let us quote two theorems which give us many examples of ANRs.

**Theorem 85.14. (Dugundji Extension Theorem)** Let $V$ be a real vector space and $\| \cdot \| : V \to \mathbb{R}_{\geq 0}$ a norm on $V$. We equip $V$ with the corresponding metric and we use this metric to view $V$ as a topological space. With respect to this topology every convex subset of $V$ is an ANR.

**Example.** The only consequence of the Dugundji Extension Theorem 85.14 that we will use is that every convex subset of some $\mathbb{R}^n$ is an ANR.

**Proof.** This theorem was proved by James Dugundji [Dug51, Corollary 4.2] in 1952. A proof is also given in [MaS82, Theorem I.3.1], [Maye89, Theorem I.5.7] and [Saka13, Theorem 6.1.1].

**Theorem 85.15. (Hanner’s Theorem)** Let $X$ be a topological space which is second-countable and metrizable. If $X$ is the union of a family $\{U_i\}_{i \in I}$ of open subsets such that each $U_i$ is an ANR, then $X$ itself is an ANR.

**Proof.** This theorem was proved by Olof Hanner [Han51, Theorem 3.3] in 1950. An exposition of the proof is also given in [Fera04, Theorem 2.77] and in [Hu65, Theorem III.8.1].

**Corollary 85.16.** Every topological manifold is an ANR.

**Proof.** Let $X$ be an $n$-dimensional topological manifold. By definition $X$ is second-countable. By Corollary 9.2 we know that $X$ is metrizable. In Lemma 6.9(1) we showed that $X$ is locally homeomorphic to some non-empty convex subset of $\mathbb{R}^n$. By the Dugundji Extension Theorem 85.14 every non-empty convex subset of $\mathbb{R}^n$ is an ANR. In other words, we have shown that $X$ admits an open cover by ANRs. Thus we obtain from Hanner’s Theorem 85.15 that $X$ is indeed an ANR.

The following amazing theorem now tells us what ANRs are good for.

**Theorem 85.17.** Let $X$ be a topological space. The following statements are equivalent:

1. $X$ is dominated by a countable CW-complex.
2. $X$ is homotopy equivalent to a countable CW-complex.
3. $X$ is homotopy equivalent to a countable simplicial complex.
3'. $X$ is homotopy equivalent to a countable simplicial complex that is locally finite.

---

Note that there are no other hidden conditions on the subset except for convexity, in particular we do not demand that the subset is open, closed or compact.
X is homotopy equivalent to an ANR which is second-countable. Furthermore the following refinement of the equivalence of (2) and (3) holds: If X is homotopy equivalent to an n-dimensional countable CW-complex, then it is also homotopy equivalent to an n-dimensional countable simplicial complex, and vice versa.

Proof. The fact that all the statements are equivalent goes well beyond the scope of these notes. Thus we just give the necessary references. The implications (3')⇒(3)⇒(2)⇒(1) are of course trivial. Next note that the equivalence of (2) and (3) is a consequence of Lemma 61.24 and Proposition 62.12. As is explained in [Miln59, Theorem 1], the implication (1)⇒(3') follows from work of James Whitehead [WhdJ50, Theorem 24] and the implication (3')⇒(4)⇒(1) follows from the work of Olof Hanner [Han51, Corollary 3.5 and Theorem 6.1]. Alternatively we refer to [FrPi90a, Theorem 5.2.1] or [LW69, p. 137] for a proof that the five statements are equivalent.

The above results now give us several corollaries on topological manifolds.

**Corollary 85.18.**

1. Every topological manifold is homotopy equivalent to a countable locally finite simplicial complex.
2. The homology groups, the fundamental group and the higher homotopy groups of a 0-connected topological manifold are countable.

Remark. Let M be a 0-connected topological manifold. By Corollary 85.18 we now know that π_1(M) is countable. A significantly more down-to-earth proof for this statement is given in [Lee00, Proposition 7.21].

Proof.

1. This statement follows from Corollary 85.16 together with Theorem 85.17 (4)⇒(3') and the fact that topological manifolds are by definition second-countable.
2. Let X be a 0-connected topological manifold. By (1) we know that X is homotopy equivalent to a 0-connected countable simplicial complex Y. It follows from Proposition 62.9 and Lemma 61.24 together with Proposition 48.5 that all homotopy groups and all homology groups of Y are countable. Finally note that it is a consequence of Proposition 40.7 and Corollary 42.8 that the same statements hold for X.

By Proposition 54.13 we know that π_2(S^1 ∨ S^2) is isomorphic to \(\mathbb{Z}^\infty\), in particular it is infinitely generated. This result, foreshadowed by our discussion on page 1069, shows that homotopy groups of finite CW-complexes can be infinitely generated. In Question 40.16 we asked, somewhat apprehensively, whether the homotopy groups of a countable CW-complex are necessarily countable. With a slight sigh of relief we can now give an affirmative answer to this question.

**Proposition 85.19.** If X is a CW-complex with countably many cells, then for any \(n \in \mathbb{N}\) and any \(x_0 \in X\) the group \(\pi_n(X, x_0)\) is countable.

---

1229 For the fundamental group we could alternatively use the argument given on page 1032.
Theorem 85.20. If \( X \) is a topological space, then the following statements are equivalent:

1. \( X \) is dominated by a CW-complex.
2. \( X \) is homotopy equivalent to a CW-complex.
3. \( X \) is homotopy equivalent to a simplicial complex.
4. \( X \) is homotopy equivalent to an ANR.

**Proof.** The implication \((1) \Rightarrow (2)\) is precisely the statement of Proposition 119.12. The fact that \((2)\) and \((3)\) are equivalent is a consequence of Lemma 61.24 and Proposition 62.12. The statement that in fact all four statements are equivalent is proved in [FrPi90a, Theorem 5.2.1].

Theorem 85.21. Let \( X \) be a topological space. The following statements are equivalent:

1. \( X \) is homotopy equivalent to a finite CW-complex.
2. \( X \) is homotopy equivalent to a finite simplicial complex.
3. \( X \) is homotopy equivalent to a compact ANR.

Furthermore the following refinement of the equivalence of \((2)\) and \((3)\) holds: If \( X \) is homotopy equivalent to a finite \( n \)-dimensional CW-complex, then it is also homotopy equivalent to a finite \( n \)-dimensional simplicial complex, and vice versa.

**Proof.** The fact that \((2)\) and \((3)\) are equivalent is a consequence of Lemma 61.24 and Proposition 62.12. Next note that one can show, with some effort, that it is a consequence of the Dugundji Extension Theorem 85.14 that every finite simplicial complex is an ANR, we refer to [LW69, p. 210] and [HNV04, p. 472] for details. This observation gives us the implication \((3) \Rightarrow (4)\). Finally the implication \((4) \Rightarrow (2)\) was shown by James West [Wes77] in 1977.

The attentive reader will have noticed that the dog that did not bark is the \((1) \Rightarrow (2)\) implication. It turns out that there is a good reason why it did not bark. The following theorem, proved by C.T.C. Wall shows that in general the statement one would hope for is actually incorrect.

Theorem 85.22. There exists a topological space that is dominated by a finite CW-complex but that is not homotopy equivalent to a finite CW-complex.

**Proof.** The statement is proved in [Wall65a, p. 66]. Alternatively see [Var89, p. 163] and [FR01, Theorem 3.1]. More precisely, in [Wall65a, Var89] it is shown that to a topological space \( X \) that is dominated by a finite CW-complex one can associate an invariant in the
“K-group $\tilde{K}_0(\mathbb{Z}[\pi_1(X)])$” which vanishes if and only if $X$ is homotopy equivalent to a finite CW-complex. It is shown in the above references that there exist examples where the invariant is indeed non-zero. Interestingly it is is conjectured, see e.g. [KrL05, p. 179], that the group $\tilde{K}_0(\mathbb{Z}[\pi_1(X)])$ is zero, whenever $\pi_1(X)$ is a torsion-free group.

From this discussion we obtain the following corollary.

**Corollary 85.23.** Every compact topological manifold is homotopy equivalent to a finite simplicial complex.

**Proof.** This statement follows immediately from Corollary 85.16 together with Theorem 85.21 (4) $\Rightarrow$ (3). A very different proof for the corollary was given by Rob Kirby and Larry Siebenmann in [KSi69, Chapter III.2] and [KSi77, p. 744].

Let $M$ be a (compact) $n$-dimensional topological manifold. By the above we now know that $M$ is homotopy equivalent to a (finite) simplicial complex $X$. But the above results do not say anything about the dimension of the simplicial complex $X$. But it turns out, that at least for compact topological manifolds this can mostly be fixed.

**Theorem 85.24.**

1. Every closed $n$-dimensional topological manifold is homotopy equivalent to a finite $n$-dimensional simplicial complex.
2. Every compact connected $n$-dimensional topological manifold with non-empty boundary is homotopy equivalent to a finite $(n-1)$-dimensional simplicial complex.

**Remark.** It seems like a nice project to figure out whether Theorem 85.24 (2) can be generalized to non-compact topological manifolds.

**Sketch of proof.** First note that the 1-dimensional case follows immediately from the classification result proved in Theorem 7.1. Furthermore the 2-dimensional case and the 3-dimensional case follow from Radó’s Theorem 85.27 and Moise’s Theorem 85.28 below. Thus we can now assume that $n \geq 4$.

First note that by Theorem 85.20 (2) $\Leftrightarrow$ (3) it suffices to prove the statement with simplicial complexes replaced by CW-complexes.

Next we cite the following theorem of C.T.C. Wall [Wall66a, Corollary 5.1] (see also [Wall65a, Theorem E] and [Var89, Chapter 5.2]):

Wall’s Finiteness Theorem. Let $Y$ be a connected finite CW-complex such that there exists an $r \in \mathbb{N}_0$ such that all twisted cohomology groups $H^s(Y; V)$ vanish for $s > r$. (The precise definition of twisted cohomology is irrelevant to our discussion, so stay with us.) Now [Wall66a, Corollary 5.1] says that if these conditions are satisfied and if $r \geq 3$, then $Y$ is homotopy equivalent to a finite $r$-dimensional CW-complex.

Theorem 85.24 is now a consequence of Wall’s Theorem and some reasonably standard facts in algebraic topology. In the discussion below we will outline the argument, the detailed proof for reducing Theorem 85.24 to Wall’s Theorem is given in [FNOP19, Theorem 4.1].

\[\text{To the best of my knowledge it seems to be unknown whether the statement holds for } r = 2.\]
Now let $X$ be a compact orientable $n$-dimensional topological manifold. It follows from Theorem \[85.24\] that $X$ is homotopy equivalent to a finite CW-complex $Y$. It follows from “Poincaré duality with twisted coefficients”, see [FNOP19, Theorem A.15], that for any $r \in \mathbb{N}$ and any $\mathbb{Z}[\pi_1(X, x_0)]$-left module $V$ we have $H^r(Y; V) \cong H^r(X; V) \cong H_{n-r}(X, \partial X; V)$.

If $r > n$, i.e. if $n-r < 0$, then we have $H_{n-r}(X, \partial X; V) = 0$. Furthermore, if $X$ is connected and if $\partial X \neq 0$ and if $r = n$, i.e. if $n-r = 0$ we have, by an argument similar to the one given on page \[1120\] that $H_{n-r}(X, \partial X; V) = 0$. The desired statement now follows from these calculations together with Wall’s Theorem.

Finally we consider the case of a compact non-orientable $n$-dimensional topological manifold. The argument is basically the same, except that one needs Poincaré Duality for non-orientable manifolds. For untwisted coefficients this can be found in [DaK01, Theorem 5.7]. For twisted coefficients this follows from an argument as in [FNOP19, Theorem A.15], but it is conceivable that nobody ever bothered to work out the details.

We conclude this section with the following proposition which can be viewed as an analogue of Proposition \[66.16\].

**Proposition 85.25.** Every closed connected non-empty $n$-dimensional topological manifold is homotopy equivalent to a finite $n$-dimensional CW-complex which has a single 0-cell and which has a single $n$-cell.

**Proof.** Let $X$ be a closed connected non-empty $n$-dimensional topological manifold. We pick an embedding $\varphi: B^n \to X$. It follows from Proposition \[44.3\] that $Y := X \setminus \varphi(B^n)$ is a compact connected non-empty $n$-dimensional topological manifold with $\partial Y = \varphi(S^{n-1})$.

By Theorem \[85.24\] we know that there exists a finite $(n-1)$-dimensional CW-complex $Z$ and a homotopy equivalence $h: Y \to Z$. We consider the following diagram:

\[
\begin{array}{ccc}
B^n & \xrightarrow{i} & S^{n-1} & \xrightarrow{f} & Y \\
| id & & \downarrow{id} & & \downarrow{h} \\
B^n & \xleftarrow{i} & S^{n-1} & \xleftarrow{\varphi \circ f} & Z.
\end{array}
\]

Note that the diagram commutes, note that the vertical maps are homotopy equivalences and note that it follows from Proposition \[39.4\] that the inclusion map $i: S^{n-1} \to B^n$ is a closed cofibration. Thus it follows from the Homotopy Pushout Theorem \[39.18\] that the pushouts $B^n \cup_{\partial B^n} Y$ and $B^n \cup_{\partial B^n} Z$ are homotopy equivalent. By Lemma \[3.45\] the former pushout is homeomorphic to $X$. Furthermore by Lemma \[36.32\] the latter pushout admits a CW-structure with a single $n$-cell and no cells of dimension $> n$. Finally note that it follows from Proposition \[39.11\] that we can in fact find a CW-complex that is homotopy equivalent to $X$ that contains not only a single $n$-cell but that also contains only a single 0-cell.

85.6. **Topological manifolds and CW-structures.** Recall that by Theorem \[64.5\] we know that every smooth manifold admits a simplicial structure. By Corollaries \[85.18\] and \[85.23\] we now know that every (compact) topological manifold is homotopy equivalent to a (finite) CW-complex. The following question naturally arises.
Question 85.26.

(1) Does every topological manifold admit a simplicial structure?
(2) Does every topological manifold admit a CW-structure?

In the following we will survey what is known regarding Question 85.26. Let us start out with some positive statements.

Theorem 85.27. (Radó’s Theorem) Every 2-dimensional topological manifold admits a PL-structure, in particular it admits a simplicial and a CW-structure.

Proof. In 1926 it was shown by Tibor Radó [Rad26] that every 2-dimensional topological manifold admits a simplicial structure. It is elementary to see that the simplicial structure of any 1-dimensional topological manifold is in fact a PL-structure. It follows from Proposition 64.11 that the simplicial structure of any 2-dimensional topological manifold is in fact a PL-structure.

Note that we already mentioned the above result of Tibor Radó in the proof of Theorem 23.5. We refer to that proof to alternative references. ■

Theorem 85.28. (Moise’s Theorem) Every 3-dimensional topological manifold admits a PL-structure, in particular it admits a simplicial and a CW-structure.

Proof. This theorem was first proved in 1952 by Edwin Moise [Moi52]. Alternative proofs are given in [Moi77, p. 252 and 253], [Moi52, Theorem 6], [Bin83, Theorem XVIII.3.B], [Ham76, Theorem 2] and [Sha84]. ■

Now we turn to the higher dimensional setting. In this setting the stories between CW-structures and simplicial structures diverge. In the following we first consider CW-structures on high-dimensional topological manifolds. It turns out that the 4-dimensional case is a no-show, in the sense that the following question is still open.

Question 85.29. Does every closed 4-dimensional topological manifold admit a CW-structure?

Once we move beyond dimension 4, the situation becomes somewhat clearer again.

Theorem 85.30. (Kirby-Quinn-Siebenmann Theorem) Every closed topological manifold of dimension ≥ 5 has a CW-structure.

Proof. For dimensions ≥ 6 this theorem was proved in the 1970s by Rob Kirby and Larry Siebenmann [KSi77, Essay III.2]. In 1982 this result was extended to the 5-dimensional case by Frank Quinn [Qu82, Theorem 2.3.1]. ■

Note that the Kirby-Quinn-Siebenmann Theorem 85.30 only deals with closed topological manifolds. The following question is still open.

Question 85.31. Let n ∈ N≥5. Does every compact n-dimensional topological manifold admit a CW-structure?

Now what about simplicial structures?
Theorem 85.32. There exists a closed 4-dimensional topological manifold that does not admit a simplicial structure.

Proof. This theorem was proved by Andrew Casson, see [AkM90, page xvi], in the 1980s building on the work of Mike Freedman [Fre82]. An account of the proof is also given in [Sav12, Theorem 18.3].

The question whether topological manifolds of dimension \( \geq 5 \) admit a simplicial structure had been open for a very long time and it was finally resolved in 2013 by Ciprian Manolescu [Man16a].

Theorem 85.33. (Manolescu’s Theorem) For every \( n \in \mathbb{N}_{\geq 5} \) there exists a closed \( n \)-dimensional topological manifold that does not admit a simplicial structure.

Proof. The theorem is proved in [Man16a]. A more relaxed exposition of the key ideas of the proof is also given in [Man16b]. Note that, as is explained in [Man16a, Man16b], in dimension 5 the examples are necessarily non-orientable, whereas for every \( n \geq 5 \) there exists a closed orientable \( n \)-dimensional topological manifold that does not admit a simplicial structure. \[\square\]

In the unlikely event that the reader got slightly confused by the various theorems and counterexamples we now summarize some of the key statements about the topology of compact topological manifolds in the following table:

<table>
<thead>
<tr>
<th>( n = 1, 2, 3 )</th>
<th>( n = 4 )</th>
<th>( n \geq 5 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>each closed top. ( n )-mfd. is homotopy equiv. to a finite CW-cplx.</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>each closed top. ( n )-mfd. admits a CW-structure</td>
<td>✓</td>
<td>?</td>
</tr>
<tr>
<td>each compact top. ( n )-mfd. is homotopy equiv. to a finite CW-cplx.</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>each compact top. ( n )-manifold admits a CW-structure</td>
<td>✓</td>
<td>?</td>
</tr>
<tr>
<td>each compact top. ( n )-manifold admits a simplicial structure</td>
<td>✓</td>
<td>✗</td>
</tr>
</tbody>
</table>

Finally we note that we will discuss the existence and uniqueness of PL-structures and smooth structures on topological manifolds in greater detail in Chapter ??.

85.7. The Euler characteristic of compact topological manifolds. The Euler characteristic of a finite CW-complex is one of the most convenient invariants and often it gives a convenient approach to calculating invariants of CW-complexes. As we just saw, it is not clear whether (compact) topological manifolds admit CW-structures. But fortunately we

\[1231\] We will explain later on in Chapter 86 what it means for a topological manifold to be orientable.
assembled just enough results on compact topological manifolds to be able to develop the
theory of Euler characteristics of compact topological manifolds.

The first part of the following definition was already introduced on page 1422.

**Definition.**

1. Given a pair \((X, A)\) of topological spaces and \(n \in \mathbb{N}_0\) we refer to
   \[ b_n(X, A) := \text{rank}(H_n(X, A)) \]
as the \(n\)-th Betti number of \((X, A)\). For \(A = \emptyset\) we write of course
   \(b_n(X) := b_n(X, \emptyset)\).

2. Let \((X, A)\) be a pair of topological spaces. If all \(b_n(X, A)\) are finite and if the sum
   \[ \sum_{n \in \mathbb{N}_0} b_n(X, A) \]
is finite, then we define the Euler characteristic of \((X, A)\) to be
   \[ \chi(X, A) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot b_n(X, A). \]
   For \(A = \emptyset\) we write \(\chi(X) := \chi(X, \emptyset)\).

**Remark.**

1. It follows from Proposition 55.1 that for a finite CW-complex the above definition
   agrees with the original definition of the Euler characteristic of a finite CW-complex.

2. Let \(X\) be a compact topological manifold and let \(A\) be a compact submanifold or
   let \(A\) be a union of components of \(\partial X\). It follows from Propositions 44.2 (3) and
   (4) and Proposition 85.13 (0) and (4), together with Lemma 64.7, that the Euler
   characteristic \(\chi(X, A)\) is defined.

   It turns out that the formulas we proved before for the Euler characteristic of CW-complexes
   also hold for topological manifolds. More precisely, we have the following proposition,
   of which the first three statements are the analogue of Lemmas 55.8 and 55.5 and of
   Proposition 37.4 in our new context.

**Proposition 85.34.**

1. Let \(X\) and \(Y\) be homotopy equivalent topological spaces. If the Euler characteristic is
   defined for one of the two topological spaces, then it is defined for the other topological
   space and we have
   \[ \chi(X) = \chi(Y). \]

2. Let \(X\) be and \(Y\) be two compact topological manifolds, then
   \[ \chi(X \times Y) = \chi(X) \cdot \chi(Y). \]

3. Let \(X = Y \cup Z\) be a decomposition of a compact topological manifold into two compact
   submanifolds \(Y\) and \(Z\) such that \(Y \cap Z\) is also a compact submanifold of \(X\). Then
   the following equality holds
   \[ \chi(X) = \chi(Y) + \chi(Z) - \chi(Y \cap Z). \]

4. Let \(X\) be a compact topological manifold and let \(A \subset X\) be a subspace that is a
   compact topological manifold in its own right. Then
   \[ \chi(X, A) = \chi(X) - \chi(A). \]
Furthermore, for any field $\mathbb{F}$ we have
\[ \chi(X, A) = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X, A; \mathbb{F})). \]

(5) Let $X$ be a compact topological manifold and let $p: \widetilde{X} \to X$ be a finite covering. Then
\[ \chi(\widetilde{X}) = [\widetilde{X} : X] \cdot \chi(X). \]

Sketch of proof.

(1) This statement follows immediately from Corollary 42.8.

(2) This equality can be proved using the Künneth Theorem 58.7 for Chain Complexes. We will fill in the details in Exercise 85.9.

(3) We will not make use of this statement. Therefore we hide, with a good conscience, the proof in Exercise 85.10.

(4) Let $X$ be a compact topological manifold and let $A \subset X$ be a subspace that is a compact topological manifold in its own right.

(a) It follows immediately from considering the long exact sequence in homology of the pair $(X, A)$ together with Lemma 55.4 that $\chi(X, A) = \chi(X) - \chi(A)$.

(b) Let $\mathbb{F}$ be a field. Let $Y$ be a compact topological manifold. From Corollary 85.23 we know that $Y$ is homotopy equivalent to a finite CW-complex $Z$. We observe that
\[ \chi(Y) = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(Z; \mathbb{F})) = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(Y; \mathbb{F})). \]

Corollary 42.8 see page 1402 by the generalization of Corollary 42.8 to $\mathbb{F}$-coefficients, see page 1401.

Using this observation we can now prove that
\[ \chi(X, A) = \chi(X) - \chi(A) = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X; \mathbb{F})) - \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(A; \mathbb{F})). \]

by (a) by the above observation
\[ = \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X, A; \mathbb{F})). \]

by the long exact sequence of the pair $(X, A)$ with $\mathbb{F}$-coefficients and Lemma 55.3.

(5) Let $X$ be a compact topological manifold and let $p: \widetilde{X} \to X$ be a finite covering. Without loss of generality we can assume that $X$ and $\widetilde{X}$ are connected. By Corollary 85.23 there exists a homotopy equivalence $f: X \to Y$, where $Y$ is a finite CW-complex. By Proposition 29.5 there exists a connected covering $q: \widetilde{Y} \to Y$ such that $q_*(\pi_1(\widetilde{Y})) = f_*(p_*(\pi_1(\widetilde{X})))$. Using Proposition 29.2 one can now easily show that $f: X \to Y$ lifts to map $\widetilde{f}: \widetilde{X} \to \widetilde{Y}$ and that this map is again a homotopy equivalence.

\[ \text{For example } A \text{ could be compact submanifold or } A \text{ could be a union of boundary components.} \]
Now we obtain that
\[
\chi(\tilde{X}) = \chi(\tilde{Y}) = [\pi_1(Y) : q_*[\pi_1(\tilde{Y})]] \cdot \chi(Y) = [\pi_1(X) : p_*[\pi_1(\tilde{X})]] \cdot \chi(X)
\]
by (1) since \(\tilde{X}\) and \(\tilde{Y}\) are homotopy equivalent and Lemma 16.15

\[\chi(Y) = \chi(X) \quad \text{since} \quad X \text{ and } Y \text{ are homotopy equivalent}
\]

\[\chi(Y) = \chi(X) \quad \text{since} \quad X \text{ and } Y \text{ are homotopy equivalent}
\]

\[\chi(Y) = \chi(X) \quad \text{since} \quad X \text{ and } Y \text{ are homotopy equivalent}
\]

\[\chi(Y) = \chi(X) \quad \text{since} \quad X \text{ and } Y \text{ are homotopy equivalent}
\]

Exercises for Chapter 85

Exercise 85.1.

(1) Show that there are only countably many homotopy types of finite CW-complexes.

*Hint.* Use Theorem 85.21

(2) Show that there are uncountably many homotopy types of countable CW-complexes.

(3) Let \(k, n \in \mathbb{N}\).

(a) Are there only finitely many homotopy types of \(k\)-dimensional CW-complexes with at most \(n\) cells?

(b) Are there only finitely many homotopy types of \(k\)-dimensional simplicial complexes with at most \(n\) simplices?

Exercise 85.2. We consider \(X = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}\) as a subset of \(Y = \mathbb{R}\). Show that there is no open neighborhood of \(X\) in \(Y\) that admits a retraction onto \(X\).

Exercise 85.3. We consider the embedding \(\gamma : S^1 \to \mathbb{R}^3\) that is shown in Figure 1203. We set \(K := \gamma(S^1)\).

(a) Show that \(\pi_1(\mathbb{R}^3 \setminus K)\) is an infinitely generated group.

*Remark.* The rigor of the solution is bounded from above by the precision of the statement of the problem.

(b) What do you think are the homology groups of \(\mathbb{R}^3 \setminus K\)?

(c) Show that there is no neighborhood \(U\) of \(K\) that admits a deformation retraction to \(K\).

*Remark.* Write to the author if you have a solution.

Here the point is that not only the homotopy equivalences but also the homotopies lift to the covering spaces. We leave the details to the reader.
Exercise 85.4. Show that there exist embeddings \( f : S^1 \to S^3 \) which do not admit a tubular neighborhood, i.e. for which there is no map \( \Phi : B^2 \times S^1 \to S^3 \) with \( f(P) = \Phi(P,0) \) for all \( P \in S^1 \).

Exercise 85.5. Let \( C \) be the Cantor set as defined on page 100. Note that basically by construction the complement of \( C \) in \([0, 1]\) is the disjoint union of countably many open intervals \( \{(a_n - \epsilon_n, a_n + \epsilon_n)\}_{n \in \mathbb{N}} \). We set

\[
X := \{(c, 0) \in \mathbb{R}^2 \mid c \in C\} \cup \bigcup_{n \in \mathbb{N}} B^2_{\epsilon_n}(a_n, 0) \subset \mathbb{R}^2.
\]

(We refer to Figure 1204 for an illustration.) In the following we will show that \( X \) is a retract of a finite CW-complex but that \( X \) itself is not a CW-complex.

(a) Show that \( X \) is a deformation retract of the CW-complex \([0, 1] \times [-1, 1] \subset \mathbb{R}^2\).

(b) Show that \( X \) is compact.

Given a path-connected topological space \( Y \) we define

\[
S(Y) := \{ y \in Y \mid Y \setminus \{y\} \text{ is not path-connected}\}.
\]

(c) Show that \( S(X) = \{(c, 0) \mid c \in C \setminus \{0, 1\}\}\).

(d) Let \( Y \) be a finite CW-complex. Show that \( S(Y) \) has only finitely many path-components.

(e) Show that \( X \) does not admit the structure of a CW-complex.

Exercise 85.6. We say that a topological space \( X \) is \textit{weakly regionally compact} if every point \( x \in X \) admits a compact neighborhood. Now let \( X \subset \mathbb{R}^n \) be a subset that is weakly regionally compact. In the following we will show that there exists an embedding \( g : X \to \mathbb{R}^{n+1} \) such that \( g(X) \) is a \textit{closed} subset of \( \mathbb{R}^{n+1} \).

(a) Show that there exists an open subset \( U \subset \mathbb{R}^n \) with \( U \cap \overline{X} = X \).

(b) We set \( C := \overline{X} \setminus X = \overline{X} \setminus U \). Note that it follows from Lemma 2.8 that \( C \) is a closed subset of \( \mathbb{R}^n \) and note that it follows from Corollary 3.19 that \( d(x, C) > 0 \) for every \( x \in X \). Now we consider the map \( f : X \to \mathbb{R} \) given by \( x \mapsto d(x, C) \). Show that the map \( g : X \to \mathbb{R}^{n+1} \) given by \( x \mapsto (x, \frac{1}{f(x)}) \) is an embedding such that \( g(X) \) is a closed subset of \( \mathbb{R}^{n+1} \).
Exercise 85.7. Let $X$ be a compact topological space that is a retract of a finite simplicial complex $X$. Show that $X$ is an ENR.

Remark. This is the, very easy, converse to Proposition 85.6.

Exercise 85.8. Let $X$ be a compact topological space. Is $H_1(X)$ necessarily finitely generated?

Exercise 85.9. Let $X$ be and $Y$ be two compact topological manifolds. Show that

$$\chi(X \times Y) = \chi(X) \cdot \chi(Y).$$

Exercise 85.10. Let $X = Y \cup Z$ be a decomposition of a compact topological manifold into two compact submanifolds $Y$ and $Z$ such that $\partial Y = \partial Z$ is a submanifold of $X$. Show that

$$\chi(X) = \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$
86. Orientations of topological manifolds

In Section 6.11 we introduced the notion of an orientation of a smooth manifold. The basic idea is that an orientation of a smooth manifold is a “continuous” choice of orientations for each tangent space. Since topological manifolds do not come with tangent spaces there is no obvious extension of this definition of an orientation to the context of topological manifolds. In this chapter we will use “orientations of local homology groups” to introduce the concept of an orientation on a topological manifold.

86.1. Relative homology and convex subsets of $\mathbb{R}^n$. The next lemma is at first glance a little dull, but I will come in handy on several occasions later on in this chapter. In all likelihood it is best to have a quick glance at the statement and to move on to the next section.

**Lemma 86.1.** Let $n \in \mathbb{N}$, let $U$ be an open subset of $\mathbb{R}^n$, let $A$ be a convex bounded subset of $U$ with $\overline{A} \subset U$ and let $x \in A$. Then for every abelian group $G$ and every $i \in \mathbb{N}_0$ the following inclusion induced maps are isomorphisms:

1. $H_i(\mathbb{R}^n \setminus A; G) \rightarrow H_i(\mathbb{R}^n \setminus \{x\}; G)$
2. $H_i(\mathbb{R}^n \setminus A; G) \rightarrow H_i(\mathbb{R}^n \setminus \{x\}; G)$
3. $H_i(U, U \setminus A; G) \rightarrow H_i(U, U \setminus \{x\}; G)$

If $\hat{A}$ is non-empty and if $x \in \hat{A}$ is a point, then also the following inclusion induced maps are isomorphisms:

4. $H_i(\partial \hat{A}; G) \rightarrow H_i(\mathbb{R}^n \setminus \{x\}; G)$
5. $H_i(\mathbb{R}^n \setminus \partial \hat{A}; G) \rightarrow H_i(\mathbb{R}^n \setminus \{x\}; G)$

**Figure 1206. Illustration of Lemma 86.1**

**Proof.** Let $U$ be an open subset of $\mathbb{R}^n$, let $A$ be a convex bounded subset of $U$ with $\overline{A} \subset U$ and let $x \in A$. To simplify the notation we drop the coefficients $G$ from the notation and without loss of generality we assume that $x = 0$. Now let $i \in \mathbb{N}_0$.

1. We have to show that the inclusion induced map $H_i(\mathbb{R}^n \setminus A) \rightarrow H_i(\mathbb{R}^n \setminus \{0\})$ is an isomorphism. We had already stated this fact in Exercise 42.2. Now that we actually need the statement we give the full details.

   Since $A$ is bounded we can pick an $r > 0$ such that $A \subset B_r^n(0)$. We consider the following map:

   $$F: (\mathbb{R}^n \setminus A) \times [0, 1] \rightarrow \mathbb{R}^n$$

   $$(x, t) \mapsto \begin{cases} x, & \text{if } x \in \mathbb{R}^n \setminus B_r^n(0), \\ x \cdot ((1 - t) + t \cdot \frac{r}{\|x\|}), & \text{if } x \in B_r^n(0) \setminus A. \end{cases}$$

   $\geq 1$ since $r > \|x\|$
Note that if \( y \notin A \), then it follows from the convexity of \( A \) and the fact that \( 0 \in A \), that for any \( s \geq 1 \) the point \( sy \) cannot lie in \( A \) either. This shows that the above map actually takes values in \( \mathbb{R}^n \setminus A \).

Now it is obvious that the map \( F \) defines a deformation retraction from \( \mathbb{R}^n \setminus A \) to \( \mathbb{R}^n \setminus B^n_0(0) \). Clearly \( \mathbb{R}^n \setminus B^n_0(0) \) is also a deformation retract of \( \mathbb{R}^n \setminus \{0\} \).

Now we consider the following commutative diagram of inclusion induced maps:

\[
\begin{array}{ccc}
H_i(\mathbb{R}^n \setminus A) & \longrightarrow & H_i(\mathbb{R}^n \setminus \{0\}) \\
\downarrow \cong & & \downarrow \cong \\
H_i(\mathbb{R}^n \setminus B^n_0(0)) & & \\
\end{array}
\]

It follows from Corollary 42.8 and the above discussion that the two diagonal maps are isomorphisms. It follows that the horizontal map is also an isomorphism.

(2) Now we consider the following commutative diagram of long exact sequences:

\[
\begin{array}{c}
\ldots \rightarrow H_i(\mathbb{R}^n \setminus A) \rightarrow H_i(\mathbb{R}^n) \rightarrow H_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) \rightarrow H_{i-1}(\mathbb{R}^n \setminus A) \rightarrow H_{i-1}(\mathbb{R}^n) \rightarrow \ldots \\
\downarrow \cong & \downarrow = & \downarrow \cong & \downarrow = & \\
\ldots \rightarrow H_i(\mathbb{R}^n \setminus \{x\}) \rightarrow H_i(\mathbb{R}^n) \rightarrow H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \rightarrow H_{i-1}(\mathbb{R}^n \setminus \{x\}) \rightarrow H_{i-1}(\mathbb{R}^n) \rightarrow \ldots 
\end{array}
\]

By (1) the first and the fourth vertical maps are isomorphisms. The second and the fifth vertical map are the identity. It follows from the Five Lemma 43.12 that the middle vertical map is also an isomorphism.

(3) We consider the following commutative diagram:

\[
\begin{array}{ccc}
H_i(U, U \setminus A) & \longrightarrow & H_i(U, U \setminus \{x\}) \\
\downarrow & & \downarrow \\
H_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) & \longrightarrow & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) 
\end{array}
\]

of inclusion induced homomorphisms. Since \( \overline{A} \subset U \) we deduce from the Excision Theorem 43.20 that the two vertical maps are isomorphisms. By (2) we know that the bottom horizontal map is an isomorphism. Hence the top horizontal map is also an isomorphism.

---

1234 Note that the fact that \( 0 \in A \) and the convexity of \( A \) imply that for any \( x \notin A \) and any \( s \geq 1 \) we have \( s \cdot x \notin A \), in particular the map \( F \) does indeed take values in \( \mathbb{R}^n \setminus A \).
1235 As always, checking that a map is a deformation retraction also requires showing that the map is continuous. In this case the map is continuous by Lemma 2.74 and the fact that \( B^n_0(0) \setminus A \) is a closed subset of \( \mathbb{R}^n \setminus A \).
Now we suppose that $\hat{A}$ is non-empty and we suppose that $x$ is a point in $\hat{A}$. It follows from Exercise 2.32 that without loss of generality we can assume that $x = 0$ and that $A = \hat{A}$.

(4) Since $A$ is compact, convex with non-empty boundary we can apply Lemma 18.2. Thus we now know that there exists an isotopy $F: A \times [0, 1] \to \mathbb{R}^n$ from the inclusion map $i: A \to \mathbb{R}^n$ to a homeomorphism $\varphi: A \to \overline{B}^n$ that has the following two properties:

(a) $F_1 = \varphi$ restricts to a homeomorphism $\partial A \to S^{n-1}$, and

(b) $F$ has the property that $F(0, t) = 0$ for all $t \in [0, 1]$.

Now we have the following diagram

$$H_i(S^{n-1}) \xrightarrow{\varphi_*} H_i(\mathbb{R}^n \setminus \{0\}) \xrightarrow{\varphi_*} H_i(\mathbb{R}^n \{0\}).$$

Here all the unmarked maps are induced by inclusions. The right-hand triangle commutes by Corollary 42.8 since, by the above property (b), the isotopy $F$ restricts to an isotopy $\partial A \times [0, 1] \to \mathbb{R}^n \setminus \{0\}$. The left horizontal map is an isomorphism since $S^{n-1}$ is a deformation retract of $\mathbb{R}^n \setminus \{0\}$. It is now clear that the right-hand diagonal map is also an isomorphism.

(5) With the same argument as in (2) we can reduce the proof of this statement to (4). ■

86.2. The local homology of topological manifolds. We recall the following definition from page 1151.

**Definition.** Given a topological space $X$ and a point $x_0 \in X$ the homology groups $H_n(X, X \setminus \{x_0\}; R)$ is called the $n$-local homology group of $X$ at the point $x_0$.

In this section we will study the local homology of topological manifolds, in particular we want to gain a good understanding of generators of these groups.

Some of the following definitions and conventions we had already introduced earlier.

**Definition and notation.** Let $n \in \mathbb{N}$.

(1) We equip $\mathbb{R}^n$ with the orientation given by the standard basis $e_1, \ldots, e_n$. With this orientation we can view any open subset of $\mathbb{R}^n$ as an oriented smooth manifold.

(2) We write

$$\partial \Delta^n = \bigcup_{i=0}^n \{(t_0, \ldots, t_n) \in \Delta^n | t_i = 0\}.$$

and we refer to $\hat{\Delta}^n := \Delta^n \setminus \partial \Delta^n$ as the interior of $\Delta^n$.

(3) As on page 1075 we say that a basis $\{v_1, \ldots, v_n\}$ for $T_P \Delta^n$ is positive, if the ordered set of vectors $\{(1, \ldots, 1), v_1, \ldots, v_n\}$ is a positive basis for $\mathbb{R}^{n+1}$. This equips $\hat{\Delta}^n$ with the structure of an oriented smooth manifold.
(4) Given a subset $V$ of $\mathbb{R}^n$ we say that a map $f: V \to \mathbb{R}^k$ is affine linear if there exists a $P \in \mathbb{R}^k$ and a $k \times n$-matrix $A$ such that $f(v) = P + Av$ for all $v \in V$.

![Figure 1208](image1.png)

**Example.** The projection map

$$p: \Delta^n \to \mathbb{R}^n$$

$$(x_1, \ldots, x_{n+1}) \mapsto (x_1, \ldots, x_n)$$

is an injective affine linear map. One can easily verify that the restriction of this map to the interior $\Delta^n$ is orientation-preserving if and only if $n$ is even. We refer to Figure 1209 for an illustration.

![Figure 1209](image2.png)

We continue with the following lengthy lemma.

**Lemma 86.2.** Let $R$ be a commutative ring.

1. For any $k \in \mathbb{N}_0$ we have

$$H_k(\Delta^n, \partial \Delta^n; R) = \begin{cases} 0, & \text{if } k \neq n, \\ R \cdot [\text{id}_{\Delta^n} \otimes 1], & \text{if } k = n. \end{cases}$$

2. Let $\Phi: \Delta^n \to \mathbb{R}^n$ be an injective affine linear map such that $0$ lies in the image of $\Delta^n$ and such that the restriction of $\Phi$ to $\Delta^n$ is orientation-preserving. Then for any $k \in \mathbb{N}_0$ the induced map

$$\Phi_*: H_k(\Delta^n, \partial \Delta^n; R) \to H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$$

is an isomorphism and this map does not depend on the choice of $\Phi$.

3. Let $P \in \mathbb{R}^n$. We pick $r > 0$ such that $B^r(0)$ contains $P$. Then for any $k \in \mathbb{N}_0$ the inclusion induced maps

$$H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \leftarrow H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^r(0); R) \leftarrow H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

are isomorphisms and the resulting isomorphism

$$H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \xrightarrow{\cong} H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$
does not depend on the choice of \( r \).

(4) Let \( P \in \mathbb{R}^n \) be a point. If \( \rho: \mathbb{R}^n \to \mathbb{R}^n \) is the reflection in an affine hyperplane through \( P \), then the induced map

\[
\rho_*: H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{ P \}; R) \to H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{ P \}; R)
\]

is given by multiplication by minus \(-1\). The same conclusion also holds if we replace \( \mathbb{R}^n \) by any open ball centered at \( P \).

(5) Let \( U \subset \mathbb{R}^n \) be an open set and let \( B^n_r(Q) \subset U \) be a closed ball. Then for any \( P \in B^n_r(Q) \) the inclusion induced maps

\[
\begin{align*}
H_k(U, U \setminus B^n_r(Q); R) & \to H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_r(Q); R) \\
\downarrow & \\
H_k(U, U \setminus \{ P \}; R) & \to H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{ P \}; R)
\end{align*}
\]

are isomorphisms and they form a commutative diagram.

**Figure 1210.** Illustration for Lemma 86.2 (2), (3) and (5)

**Proof (•).**

(1) For \( k \neq n \) the statement is proved the same way as Lemma 45.1. Next recall that in Lemma 45.2 (2) we saw that the identity map \( \text{id}: \Delta^n \to \Delta^n \) represents a generator of \( H_n(\Delta^n, \partial \Delta^n; \mathbb{Z}) \cong \mathbb{Z} \). Basically the same proof shows that for any commutative ring \( R \) the element \( \text{id}_{\Delta^n} \otimes 1 \in C_n(\Delta^n, \partial \Delta^n; R) \) represents a generator of the homology group \( H_n(\Delta^n, \partial \Delta^n; R) \cong R \).

(2) Let \( \Phi: \Delta^n \to \mathbb{R}^n \) be an injective affine linear map such that \( 0 \) lies in the image of \( \Delta^n \) and such that the restriction of \( \Phi \) to \( \Delta^n \) is orientation-preserving. Note that it follows from Proposition 2.43 (2) that \( \Phi \) is an embedding.

Then we have the following commutative diagram

\[
\begin{array}{ccc}
H_k(\Delta^n, \partial \Delta^n; R) & \xrightarrow{\Phi_*} & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{ 0 \}; R) \\
\downarrow{\Phi} & & \uparrow \\
H_k(\Phi(\Delta^n), \Phi(\partial \Delta^n); R) & \to & H_k(\mathbb{R}^n, \Phi(\partial \Delta^n); R)
\end{array}
\]

where the bottom and the right vertical map are induced by inclusions. Here the left vertical map is an isomorphism since \( \Phi \) is an embedding.

Since \( \Phi \) is an injective affine linear map we see that \( \Phi(\Delta^n) \) is a convex subset of \( \mathbb{R}^n \) with non-empty interior. By our hypothesis the point \( 0 \) lies in the interior of \( \Phi(\Delta^n) \). It follows from Lemma 86.1 (5) that the right vertical map is an isomorphism. Clearly \( \Phi(\Delta^n) \to \mathbb{R}^n \) is a homotopy equivalence, hence it follows from Corollary 43.18...
that the bottom horizontal map is an isomorphism. Since the diagram commutes we have thus now shown, as desired, that the top horizontal map is also an isomorphism.

If $\Psi: \Delta^n \to \mathbb{R}^n$ is another such injective affine linear orientation-preserving map, then it follows from elementary linear algebra that there exists some $P \in \mathbb{R}^n$ and a matrix $A$ with positive determinant such that

$$\Phi = (v \mapsto P + A \cdot v) \circ \Psi: \Delta^n \to \mathbb{R}^n.$$ 

We write $\Omega = A \circ \Psi$. It suffices to show that $\Psi$ and $\Omega$ and also $\Omega$ and $\Phi$ induce the same maps $H_k(\Delta^n, \partial \Delta^n; R) \to H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$.

(a) By Lemma 2.65 (1) we know that $\{A \in \text{GL}(n, \mathbb{R}) \mid \det(A) > 0\}$ is path-connected. This implies in particular that there exists a path $\gamma: [0, 1] \to \text{GL}(n, \mathbb{R})$ with $\gamma(0) = \text{id}$ and $\gamma(1) = A$. We consider the map

$$F: \Delta^n \times [0, 1] \to \mathbb{R}^n$$

$$(Q, t) \mapsto \gamma(t) \cdot \Psi(Q).$$

Since by hypothesis we have $0 \notin \Phi(\partial \Delta^n)$ and since $\gamma(t)(0) = 0$ we see that $\gamma(t)(\partial \Delta^n) \subset \mathbb{R}^n \setminus \{0\}$ for all $t$. In particular we deduce that $F$ defines a homotopy between $\Psi$ and $\Omega$ as maps $(\Delta^n, \partial \Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But by Proposition 43.17 this means that $\Psi_s = \Omega_s$ as maps on relative homology.

(b) Now we compare $\Omega$ and $\Phi = (w \mapsto P + w) \circ \Omega$. We consider the map

$$G: \Delta^n \times [0, 1] \to \mathbb{R}^n$$

$$(Q, t) \mapsto (P \cdot t + \Omega(Q)).$$

Note that $0 \in \Omega(\Delta^n) = A(\Psi(\Delta^n))$ and that $0 \notin \Phi(\Delta^n)$ which implies by $\Phi = P + \Omega$ that $-P \in \Omega(\Delta^n)$. Since $\Omega(\Delta^n)$ is convex we see that $G$ defines a homotopy between $\Omega$ and $\Phi$ as maps $(\Delta^n, \partial \Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But again by Proposition 43.17 this means that $\Omega_s = \Phi_s$ as maps on relative homology.

(3) The fact that both inclusion induced maps are isomorphisms is an immediate consequence of Lemma 86.1 (2). Now suppose we are given another such $s > 0$. Without loss of generality we can assume that $r \geq s$. We obtain the following commutative diagram:

$$\begin{align*}
H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \cong & \quad \cong \quad H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_r(0); R) \cong \quad H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \\
\cong & \quad \cong \quad H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_s(0); R) \cong \quad H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R). 
\end{align*}$$

All maps are induced by inclusions, so the diagram commutes. By Lemma 86.1 the diagonal maps are isomorphisms. It is now obvious that the composition of the top maps and the composition of the bottom maps agree.

(4) Let $\rho: \mathbb{R}^n \to \mathbb{R}^n$ be the reflection in an affine hyperplane $V$ through a point $P$. We denote by $f: \mathbb{R}^n \to \mathbb{R}^n$ the map that is given by addition by $P$ and furthermore we write $W = f^{-1}(V)$. Note that $W$ goes through the origin. Finally we denote by
\( \sigma : \mathbb{R}^n \to \mathbb{R}^n \) the reflection in the hyperplane \( W \). We consider the following diagram

\[
\begin{array}{c}
\text{H}_{n-1}(S^{n-1}) \otimes R \xrightarrow{\mu} \text{H}_{n-1}(S^{n-1}; R) \xrightarrow{f} \text{H}_{n-1}(\mathbb{R}^n \setminus \{ P \}; R) \xrightarrow{\partial} \text{H}_{n}(\mathbb{R}^n, \mathbb{R}^n \setminus \{ P \}; R)
\end{array}
\]

where \( \mu \) is the natural map from page 1417 and where the right-hand horizontal maps are the connecting homomorphisms from Corollary 43.16.

It follows from Lemma 43.11 that the vertical map on the left is given by multiplication by \(-1\). It is straightforward to verify that the diagram commutes and that all horizontal maps are isomorphisms. Furthermore the horizontal maps on the top and bottom are identical. Thus it follows that the vertical map on the right is also given by multiplication by \(-1\).

(5) It is clear that the diagram commutes since all maps are induced by inclusions. The horizontal maps are isomorphisms by the Excision Theorem 43.20 and the vertical maps are isomorphisms by Lemma 86.1.

**Convention.** We use the isomorphisms from Lemma 86.2 to identify the various relative homology modules. In particular, for any open set \( U \) of \( \mathbb{R}^n \), any open ball \( B_r(P) \) with \( B_r(P) \subset U \), any point \( Q \in U \) and any commutative ring \( R \) we make the identifications

\[
R = \text{H}_n(\Delta^n, \partial \Delta^n; R) = \text{H}_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) = \text{H}_n(U, U \setminus \{Q\}; R).
\]

Furthermore, we refer to the image of the generator \([\text{id}_{\Delta^n} \otimes 1]\) in \( \text{H}_n(\Delta^n, \partial \Delta^n; R) \) as the **standard generator** of the various relative homology modules.

**Example.** We refer to Figure 1211 for an illustration of representatives of the standard generators. Here, for simplicity, given a singular 2-simplex \( \Delta^2 \to \mathbb{R}^2 \) we only sketch the image of \( \partial \Delta^2 \) with the given orientation. Finally note that it follows from Lemma 86.2 (4) that the singular simplex illustrated in the middle of Figure 1211 represents **minus** the standard generator.

---

1236 At this occasion it is good to remember that if \( \sigma : \Delta^k \to X \) is a map with \( \sigma(\partial \Delta^n) \subset A \), then \( \sigma \) is a cycle in \( C_k(X, A) \), i.e. it represents a class in \( H_k(X, A) \).
Lemma 86.3. Let $R$ be a commutative ring, let $U$ be an open subset of $\mathbb{R}^n$, let $P \in U$ and let $\sigma : \Delta^n \to U$ be a singular $n$-simplex with the following properties:

1. the point $P$ lies in the image of $\sigma$,
2. the restriction of $\sigma$ to a map $\Delta^n \to U$ is a diffeomorphism onto its image.

Then $\sigma \otimes 1 \in C_n(U) \otimes R$ represents a generator of $H_n(U, U \setminus \{P\}; R)$\(^{1237}\). Furthermore, if
3. the restriction of $\sigma$ to a map $\Delta^n \to U$ is orientation-preserving,
then $\sigma \otimes 1$ represents the standard generator of $H_n(U, U \setminus \{P\}; R)$.

We refer to Figure 1212 for an illustration of Lemma 86.3.

![Figure 1212](image)

**Figure 1212**

\[ \sigma \text{ represents the standard generator of } H_2(U, U \setminus \{P\}; \mathbb{Z}) \]

**Proof.** We denote by $Q \in \Delta^n$ the point with $\sigma(Q) = P$. To simplify the notation we work throughout the proof with the coefficients $R = \mathbb{Z}$. Using the fact that the inclusion induced map

\[ H_n(U, U \setminus \{P\}) \xrightarrow{\sim} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) \]

is an isomorphism by the Excision Theorem 43.20 we can without loss of generality assume that $U = \mathbb{R}^n$. As always we denote by $D \sigma_Q : T_Q \Delta^n \to T_P U = \mathbb{R}^n$ the differential of $\sigma$ at the point $Q$. We denote by

\[ f : \Delta^n \to \mathbb{R}^n \]

\[ x \mapsto (D \sigma_Q)(x - Q) + P \]

the linear approximation of $\sigma$ at the point $Q$. We make the following two observations:

1. Since $\sigma : \Delta^n \to U$ is a diffeomorphism onto its image we obtain that $D \sigma_Q$ is an isomorphism of vector spaces, in particular $f$ is an injective affine linear map.
2. Basically the same argument as in the proof of Lemma 45.17 shows that there exists an open neighborhood $V$ of $Q$ in $\Delta^n$ such that the restrictions of $\sigma$ and $f$ to maps

\[ \sigma, f : (V, V \setminus \{Q\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}) \]

are homotopic.

\(^{1237}\)Note that we do not make any assumptions on the behavior of $\sigma$ restricted to $\partial \Delta^n$. If one looks very carefully, then one realizes that one has to convince oneself that $\sigma(\partial \Delta^n)$ is a subset of $U \setminus \{P\}$, i.e. one has to show that it follows from (1) and (2), that $P \notin \sigma(\partial \Delta^n)$. How can one prove this statement?
Now consider the following diagram

\[
\begin{array}{c}
\Delta^n, \partial \Delta^n \to H_n(\Delta^n, \Delta^n \{Q\}) \\
\downarrow \sigma_* \downarrow \sigma_* \downarrow \sigma_* \downarrow \sigma_* \\
H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \to H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \\
\to H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \to H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \\
\to H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \\
\end{array}
\]

It is clear that the first two squares and the last square commute. Furthermore the third square commutes by the above observation (2) together with Proposition 43.17. As in the proof of Lemma 86.2 (2) we see that the last vertical map is an isomorphism. It now follows easily that \( \sigma \in C_n(\mathbb{R}^n) \) represents a generator of \( H_n(\mathbb{R}^n, \mathbb{R}^n \{P\}) \).

Finally suppose that the restriction of \( \sigma \) to a map \( \Delta^n \to U \) is orientation-preserving. In this case, by definition of orientation-preserving, the map \( f \) is also orientation-preserving, therefore by the above commutative diagram the singular \( n \)-simplex \( \sigma \) does indeed represent the standard generator of \( H_n(U, U \setminus \{P\}) \). \( \blacksquare \)

We continue with the following lemma which is almost identical to Lemma 44.1.

**Lemma 86.4.** Let \( M \) be an \( n \)-dimensional topological manifold and let \( R \) be a commutative ring. Then for every \( x \in M \setminus \partial M \) and any \( k \in \mathbb{N}_0 \) we have

\[
H_k(M, M \setminus \{x\}; R) \cong \begin{cases} R, & \text{if } k = n, \\ 0, & \text{otherwise}. \end{cases}
\]

Furthermore, if \( \Phi: U \to V \) is a chart around \( x \) and if \( \sigma: \Delta^n \to V \) represents a generator of \( H_n(V, V \setminus \{\Phi(x)\}; R) \), then \( \Phi^{-1} \circ \sigma \) represents a generator of \( H_n(M, M \setminus \{x\}; R) \).

We refer to Figure 1213 for an illustration of Lemma 86.4.

![Figure 1213](image)

**Remark.** Let \( n \in \mathbb{N}_0 \). A topological space \( X \) that has the property that for each \( x \in X \) we have

\[
H_k(X, X \setminus \{x\}; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise} \end{cases}
\]

is often called a \textit{k-dimensional homology manifold}. By Lemma 86.4, such topological spaces can be viewed as generalizations of closed topological manifolds.

Let \( Y \) be an homology \( n \)-sphere. By Proposition 45.7, we know that the suspension \( \Sigma(Y) \) of \( Y \) is an \((n+1)\)-dimensional homology manifold. On the other hand we saw

---

Recall that by the definition on page 1670 an homology \( n \)-sphere is an \( n \)-dimensional topological manifold \( X \) such that for any \( k \in \mathbb{N}_0 \) we have \( H_k(X; \mathbb{Z}) \cong H_k(S^n; \mathbb{Z}) \). On page 1672 we saw that there exists a smooth homology 3-sphere with non-trivial fundamental group, namely the Poincaré Homology Sphere.
in Exercise 45.9 that the suspension $\Sigma(Y)$ is not a topological manifold. \footnote{To be super-precise we showed that it is not an $(n + 1)$-dimensional topological manifold, but it follows easily from Proposition 44.4 that if $\Sigma(Y)$ was a topological manifold it would need to be $(n + 1)$-dimensional.} Recall that the Double Suspension Theorem 64.17 says that the double suspension $\Sigma(\Sigma(Y))$ of any homology $n$-sphere is actually homeomorphic to $S^{n+2}$.

The proof of Lemma 86.4 is basically identical to the proof of Lemma 44.1. We recall the argument just in case some readers might have forgotten.

**Proof.** Let $M$ be an $n$-dimensional topological manifold, let $R$ be a commutative ring and let $x \in M \setminus \partial M$. Since $x \notin \partial M$ we can pick a chart $\Phi: U \to V$ such that $V$ is an open subset of $\mathbb{R}^n$. We write $y = \Phi(x)$. For any $k \in \mathbb{N}_0$ we then have

$$H_k(M, M \setminus \{x\}; R) \xrightarrow{\cong} H_k(U, U \setminus \{x\}; R) \xrightarrow{\Phi_*} H_k(V, V \setminus \{y\}; R) \xrightarrow{\cong} \begin{cases} \mathbb{R}, & \text{if } k = n, \\ 0, & \text{otherwise}. \end{cases}$$

Excision Theorem 43.20 since $\Phi$ is a homeomorphism see Lemma 86.2 (5)

The last statement regarding generators now follows immediately from the above isomorphisms. \hfill ■

86.3. \textbf{$R$-Sections on topological manifolds.} In Section 6.11 we defined the notion of an oriented smooth manifold via orientations of the tangent spaces. The notion of a tangent space requires the smooth structure on a smooth manifold, put differently, topological manifolds do not come with tangent spaces. In the next section we will see that we can still define the notion of an orientation of a topological manifold. Furthermore we will see that for smooth manifolds this new notion of an orientation will be equivalent to the previous notion of an orientation.

The key to defining the new notion of orientation is the following, initially rather obscure definition.

**Definition.** Let $M$ be an $n$-dimensional topological manifold and let $R$ be a commutative ring.

1. An $R$-section for $M$ at $x \in M \setminus \partial M$ is an element $\mu_x \in H_n(M, M \setminus \{x\}; R) \cong R$.
2. Let $W \subset M$ and let $x \in W$. Given any $k \in \mathbb{N}_0$ we denote by $\rho_x$ the natural map

$$\rho_x: H_k(M, M \setminus W; R) \to H_k(M, M \setminus \{x\}; R).$$

Given $\varphi \in H_k(M, M \setminus W; R)$ we often write $\varphi_x := \rho_x(\varphi)$, i.e. the above map is also written as

$$\varphi \mapsto \varphi_x.$$  

3. Let $A$ be a subset of $M \setminus \partial M$. (In the following we will mostly be interested in the case $A = M \setminus \partial M$). An $R$-section for $M$ along $A$ is a choice for each $x \in A$ of an $R$-section $\mu_x \in H_n(M, M \setminus \{x\}; R)$ at $x$ such that the following “continuity condition” is satisfied: for each $x \in A$ there exists an open neighborhood $U$ of $x$ in $A$ and a homology class $\mu_U \in H_n(M, M \setminus U; R)$ such that for each $y \in U$ the image of $\rho_x$.
Example. In Figure 12.14 we attempt to illustrate the definition of a $\mathbb{Z}$-section on a surface $M$. Here, for simplicity, given a singular 2-simplex $\Delta^2 \to M$ we only sketch the image of $\partial \Delta^2$ with the given orientation.

(1) On the left of Figure 12.14 we show two points $x$ and $y$ with singular 2-simplices representing $\mu_x \in H_2(M, M \setminus \{x\}; \mathbb{Z})$ and $\mu_y \in H_2(M, M \setminus \{y\}; \mathbb{Z})$. Furthermore we sketch an open set $U$ that contains $x$ and $y$ and we sketch a homology class $\mu_U \in H_2(M, M \setminus U; \mathbb{Z})$ that gets sent to $\mu_x$ and $\mu_y$ via the natural maps.

$$H_n(M, M \setminus U; \mathbb{Z}) \xrightarrow{\rho_x} H_n(M, M \setminus \{x\}; \mathbb{Z}) \text{ and } H_n(M, M \setminus U; \mathbb{Z}) \xrightarrow{\rho_y} H_n(M, M \setminus \{y\}; \mathbb{Z}).$$

In fact these $\mathbb{Z}$-sections at $x$ and $y$ form part of a $\mathbb{Z}$-section of $M$.

(2) To the right of Figure 12.14 we show two $\mathbb{Z}$-sections $\nu_x$ and $\nu_y$ that cannot be part of a $\mathbb{Z}$-section of $M$.

here the $\mathbb{Z}$-sections at the points correspond to a $\mathbb{Z}$-section on $M$

here the $\mathbb{Z}$-sections at the points do not come from a $\mathbb{Z}$-section on $M$

**Figure 12.14**

**Lemma 86.5.** Let $M$ be an $n$-dimensional topological manifold and let $R$ be a commutative ring.

(1) Given any subset $A \subset M \setminus \partial M$ the set $\Gamma_R^A(M)$ admits a unique $R$-module structure such that for each $y \in A$ the map $\Gamma_R^A(M) \to H_n(M, M \setminus \{y\}; R)$ that is given by

$$\{\alpha_x\}_{x \in A} \mapsto \alpha_y$$

is an $R$-module homomorphism.

(2) For every subset $A \subset M \setminus \partial M$ (often we will take $A = M \setminus \partial M$) the map

$$H_n(M, M \setminus A; R) \to \Gamma_R^A(M)$$

$$\alpha \mapsto \{\alpha_x\}_{x \in A}$$

is a well-defined homomorphism of $R$-modules.

---

Note that in this example the group $H_2(M, M \setminus U; \mathbb{Z})$ is not isomorphic to $\mathbb{Z}$, i.e. the two maps are not isomorphisms.
Remark. In Theorem 87.10 we will see that in many settings the converse to Lemma 86.5 holds.

Proof (*).

1. We will prove this statement in Exercise 86.2.
2. Let $A \subset M \setminus \partial M$ be a subset and let $\alpha \in H_n(M, M \setminus A; R)$. Let $x \in A$. We need to show that there exists an open neighborhood $U$ of $x$ in $A$ and a homology class $\varphi \in H_n(M, M \setminus U; R)$ such that for each $y \in U$ we have $\rho_x(\varphi) = \alpha_x$. But this is trivial, we just take $U = A$ and $\varphi = \alpha$.

The following proposition contains much more interesting results on $\Gamma^A_{\partial}(M)$.

Proposition 86.6. Let $M$ be a topological manifold and let $A$ be a connected subset of $M \setminus \partial M$.[121]

1. Let $R$ be a commutative ring and let $\{\alpha_x\}_{x \in A}$ and $\{\beta_x\}_{x \in A}$ be two $R$-sections for $M$ along $A$. If there exists an $x \in A$ with $\alpha_x = \beta_x$, then the two $R$-sections agree.
2. Let $\{\alpha_x\}_{x \in A}$ be a $\mathbb{Z}$-section for $M$ along $M$. Suppose there exists a $y \in A$, an $m \in \mathbb{Z}$ and a $\beta_y \in H_n(M, M \setminus \{y\}; \mathbb{Z})$ such that $\alpha_y = m \cdot \beta_y$, then there exists a $\mathbb{Z}$-section $\{\beta_x\}_{x \in A}$ along $A$ such that $\alpha_x = m \cdot \beta_x$ for every $x \in A$.
3. Let $\{\alpha_x\}_{x \in A}$ be a $\mathbb{Z}$-section along $A$ for $M$. If there exists a $y \in A$ such that $\alpha_y$ is a generator of $H_n(M, M \setminus \{y\}; \mathbb{Z}) \cong \mathbb{Z}$, then $\alpha_x$ is a generator of $H_n(M, M \setminus \{x\}; \mathbb{Z}) \cong \mathbb{Z}$ for every $x \in A$.

Before we provide the proof of Proposition 86.6 we need to prove one little lemma which in turn requires the following definition.

Definition. Let $M$ be an $n$-dimensional topological manifold. We say that $Y \subset M$ is a small ball in $M$ if there exists a chart $\Phi: U \to V$ such that $B^n_2(0) \subset V$ and such that $\Phi(Y) = B^n$. We illustrate the definition of a small ball in Figure 1215.

![Figure 1215](chartΦ.png)

**Figure 1215**

Lemma 86.7. Let $M$ be an $n$-dimensional topological manifold.

1. Given any point $x \in M \setminus \partial M$ and any neighborhood $U$ of $x$ there exists a small ball contained in $U$ that contains $x$.

Let $R$ be a commutative ring.

2. For any point $y$ in a small ball $Y$ and any $k \in N_0$ the map

$$\rho_y: H_k(M, M \setminus Y; R) \to H_k(M, M \setminus \{y\}; R)$$

[121] In some applications we will use that by Exercise 44.4 we know that if $M$ is a connected topological manifold, then $M \setminus \partial M$ is also connected.
is an isomorphism.

(3) Let $A$ be a subset of $M \setminus \partial M$, let $\{\alpha_x\}_{x \in A}$ be an $R$-section along $A$ and let $x \in A$. There exists a small ball $Y$ in $M \setminus \partial M$ that contains $x$ and a $\varphi \in H_k(M, M \setminus Y; R)$ such that for every $y \in Y \cap A$ we have $\rho_y(\varphi) = \alpha_y \in H_n(M, M \setminus \{y\}; R)$.

**Proof.** Let $M$ be an $n$-dimensional topological manifold.

(1) The proof of the first statement is elementary.

(2) Now let $y$ be a point that is contained in a small ball $Y$. To simplify the notation we drop the commutative ring $R$ from the notation. We consider the long exact sequence of the triple $(M, M \setminus \{y\}, M \setminus Y)$ given by Corollary 43.16

$$\rightarrow H_k(M \setminus \{y\}, M \setminus Y) \rightarrow H_k(M, M \setminus Y) \rightarrow H_k(M, M \setminus \{y\}) \rightarrow H_{k-1}(M \setminus \{y\}, M \setminus Y) \rightarrow$$

We see immediately that it suffices to show that all the relative homology groups $H_k(M \setminus \{y\}, M \setminus Y)$ vanish. Since $Y$ is a small ball we can pick a chart $\Phi: U \rightarrow V$ such that $B^n_s(0) \subset V$ and such that $\Phi(Y) = B^n$. We pick $s \in (1, 2)$ and we write $Z = \Phi^{-1}(B^n_s(0))$. Then

$$H_k(M \setminus \{y\}, M \setminus Y) \leftrightarrow H_k(Z \setminus \{y\}, Z \setminus Y) \xrightarrow{\Phi_*} H_k(B^n_s(0) \setminus \{\Phi(y)\}, B^n_s(0) \setminus B^n_s) = 0.$$

by Corollary 43.18 since $B^n_s(0) \setminus B^n$ is a deformation retract of $B^n_s(0) \setminus \{\Phi(y)\}$

We refer to Figure 1216 for an illustration of the proof.

![Figure 1216](image)

**Figure 1216.** Illustration for the proof of Lemma 86.7 (2).

(3) Let $A$ be a subset of $M$, let $\{\alpha_x\}_{x \in A}$ be an $R$-section along $A$ and let $x \in A$. By definition of an $R$-section along $A$ and by definition of the subspace topology there exists an open neighborhood $V$ of $x \in M \setminus \partial M$ and a singular chain $\sigma \in C_n(M; R)$ that represents a cycle in $C_n(M, M \setminus (V \cap A); R)$ such that for each $y \in V \cap A$ we have $\alpha_y = \rho_y([\sigma]) \in H_n(M, M \setminus \{y\}; R)$.

Since $\sigma$ represents a cycle in the relative chain complex $C_*(M, M \setminus (V \cap A); R)$ we know that $\partial \sigma \in C_{n-1}(M \setminus (V \cap A); R)$. It follows from the fact that $\Delta^{n-1}$ is compact together with Lemmas 2.40 and 2.17 that there exists an open neighborhood $U \subset M$ of $x$ with $U \subset V$ such that $\partial \sigma \in C_{n-1}(M \setminus U; R)$. In other words, $\sigma$ represents a cycle in $C_n(M, M \setminus U)$. By (1) there exists a small ball $Y$ with $x \in Y \subset U$. It follows immediately from the functoriality of homology groups that the homology class $[\sigma] \in H_n(M, M \setminus Y; R)$ has all the desired properties. ■

Now we can provide the proof of Proposition 86.6.
Proof of Proposition 86.6. Let $M$ be a $n$-dimensional topological manifold, let $A$ be a connected subset of $M \setminus \partial M$ and let $R$ be a commutative ring.

1. Let $\{\alpha_x\}_{x \in A}$ and $\{\beta_x\}_{x \in A}$ be two $R$-sections for $M$ along $A$. We assume that there exists a $z \in A$ with $\alpha_z = \beta_z$. We consider the $R$-section along $A$ that is given by $\gamma_x = \alpha_x - \beta_x$ for $x \in A$. Next we consider the following two subsets of $A$:

$$V := \{y \in A \mid \gamma_y = 0\} \quad \text{and} \quad W := \{y \in A \mid \gamma_y \neq 0\}.$$ 

We need to show that $V = A$. Since $V$ is by hypothesis non-empty and since $A$ is connected it suffices to show that $V$ and $W$ are both open. In other words, it suffices to prove the following claim.

Claim. Let $x \in A$. There exists an open neighborhood $U$ of $x$ in $A$ such that either $\gamma_y$ is zero for every $z \in U$ or $\gamma_y$ is non-zero for every $z \in U$.

2. Let $n \in \mathbb{N}$. We start out with the following definition: Given an element $g$ of a group $G$ with $G \cong \mathbb{Z}$ we say that $g$ is divisible by $n$ if there exists an $h \in G$ with $n \cdot h = g$. In this case we write $g/n := h$. Note that $h$ is well-defined since $G \cong \mathbb{Z}$.

Let $\{\alpha_x\}_{x \in A}$ be a $\mathbb{Z}$-section for $M$ along $A$. Given $n \in \mathbb{N}$ we consider the two sets

$$V := \{y \in A \mid \alpha_y \text{ is divisible by } n\}$$

and

$$W := \{y \in A \mid \alpha_y \text{ is not divisible by } n\}.$$ 

The same argument as in (1) one shows that $V$ and $W$ are open.

3. If $V$ is non-empty, then $V = M \setminus \partial M$ and it is straightforward to verify that $\beta_y := \alpha_y/n$, $y \in A$, is in fact a $\mathbb{Z}$-section along $A$. We leave it to the reader to fill in the details.

Illustration for the proof of Lemma 86.7 (3). Figure 1217.
86.4. Orientations of topological manifolds. After the technical preparations from the last section we can now finally introduce the notion of an orientation of a topological manifold.

**Definition.** Let $M$ be an $n$-dimensional topological manifold and let $R$ be a commutative ring.

(1) An $R$-section for $M$ at a point $x \in M \setminus \partial M$ that is in fact a generator of the $R$-module $H_n(M, M \setminus \{x\}; R) \cong R$ is called an $R$-orientation for $M$ at $x \in M$.

(2) An $R$-section for $M$ that is an $R$-orientation at each point $x \in M \setminus \partial M$ is called an $R$-orientation of $M$.

(3) The topological manifold $M$ is called $R$-orientable if it admits an $R$-orientation.

(4) Let $M$ and $N$ be two $n$-dimensional topological manifolds that are equipped with $R$-orientations $\{\alpha_x\}_{x \in M \setminus \partial M}$ and $\{\beta_x\}_{x \in N \setminus \partial N}$. Let $f: M \to N$ be a map that is a local homeomorphism. We say the map $f$ is orientation-preserving if the following holds: for any open set $U \subset M$, such that $f: U \to f(U)$ is a homeomorphism and such that $f(U)$ is open, and any $x \in U \setminus \partial M$ the image of $\alpha_x$ under the map $f$; these maps are isomorphisms by the Excision Theorem.

$$H_n(M, M \setminus \{x\}) \xrightarrow{\cong} H_n(U, U \setminus \{x\}) \xrightarrow{f_*} H_n(f(U), f(U) \setminus \{f(x)\}) \xrightarrow{\cong} H_n(N, N \setminus \{f(x)\}).$$

equals $\beta_{f(x)}$. Otherwise we call $f$ orientation-reversing.

**Remark.** Note that the above definition of an orientation of an $n$-dimensional topological manifold also makes perfect sense if $n = 0$. In particular for topological manifolds we do not have to make the slightly awkward distinction between 0-dimensional case and the higher dimensional case that we had to make for smooth manifolds, see pages 297 and page 1718.

We leave the proof of the following lemma as an amusing exercise to the reader.

**Lemma 86.8.** Let $M$ and $N$ be two $n$-dimensional topological manifolds and furthermore let $f, g: M \to N$ be two homeomorphisms. If $f$ and $g$ are isotopic, then $f$ is orientation-preserving if and only if $g$ is orientation-preserving.

Before we start with the discussions of orientations in detail we get the following technical lemma out of the way.

**Lemma 86.9.** Let $M$ be an $n$-dimensional topological manifold.

(1) Let $R$ be a commutative ring and let $A \subset M \setminus \partial M$ be a connected subset. If $M$ is $R$-orientable, then for every $x \in M \setminus \partial M$ the map $\Phi: \Gamma^A_R(M) \to \overline{\{\alpha_x\}_{y \in A}}$.

---

1242 Since $f: U \to f(U)$ is a homeomorphism we have $f(U \setminus \{x\}) = f(U) \setminus \{f(x)\}$.

1243 It follows from the fact that $f: U \to f(U)$ is a homeomorphism, the fact that $x \in U \setminus \partial U$ and Proposition 44.2 that $f(x) \notin \partial N$.

1244 We suppress the $R$-coefficients from the notation for space reasons.
is an isomorphism of $R$-modules.

(2) If $M$ is non-orientable and connected, then $\Gamma_\mathbb{Z}(M) = 0$.

**Proof.** Let $M$ be a connected $n$-dimensional topological manifold.

(1) Let $R$ be a commutative ring such that $M$ is $R$-orientable. We pick an $R$-orientation $\{\mu_y\}_{y \in M \setminus \partial M}$ for $M$. Next let $A \subset M \setminus \partial M$ be a connected subset and let $x \in M \setminus \partial M$. By definition $\mu_x$ is a generator of the $R$-module $H_n(M, M \setminus \{x\}; R) \cong R$, i.e. every element in $H_n(M, M \setminus \{x\}; R)$ is of the form $r \cdot \mu_x$ for some unique $r \in R$. We consider the map

$$
\Psi: H_n(M, M \setminus \{x\}; R) \to \Gamma_R^A(M)
$$

where $r \cdot \mu_x \mapsto \{r \cdot \mu_y\}_{y \in A}$.

Evidently we have $\phi \circ \Psi = \text{id}$. It follows from our hypothesis that $A$ is connected and from Proposition [86.6](1) that $\Psi \circ \Phi$ is also the identity.

(2) Now we suppose that $M$ admits a non-zero $\mathbb{Z}$-section $\{\alpha_x\}_{x \in M \setminus \partial M}$. We need to show that $M$ is orientable. We pick $y \in M \setminus \partial M$ such that $\alpha_y \neq 0$. We pick a generator $\beta_y \in H_n(M, M \setminus \{y\}; \mathbb{Z}) \cong \mathbb{Z}$. Then $\alpha_y = n \cdot \beta_y$ for some $n \in \mathbb{Z}$. It follows again from our hypothesis that $M$ is connected and from Proposition [86.6](2) that there exists a $\mathbb{Z}$-section $\{\beta_x\}_{x \in M \setminus \partial M}$ such that $\alpha_x = n \cdot \beta_x$ for all $x \in M \setminus \partial M$. It follows immediately from Proposition [86.6](3) that $\{\beta_x\}_{x \in M \setminus \partial M}$ is an orientation for $M$.

In the following lemma we collect some basic facts about $\mathbb{Z}$-orientations.

**Lemma 86.10.** Let $M$ be a topological manifold.

(1) For any point $x \in M \setminus \partial M$ there exist precisely two $\mathbb{Z}$-orientations for $M$ at $x$.

(2) If $M$ is connected and orientable, then $M$ admits precisely two $\mathbb{Z}$-orientations.

**Proof.** The first statement is an immediate consequence of the fact, proved in Lemma [86.4] that for any $x \in M \setminus \partial M$ we have $H_n(M, M \setminus \{x\}; \mathbb{Z}) \cong \mathbb{Z}$. The second statement follows easily from Proposition [86.6] and the definitions.

**Examples.**

(1) Let $V$ be a connected open subset of $\mathbb{R}^n$. For any $x \in V$ we define

$$
\mu_x := \text{the standard generator of } H_n(V, V \setminus \{x\}; \mathbb{Z}) \text{ as defined on page 2097}
$$

We claim that the $\mu_x$ define a $\mathbb{Z}$-orientation for $V$. Indeed, let $x \in V$. We pick an $r > 0$ such that $\overline{B_r}(x) \subset V$. We set $U := B_r(x)$. We denote by $\mu_U$ the standard generator of $H_n(V, V \setminus U; \mathbb{Z})$ as defined on page 2097. It follows from Lemma [86.2](5) that $\mu_U$ has the desired property. We refer to this $\mathbb{Z}$-orientation as the standard $\mathbb{Z}$-orientation of $V$.

By Lemma [86.10](2) the topological manifold $V$ admits precisely two different $\mathbb{Z}$-orientations. We have already given one orientation above. By Lemma [86.2] the other one is given by a reflection of the standard generators in hyperplanes. In Figure [1218] we sketch the two different orientations of $V$.

(2) In Figure [1219] we sketch the two different orientations of the torus.
(3) Let \( R \) be a commutative ring. Recall that for \( n \geq 1 \) we denote by \([S^n] \in H_n(S^n; \mathbb{Z})\) the standard generator that we introduced on page \([1174]\). It follows from the Universal Coefficient Theorem \([57.19]\) together with Lemma \([57.17]\) (3) that the natural map
\[
H_n(S^n) \otimes R \to H_n(S^n; R)
\]
is an isomorphism. By a slight abuse of notation we denote by \([S^n]\) also the image of \([S^n] \otimes 1 \in H_n(S^n; R)\) under the above map. Note that \([S^n] \in H_n(S^n; R) \cong R\) is a generator. We refer to it as the standard generator of \(H_n(S^n; R)\). For any \(x \in S^n\) it follows easily from the long exact sequence of homology groups with \(R\)-coefficients of the pair \((S^n, S^n \setminus \{x\})\) that the natural map
\[
H_n(S^n; R) \to H_n(S^n, S^n \setminus \{x\}; R)
\]
is an isomorphism. We denote by \(\mu_x \in H_n(S^n, S^n \setminus \{x\}; R)\) the image of \([S^n]\). By the above \( \mu_x \) is an \(R\)-orientation at \(x\). In fact all these \(R\)-orientations \(\{\mu_x\}_{x \in S^n}\) define an \(R\)-orientation of \(S^n\). Indeed, in the definition on page \([2105]\) we just need to set \(U = S^n\) and \(\mu_U = [S^n] \in H_n(S^n, S^n \setminus \{x\}; \mathbb{Z})\). We refer to this orientation of \(S^n\) as the standard \(R\)-orientation of \(S^n\).

The following proposition shows in particular that for smooth manifolds the notion of orientability from Section agrees with the above notion of orientability.

**Proposition 86.11.**

1. Give any smooth manifold \(M\) there exists a natural bijection
\[
\left\{\text{orientations on } M \text{ in the sense of Section}\right\} \cong \{\mathbb{Z}\text{-orientations on } M\}
\]
such that the following two statements hold:
(a) For any open subsets of some \( \mathbb{R}^n \) the above bijections sends the standard orientation from page 297 to the above standard \( \mathbb{Z} \)-orientation.
(b) If \( f : M \to N \) is a local diffeomorphism between oriented connected smooth manifolds, then the following two statements are equivalent:
   (i) \( f \) preserves the orientations on \( M \) and \( N \) in the sense of Section ,
   (ii) \( f \) preserves the \( \mathbb{Z} \)-orientations on \( M \) and \( N \).

(2) Given an \( n \)-dimensional smooth manifold \( M \) we have

\[
\text{\( M \) is orientable in the sense of Section} \iff \text{\( M \) is \( \mathbb{Z} \)-orientable.}
\]

In the proof of Proposition \textbf{86.11} we will use the following lemma.

**Lemma 86.12.** Let \( \Psi : V \to V' \) be a diffeomorphism between two open subsets of \( \mathbb{R}^n \). Then for any \( x \in V \) we have

\[
\Psi \text{ preserves the standard } \mathbb{Z}\text{-orientation of } V \text{ at the point } x \iff \Psi \text{ preserves the orientation of } V \text{ in the sense of Section at the point } x.
\]

**Proof** (*) Let \( \Psi : V \to V' \) be a diffeomorphism between two open subsets of \( \mathbb{R}^n \) and let \( x \in V \). We write \( x' = \Psi(x) \). Given \( w \in \mathbb{R}^n \) we denote by \( t_w \) the translation \( \mathbb{R}^n \to \mathbb{R}^n \) that is given by \( v \mapsto v + w \). We set \( \epsilon := 1 \) if \( \Psi \) preserves the orientation of \( V \) in the sense of Section at the point \( x \). Otherwise we set \( \epsilon := -1 \). We consider the following diagram

\[
\begin{array}{ccc}
H_n(V, V \setminus \{x\}; \mathbb{Z}) & \xleftarrow{t_{x'}} & H_n(t_{-x}(V), t_{-x}(V) \setminus \{0\}) \\
\downarrow{\Psi*} & & \downarrow{(t_{x} \circ \Psi \circ t_{-x})*} \\
H_n(V', V' \setminus \{x'\}; \mathbb{Z}) & \leftarrow & H_n(t_{-x}(V), t_{-x}(V) \setminus \{0\}) \\
& & \downarrow{\epsilon}
\end{array}
\]

We make the following observations:

1. It follows easily from the definitions that each translation \( t_v \) is orientation-preserving in both senses of an orientation.
2. It follows from Proposition \textbf{45.16} together with (1) that the square at the right commutes.
3. It is clear that the square at the left commutes.
4. The statement of the lemma follows from (2) and (3).

Now we can provide the proof of Proposition \textbf{86.11}.

**Sketch of the proof of Proposition \textbf{86.11}** First we note that the case of 0-dimensional smooth manifolds is basically a tautology, at least as long as all statements are interpreted in a reasonable way. Thus in the following we assume that we are dealing with smooth manifolds of dimension \( \geq 1 \).

Next note that statement (2) is just a reader-friendly condensation of statement (1). Thus we need to prove statement (1). We define the promised natural bijections. Thus let \( M \) be an \( n \)-dimensional smooth manifold where \( n \geq 1 \). We first suppose that \( M \) is oriented in the sense of Section . Let \( x \in M \setminus \partial M \). We pick a chart \( \Phi : U \to V \) around \( x \)...
that is orientation-preserving in the sense of Section . We define

\[ \mu_x := \Phi_*^{-1}(\text{standard generator of } H_n(V, V \setminus \{\Phi(x)\}; \mathbb{Z}) \text{ as defined on page } 2097). \]

It follows from Lemma 86.12 that this definition does not depend on the choice of the orientation-preserving chart \( \Phi \). We claim that the classes \( \{\mu_x\}_{x \in M \setminus \partial M} \) form a \( \mathbb{Z} \)-orientation for \( M \). We only have to show that these classes satisfy the “continuity condition”. We claim that for any \( x \in M \setminus \partial \) a sufficiently small ball \( U \) containing \( x \) has the desired property. The proof of this fact is very similar to the arguments used in the proof of Proposition 86.6. We leave it to the reader to fill in the details.

Now we define the inverse map. So suppose we are given a \( \mathbb{Z} \)-orientation \( \{\mu_x\}_{x \in M \setminus \partial M} \) for \( M \). Note that by Lemma 6.46 we only need to find an orientation for \( M \setminus \partial M \). Thus let \( x \in M \setminus \partial M \). We pick a chart \( \Phi: U \to V \) around \( x \) such that \( V \) is connected. It follows from Lemma 86.2 that, after possibly reflecting \( V \) in a hyperplane, we can assume that \( \Phi \) preserves the \( \mathbb{Z} \)-orientation at \( x \), i.e. it sends the given \( \mathbb{Z} \)-orientation \( \mu_x \) to the standard orientation of the open subset \( V \) of \( \mathbb{R}^n \) that we introduced on page 2106. We define

\[ \text{orientation of } T_x M := \Phi^*(\text{standard orientation of } T_{\Phi(x)} V = \mathbb{R}^n). \]

It follows from Lemma 86.12 that this definition does not depend on the choice of \( \Phi \). As before, using small balls, one can show that this defines an orientation of \( M \) in the sense of Section . We leave the verification of the details once again to the surely highly motivated reader.

It is basically clear, that by construction, the bijections have the desired properties (a) and (b). This concludes the proof of statement (1).

\[ \square \]

**Convention.** Proposition 86.11 says in particular that for smooth manifolds the notion of orientability that we introduced in Section agrees with the notion of \( \mathbb{Z} \)-orientability that we had just introduced. For \( R = \mathbb{Z} \) we will therefore often drop the “\( R \)” from the definitions on page 2105 i.e. often we just say orientation at a point, orientation and orientable.

**Remark.** It follows basically from the definitions that under the equivalence of Proposition 86.11 the orientations of \( S^n \) introduced on page 299 and page 2107 agree.

The following proposition shows that the notion of \( R \)-orientability is more flexible than the previous notion of orientability.

**Proposition 86.13.** Every topological manifold is \( \mathbb{F}_2 \)-orientable.

**Example.** Proposition 86.13 says in particular that the real projective plane, the Klein bottle and the Möbius band are \( \mathbb{F}_2 \)-orientable.
Proof. Let $M$ be an $n$-dimensional topological manifold. Let $x \in M \setminus \partial M$. By Lemma \ref{lemma86.4} we know that $H_n(M, M \setminus \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. We define $\mu_x$ to be the unique non-trivial element in $H_n(M, M \setminus \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. Using Lemma \ref{lemma86.7} it is straightforward to show that the continuity condition is satisfied, in particular we have defined an $\mathbb{F}_2$-orientation on $M$. ■

**Lemma 86.14.** Let $M$ be a topological manifold. If $M$ is orientable, then it is $R$-orientable for any commutative ring $R$.

Proof. Let $M$ be an $n$-dimensional orientable topological manifold and let $R$ be a commutative ring. Let $x \in M \setminus \partial M$. It follows from the Universal Coefficient Theorem together with the fact that $H_{n-1}(M, M \setminus \{x\}; \mathbb{Z}) = 0$ obtained in Lemma \ref{lemma86.4} that the natural map
\[
\mu: H_n(M, M \setminus \{x\}; \mathbb{Z}) \otimes_R \to H_n(M, M \setminus \{x\}; R)
\]
\[
\sum_{i=1}^k [\sigma_i] \otimes r_i \mapsto \left[ \sum_{i=1}^k \sigma_i \otimes r_i \right]
\]
is an isomorphism.

Now we pick an orientation $\{\alpha_x\}_{x \in M \setminus \partial M}$ for $M$. For each $x \in M \setminus \partial M$ we denote by $\tilde{\alpha}_x \in H_n(M, M \setminus \{x\}; R)$ the image of $\alpha_x \otimes 1$ under the above isomorphism. It is straightforward to verify that these generators $\{\tilde{\alpha}_x\}_{x \in M \setminus \partial M}$ define an $R$-orientation for the topological manifold $M$. ■

We continue with the following proposition which is a variation on Proposition \ref{proposition17.3}.

**Proposition 86.15.**

1. To each topological manifold $M$ we can canonically associate an oriented topological manifold $\tilde{M}$ together with a 2-fold covering $p: \tilde{M} \to M$ and to each local homeomorphism $f: M \to N$ we can associate an orientation-preserving local homeomorphism $\tilde{f}: \tilde{M} \to \tilde{N}$ such that the following diagram commutes:
\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\tilde{f}} & \tilde{N} \\
p & & p \\
M & \xrightarrow{f} & N.
\end{array}
\]

2. Let $M$ be a connected topological manifold and let $p: \tilde{M} \to M$ be the 2-fold covering constructed in (1).
   
   (a) If $M$ is orientable, then there exists an orientation-preserving homeomorphism to $\Theta: \tilde{M} \to M \sqcup -M$ such that the following diagram commutes:
\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\Theta} & M \sqcup -M \\
p & & q \\
M & \xrightarrow{q} & M
\end{array}
\]
   where $q$ is the obvious map given by the identity on each component of $M \sqcup -M$.

   (b) If $M$ is non-orientable, then $\tilde{M}$ is connected.
(c) In either case, the oriented topological manifold \( \tilde{M} \) admits an orientation-reversing self-homeomorphism \( \Xi_M: \tilde{M} \to \tilde{M} \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\Xi_M} & \tilde{M} \\
p & \approx & p \\
\downarrow & & \downarrow \\
M & \xrightarrow{\sim} & M
\end{array}
\]

Furthermore, given an orientation-preserving local homeomorphism \( f: M \to N \) we have \( \tilde{f} \circ \Xi_M = \Xi_N \circ \tilde{f} \).

(3) Let \( M \) be a connected non-orientable topological manifold. Suppose that \( p: \tilde{M} \to M \) and \( q: \hat{M} \to M \) are two connected 2-fold coverings such that \( \tilde{M} \) and \( \hat{M} \) are orientable. There exists a homeomorphism \( \Phi: \tilde{M} \to \hat{M} \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\Phi} & \hat{M} \\
p & & q \\
\downarrow & & \downarrow \\
M & & M
\end{array}
\]

If \( \tilde{M} \) and \( \hat{M} \) are oriented, then we can arrange that \( \Phi \) is orientation-preserving.

**Definition.** Let \( M \) be a connected non-orientable topological manifold without boundary. We refer to the connected 2-fold covering \( p: \tilde{M} \to M \) from Proposition 86.15 which is unique up to equivalence, as the **orientation covering** of \( M \).

**Sketch of proof.** The proof is very similar to the proof of Proposition 17.3

1. Let \( M \) be a topological manifold.
   (a) For \( x \in M \setminus \partial M \) we define an orientation at \( x \) to be a \( \mathbb{Z} \)-orientation for \( M \) at the point \( x \).
   (b) Let \( x \in \partial M \). An orientation-neighborhood for \( x \) is a triple \((U, \mu, x)\) where \( U \) is an open neighborhood of \( x \in M \) and \( \mu \) is a \( \mathbb{Z} \)-orientation on \( U \). We say that two orientation-neighborhoods \((U, \mu, x)\) and \((V, \nu, x)\) are equivalent if the orientations \( \mu \) and \( \nu \) agree on \( U \cap V \). For the purpose of this proof we define an orientation for \( x \) to be an equivalence class of orientation-neighborhoods for \( x \).

We consider the set

\[
\tilde{M} := \{ \mu_x \mid x \in M \text{ and } \mu_x \text{ is an orientation for } M \text{ at the point } x \}
\]

and the projection map \( p: \tilde{M} \to M \) that is given by \( \mu_x \mapsto x \) for \( x \in M \setminus \partial M \) and \( [(U, \mu, x)] \mapsto x \) for \( x \in \partial M \). It follows from Lemma 86.10 (1) that for every \( x \in M \setminus \partial M \) the preimage \( p^{-1}(x) \) has precisely two elements. We leave it to the reader to verify that for every \( x \in \partial M \) the preimage \( p^{-1}(x) \) also has precisely two elements.

We leave it to the reader to express this statement in categorical language.
We equip $\tilde{M}$ with a topology similar to the proof of Proposition 17.3. It is then straightforward to see that $p: \tilde{M} \to M$ is a 2-fold covering. Similar to the proof of Proposition 17.3 one can show that $\tilde{M}$ admits a canonical orientation.

Now let $\tilde{f}: \tilde{M} \to N$ be a local homeomorphism. We leave it to the reader to define the map $\tilde{f}: \tilde{M} \to \tilde{N}$ that has the promised properties.\textsuperscript{1246}

(2) The proof of this statement is almost identical to the proof of Proposition 17.3 (2).

(3) Not surprisingly the proof of this statement is almost identical to the proof of Proposition 17.3 (2).

We leave it to the reader to flesh out all the details. ■

Finally we conclude this section with the following corollary which is closely related to Corollary 17.4.

**Corollary 86.16.** Let $M$ be a connected topological manifold without boundary. If $M$ is non-orientable, then there exists an epimorphism $\pi_1(M) \to \mathbb{Z}_2$.

**Proof.** The proof of the corollary is basically identical to the proof of Corollary 17.4, we just need to replace Proposition 17.3 by Proposition 86.15. ■

**86.5. Induced orientations.** (*) In this final section we will show that various constructions of new topological manifolds out of a given oriented topological manifold are naturally equipped with orientations. For the most part the statements sound reasonable and familiar from the setting of smooth manifolds. Nonetheless, the constructions of the induced representations for topological manifolds are at times quite different from the constructions of induced orientations for smooth manifolds. Truth be told, the reader will not miss out on much by just moving on to the next chapter.

**Lemma 86.17.** Let $R$ be a commutative ring and let $M$ be a topological manifold that is equipped with an $R$-orientation.

(1) Let $N$ be a topological manifold and let $f: N \to M$ be a map. If $f: N \setminus \partial N \to M$ is a local homeomorphism, then there exists a unique $R$-orientation on $N$ such that $f$ is orientation-preserving.

(2) If $N$ is a submanifold of codimension zero (for example $N$ could be an open subset of $M$), then $N$ admits a unique $R$-orientation such that the inclusion map $N \to M$ is orientation-preserving.

(3) If $p: \tilde{M} \to M$ is a covering, then there exists a unique orientation on $\tilde{M}$ that turns $p$ into an orientation-preserving map.

**Proof.** To simplify the notation we suppress the ring $R$ from the notation. Thus let $M$ be an $n$-dimensional topological manifold that is equipped with an orientation $\{\alpha_x\}_{x \in M \setminus \partial M}$.

(1) Let $N$ be a topological manifold and let $f: N \to M$ be a local homeomorphism. Let $x \in N \setminus \partial N$. We pick an open neighborhood $U$ of $x$ such that $f: U \to f(U)$ is a

\textsuperscript{1246}It is obvious how to define the map if $\partial M = \partial N = \emptyset$. Dealing with the boundaries is slightly awkward.
homeomorphism and such that the image \( f(U) \) is an open subset of \( M \). We define
\[
\beta_x \in H_n(N, N \setminus \{x\}; R)
\]
to be the image of \( \alpha_x \) under the map\(^{1247}\)

these maps are isomorphisms by the Excision Theorem\(^{43.20}\)

\[
\downarrow \quad \downarrow
\]

\[
H_n(M, M \setminus \{f(x)\}) \cong H_n(f(U), f(U) \setminus \{f(x)\}) \xrightarrow{f_\ast^{-1}} H_n(U, U \setminus \{x\}) \cong H_n(N, N \setminus \{x\}).
\]

We leave it to the reader to verify that these classes \( \beta_x \) define an orientation on \( N \). By
definition the map \( f \) is orientation-preserving with respect to the orientations on \( M \)
and \( N \). It is elementary to verify that the orientation on \( N \) is uniquely determined.

(2) This statement follows from (1) since the inclusion map of a codimension-zero sub-
manifold is, basically by definition, a local homeomorphism.

(3) This statement also follows from (1) since a covering map is a local homeomorphism.

\[\blacksquare\]

The following lemma, which can be viewed as an analogue of Lemma\(^{44.12}\)\((5)\), says in
particular that the double of an \( R \)-orientable topological manifold is again \( R \)-orientable.

**Lemma 86.18.** Let \( M \) be a connected topological manifold with non-empty boundary and
let \( R \) be a commutative ring. Then

\( M \) is \( R \)-orientable \iff the double \( D M \) is \( R \)-orientable.

Furthermore, if \( M \) is equipped with an \( R \)-orientation, then \( D M \) admits a unique \( R \)-ori-
entation such that the inclusion map \( M \to D M \) is orientation-preserving.

**Sketch of proof (\(*\).** Let \( M \) be a connected topological manifold. In the following we
write \( D M = (M \sqcup M')/\sim \) where \( M' \) is another copy of \( M \). We apply the Topological
Collar Neighborhood Theorem\(^{44.5}\) to obtain a collar neighborhood \([-2, 0] \times \partial M \) of \( \partial M \) in
\( M \). To simplify the notation we henceforth drop the coefficient ring \( R \) from the notation.

If \( D M \) is orientable, then it follows immediately from Lemma\(^{86.17}\) that the submanifold
\( M \) is also orientable.

Now suppose that \( M \) is equipped with an orientation \( \{\mu_x\}_{x \in M \setminus \partial M} \). We define orientations
for the points of \( D M \) in \( M \setminus \partial M \), \( M' \setminus \partial M' \) and in \( \partial M = \partial M' \) separately.

1. Given \( x \in M \setminus \partial M \) we denote by \( \alpha_x \) the image of \( \mu_x \) under the inclusion induced
isomorphism \( H_n(M, M \setminus \{x\}) \to H_n(D M, D M \setminus \{x\}) \) given by the Excision Theorem\(^{44.10}\).

2. We denote by \( r : D M \to D M \) the obvious homeomorphism given by interchanging
the two copies of \( M \) in \( D M \). Given \( x \in M' \setminus \partial M' \) we define \( \alpha_x := -r_\ast^{-1}(\alpha_{r(x)}) \).

3. Finally let \( x \in \partial M \). We define \( \alpha_x \in H_n(D M, D M \setminus \{x\}) \) to be the image of the
class \( \alpha_{\{-1\} \times x} \in H_n(D M, D M \setminus (\{-1\} \times x)) \), which we defined in (1), under the

\[\blacksquare\]

\(^{1247}\)Since \( f : U \to f(U) \) is a homeomorphism we have \( f(U \setminus \{x\}) = f(U) \setminus \{f(x)\} \). Furthermore it
follows from the fact that \( x \in U \setminus \partial U \) and Proposition\(^{44.2}\) that \( f(x) \notin \partial N \).
We leave it as a slightly annoying exercise to the indefatigable reader to show that \( \{ \alpha_x \}_{x \in D_M} \) does indeed define an orientation on \( D_M \). By construction of the orientation on \( D_M \) the inclusion \( M \to D_M \) is orientation-preserving. The uniqueness of the orientation on \( D_M \) is a consequence of Proposition 86.6(1) and of our hypothesis that \( M \) is connected. 

\[
H_n(D_M, D_M \setminus \{(−1, x)\}) \xleftarrow{\cong} H_n(D_M, D_M \setminus ([−1, 0] \times \{x\})) \xrightarrow{\cong} H_n(D_M, D_M \setminus \{(0, x)\}).
\]

These maps are isomorphisms by an excision argument together with Lemma 86.1.

Finally let \( M \) be an \( n \)-dimensional topological manifold equipped with an orientation \( \{ \mu_x \}_{x \in M \setminus \partial M} \). Now we will see that the given orientation induces an orientation on \( \partial M \).

**Proposition 86.19.** Let \( R \) be a commutative ring. Given any topological manifold \( M \) of dimension \( \geq 2 \) there exists a natural map

\[ \{ R\text{-orientations of } M \} \to \{ R\text{-orientations of } \partial M \}. \]

Here natural means that if \( f : M \to N \) is a homeomorphism, then the following diagram commutes:

\[
\begin{array}{ccc}
\{ R\text{-orientations of } M \} & \xrightarrow{f^*} & \{ R\text{-orientations of } \partial M \} \\
\downarrow{f^*} & & \downarrow{f^*} \\
\{ R\text{-orientations of } N \} & \xrightarrow{f^*} & \{ R\text{-orientations of } \partial N \}.
\end{array}
\]

**Convention.** If \( M \) is an \( R \)-oriented topological manifold of dimension \( \geq 2 \), then invariably we will equip \( \partial M \) with the \( R \)-orientation provided by the construction in the proof of Proposition 86.19.

**Proof (\(*\)).** To simplify the notation we will only deal with case \( R = \mathbb{Z} \), which is anyway the only case we care about. We suppose we are given an orientation \( \{ \mu_y \}_{y \in M \setminus \partial M} \) for \( M \). In the following we will define a natural orientation for \( \partial M \).

We set \( n := \dim(M) \) and we write \( A = [0, 1] \times [-1, 1]^n \), we write \( A_0 := \{0\} \times [-1, 1]^{n-1} \) and we write \( A' = (0, 1) \times (-1, 1)^{n-1} \). Now let \( x \in \partial M \). Since \( M \) is a topological manifold and since \( x \in \partial M \) we can pick a chart \( \Phi : U \to [0, 2) \times (-2, 2)^{n-1} \) with \( \Phi(x) = (0, 0) \). We write \( \Psi := \Phi^{-1} \). Furthermore we write \( V = \Psi(A) \), \( V_0 = \Psi(A_0) \) and we write \( V' = \Psi(A') \). Finally we pick a point \( y \in V' \). (We refer to Figure 1222 for an illustration.)
We consider the following sequence of maps

\[
\begin{align*}
H_n(M, M \setminus \{y\}) &\xrightarrow{(1)} H_n(M, M \setminus V') \\
&\xrightarrow{(2)} H_{n-1}(M \setminus V', (M \setminus V') \setminus \{x\}) \\
\downarrow & \\
H_{n-1}(V_0, V_0 \setminus \{x\}) &\xrightarrow{(3)} H_{n-1}(\partial M, \partial M \setminus \{x\}). \\
&\xrightarrow{(4)} H_{n-1}(\partial M, \partial M \setminus \{x\}). \\
\end{align*}
\]

Here all the maps are induced by the obvious inclusions of pairs of topological spaces, except for the second map which is the connecting homomorphism of the long exact sequence of the triple \((M, M \setminus V', (M \setminus V') \setminus \{x\})\) that is provided by Proposition 43.15.

**Claim.** All the maps in the above diagram are isomorphisms.

In the following we treat the four maps separately.

1. It is elementary to see that \(A \setminus \Psi^{-1}(y)\) is a deformation retract of \(\partial A\). It follows that \(M \setminus V'\) is a deformation retract of \(M \setminus \{y\}\). We obtain from Corollary 43.18 that (1) an isomorphism.

2. We consider the long exact sequence of the triple \((M, M \setminus V', (M \setminus V') \setminus \{x\})\) that is provided by Proposition 43.15:

\[
\begin{align*}
H_n(M, (M \setminus V') \setminus \{x\}) &\to H_n(M, M \setminus V') \\
&\xrightarrow{\partial} H_{n-1}(M \setminus V', M \setminus V) \\
&\to H_{n-1}(M, (M \setminus V') \setminus \{x\}). \\
\end{align*}
\]

Similarly to (1) one sees that \((M \setminus V') \setminus \{x\}\) is a deformation retract of \(M\). Therefore it follows from Corollary 43.18 that the groups at the two extremes are zero. In other words, the connecting homomorphism is an isomorphism.

3. It follows quite easily from the Excision Theorem 43.20 that (3) is an isomorphism.

4. Replace (3) by (4) in the previous sentence.

5. The triangle is given by inclusion induced maps, hence it commutes. It now follows from (3) and (4) that (5) is also an isomorphism.

Given \(x \in \partial M\) we now define \(\nu_x \in H_{n-1}(\partial M, \partial M \setminus \{x\})\) to be the image of the generator \(\mu_y \in H_n(M, M \setminus \{y\})\) under the above sequence of isomorphisms. We continue with our next claim.

**Claim.**

1. The definition of \(\nu_x\) is independent of the choice of \(y\).
2. The definition of \(\nu_x\) is independent of the choice of \(\Phi\).

Looking at Figure 1222 this statement sounds reasonable. But the statement nonetheless requires a proof. So let \(r\) be a deformation retraction from \(A \setminus \Psi^{-1}(y)\) to \(\partial A\). We consider the map

\[
s: (M \setminus \{y\}) \times [0,1] \to M \setminus \{y\} \\
(P,t) \mapsto \begin{cases} 
  P, & \text{if } P \notin V \setminus \{y\}, \\
  \Psi(r(\Psi^{-1}(P),t)), & \text{if } P \in V \setminus \{y\}.
\end{cases}
\]

Note that \(V \setminus \{y\}\) and \(M \setminus \Psi(A')\) are closed subsets of \(M \setminus \{y\}\). (Hmm, why is that?) It follows from Lemma 3.10 that the map \(s\) is continuous.
We turn to the proof of the two statements.

(1) We need to show that for any \( z \in \Psi(V') \) we have

\[
\text{preimage of } \mu_y \text{ under the map } H_n(M, M \setminus V') \xrightarrow{\cong} H_n(M, M \setminus \{y\}) = \text{preimage of } \mu_z \text{ under the map } H_n(M, M \setminus V') \xrightarrow{\cong} H_n(M, M \setminus \{z\}).
\]

But this statement can be shown in a similar fashion as Proposition 86.6 (1). We leave it to the reader to fill in the details.

(2) Suppose we are given a different chart than \( \Phi \). We define \( W, W_0, W' \) in the obvious way. By possibly taking a third chart whose image lies in the intersection of \( V \) and \( W \) we can assume, without loss of generality, that \( W \subset V \). (We refer to Figure 1223 for an illustration.) Furthermore by (1) we can work with a point \( y \in W \) for both charts. We consider the following diagram

\[
\begin{array}{c}
H_n(M, M \setminus \{y\}) \xrightarrow{(1)} H_n(M, M \setminus V') \\
\cong \downarrow \phi \downarrow \phi \downarrow \phi \downarrow \phi \\
H_n(M, M \setminus W') \xrightarrow{(2)} H_{n-1}(M \setminus V', (M \setminus V') \setminus \{x\}) \\
\cong \downarrow \phi \downarrow \phi \downarrow \phi \downarrow \phi \\
H_{n-1}(M \setminus W', (M \setminus W') \setminus \{x\}) \xrightarrow{(3)} H_{n-1}(V_0, V_0 \setminus \{x\}) \\
\cong \downarrow \phi \downarrow \phi \downarrow \phi \downarrow \phi \\
H_{n-1}(W_0, W_0 \setminus \{x\}) \xrightarrow{(4)} H_{n-1}(\partial M, \partial M \setminus \{x\}).
\end{array}
\]

Here the two “outer paths” from the top left to the lower right correspond to the two “competing” definitions of \( \nu_x \). The dashed arrows are given by inclusions. We make the following observations:

(a) The triangle on top commutes since all maps are induced by inclusions.

(b) The upper parallelogram commutes since the connecting homomorphism is natural, see Proposition 43.15 (3) for details.

(c) The lower parallelogram commutes since all the maps are induced by inclusions. (Note that the reversal of the direction of the arrow is not a typo.)

(d) The triangle on the bottom commutes since all maps are induced by inclusions. We saw above that all maps (1), (2), (3) and (4) are isomorphisms. By going from the top to the bottom we see that all the dashed arrows are isomorphisms.

Since all pieces of the diagram commute and since all maps are isomorphisms we see that the total diagram commutes. This shows that the two “competing” definitions of \( \nu_x \) agree.

Using the previous claim it is now straightforward to show that the \( \{\nu_x\}_{x \in \partial M} \) form an orientation for \( \partial M \) and that this orientation is natural.

\[\square\]

\textbf{Remark.} Let \( M \) be an \( n \)-dimensional smooth manifold that is equipped with an orientation in the sense of Section 6.11. On page 303 we had equipped the \( (n-1) \)-dimensional smooth manifold \( \partial M \) with an orientation in the sense of Section 6.11. If one takes the
strenuous journey through all conventions and definitions one sees that the boundary orientations from page 303 and the proof of Proposition 86.19 are compatible. More precisely, for any oriented $n$-dimensional $M$ we have the following commutative “diagram”

$$
\begin{array}{c}
\text{oriented smooth manifold } M \\
\downarrow \text{take boundary} \\
\text{Z-oriented smooth manifold } M \\
\end{array} 
\xrightarrow{\text{Proposition 86.11}}
\begin{array}{c}
\text{oriented smooth manifold } \partial M \\
\downarrow \text{take boundary} \\
\text{Z-oriented smooth manifold } \partial M.
\end{array}
$$

**Remark.** Given topological manifolds $M$ and $N$ we can form the product $M \times N$. If $M$ and $N$ are oriented, then one would expect that $M \times N$ comes with a natural orientation. This is indeed the case, but the definition of this natural orientation requires more tools than we have at the moment. Thus we postpone the definition of the product orientation to Section 80.5.

**Exercises for Chapter 86**

**Exercise 86.1.** We view $\mathbb{R}$ as a topological manifold and we equip it with the standard $\mathbb{Z}$-orientation that we had introduced on page 2106. Let $f: \mathbb{R} \to \mathbb{R}$ be a map that is a local homeomorphism and that is orientation-preserving. Show that $f$ is strictly monotonously increasing.

**Exercise 86.2.** Let $M$ be an $n$-dimensional topological manifold, let $R$ be a commutative ring and let $A \subset M \setminus \partial M$ be a subset.
(a) Show that for $R$-sections $\{\alpha_x\}_{x \in A}$ and $\{\beta_x\}_{x \in A}$ along $A$ the collection $\{\alpha_x + \beta_x\}_{x \in A}$ is also an $R$-section along $A$.

(b) Show that the set $\Gamma^A_R(M)$ admits a unique $R$-module structure such that for each $y \in A$ the map $\Gamma^A_R(M) \to H^n(M, M \setminus \{y\}; R)$ given by $\{\alpha_x\}_{x \in A} \mapsto \alpha_y$ is an $R$-module homomorphism.

Exercise 86.3. Let $M$ be an oriented $n$-dimensional topological manifold. Furthermore let $f, g: M \to M$ be two homeomorphisms. Show that if $f$ is orientation-preserving and if $g$ is homeotopic to $f$, then $g$ is also orientation-preserving.

Remark. In Lemma 8.6 we proved the analogue in the setting of smooth manifolds.

Exercise 86.4. Let $M$ be an oriented $n$-dimensional topological manifold, let $A$ and $B$ be disjoint unions of boundary components of $M$ and let $f: A \to B$ be a homeomorphism. We equip $A$ and $B$ with the boundary orientations, as defined in Proposition 86.19.

(a) If $f$ is orientation-reversing, then $M/a \sim f(a)$ admits an orientation such that the inclusion $M \setminus (A \cup B) \to M/a \sim f(a)$ is orientation-preserving.

(b) If $M$ is connected and if $f$ is not orientation-reversing, then $M/a \sim f(a)$ is non-orientable.

Remark. This is the long overdue proof of Proposition 44.8 (6).
87. The fundamental class of topological manifolds

In several previous chapters, e.g. in Chapter 64 and 66, we have assembled lots of information on homology groups of smooth manifolds. Let us recall some of the results. Thus let \( M \) be a connected \( n \)-dimensional smooth manifold.

(1) In Proposition 64.6 we saw, using Theorem 64.5, that \( H_i(M;\mathbb{Z}) = 0 \) for \( i > n \).

(2) Furthermore, in Theorem 66.6 and Theorem 66.8 we showed that
\[
H_n(M;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ closed and orientable,} \\ 0, & \text{otherwise.} \end{cases}
\]

and
\[
H_n(M,\partial M;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ compact and orientable,} \\ 0, & \text{otherwise.} \end{cases}
\]

Furthermore, if \( M \) is compact and orientable, then we used (2) to define the corresponding fundamental class \([M] \in H_n(M,\partial M;\mathbb{Z})\) which turned out to be very useful tool.

The key tool in proving the above statements was the fact, established in Theorem 64.2, that smooth manifolds admit simplicial structures. As we discussed in Section 85.6, in general topological manifolds do not admit simplicial structures, so if we want to replicate the above results for topological manifolds we will have to use a very different approach.

In this chapter we will indeed manage to reprove all of the above statements for topological manifolds. The advantage of the new approach is that it is more general, it covers topological manifolds, and that it does not require any extra topological input, i.e. it does not require the existence of a simplicial or cellular structure. The flip side of this chapter’s approach is that the proofs are arguably less intuitive.

87.1. The fundamental class of an oriented topological manifold. We recall the following notation that we introduced on page 2119.

**Notation.** Let \( M \) be a topological manifold, let \( R \) be a commutative ring and finally let \( x \in M \setminus \partial M \). Given any \( k \in \mathbb{N}_0 \) we denote by \( \rho_x \) the obvious map
\[
\rho_x : H_k(M,\partial M;R) \to H_k(M,M\setminus\{x\};R).
\]
Given \( \alpha \in H_k(M,\partial M;R) \) we often write \( \alpha_x := \rho_x(\alpha) \), i.e. the above map is also written as \( \alpha \mapsto \alpha_x \).

The following three theorems contain most of the main results of this chapter.

**Theorem 87.1.** Let \( M \) be a compact connected non-empty \( n \)-dimensional topological manifold. Then the following statements are equivalent:

1. the topological manifold \( M \) is orientable,
2. \( H_n(M,\partial M;\mathbb{Z}) \neq 0 \),
3. \( H_n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z} \),
4. for every \( x \in M \setminus \partial M \) the map
\[
\rho_x : H_n(M,\partial M;\mathbb{Z}) \to H_n(M,M\setminus\{x\};\mathbb{Z})
\]
\[
\alpha \mapsto \alpha_x
\]
is an isomorphism.
Theorem 87.2. Let $M$ be a compact connected non-empty $n$-dimensional topological manifold $M$. Then the following two statements hold:

1. $H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$, and
2. for every $x \in M \setminus \partial M$ the map

$$\rho_x : H_n(M, \partial M; \mathbb{F}_2) \to H_n(M, M \setminus \{x\}; \mathbb{F}_2)$$

$$\alpha \mapsto \alpha_x$$

is an isomorphism.

Theorem 87.3. Let $M$ be a connected $n$-dimensional topological manifold and let $R$ be a commutative ring. Then the following two statements hold:

1. If $M$ is not closed, then $H_i(M; R) = 0$ for $i \geq n$.
2. If $M$ is closed, then we have $H_i(M; R) = 0$ for $i > n$.

Remark.

1. As mentioned before, the above theorems generalize most of the results of Proposition 64.6 (2), Theorem 66.6 and Theorem 66.8 from smooth manifolds to topological manifolds.
2. One might be tempted to consider Theorem 87.3 (2) as intuitively clear. After all, how could an $n$-dimensional object possibly have homology groups in higher dimensions? To shatter this belief, fix some $n \geq 2$. We consider the following subset of $\mathbb{R}^n$:

$$X := \bigcup_{n \in \mathbb{N}} \text{n-dimensional sphere of radius } \frac{1}{n} \text{ around } \left(\frac{1}{n}, 0, \ldots, 0\right)$$

$$= \bigcup_{n \in \mathbb{N}} \{x \in \mathbb{R}^n \mid \|x - \left(\frac{1}{n}, 0, \ldots, 0\right)\| = \frac{1}{n^2}\}.$$  

In [BaM62] it is shown, rather shockingly, that for every $q$ with $q \equiv 1 \mod (r - 1)$ the group $H_q(X; \mathbb{Q})$ is not only non-zero, it is even uncountable.

We will not immediately prove these three theorems, but we will first draw many conclusions, before we head towards the somewhat intricate proofs of the above three theorems.

Definition. Let $M$ be a compact $n$-dimensional topological manifold and let $R$ be a commutative ring. An $R$-fundamental class of $M$ is an element $\beta \in H_n(M, \partial M; R)$ with the property that for any $x \in M \setminus \partial M$ the element $\beta_x \in H_n(M, M \setminus \{x\}; R)$ is a generator. For $R = \mathbb{Z}$ we just say fundamental class.

Remark. Let $M$ be a compact $n$-dimensional topological manifold and let $R$ be a commutative ring.

1. Let $[M]$ be a $\mathbb{Z}$-fundamental class for $M$. The image of $[M] \otimes 1$ under the natural map

$$\mu : H_n(M; \mathbb{Z}) \otimes R \to H_n(M; R)$$

is an $R$-fundamental class. Indeed, let $x \in M \setminus \partial M$.

\[\text{As the reader will surely have noticed, this example can be viewed as a high-dimensional analogue of the Hawaiian Earings that we introduced in Exercise 25.1.}\]
From Lemma 87.7 (4) we obtain a commutative diagram

\[
\begin{array}{ccc}
H_n(M; \mathbb{Z}) \otimes R & \xrightarrow{\mu} & H_n(M; R) \\
\downarrow & & \downarrow \\
H_n(M, M \setminus \{x\}; \mathbb{Z}) \otimes R & \xrightarrow{\mu} & H_n(M, M \setminus \{x\}; R)
\end{array}
\]

By Lemma 86.4 and the Universal Coefficient Theorem 87.19 the bottom horizontal map is an isomorphism. Since the image of the \(\mathbb{Z}\)-fundamental class \([M]\) under the obvious map \(H_n(M; \mathbb{Z}) \to H_n(M, M \setminus \{x\}; \mathbb{Z})\) is a generator it follows from the commutative diagram that the image of \(\mu([M] \otimes 1)\) under the obvious map \(H_n(M; R) \to H_n(M, M \setminus \{x\}; R)\) is indeed a generator.

(2) If \(M\) has connected components \(M_1, \ldots, M_k\) and if for \(i = 1, \ldots, k\) we are given \(R\)-fundamental classes \([M_i]_R \in H_n(M_i, \partial M_i; R)\), then

\[
\sum_{i=1}^k [M_i]_R \in H_n(M, \partial M; R) = \bigoplus_{i=1}^k H_n(M_i, \partial M_i; R)
\]

is easily seen to be a \(R\)-fundamental class of \(M\). The fundamental classes for the \(M_i\) are unique if and only if the fundamental class for \(M\) is unique.

**Example.** Let \(M\) be the empty topological space. As we mentioned on page 264, basically by definition the empty set is a topological manifold of any dimension. Note that for the empty manifold \(\varnothing\) we have the equality \(H_0(\varnothing) = H_1(\varnothing) = H_2(\varnothing) = \cdots = \{0\}\). By definition this element 0 is a fundamental class of the empty manifold and it is evidently unique. We write \([\varnothing] := 0\). This is consistent with the discussion on page 1719.

The following corollary to Theorem 87.1 says in particular that an orientation determines and is in turn uniquely determined by a fundamental class.

**Corollary 87.4.** Let \(M\) be a compact \(n\)-dimensional topological manifold.

1. If \([M]\) is a fundamental class, then \(\{[M]_x\}_{x \in M \setminus \partial M}\) defines an orientation for \(M\).
2. If \(\{\alpha_x\}_{x \in M \setminus \partial M}\) is an orientation for \(M\), then there exists a unique fundamental class \([M] \in H_n(M, \partial M; \mathbb{Z})\) with \([M]_x = \alpha_x\) for all \(x \in M \setminus \partial M\).

Furthermore, if \(M\) is connected, non-empty and orientable, then the following two statements hold:

3. Every fundamental class \([M] \in H_n(M, \partial M; \mathbb{Z})\) is a generator of \(H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}\).
4. Every generator of \(H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}\) is a fundamental class.

**Proof.** Let \(M\) be a compact non-empty \(n\)-dimensional topological manifold. By considering the components of \(M\) separately we see that without loss of generality we can assume that \(M\) is connected. It is also clear that we only have to study the case that \(M\) is non-empty.

(1) Let \([M]\) be a fundamental class for the topological manifold \(M\). It follows from Lemma 86.5 (2) that the homology classes \(\{\rho_x([M])\}_{x \in M \setminus \partial M}\) form a section on \(M\).

1250 Here we use that in Theorem 87.1 we saw that for a compact orientable, non-empty \(n\)-dimensional topological manifold we have \(H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}\).
By definition of a fundamental class each \( \rho_x([M]) \) is a generator. Therefore the section \( \{\rho_x([M])\}_{x \in M \setminus \partial M} \) is indeed an orientation.

(2) Suppose we are given an orientation \( \{\alpha_x\}_{x \in M \setminus \partial M} \) for \( M \). By Theorem 87.1 (1) \( \Rightarrow \) (4) we know that for every \( x \in M \setminus \partial M \) the map

\[
\rho_x: H_n(M, \partial M; \mathbb{Z}) \to H_n(M, \partial M \setminus \{x\}; \mathbb{Z})
\]

is an isomorphism. Now pick a \( y \in M \). We write \( [M] := \rho_y^{-1}(\alpha_y) \). Since \( \rho_y \) is an isomorphism the class \( [M] \) is uniquely determined. So it remains to show that \( [M]_x = \alpha_x \) for all \( x \in M \setminus \partial M \). By Lemma 86.5 (2) the classes \( \{[M]_x\}_{x \in M \setminus \partial M} \) form a \( \mathbb{Z} \)-section. It follows from Proposition 86.6 that \( [M]_x = \alpha_x \) for all \( x \in M \setminus \partial M \).

(3) This statement follows immediately from the definition of a fundamental class and Theorem 87.1 (1) \( \Rightarrow \) (4).

(4) The last statement is an immediate consequence of Lemma 86.5 (2) and Theorem 87.1 (1) \( \Rightarrow \) (4).

We also have the following corollary to Theorem 87.2 which deals with \( \mathbb{F}_2 \)-coefficients.

Corollary 87.5. Let \( M \) be a compact, non-empty \( n \)-dimensional topological manifold.

(1) If \( M \) is connected, then\footnote{Here in the formulation we already use Theorem 87.2 (1) to guarantee that \( H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2 \).}

\[
[M]_{\mathbb{F}_2} := \text{the unique non-zero element of } H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2
\]

is the unique \( \mathbb{F}_2 \)-fundamental class of \( M \).

(2) If \( M \) has connected components \( M_1, \ldots, M_k \), then

\[
[M]_{\mathbb{F}_2} := \sum_{i=1}^k [M_i]_{\mathbb{F}_2} \in H_n(M, \partial M; \mathbb{F}_2) = \bigoplus_{i=1}^k H_n(M_i, \partial M_i; \mathbb{F}_2)
\]

is the unique \( \mathbb{F}_2 \)-fundamental class of \( M \).

Proof. It follows immediately from Theorem 87.2 (2) that the class \( [M]_{\mathbb{F}_2} \) that we had just defined in (1) is indeed an \( \mathbb{F}_2 \)-fundamental class for \( M \) and that it is unique. As we pointed out on page 2121 the second statement is an immediate consequence of the first statement.

Remark. Let \( R \) be a commutative ring. We consider the empty topological manifold \( \emptyset \). Note that we have the equality of sets \( H_0(\emptyset; R) = H_1(\emptyset; R) = H_2(\emptyset; R) = \cdots = \{0\} \). As on page 1719 we now define the fundamental class \( [\emptyset] \) of the empty topological manifold \( \emptyset \) to be the unique element in the group \( H_0(\emptyset; R) = H_1(\emptyset; R) = H_2(\emptyset; R) = \cdots = \{0\} \).

Let \( M \) be a compact non-empty \( n \)-dimensional smooth manifold. On page 1730 we introduced the corresponding \( \mathbb{F}_2 \)-fundamental class \( [M]_{\mathbb{F}_2} \in H_n(M, \partial M; \mathbb{F}_2) \). Furthermore, if \( M \) is in fact oriented, then on page 1712 we introduced the corresponding fundamental class \( [M] \in H_n(M, \partial M; \mathbb{Z}) \). We will now see that the previous definitions are consistent with the definitions from this chapter.

First let us consider the case of \( \mathbb{F}_2 \)-fundamental classes. This case is easy: it follows basically immediately from Corollary 87.5 (1) that the two definitions actually agree.
Now let us assume that the smooth manifold $M$ is oriented in the sense of Section 6.11. In Theorem \[68.1\] we defined the fundamental class $[M]$ in $H_n(M, \partial M; \mathbb{Z})$. On the other hand, in Proposition \[86.11\] we saw that the orientation of $M$ also determines a $\mathbb{Z}$-orientation and thus we obtain a fundamental class $[M] \in H_n(M, \partial M; \mathbb{Z})$ by Corollary \[87.4\]. Not surprisingly we will now see that these two definitions agree.

**Lemma 87.6.** The two definitions of the fundamental class of a compact oriented nonempty smooth manifold agree.

**Remark.** Let $M$ be a compact oriented non-empty smooth manifold. In Algorithm \[68.2\] and Proposition \[68.4\] we developed some techniques for finding explicit cycles representing the fundamental class of the oriented smooth manifold $M$. By Lemma \[87.6\] these approaches also work for finding explicit cycles representing the fundamental class of a smooth manifold that is equipped with a $\mathbb{Z}$-orientation.

**Proof (\#).** Let $M$ be a compact $n$-dimensional smooth manifold that is oriented in the sense of Section 6.11. The case $n = 0$ is basically trivial. Hence we now only consider the case $n \geq 1$. As we will see, the lemma follows almost immediately from the definitions.

Now let us first recall the construction, in the proof of Proposition \[86.11\] of the corresponding $\mathbb{Z}$-orientation of $M$. Let $x \in M \setminus \partial M$. We pick a chart $\Phi: U \to V$ around $x$ that is orientation-preserving in the sense of Section \[6.11\]. We define

$$
\mu_x := \Phi_*^{-1}(\text{standard generator of } H_n(V, V \setminus \{\Phi(x)\}; \mathbb{Z}), \text{as defined on page 2097}.
$$

In the proof of Proposition \[86.11\] we saw this definition of $\mu_x$ does not depend on the choice of the orientation-preserving chart. Furthermore we saw these classes $\{\mu_x\}_{x \in M \setminus \partial M}$ define a $\mathbb{Z}$-orientation for $M$.

We denote by $\alpha \in H_n(M; \mathbb{Z})$ the fundamental class of Theorem \[68.1\]. By definition of the fundamental class from Corollary \[87.4\] it now remains to prove the following claim.

**Claim.** Given any $x \in M \setminus \partial M$ we have $\alpha_x = \mu_x \in H_n(M, M \setminus \{x\})$.

Let $x \in M \setminus \partial M$. We pick a chart $\Phi: U \to V$ around $x$ with $\Phi(x) = 0$ that is orientation-preserving. Furthermore let $\Theta: \Delta^n \to V$ be an affine linear map such that $0$ lies in the image of $\Theta(\tilde{\Delta}^n)$ and which has the property that $\Theta: \tilde{\Delta}^n \to V$ is orientation-preserving. We see that

$$
[\Theta: \Delta^n \to V] \text{ is by definition a standard generator of } H_n(V, V \setminus \{0\}; \mathbb{Z})
$$

$$
\alpha_x = [\Phi^{-1} \circ \Theta: \Delta^n \to M] = \Phi_*^{-1}(\text{standard generator of } H_n(V, V \setminus \{0\}; \mathbb{Z})) = \mu_x.
$$

follows from Theorem \[68.1\] and the fact that $\Phi^{-1} \circ \Theta$ is orientation-preserving.

\[\square\]

**Figure 1224.** Illustration for the proof of Lemma \[87.6\].
We continue with the following two propositions which can be viewed as a generalizations of Propositions 68.4 and 68.18.

**Proposition 87.7.** Let \( M \) be a compact oriented connected \( n \)-dimensional topological manifold. Let \( r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \in C_n(M, \partial M) \) be a cycle. Suppose there exists a \( j \in \{1, \ldots, m\} \) such that the following three conditions are satisfied:

1. The map \( \sigma_j : \Delta^n \to M \) is an orientation-preserving embedding. \(^{1252}\)
2. There exists an \( x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n) \) which is not contained in the image of any other \( \sigma_i : \Delta^n \to M \).
3. \( r_j = 1 \).

Then the cycle \( r_1 \cdot \sigma_1 + \cdots + r_m \cdot \sigma_m \) represents the fundamental class of the oriented topological manifold.

**Proposition 87.8.** Let \( M \) be a compact connected \( n \)-dimensional topological manifold. Let \( (\sigma_1 + \cdots + \sigma_m) \otimes 1 \in C_n(M, \partial M; \mathbb{F}_2) = C_n(M, \partial M) \otimes \mathbb{F}_2 \) be a cycle. Suppose there exists a \( j \in \{1, \ldots, m\} \) such that the following two conditions are satisfied:

1. The map \( \sigma_j : \Delta^n \to M \) is an embedding.
2. There exists an \( x \in \sigma_j(\Delta^n) \setminus \sigma_j(\partial \Delta^n) \) which is not contained in the image of any other \( \sigma_i : \Delta^n \to M \).

Then the cycle \( (\sigma_1 + \cdots + \sigma_m) \otimes 1 \) represents the \( \mathbb{F}_2 \)-fundamental class of \( M \).

**Proof.** We leave it to the reader to modify the proofs of Propositions 68.4 and 68.18 to obtain the above result. \( \blacksquare \)

For the readers convenience we recall the discussion of cycles representing fundamental classes of the torus and the surface of genus 2 which we already gave in Figures 1054 and 1055. There is always the outside chance that a reader decided to give Chapter 68 a pass.

**Example.** We will give some examples of fundamental classes of \( 2 \)-dimensional topological manifolds. We use the notation from Figure 1225 to indicate a singular simplex. In Figure 1226 we now show cycles representing the fundamental classes of the torus stands for

\[ v_2 \]

\[ \text{affine linear} \]

\[ v_1 \]

\[ v_0 = (1, 0, 0) \]

**Figure 1225**

and the surface of genus 2 and we show a cycle representing the \( \mathbb{F}_2 \)-fundamental class of \( \mathbb{R}P^2 = \overline{B^2}/\mathbb{Z} \sim -z \).

\(^{1252}\) We equip \( \Delta^n \), and thus also its submanifold \( \overset{\circ}{\Delta^n} \), with the \( \mathbb{Z} \)-orientation which is given by considering the orientation given by \([\text{id}_{\Delta^n}] \in H_n(\Delta^n, \Delta^n \setminus \{x\})\) for each \( x \in \overset{\circ}{\Delta^n} \).
87.2. Lifts of sections on topological manifolds. In this section we will prove the fundamental theorem of topological manifolds which lies at the heart of the proofs of Theorems 87.1, 87.2 and 87.3. Before we can state the lemma we introduce the following helpful notation.

Notation. Let $M$ be a topological manifold without boundary, let $R$ be a commutative ring and let $A \subset M$ be a subset.

1. We write $H_n(M; A; R) := H_n(M, M \setminus A; R)$. Given a point $x \in M$ we use the obvious abbreviation $H_n(M; \{x\}; R) := H_n(M; \{x\}; R)$.

2. Given a homology class $\alpha \in H_n(M; A; R)$ and a point $x \in A$ we denote by $\alpha_x$ the image of $\alpha$ under the obvious map $H_n(M; A; R) \to H_n(M; \{x\}; R)$.

3. Let $\{\alpha_x\}_{x \in M}$ be an $R$-section on $M$ and let $A \subset M$ be a subset. We call a class $\beta \in H_n(M; A; R)$ a lift to $A$ if for all $x \in A$ we have $\beta_x = \alpha_x$.

4. As on page 2101 we denote by $\Gamma^R_A(M)$ the set of all $R$-sections of $M$ along $A$.

The following lemma follows immediately from the definitions. But since we will refer to it on several occasions it is good to write it down.

Lemma 87.9. Let $M$ be a topological manifold without boundary, let $R$ be a commutative ring and let $A \subset B \subset M$ be subsets:

1. Since $M \setminus B \subset M \setminus A$ we have an inclusion induced map $H_n(M; B; R) \to H_n(M; A; R)$.

2. Let $\{\alpha_x\}_{x \in M}$ be an $R$-section on $M$. If $\mu_B \in H_n(M; B; R)$ is a lift to $B$, then the image of $\mu_B$ under the above map $H_n(M; B; R) \to H_n(M; A; R)$ is a lift of the $R$-section to the subset $A$.

The following theorem is the main technical result of this chapter.
Theorem 87.10. Let $M$ be an $n$-dimensional topological manifold with empty boundary and let $A \subset M$ be a compact subset. Let $R$ be a commutative ring. Then the following hold:

(i) The map

$$H_n(M\mid A; R) \to \Gamma^A_M(R)$$

$$\varphi \mapsto \{\varphi_x\}_{x \in A}$$

is an isomorphism. In other words, if $\{\alpha_x\}_{x \in A}$ is an $R$-section for $M$ along $A$, then there exists a unique lift $\alpha^M_A = \alpha_A$ to $A$, i.e. there exists a unique homology class $\alpha^M_A = \alpha_A \in H_n(M\mid A; R)$ such that for each $x \in A$ we have $\alpha_{A,x} = \alpha_x$.

(ii) For $i > n$ we have $H_i(M\mid A; R) = 0$.

Remark. To avoid any nervousness later on we remark that the statements (i) and (ii) hold trivially for $A = \emptyset$ since $H_n(M\mid \emptyset; R) = H_n(M, M; R) = 0$.

Corollary 87.11. Let $M$ be an $n$-dimensional topological manifold with empty boundary, let $R$ be a commutative ring and let $A \subset M$ be a compact connected subset. If $M$ is $R$-orientable, then for every $x \in A$ the map

$$H_n(M, M \setminus A; R) \to H_n(M, M \setminus \{x\}; R) \cong R$$

isomorphic by Lemma 86.4

Proof. We consider the following diagram:

The diagram commutes by definition. Since $A$ is compact we know by Theorem 87.10 (i) that the left diagonal map is an isomorphism. Furthermore, since $A$ is connected we obtain from Lemma 86.9 that the right diagonal map is an isomorphism. Thus we see that the horizontal map is an isomorphism, as promised.

For later on we also record the following corollary to Theorem 87.10.

Corollary 87.12. Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary and let $R$ be a commutative ring. We suppose that $M$ is equipped with an $R$-orientation. We use the notation from Theorem 87.10.

(1) Let $K \subset L \subset M$ be compact subsets. We denote by $f_{KL} : (M, M \setminus L) \to (M, M \setminus K)$ the inclusion map of pairs. The map $f_{KL*} : H_n(M, M \setminus L) \to H_n(M, M \setminus K)$ sends $\alpha^L_A$ to $\alpha^M_A$.

(2) Let $U$ be an open subset of $M$ and let $A \subset U$ be a compact subset. We use Lemma 86.17 to view $U$ as an oriented topological manifold. If $i : U \to M$ denotes the inclusion map, then $i_*(\alpha^U_A) = \alpha^M_A$. 
Proof. The lemma follows easily from the functoriality of homology groups and the uniqueness statement of Theorem 87.10. ■

Now we turn to the proof of Theorem 87.10. The very rough idea behind the proof of the fundamental theorem of topological manifolds can be summarized as follows:

1. Using Mayer–Vietoris sequences we want to show that if the compact subsets \( A, B \) and \( A \cap B \) have the desired properties, then so does \( A \cup B \).
2. Using charts we want to reduce the proof of the theorem to the case that \( M = \mathbb{R}^n \).
3. Finally for \( M = \mathbb{R}^n \) we want to reduce the proof of the theorem to compact convex subsets \( A \) of \( \mathbb{R}^n \).

The following lemmas give us the tools to put this idea into practice.

**Lemma 87.13.** Let \( M \) be an \( n \)-dimensional topological manifold, let \( R \) be a commutative ring and let \( A \) and \( B \) be two compact subsets of \( M \). If the statements (i) and (ii) from Theorem 87.10 hold for \( A, B \) and \( A \cap B \), then they also hold for \( A \cup B \).

Proof. Let \( M \) be an \( n \)-dimensional topological manifold, let \( R \) be a commutative ring and let \( A \) and \( B \) be two compact subsets of \( M \) such that \( A, B \) and \( A \cap B \) satisfy statements (i) and (ii). To simplify the notation we drop \( R \) from the notation. We consider the inverted Mayer–Vietoris Sequence from Theorem 86.7

\[
\cdots \rightarrow H_{n+1}(M|A \cap B) \rightarrow H_n(M|A \cup B) \xrightarrow{\Phi} H_n(M|A) \oplus H_n(M|B) \xrightarrow{\Psi} H_n(M|A \cap B) \rightarrow \cdots
\]

\( \alpha \mapsto (\alpha, -\alpha) \)

\( (\alpha, \beta) \mapsto \alpha + \beta \)

Now we can prove that \( A \cup B \) also satisfies statements (i) and (ii).

(i) Now suppose we are given a section \( \{\alpha_x\}_{x \in M} \). We denote by \( \alpha_A, \alpha_B \) and \( \alpha_{A \cap B} \) the unique lifts to \( A, B \) and \( A \cap B \), between groups that are zero, thus we see that \( H_i(M|A \cup B) = 0 \) for \( i > n \).

(ii) For \( i > n \) the group \( H_i(M|A \cup B) \) is stuck, by our hypothesis on \( A, B \) and \( A \cap B \), as groups that are zero. Thus we see that \( H_i(M|A \cup B) = 0 \) for \( i > n \).

We see that the image of \( \alpha_{A \cup B} \) in \( H_n(M|x) \) is the image of \( \alpha_A \) in \( H_n(M|x) \), hence it equals \( \alpha_x \). The same argument applies to the case that \( x \in B \).

It remains to prove the uniqueness of the lift \( \alpha_{A \cup B} \). If \( \beta \in H_n(M|A \cup B) \) is another lift, then it follows immediately from Lemma 87.9 and the uniqueness of \( \alpha_A \) and \( \alpha_B \) that \( \Phi(\beta) = (\alpha_A, -\alpha_B) \). By the exactness of the sequence we see that we already have the equality \( \alpha_{A \cup B} = \beta \) in \( H_n(M|A \cup B) \). ■
Later on we will need the following variation on Lemma 87.13.

**Lemma 87.14.** Let $M$ be an $n$-dimensional topological manifold, let $R$ be a commutative ring. Let $\mathcal{A}$ be a family of compact subsets of $M$ with the following two properties:

1. Statements (i) and (ii) from Theorem 87.10 hold for each $A \in \mathcal{A}$.
2. The family $\mathcal{A}$ is closed under intersections, i.e. whenever $A, B \in \mathcal{A}$, then $A \cap B \in \mathcal{A}$.

Then the statements hold for all finite unions of elements in $\mathcal{A}$.

**Proof.** Given $k \in \mathbb{N}$ we write

$$U_k := \{\text{all subsets of } M \text{ that are the union of at most } k \text{ subsets in } \mathcal{A}\}.$$  

We claim that for every $k \in \mathbb{N}$ statements (i) and (ii) hold for all elements in $U_k$. We prove this claim by induction on $k$.

1. If $k = 1$, then the claim holds by hypothesis (1).
2. Suppose that the claim holds for some $k$. Let $A_1, \ldots, A_k, A_{k+1} \in \mathcal{A}$. We write $B = A_2 \cup \cdots \cup A_{k+1}$. Note that

$$A_1 \cap B = A_1 \cap (A_2 \cup \cdots \cup A_{k+1}) = \bigcup_{i=2}^{k+1} (A_1 \cap A_i) \in U_k.$$  

Thus by induction hypothesis we see that the statements hold for $A_1, B$ and also for $A_1 \cap B$. So the statements also hold for $A_1 \cup B = A_1 \cup \cdots \cup A_{k+1}$ by Lemma 87.13. ■

Our next goal is to prove Theorem 87.10 for $M = \mathbb{R}^n$. We will proceed in several steps.

**Lemma 87.15.** Let $R$ be a commutative ring and let $\{\mu_x\}_{x \in \mathbb{R}^n}$ be an $R$-section on $\mathbb{R}^n$, let $A \subset \mathbb{R}^n$ be a convex bounded subset and let $\beta \in H_n(\mathbb{R}^n|A; R)$. If $\mu_y = \beta_y$ for some $y \in A$, then $\mu_x = \beta_x$ for all $x \in A$, i.e. $\beta$ is a lift to $A$.

**Proof.** The proof is very similar to the proof of Proposition 86.6. The following are the two key observations:

1. A convex set is path-connected and thus connected,
2. Since $A$ is convex, for any $x \in A$ and any $\epsilon > 0$ the intersection $A \cap B_\epsilon(x)$ is the intersection of two convex bounded sets, hence convex and bounded.

In the proof of Proposition 86.6 we now need to replace Lemma 86.7 by Lemma 86.1.

We leave it to the reader to modify the proof of Proposition 86.6 to obtain a proof of Lemma 87.15. ■

**Lemma 87.16.** Statements (i) and (ii) from Theorem 87.10 hold for $M = \mathbb{R}^n$, any commutative ring $R$ and any convex compact subset $A$ of $\mathbb{R}^n$.

**Proof.** Let $A$ be a convex compact subset of $\mathbb{R}^n$ and let $R$ be a commutative ring. As pointed out above, if $A = \emptyset$, then there is nothing to prove. Thus we can assume that $A \neq \emptyset$. 

Now we can prove that $A$ satisfies the statements (i) and (ii).

(i) Let $\{\alpha_x\}_{x \in \mathbb{R}^n}$ be a section for $\mathbb{R}^n$. Since $A \neq \emptyset$ we can pick a $y \in A$. We denote by $\alpha_A \in H_n(\mathbb{R}^n|A)$ the preimage of $\alpha_y$ under the isomorphism

$$H_n(\mathbb{R}^n|A; R) \rightarrow H_n(\mathbb{R}^n|\{y\}; R)$$

given by Lemma 86.1. It follows from Lemma 87.15 that $\alpha_{A,x} = \alpha_x$ for all $x \in A$, i.e. we have shown that $\alpha_A$ is a lift to $A$. The uniqueness of the lift $\alpha_A$ follows again from the above isomorphism.

(ii) It follows Lemma 86.1 and 44.1 that $H_i(\mathbb{R}^n|A; R) = H_i(\mathbb{R}^n|\{y\}; R) = 0$ for every $i > n$. ■

**Lemma 87.17.** Every subset of $\mathbb{R}^n$ that is the union of finitely many convex compact sets satisfies the statements (i) and (ii) from Theorem 87.10.

**Proof.** We consider

$$A := \{\text{all convex compact subsets of } \mathbb{R}^n\}.$$ 

This family of subsets of $\mathbb{R}^n$ is closed under intersections. By Lemma 87.16 the two statements hold for each $A \in A$. The lemma is now an immediate consequence of Lemma 87.14. ■

The following lemma is arguably the hardest step towards proving the fundamental theorem of topological manifolds.

**Lemma 87.18.** Statements (i) and (ii) from Theorem 87.10 hold for $M = \mathbb{R}^n$, any commutative ring $R$ and any compact subset $A$ of $\mathbb{R}^n$.

**Proof.** To simplify the notation we again drop the $R$ from the notation. Let $\{\alpha_x\}_{x \in \mathbb{R}^n}$ be a section for $\mathbb{R}^n$ and let $A \subseteq \mathbb{R}^n$ be an arbitrary compact set.

We first prove statement (i). We pick a closed ball $B$ that contains $A$. We denote by $\alpha_B \in H_n(\mathbb{R}^n|B)$ the lift constructed in Lemma 87.16. By Lemma 87.9 the image $\alpha_A$ of the class $\alpha_B$ under the map $H_n(\mathbb{R}^n|B) \rightarrow H_n(\mathbb{R}^n|A)$ is a lift to $A$. To complete the proof of statement (i) we still need to prove the uniqueness of $\alpha_A$.

This uniqueness statement is equivalent to showing that if $\beta \in H_n(\mathbb{R}^n|A)$ is a class such that $\beta_x = 0$ for all $x \in A$, then $\beta$ is already zero. So let $\beta \in H_n(\mathbb{R}^n|A)$. We pick a singular $n$-chain $z \in C_n(\mathbb{R}^n)$ that represents $\beta$. We denote by $C \subseteq \mathbb{R}^n \setminus A$ the union of the images of the singular simplices appearing in $\partial z \in C_{n-1}(\mathbb{R}^n \setminus A)$. Note that $C$ is the union of finitely many compact sets, hence $C$ itself is compact.

**Claim.** There exist finitely many closed balls $B_1, \ldots, B_m$ with the following three properties:

1. each $B_i$ is contained in $\mathbb{R}^n \setminus C$,
2. each $B_i$ contains a point $x_i \in A$,
3. we have $A \subseteq B_1 \cup \cdots \cup B_m$.

Here we use one of the most convenient properties of convex sets: the intersection of two convex sets is again convex.
Since $C$ is compact and since $A \cap C = \emptyset$ we can find for each $x \in A$ an $r_x > 0$ with $B_{2r_x}(x) \subset \mathbb{R}^n \setminus C$. Since $A$ is compact there exist finitely many points $x_1, \ldots, x_m$ in $A$ such that $A$ is contained in $B_{r_{x_1}}(x_1) \cup \cdots \cup B_{r_{x_m}}(x_m)$. It is now clear that $B_i := B_{r_{x_i}}(x_i)$, $i = 1, \ldots, m$ have the desired property. We refer to Figure 1227 for an illustration. \[ \square \]

We write $K := B_1 \cup \cdots \cup B_m$. By (1) the singular $n$-chain $z \in C_n(\mathbb{R}^n)$ also represents an element $\gamma \in H_n(\mathbb{R}^n|K)$. Note that for each $x \in A$ we have a commutative diagram

$$
\begin{array}{ccc}
H_n(\mathbb{R}^n|K) & \xrightarrow{\gamma=\partial z=} & H_n(\mathbb{R}^n|A) \\
\gamma \rightarrow \gamma_x & & \beta \rightarrow \beta_x \\
\end{array}
$$

It follows in particular from the commutative diagram that it suffices to show that we have $\gamma = 0 \in H_n(\mathbb{R}^n|K)$. We do so as follows:

1. By our hypothesis on $\beta$ and by the above commutative diagram we know that for each $i \in \{1, \ldots, m\}$ we have $\gamma_{x_i} = \beta_{x_i} = 0$.
2. Let $i \in \{1, \ldots, m\}$. Since $\gamma_{x_i} = 0$ and since $B_i$ is convex and bounded it follows from Lemma 87.15 (applied to the zero section and to the image of $\gamma \in H_n(\mathbb{R}^n|B_i)$) that $\gamma_x = 0$ for all $x \in B_i$.
3. By (2) we know that $\gamma_x = 0$ for all $x \in K = B_1 \cup \cdots \cup B_m$.
4. But now it follows from Lemma 87.17 that $\gamma = 0$.

This concludes the proof of statement (i).

---

**Figure 1227.** Illustration for the proof of Theorem 87.10.

Finally we need to show statement (ii) for $A$, i.e., we need to show that $H_i(\mathbb{R}^n|A) = 0$ for $i > n$. So let $\beta \in H_i(\mathbb{R}^n|A)$. As above we pick a singular $n$-chain $z \in C_n(\mathbb{R}^n)$ that represents $\beta$. We define $C$, $K$ and $\gamma$ as above. By Lemma 87.17 we have $\gamma = 0 \in H_i(\mathbb{R}^n|K)$. But as before this implies that also $\beta = 0 \in H_i(\mathbb{R}^n|A)$. \[ \square \]

**Lemma 87.19.** Let $M$ be an $n$-dimensional topological manifold with empty boundary and let $A \subset M$ be a compact subset. If there exists a chart $\Phi: U \to \mathbb{R}^n$ such that $A$ is contained in $U$, then statements (i) and (ii) hold for $A$. 

---

\[ \begin{array}{c}
A \\
\text{cycle } z
\end{array} \]
Proof. The lemma is a fairly straightforward consequence of Lemma 87.18 and the fact that we have isomorphisms
\[ H_n(M, M \setminus A; R) \xrightarrow{(\text{Excision Theorem 43.20})} H_n(U, U \setminus A; R) \xrightarrow{\Phi} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \Phi(A); R) \]

We leave it to the reader to fill in the details. ■

Now we can finally complete the proof of Theorem 87.10.

Proof of Theorem 87.10. Let \( M \) be an \( n \)-dimensional topological manifold with empty boundary. We consider \( \mathcal{A} := \) all compact subsets \( A \) of \( M \) for which there exists a chart \( \Phi: U \to \mathbb{R}^n \) with \( A \subset U \).

By Lemma 87.19 statements (i) and (ii) hold for all subsets in \( \mathcal{A} \). It is clear that \( \mathcal{A} \) is closed under intersections. Thus it follows from Lemma 87.14 that the statements (i) and (ii) hold for all finite unions of sets in \( \mathcal{A} \). Therefore it suffices to prove the following claim.

Claim. Every compact subset \( A \) of \( M \) is the union of finitely many sets in \( \mathcal{A} \).

Let \( A \) be a compact subset of \( M \). It is clear that given any point \( x \in A \) there exists a chart \( \Phi_x: U_x \to V_x \) around \( x \) such that the image is some open ball in \( \mathbb{R}^n \). But since each open ball in \( \mathbb{R}^n \) is homeomorphic to \( \mathbb{R}^n \) we can find around each \( x \in A \) a chart around \( x \) such that the image \( V_x \) equals \( \mathbb{R}^n \). Now we write \( A_x := A \cap \Phi^{-1}_x(B^n_1(0)) \) and \( U'_x := \Phi^{-1}_x(B^n_1(0)) \).

Since \( A \) is compact we can find finitely many \( x_1, \ldots, x_m \) in \( A \) such that \( A \) is contained in \( U'_{x_1} \cup \cdots \cup U'_{x_m} \). By construction the corresponding charts \( \Phi_i := \Phi_{x_i}: U_{x_i} \to \mathbb{R}^n \) and the sets \( A_i := A_{x_i} \) have the desired properties. ■

Figure 1228. Illustration for the proof of Lemma 87.19

It follows from Lemma 87.19 that statements (i) and (ii) hold for all the \( A_i \) and for all arbitrary intersections of the \( A_i \). But then Lemma 87.13 implies that they also hold for \( A = A_1 \cup \cdots \cup A_m \). ■

87.3. Proof of Theorem 87.3. Now we are in a position that we can provide the long-delayed proofs of Theorems 87.1, 87.2 and 87.3. We start out with the proof of Theorem 87.3 since we will use that theorem in the proof of Theorem 87.1.

The key extra ingredient in the proof of Theorem 87.3 is the following proposition.

Proposition 87.20. Let \( M \) be a connected \( n \)-dimensional topological manifold and let \( R \) be a commutative ring. If \( M \) is non-compact and if \( \partial M = \emptyset \), then \( H_k(M; R) = 0 \) for every \( k \geq n \).
Proof. Let $M$ be a connected non-compact $n$-dimensional topological manifold such that $\partial M = \emptyset$, let $R$ be a commutative ring and let $k \geq n$. Let $\alpha \in H_k(M; R)$. We need to show that $\alpha = 0$. We represent $\alpha$ by a cycle $z = \sum_{i=1}^m \sigma_i \otimes r_i \in C_k(M; R) = C_k(M) \otimes R$. The union of the images of $\sigma_1, \ldots, \sigma_m$ is a compact subset $K$ of $M$. Since $K$ is compact it follows from Exercise 87.1 that there exists an open subset $U \subset M$ that contains $K$ and such that the closure $\bar{U}$ is compact. We consider the open subset $V = M \setminus \bar{U}$ and we consider the long exact sequence of the triple $(M, U \cup V, V)$, see Corollary 43.16. It fits into the following commutative diagram

\[ \cdots \to H_{k+1}(M, U \cup V; R) \xrightarrow{\partial} H_k(U \cup V, V; R) \to H_k(M, V; R) \to \cdots \]

Here the left vertical map is an isomorphism since $U \cup V$ is the disjoint union of the open sets $U$ and $V$.

![Diagram of a manifold with subsets](image)

Figure 1229. Illustration for the proof of Proposition 87.20

Now we consider the modules to the top-left and top-right of the diagram. We have

$H_{k+1}(M, U \cup V; R) = H_{k+1}(M | (M \setminus (U \cup V); R) = 0$ if $k > n - 1$

by Theorem 87.10 (ii) since $M$ has no boundary and since $\bar{U}$ and $\bar{U} \setminus U$ are compact

$H_k(M, V; R) = H_k(M | M \setminus V; R) = 0$ if $k > n$.

After these preparations we come to the actual proof that $\alpha = [z] = 0 \in H_k(M; R)$. We first consider the case $k > n$. We deduce from the above exact sequence and the above calculations that $H_k(U; R) = 0$. But $z$ represents an element in $H_k(U; R)$. It follows that $[z] = 0$ in $H_k(M; R)$.

\[1254\] One could at this point refer to the Excision Theorem 43.19 but this isomorphism follows already from the observation that $C_\ast(U \cup V) = C_\ast(U) \oplus C_\ast(V)$ as chain complexes, since $U$ and $V$ are both open subsets of $U \cup V$. 
Now we consider the case $k = n$. It follows from the above discussion that we have a commutative diagram
\[
\begin{array}{c}
H_n(U \cup V, V; R) \cong H_n(M, V; R) \\
\uparrow \quad \uparrow \\
H_n(U; R) \longrightarrow H_n(M; R).
\end{array}
\]
Thus it suffices to show that the image of $\alpha$ in $H_n(M, V; R)$ is zero. We showed in Lemma 86.5 (2) that $\{\alpha_x\}_{x \in M}$ is an $R$-section of $M$. Since $M$ is non-compact we can find a point $x$ outside of the compact set $K$. The class $\alpha_x \in H_n(M, M \setminus \{x\}; R)$ is again represented by $z$ which lies in $K \subset M \setminus \{x\}$. It is thus clear that $\alpha_x = 0 \in H_n(M, M \setminus \{x\}; R)$. But since $M$ is connected it follows from Proposition 86.6 (1) that $\{\alpha_x\}_{x \in M}$ is the zero section. Both the image of $\alpha$ in $H_n(M, V; R)$ and the zero-class are lifts of the zero section to $H_n(M, V; R)$. By Theorem 87.10 (i) both lifts agree, i.e. the image of $\alpha$ in $H_n(M, V; R)$ is zero.

Now we can easily provide the proof of Theorem 87.3.

Proof of Theorem 87.3 Let $M$ be a connected $n$-dimensional topological manifold and let $R$ be a commutative ring. Recall that we need to prove the following two statements.

1. If $M$ is not closed, then $H_i(M; R) = 0$ for $i \geq n$.
2. If $M$ is closed, then we have $H_i(M; R) = 0$ for $i > n$.

First suppose that $M$ is not closed. The hypothesis that $M$ is not closed means that $M$ is not compact or that it has a non-empty boundary. If $M$ is not compact without boundary, then we had just proved in Proposition 87.20 that $H_i(M; R) = 0$ for $i \geq n$. If $M$ has non-empty boundary, then we saw in Corollary 44.7 that $M$ is homotopy equivalent to a non-compact $n$-dimensional topological manifold $N$ without boundary. It follows from Corollary 42.8 and Proposition 87.20 that for any $i \geq n$ we have $H_i(M; R) \cong H_i(N; R) = 0$.

Now suppose that $M$ is closed. Let $i > n$. We have

$$H_i(M; R) = H_i(M, M \setminus M; R) = H_i(M|M; R) = 0.$$  

by Theorem 87.10 (ii) since $M$ is compact and since $M$ has no boundary.

87.4. Proof of Theorems 87.1 and 87.2 The key to proving Theorems 87.1 and 87.2 is the following proposition which later on we will apply to $R = \mathbb{Z}$ and $R = \mathbb{F}_2$.

Proposition 87.21. Let $M$ be a connected, compact $n$-dimensional topological manifold and let $R$ be a commutative ring. Then the following hold:

1. If $M$ is $R$-orientable, then for any $x \in M \setminus \partial M$ the map

$$H_n(M, \partial M; R) \to H_n(M, M \setminus \{x\}; R) \cong R$$

isomorphic by Lemma 86.4.
is an isomorphism.

(2) If \( M \) is non-orientable, then \( H_n(M, \partial M; \mathbb{Z}) = 0 \).

**Proof.** Let \( M \) be a connected, compact \( n \)-dimensional topological manifold and let \( R \) be a commutative ring.

We first consider the case that \( M \) is actually closed. Recall that we denote by \( \Gamma_R(M) \) the set of all \( R \)-sections of \( M \). By Lemma 86.5 (2) we have a well-defined \( R \)-module homomorphism

\[
H_n(M; R) \to \Gamma_R(M)
\]

\[
\alpha \mapsto \{\alpha_x\}_{x \in M}.
\]

Since \( M \) is closed we can apply Theorem 87.10 (i) to the special case of the compact subset \( A = M \) and we obtain that the above map is an isomorphism. The desired statements (1) and (2) now both follow from Lemma 86.9.

Now we consider the case that \( M \) is not closed, i.e. we suppose that \( \partial M \neq \emptyset \). As usual we denote by \( D M \) the double of \( M \). The idea now is to prove the desired statements for \( M \) by reducing them to the equivalent statements for the closed topological manifold \( D M \) that we had just proved.

As before we think of the double as \( D M = (M \sqcup M')/\sim \) where \( M' \) is another copy of \( M \). We consider the maps

\[
\begin{align*}
H_n(M'; R) &\to H_n(D M; R) \to H_n(D M, M'; R) \to H_{n-1}(M'; R) \to H_{n-1}(D M; R) \\
&\cong H_n(M, \partial M; R),
\end{align*}
\]

where on the top we have written down the long exact sequence of the pair \((D M, M')\). Note that the vertical map is an isomorphism by the Excision Theorem 44.10. The map \( \Phi \) is defined to be the unique homomorphism that makes the triangle commute.

It follows immediately from the information provided in the above diagram that the map \( \Phi : H_n(D M; R) \to H_n(M, \partial M; R) \) is an isomorphism. Now we turn to the proof of the two statements of the proposition.

(1) Now suppose that \( M \) is \( R \)-orientable. Let \( x \in M \setminus \partial M \). We consider the following diagram

\[
\begin{array}{ccc}
H_n(D M; R) &\to & H_n(D M, D M \setminus \{x\}; R) \\
\to & & \to \\
& & \cong \\
& & \Phi \\
& & \\
& & \\
H_n(M, \partial M; R) &\to & H_n(M, M \setminus \{x\}; R).
\end{array}
\]

Here all maps are the obvious inclusion induced maps. This implies that the diagram commutes. Since \( D M \) is closed and since it is \( R \)-orientable by Lemma 86.18 we know from the first part of the proof that the top horizontal map is an isomorphism. Furthermore by the above discussion we know that the top-left diagonal map
is an isomorphism. Finally two of the maps are isomorphisms by the Excision Theorem \[44.10\]. It now follows immediately that the bottom horizontal map is also an isomorphism. But that is exactly what we were supposed to show.

(2) If \(M\) is non-orientable, then it follows from Lemma \[86.18\] that the double \(D\ M\) is non-orientable either. We obtain that
\[
H_n(M, \partial M; \mathbb{Z}) \cong H_n(D\ M; \mathbb{Z}) = 0.
\]
see above since \(D\ M\) is closed and non-orientable and since we have proved (1) in the closed case.

\[\Box\]

Remark. Note that the second statement of Proposition \[87.21\] only deals with integer coefficients. A more general statement is given by [Hat02, Theorem 3.26]. This theorem says that if \(M\) is a closed connected \(n\)-dimensional topological manifold that is not \(R\)-orientable, then for any \(x \in M\) the map \(\rho_x: H_n(M; R) \rightarrow H_n(M, M \setminus \{x\}; R) \cong R\) is injective with image \(\{r \in R \mid 2r = 0\}\). For example for \(R = \mathbb{Z}\) we have \(\{r \in \mathbb{Z} \mid 2r = 0\} = \{0\}\), i.e. the map \(\rho_x\) is the zero map and by injectivity we have \(H_n(M; \mathbb{Z}) = 0\). In the case of closed topological manifolds we can thus view [Hat02, Theorem 3.26] as a generalization of Proposition \[87.21\] (2). We will not make use of [Hat02, Theorem 3.26].

Now we can finally provide the proofs of Theorems \[87.1\] and \[87.2\].

Proof of Theorem \[87.1\] Let \(M\) be a compact connected non-empty \(n\)-dimensional topological manifold. We have to show that the following statements are equivalent:

1. the topological manifold \(M\) is orientable,
2. \(H_n(M, \partial M; \mathbb{Z}) \neq 0\),
3. \(H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}\),
4. for every \(x \in M \setminus \partial M\) the map
\[
\rho_x: H_n(M, \partial M; \mathbb{Z}) \rightarrow H_n(M, M \setminus \{x\}; \mathbb{Z})
\]
is an isomorphism.

We have (1) \(\Rightarrow\) (4) by Proposition \[87.21\] (1) applied with \(R = \mathbb{Z}\). Since \(M\) is non-empty we obtain from Proposition \[44.2\] (5) that there exists a point \(x \in M \setminus \partial M\). Therefore we have (4) \(\Rightarrow\) (3) by Lemma \[86.4\]. Evidently we have (3) \(\Rightarrow\) (2). Furthermore we have (2) \(\Rightarrow\) (1) by Proposition \[87.21\] (2).

Proof of Theorem \[87.2\] Let \(M\) be a compact connected non-empty \(n\)-dimensional topological manifold. We have to show the following two statements:

1. \(H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2\), and
2. for every \(x \in M \setminus \partial M\) the map
\[
\rho_x: H_n(M, \partial M; \mathbb{F}_2) \rightarrow H_n(M, M \setminus \{x\}; \mathbb{F}_2)
\]
is an isomorphism.

By Proposition \[86.13\] we know that \(M\) admits an \(\mathbb{F}_2\)-orientation. Statement (2) follows immediately from this fact and Proposition \[87.21\] (1) applied to \(R = \mathbb{F}_2\). As in the proof of Theorem \[87.1\], the first statement is an immediate consequence of the second statement, together with the fact that there exists a point in \(M \setminus \partial M\) and Lemma \[86.4\].

\[\Box\]
87.5. **Further properties of topological manifolds.** Let \( M \) be a compact \( n \)-dimensional topological manifold. With Theorem 87.1 we now completely understand the \( n \)-dimensional homology of \( M \). In this section we will obtain some results on the \((n-1)\)-dimensional homology of \( M \) which generalize the results of Theorem 66.6 (2) and Theorem 66.8 (2) from smooth manifolds to topological manifolds.

**Proposition 87.22.** Let \( M \) be a connected compact \( n \)-dimensional topological manifold. 

\[
\begin{align*}
H_{n-1}(M; \mathbb{Z}) &\cong \begin{cases} 
\text{free abelian group}, & \text{if } M \text{ is orientable or if } \partial M \neq \emptyset, \\
\text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable and closed.}
\end{cases} \\
H_{n-1}(M, \partial M; \mathbb{Z}) &\cong \begin{cases} 
\text{free abelian group}, & \text{if } M \text{ is orientable,} \\
\text{free abelian group } \oplus \mathbb{Z}_2, & \text{if } M \text{ is non-orientable.}
\end{cases}
\end{align*}
\]

In all cases the free abelian group is finitely generated.

**Remark.**

(1) As a reality check it is good to recall the calculation of the homology groups of closed 2-dimensional topological manifolds that we gave in Proposition 48.9. There we showed for any \( g \in \mathbb{N}_0 \) and any \( k \in \mathbb{N}_0 \) we have

\[
H_n(\Sigma_g) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
\mathbb{Z}, & \text{if } n = 2, \\
\mathbb{Z}^{2g}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0
\end{cases}
\]

and

\[
H_n(k \cdot \mathbb{R}P^2) \cong \begin{cases} 
0, & \text{if } n \geq 3, \\
0, & \text{if } n = 2, \\
\mathbb{Z}_2 \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\
\mathbb{Z}, & \text{if } n = 0,
\end{cases}
\]

where, as always, we denote by \( \Sigma_g \) the surface of genus \( g \). Fortunately these calculations are coherent with Proposition 87.22.

(2) It follows immediately from the Universal Coefficient Theorem 57.19, Theorem 87.1, Proposition 87.22 and Lemma 57.17 that for any closed orientable \( n \)-dimensional topological manifold and any abelian group \( G \) we have \( H_n(M; G) \cong G \).

In the proof of Proposition 87.22 we will use the following lemma which is an immediate consequence of the classification of finitely generated abelian groups, see Theorem 19.4 of Lemma 57.17.

**Lemma 87.23.** Let \( A \) be a finitely generated abelian group. Then the following holds:

\[
A \text{ is a free abelian group } \iff \text{Tor}(A, \mathbb{Z}_p) = 0 \text{ for all primes } p.
\]

Now we can provide the proof of Proposition 87.22. First we consider Statement (1). For that statement we consider the two cases that the topological manifold is closed and that it has non-empty boundary separately.

**Proof of Proposition 87.22 (1).** Let \( M \) be a closed connected \( n \)-dimensional topological manifold. By Proposition 85.13 (4) we know that \( H_{n-1}(M; \mathbb{Z}) \) is a finitely generated abelian group.

We first consider the case that \( M \) is orientable. We want to show that \( H_{n-1}(M; \mathbb{Z}) \) is a free abelian group. By Lemma 87.23 it suffices to show that \( \text{Tor}(H_{n-1}(M; \mathbb{Z}), F_p) = 0 \) for all primes \( p \).
So let $p$ be a prime. We have

by Proposition \[87.21\] (1), since by Lemma \[86.14\] we know that $M$ is also $\mathbb{F}_p$-orientable

$$ F_p \cong H_n(M; F_p) \cong H_n(M; \mathbb{Z}) \otimes \mathbb{F}_p \oplus \text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_p) \cong \mathbb{F}_p \oplus \text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_p). $$

Universal Coefficient Theorem \[87.24\] by Theorem \[87.1\] (3) we have $H_n(M; \mathbb{Z}) \cong \mathbb{Z}$

It follows from Lemma \[19.8\] that $\text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_p) = 0$.

Now we turn to the case that $M$ is non-orientable. By Proposition \[86.13\] there exists a connected 2-fold covering $q: \tilde{M} \to M$ such that $\tilde{M}$ is orientable. We consider the maps

$$ H_{n-1}(M; \mathbb{Z}) \xrightarrow{q^*} H_{n-1}(\tilde{M}; \mathbb{Z}) \xrightarrow{q_*} H_{n-1}(M; \mathbb{Z}). $$

Here $q^*$ denotes the transfer map that we introduced on page \[1445\] and $q_*$ denotes of course the map induced by the projection $q$. By Proposition \[59.1\] the composition of $q^*$ and $q_*$ is given by multiplication by 2. Put differently, the above diagram commutes.

Since $\tilde{M}$ is orientable we obtain from the case that we had just proved that $H_{n-1}(\tilde{M}; \mathbb{Z})$ is torsion-free. Now we see that

the torsion subgroup of $H_{n-1}(M; \mathbb{Z}) \subset \ker(q^*) \subset \ker(q_* \circ q^*) \subset \{ a \in H_{n-1}(M; \mathbb{Z}) \mid 2a = 0 \}.$

From these inclusions and the classification of finitely generated abelian groups we obtain easily that $H_{n-1}(M; \mathbb{Z}) \cong (\mathbb{Z}_2)^r \oplus \mathbb{Z}^k$ for some $r \in \mathbb{N}_0$ and some $k \in \mathbb{N}_0$.

It remains to show that $r = 1$. In light of Lemma \[57.17\] it suffices to show that we have $\text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_2) \cong \mathbb{F}_2$. The argument is very similar to the argument in the orientable case. More precisely, we have

$$ \mathbb{F}_2 \cong H_n(M; \mathbb{F}_2) \cong H_n(M; \mathbb{Z}) \otimes \mathbb{F}_2 \oplus \text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_2) \cong 0 \oplus \text{Tor}(H_{n-1}(M; \mathbb{Z}), \mathbb{F}_2). $$

Universal Coefficient Theorem \[87.24\] by Theorem \[87.1\] (3) we have $H_n(M; \mathbb{Z}) = 0$.

Now we deal with topological manifolds with non-empty boundary.

Proof of Proposition \[87.22\] (1) II (*). Let $M$ be a connected, compact $n$-dimensional topological manifold with non-empty boundary. We need to show that $H_{n-1}(M; \mathbb{Z})$ is a free abelian group. There are two approaches to the proof of this statement.

(1) We can imitate the proof of the closed case, or

(2) we reduce the proof of the proposition to the case of closed topological manifolds that we had just dealt with.

We will pursue the second approach. First recall that by Lemma \[86.18\] the double $D M$ is orientable if and only if $M$ is orientable.

We first consider the case that $M$ is orientable. By Proposition \[87.22\] we know that $H_{n-1}(D M; \mathbb{Z})$ is a finitely generated free abelian group. It follows from Lemma \[44.13\] that
the group $H_{n-1}(M; \mathbb{Z})$ is isomorphic to a subgroup of $H_{n-1}(D\ M; \mathbb{Z})$, hence by Lemma 19.8 (3) it is also a finitely generated free abelian group.

Now we consider the case that $M$ is non-orientable. We denote by $M'$ a copy of $M$ and as usual we denote by $D\ M = M \cup_{\partial M = \partial M'} M'$ the double. From the Mayer–Vietoris Theorem 46.10 for Manifolds we obtain the following long exact sequence:

$$\cdots \rightarrow H_n(D\ M; \mathbb{Z}) \rightarrow H_{n-1}(\partial M; \mathbb{Z}) \rightarrow H_{n-1}(M; \mathbb{Z}) \oplus H_{n-1}(M'; \mathbb{Z}) \rightarrow H_{n-1}(D\ M; \mathbb{Z}) \rightarrow \cdots$$

We make the following observations:

1. By Proposition 44.2 (3) and (4) we know that $\partial M$ is a closed $(n-1)$-dimensional topological manifold. Thus we obtain from Theorem 87.1 that $H_{n-1}(\partial M; \mathbb{Z})$ is isomorphic to a free abelian group $\mathbb{Z}^r$ for some $r \in \mathbb{N}_0$. (We do not have any control over the orientability of $\partial M$ and the number of components of $\partial M$ but this does not matter.)

2. Since $D\ M$ is non-orientable we know from Theorem 87.1 that $H_n(D\ M; \mathbb{Z}) = 0$ and we know from Proposition 87.22 that $H_{n-1}(D\ M; \mathbb{Z}) \cong \mathbb{Z}^s \oplus \mathbb{Z}_2$ for some $s \in \mathbb{N}_0$.

3. Since $M = M'$ we have $H_{n-1}(M; \mathbb{Z}) = H_{n-1}(M'; \mathbb{Z})$. By the classification of finitely generated abelian groups we can pick an isomorphism $H_{n-1}(M; \mathbb{Z}) \cong F \oplus T$ where $F$ is a free abelian group and $T$ is a torsion group.

We can thus rewrite the above sequence as follows:

$$0 \rightarrow \mathbb{Z}^r \xrightarrow{\varphi} F \oplus F \oplus T \oplus T \rightarrow \mathbb{Z}^s \oplus \mathbb{Z}_2 \rightarrow \cdots$$

The map $\varphi: \mathbb{Z}^r \rightarrow F \oplus F \oplus T \oplus T$ is a monomorphism, but since $\mathbb{Z}^r$ is torsion-free and since $T$ is finite we see that $\text{im}(\varphi) \cap (T \oplus T)$ is trivial. But this implies that $T \oplus T$ is isomorphic to a subgroup of $\mathbb{Z}^s \oplus \mathbb{Z}_2$. But this is only possible if $T = 0$. This concludes the proof that $H_{n-1}(M; \mathbb{Z})$ is a free abelian group.

**Proof of Proposition 87.22 (2)**. First we note that by Propositions 44.2 (3) and (4) and 85.13 (4) together with Lemma 64.7 (1) we know that $H_{n-1}(M, \partial M; \mathbb{Z})$ is finitely generated. Now there are two approaches to proving Statement (2):

1. We can use basically exactly the argument as in the proof of Theorem 66.8 (2) to reduce, via a doubling construction, the study of relative homology groups to the study of absolute homology groups. The only difference is that we need to replace Theorem 66.6 by Statement (1) of the present proposition.

2. Alternatively we can adopt the argument of Statement (1). First we assume that $M$ is orientable. By Lemma 87.23 it suffices to show that $\text{Tor}(H_{n-1}(M, \partial M; \mathbb{Z}), \mathbb{F}_p) = 0$ for all primes $p$. So let $p$ be a prime. We have

\[
\mathbb{F}_p \cong H_n(M, \partial M; \mathbb{F}_p) \xrightarrow{\text{d}} H_n(M, \partial M; \mathbb{Z}) \otimes \mathbb{F}_p \oplus \text{Tor}(H_{n-1}(M, \partial M; \mathbb{Z}), \mathbb{F}_p) \cong \mathbb{F}_p \oplus \text{Tor}(H_{n-1}(M, \partial M; \mathbb{Z}), \mathbb{F}_p),
\]

by Proposition 87.21 (1), since by Lemma 86.14 $M$ is also $\mathbb{F}_p$-orientable and by Theorem 87.1 (3) we have $H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$.
It follows from Lemma \[19.8\] that \(\text{Tor}(H_{n-1}(M, \partial M; \mathbb{Z}), F_p) = 0\). The case that \(M\) is non-orientable is very similar, we leave it to the reader to make the necessary modifications.

87.6. The fundamental class and induced orientations. In Section \[86.3\] we saw that an orientation on a topological manifold \(M\) induces orientations on codimension-zero submanifolds of \(M\), on the boundary \(\partial M\) and on covering spaces of \(M\). If \(M\) is compact, then \(M\) admits a fundamental class and we will see in this section how it is related to the fundamental classes of the various corresponding oriented topological manifolds.

First of all, in Lemma \[86.17\] we saw that a codimension-zero submanifold \(W\) of an oriented topological manifold \(M\) inherits an orientation. For compact topological manifolds the following lemma, which is the analogue of Lemma \[68.12\] shows the relationship between the corresponding fundamental classes.

**Lemma 87.24.** Let \(M\) be a compact oriented \(n\)-dimensional topological manifold. Furthermore let \(W \subset M\) be a compact non-empty codimension-zero submanifold. We write \(\hat{W} = W \setminus \partial W\). The following two statements hold:

1. The inclusion induced map \(H_n(W, \partial W; \mathbb{Z}) \to H_n(M, M \setminus \hat{W}; \mathbb{Z})\) is an isomorphism.
2. The image of the fundamental classes \([M] \in H_n(M, \partial M; \mathbb{Z})\) and \([W] \in H_n(W, \partial W; \mathbb{Z})\) under the maps

\[
H_n(M, \partial M; \mathbb{Z}) \to H_n(M, M \setminus \hat{W}; \mathbb{Z}) \leftarrow H_n(W, \partial W; \mathbb{Z})
\]

agree.

![Illustration](1230). Illustration for the proof of Lemma 87.24

**Remark.** In Lemma \[89.4\] we will generalize Lemma 87.24 to the case that \(W\) is a codimension-zero submanifold with corner.

**Proof (\(*\)).**

1. The first statement is an immediate consequence of the Excision Theorem \[44.10\].
2. We denote by \(\Phi : H_n(M, \partial M; \mathbb{Z}) \to H_n(W, \partial W; \mathbb{Z})\) the map given in statement (2). We have to show that \(\Phi([M])\) is the fundamental class for \(W\). But this follows immediately from Corollary \[87.4\] and from considering for each \(x \in W \setminus \partial W\) the
following commutative diagram

\[
\begin{array}{ccc}
H_n(M, \partial M; \mathbb{Z}) & \xrightarrow{\Phi} & H_n(M, M \setminus \tilde{W}; \mathbb{Z}) & \cong \\
\downarrow & & \downarrow & \\
H_n(M, M \setminus \{x\}; \mathbb{Z}) & \cong & H_n(W, W \setminus \{x\}; \mathbb{Z}).
\end{array}
\]

We leave the few remaining details to the reader. \(\blacksquare\)

In Lemma 86.17 (3) we showed that a covering space \(\tilde{M}\) of an oriented topological manifold \(M\) inherits an orientation from \(M\). The following proposition can now be viewed as a generalization of Exercise 68.10 and Proposition 69.8.

**Proposition 87.25.** Let \(M\) be a compact oriented non-empty \(n\)-dimensional topological manifold and let \(p: \tilde{M} \to M\) be a finite covering. We denote by \([M]\) the fundamental class of \(M\) and we denote by \(p^*: H_n(M; \mathbb{Z}) \to H_n(M; \mathbb{Z})\) the transfer map that we introduced on page 1445. \(p^*([M])\) equals the fundamental class \([\tilde{M}]\) of the oriented topological manifold \(\tilde{M}\) and we have \(p_*([\tilde{M}]) = [\tilde{M} : M] \cdot [M]\).

**Proof (\(
\).)** Let \(M\) be a compact \(n\)-dimensional topological manifold. To simplify the notation we assume that \(M\) is closed. Furthermore let \(p: \tilde{M} \to M\) be a finite covering and let \(\{\mu_x\}_{x \in \tilde{M}}\) be an orientation for \(M\). We denote by \(\{\nu_x\}_{x \in \tilde{M}}\) the orientation on \(\tilde{M}\) that we defined in Lemma 86.17 (3).

We want to show that \(p^*([M])\) equals the fundamental class \([\tilde{M}]\). By Corollary 87.4 it suffices to show that for all \(y \in \tilde{M}\) we have \(p^*([M])_y = \nu_y \in H_n(\tilde{M}, \tilde{M} \setminus \{y\}; \mathbb{Z})\). So let \(y \in \tilde{M}\). We pick an open neighborhood \(V\) around \(y\) such that \(U := p(V)\) is uniformly covered. We write \(x = p(y)\) and we denote by \(q: U \to V\) the inverse of the homeomorphism \(p: V \to U\).

We pick a representative \(z = a_1 \cdot \sigma_1 + \cdots + a_m \cdot \sigma_m \in C_n(M)\) for \([M]\). By applying Proposition 43.24 to the open covering of \(M\) given by \(\{U, M \setminus \{x\}\}\) we can arrange that the image of each \(\sigma_i\) lies in \(U\) or in \(M \setminus \{x\}\). We denote by \(z'\) the sum of all summands in \(z\) such that the image of \(\sigma_i\) lies in \(U\).

A moment’s thought shows that in \(H_n(M, M \setminus \{x\}; \mathbb{Z})\) we have \([z] = [z']\) and that in \(H_n(\tilde{M}, \tilde{M} \setminus \{y\})\) we have \([p^*(z)] = [q_*(z')]\). From these observations we deduce that the following diagram commutes:

\[
\begin{array}{ccc}
H_n(M; \mathbb{Z}) & \xrightarrow{p^*} & H_n(\tilde{M}; \mathbb{Z}) \\
\downarrow[\text{homotopy}] & & \downarrow[\text{homotopy}] \\
H_n(M, M \setminus \{x\}; \mathbb{Z}) & \cong & H_n(V, V \setminus \{y\}; \mathbb{Z}) \xrightarrow{\cong} H_n(\tilde{M}, \tilde{M} \setminus \{y\}; \mathbb{Z}).
\end{array}
\]
Note that the bottom horizontal maps to the left and right are isomorphisms by the Excision Theorem 43.20 and the middle horizontal map is an isomorphism since \( q \) is a homeomorphism. It follows from this diagram that we indeed have \( p^*([M])_y = \nu_y \).

Finally we have
\[
p_*([\tilde{M}]) = p_* (p^*([M])) = [\tilde{M} : M] \cdot [M].
\]

In Lemma 86.18 we saw that the double of an oriented topological manifold with non-
empty boundary comes with a natural orientation. The following lemma following relates
the various fundamental classes in this construction.

**Lemma 87.26.** Let \( M \) be a compact oriented \( n \)-dimensional topological manifold with
non-empty boundary. If we equip \( D M \) with the orientation coming from Lemma 86.18
then
\[
[D M] = D([M]) \in H_n(D M; \mathbb{Z}),
\]
where \( D \colon H_n(M, \partial M; \mathbb{Z}) \to H_n(D M; \mathbb{Z}) \) denotes the doubling homomorphism that we
introduced in Lemma 44.16.

**Proof.** Let \( \{\mu_x\}_{x \in M \setminus \partial M} \) be an orientation for \( M \). We denote by \( \{\alpha_x\}_{x \in D M} \) the corre-
sponding orientation for \( D M \) that we had constructed in Lemma 86.18. To simplify the
notation we write \( D M = (M \sqcup M')/\sim \) where \( M' \) is a copy of \( M \) and we view \( M \) as a
submanifold of the double. By Proposition 44.2 (5) there exists an \( x \in M \setminus \partial M \). We
consider the following diagram
Here all maps are the obvious maps for pairs of topological spaces. The lemma follows from the following observations:

1. The top triangle commutes by Lemma 44.16 (3). The parallelogram on the left and the triangle on the right commute by the functoriality of homology.
2. The homomorphism to the bottom left is an isomorphism by the Excision Theorem 44.10 for topological Manifolds.
3. The right diagonal map is an isomorphism by Theorem 87.1.
4. By definition $[M]$ gets sent to $\mu_x \in H^n(M,M \{x\};Z)$ and by definition $\mu_x$ gets sent to $\alpha_x$. It follows from the commutativity of the diagram that $D([M])$ gets sent to $\alpha_x$. But since the right diagonal map is an isomorphism it follows, from the definition of $[D M]$, that $[D M] = D([M])$.

In Proposition 86.19 we saw that the boundary of an oriented topological manifold inherits a natural orientation. The following proposition can now be seen as a generalization of Proposition 68.9 from smooth manifolds to topological manifolds.

**Proposition 87.27.** Let $M$ be a compact $n$-dimensional topological manifold with non-empty boundary.

1. We denote by $\partial_n : H_n(M, \partial M; Z) \to H_{n-1}(\partial M; Z)$ the connecting homomorphism of the long exact sequence of the pair $(M, \partial M)$. If $M$ is oriented, then $\partial_n([M]) = [\partial M] \in H_{n-1}(\partial M; Z)$.
2. Similarly, for the connecting homomorphism $\partial_n : H_n(M, \partial M; F_2) \to H_{n-1}(\partial M; F_2)$ we have $\partial_n([M]_{F_2}) = [\partial M]_{F_2} \in H_{n-1}(\partial M; F_2)$.

**Proof (\#).** As a health warning we point out that in this proof we make heavy use of the notation introduced in Proposition 86.19. We only provide the proof of Statement (1); the proof of Statement (2) is almost identical.

Let $\{\mu_y\}_{y \in M \setminus \partial M}$ be the orientation of for $M$. Next let $x \in \partial M$. We pick a chart $\Phi : U \to [0,2) \times (-2,2)^{n-1}$ with $\Phi(x) = (0,0)$. We write $V' = \Phi^{-1}((0,1) \times (-1,1)^{n-1})$. Finally we pick a point $y \in V'$. We consider the following diagram:

$$
\begin{array}{ccc}
H_n(M, M \{y\}) & \xleftarrow{\mu_y} & H_n(M, M \{V'\} \setminus \{x\}) \\
| \uparrow \mu_y | \downarrow \partial_n & & \downarrow \partial_n \\
H_n(M, \partial M) & \xrightarrow{\partial_n} & H_{n-1}(\partial M).
\end{array}
$$

We make the following observations and clarifications:

1. All the unmarked maps are induced by the obvious inclusions of pairs of topological space.

Note that $\partial M$ is a closed $(n-1)$-dimensional topological manifold by Proposition 44.2 (3) and (4).
(2) In the proof of Proposition 86.19 we showed that the blue maps on the top, connecting
\( H_n(M, M \setminus \{y\}) \) to \( H_{n-1}(\partial M, \partial M \setminus \{x\}) \), are isomorphisms.

(3) By definition of the orientation \( \{\nu_x\}_{x \in \partial M} \) of \( \partial M \) the composition of the top horizontal
maps sends \( \mu_x \) to \( \nu_y \).

(4) The maps \( \partial_n \) are the connecting homomorphism of the long exact sequence of the
triple \( (M, M \setminus V', (M \setminus V') \setminus \{x\}) \) respectively of the pair \( (M, \partial M) \).

(5) The triangles are given by inclusion induced maps, hence they both commute.

(6) Finally note that it follows from the naturality of the connecting homomorphisms,
see Proposition 43.15 (3), that the quadrilateral commutes.

It follows from the above and the defining property of \([M]\) that for any \( x \in \partial M \) the image
of \( \partial_n([M]) \in H_{n-1}(M) \) under the map \( H_{n-1}(\partial M) \rightarrow H_{n-1}(\partial M, \partial M \setminus \{x\}) \) equals \( \nu_x \). But
that means that \( \partial_n([M]) = [\partial M] \). ■

**Figure 1232.** Illustration for the proof of Proposition 87.27.

**Remark.** Given a compact oriented \( n \)-dimensional topological manifold the conclusion of
Proposition 87.27 can also be summarized in the following commutative “diagram”

\[
\begin{array}{ccc}
\text{Z-oriented topological manifold } M & \xrightarrow{\text{take boundary}} & \text{Z-oriented topological manifold } \partial M \\
& \xrightarrow{\text{take fundamental class}} & \xrightarrow{\text{apply connecting homomorphism}} \\
[M] & \xrightarrow{H_n(M, \partial M; \mathbb{Z}) \rightarrow H_{n-1}(\partial M; \mathbb{Z})} & \partial[M] = [\partial M].
\end{array}
\]

**Example.** We will illustrate Proposition 87.27 with the Möbius band \( M \). By Proposition 86.13 and Theorem 87.2 it has an \( \mathbb{F}_2 \)-fundamental class \([M] \in H_2(M, \partial M; \mathbb{F}_2)\). In Figure 1233 we consider the Möbius band with two singular 1-simplices \( \alpha_1, \alpha_2 \) and two
singular 2-simplices \( \sigma_1, \sigma_2 \). In this case we have

\[
\partial(\sigma_1 + \sigma_2) = \begin{cases} \alpha_1 + \alpha_2, & \text{if } \sigma_1 + \sigma_2 \in C_1(\partial M) \\
\end{cases}
\]

In particular, \( \mu \otimes 1 \) is a cycle in \( C_2(M, \partial M; \mathbb{F}_2) \). It easily follows from Proposition 68.18
that \( \mu \otimes 1 \) represents the \( \mathbb{F}_2 \)-fundamental class in \( H_2(M, \partial M; \mathbb{F}_2) \). Furthermore, if we
denote by \( \partial: H_2(M, \partial M; \mathbb{F}_2) \rightarrow H_1(\partial M; \mathbb{F}_2) \) the connecting homomorphism of the long
exact sequence in \( \mathbb{F}_2 \)-homology of the pair \( (M, \partial M) \), then

\[
\partial[M] = \partial[\mu \otimes 1] = [\partial \mu \otimes 1] = [(\alpha_1 + \alpha_2) \otimes 1],
\]

Proposition 43.15 by the above

but the last class is clearly an \( \mathbb{F}_2 \)-fundamental class for the circle \( \partial M \).

\footnote{Why is this clear?}
The following corollary is the generalization of Corollary 68.11 to the case of topological manifolds.

**Corollary 87.28.** Let $M$ be a compact $n$-dimensional topological manifold. Then the following two statements hold:

1. We have
   \[ \ker\left( H_{n-1}(\partial M; \mathbb{F}_2) \to H_{n-1}(M; \mathbb{F}_2) \right) = \mathbb{F}_2 \cdot [\partial M]_{\mathbb{F}_2} \in H_{n-1}(\partial M; \mathbb{F}_2). \]
   Furthermore, if $M$ is oriented, then
   \[ \ker\left( H_{n-1}(\partial M; \mathbb{Z}) \to H_{n-1}(M; \mathbb{Z}) \right) = \mathbb{Z} \cdot [\partial M] \in H_{n-1}(\partial M; \mathbb{Z}). \]

2. Let $M$ be a compact $n$-dimensional topological manifold with non-trivial boundary. Then the boundary $\partial M$ is not a retract of $M$.

**Proof.** The proof is verbatim the same as the proof of Corollary 68.11, the only difference in the proof is that we need to replace Proposition 68.9 by Proposition 87.27. As a reminder, the first statement is proved using the long exact sequence in homology of the pair $(M, \partial M)$ together with Proposition 87.27. The second statement follows from the first statement and the usual functoriality argument, this time we employ the functoriality of homology with $\mathbb{F}_2$-coefficients and the fact that $[\partial M]_{\mathbb{F}_2}$ is non-zero. \( \blacksquare \)

**Example.** It follows from Corollary 87.28 that the boundary of the Möbius band $M$ is not a retract of the Möbius band. A more down-to-earth proof is given as follows: we pick a base point $x_0 \in \partial M$ and we denote by $\alpha$ and $\beta$ the loops shown in Figure 1234. Note that $\alpha$ represents a generator of $\pi_1(\partial M, x_0) \cong \mathbb{Z}$ and that $\beta$ represents a generator of $\pi_1(M, x_0) \cong \mathbb{Z}$. We denote by $i: \partial M \to M$ the inclusion map. Note that $i_*([\alpha]) = 2 \cdot [\beta]$. If there was a retraction $r: M \to \partial M$, then we would obtain a commutative diagram

\[
\begin{array}{ccc}
\pi_1(\partial M, x_0) & \xrightarrow{i_*} & \pi_1(M, x_0) \\
(r \circ i)_* & \xrightarrow{r_*} & (\partial M, x_0)
\end{array}
\]

which by the above gives rise to the commutative diagram

\[
\begin{array}{ccc}
\mathbb{Z} & \xrightarrow{2} & \mathbb{Z} \\
\text{id} & \xrightarrow{\text{id}} & \mathbb{Z} \to \mathbb{Z},
\end{array}
\]

but such a commutative diagram cannot exist. Looking more carefully one sees that the two proofs that $\partial M$ is not a retract of the Möbius band $M$ are in some sense the same.
proof. More precisely, we have the following commutative diagram

\[
\begin{array}{ccc}
Z = \pi_1(\partial M, x_0) & \xrightarrow{i_*} & \pi_1(M, x_0) = Z \\
\downarrow & & \downarrow \\
Z = H_1(\partial M; \mathbb{Z}) & \xrightarrow{i_*} & H_1(M; \mathbb{Z}) = \mathbb{Z} \\
\downarrow & & \downarrow \\
\mathbb{F}_2 = H_1(\partial M; \mathbb{F}_2) & \xrightarrow{i_*} & H_1(M; \mathbb{F}_2) = \mathbb{F}_2.
\end{array}
\]

Here the top vertical maps are given by the Hurewicz homomorphism from page 1314 and the bottom vertical maps are given by the map \([\alpha] \mapsto [\alpha \otimes 1]\) from page 1417. Since both maps are natural, see Proposition 52.2 (4) and page 1417, we see that the diagram commutes. The above observation that the top horizontal map is given by multiplication by 2 translates into the fact that the bottom horizontal map is the zero map.

\[\text{Figure 1234}\]

87.7. \textbf{Lifts of homology orientations for topological manifolds with boundary \((\ast)\).} In this very technical section we generalize Theorem 87.10 (i) to the case of topological manifolds with boundary. Unless the reader is blessed with a surplus of energy it is best to skip this section.

\textbf{Definition.} Let \(M\) be a topological manifold. We say a compact subset \(A \subset M\) is a \textit{product close to the boundary} if there exists a collar neighborhood \([0, 1] \times \partial M\) for the boundary \(\partial M\) and a compact subset \(K \subset \partial M\) such that \(A \cap ([0, 1] \times \partial M) = [0, 1] \times K\).

\[\text{Figure 1235}\]

\textbf{Remark.} If \(M\) is a topological manifold with \textit{empty boundary}, then every compact subset is in fact a product close to the boundary.

We leave the task of providing a proof of the following elementary lemma to the reader.

\textbf{Lemma 87.29.} Let \(M\) be a topological manifold and let \([0, 1] \times \partial M\) be a collar neighborhood (which always exists by the topological Collar Neighborhood Theorem 44.3). Given any compact subset \(K\) of \(M\) there exists a compact subset \(A\) that contains \(K\) and that is a product close to the boundary.

Throughout this section we will need the following notation.
**Notation.** Given a subset \( A \) of a topological manifold \( M \) we write \( A_\partial := A \cap (M \setminus \partial M) \). In other words, we have \( A_\partial = A \setminus \partial M \). Note that \( (M \setminus A) \cup \partial M = M \setminus A_\partial \).

Now we can formulate the main result of this section.

**Theorem 87.30.** Let \( M \) be an \( n \)-dimensional topological manifold and let \( A \subset M \) be a compact subset that is a product close to the boundary. Let \( R \) be a commutative ring. If \( \{ \alpha_x \}_{x \in M \setminus \partial M} \) is an \( R \)-section for \( M \), then there exists a unique lift \( \alpha_A^M = \alpha_A \) to \( A_\partial \), i.e. there exists a unique class \( \alpha_A^M = \alpha_A \in H_n(M, M \setminus A_\partial; R) \) such that for each \( x \in A_\partial \) we have \( \alpha_{A,x} = \alpha_x \).

**Proof.** Let \( M \) be an \( n \)-dimensional topological manifold and let \( R \) be a commutative ring. Furthermore let \( A \subset M \) be a compact subset that is a product close to the boundary. We introduce the following notation and conventions:

1. As usual we denote by \( D M \) the double of \( M \). As before we think of the double as \( D M = (M \sqcup M')/\sim \) where \( M' \) is another copy of \( M \). We recall that by Lemma 44.12 we know that \( D M \) is an \( n \)-dimensional topological manifold with empty boundary such that \( M \subset D M \) is a submanifold.
2. By definition there exists a collar neighborhood \( [0, 1] \times \partial M \) for the boundary \( \partial M \) and a compact subset \( K \subset \partial M \) such that \( A \cap ([0, 1] \times \partial M) = [0, 1] \times K \).
3. We denote by \( DA = A \cup A' \subset D M \) the double of \( A \). As \( DA \) is the union of two compact sets we see that \( DA \) itself is compact.
4. Given \( t \in (0, 1] \) we write \( A_t := A \setminus ([0, t) \times K) = A \cap (M \setminus ([0, t) \times \partial M)) \). It follows easily from Lemma 2.17 that \( A_t \) is again compact.
5. It follows from the Excision Theorem 44.10 for topological manifolds that for any \( P \in M \setminus \partial M \) the inclusion induced map

\[
H_n(M, M \setminus \{P\}; R) \to H_n(D M, D M \setminus \{P\}; R)
\]

is an isomorphism. We will use this isomorphism to identify these two homology groups.

![Figure 1236. Illustration for the proof of Theorem 87.30.](image)

The idea now is the same as in the proof of Proposition 87.21. Namely we want to prove the desired statement for \( M \) by reducing it to a corresponding statement for the topological manifold \( D M \) that has no boundary.

**Claim.** The inclusion induced map

\[
\beta : H_n(M, M \setminus A_\partial; R) \to H_n(D M, (M \setminus A) \cup M'; R)
\]
is an isomorphism.

Recall that $A$ is a product close to the boundary. Using this fact and using a gentle generalization of the Excision Theorem 44.10 for topological manifolds one can easily show that the inclusion induced map is an isomorphism. We leave it to the reader to fill in the details.

We denote by $\Phi$ the composition of the following two maps

$$H_n(DM, DM \setminus DA; R) \to H_n(DM, (M \setminus A) \cup M'; R) \xrightarrow{\beta^{-1}} H_n(M, M \setminus A\partial; R).$$

After all these preparations we now turn to the actual proof of the theorem. Thus let \{\alpha_x\}_{x \in M \setminus \partial M} be an $R$-section for $M$. As in the proof of Lemma 86.18 we see that there exists an $R$-section \{\alpha_x\}_{x \in DM} for $DM$ that restricts to the given $R$-section on $M$. By Theorem 87.10 (i) there exists a lift $\mu_{DA} \in H_n(DM, DM \setminus DA; R)$ of the $R$-section on $DM$. We claim that $\Phi(\mu_{DA})$ is a lift for $M$. So let $P \in A\partial$. We have the following commutative diagram

$$\begin{array}{ccc}
H_n(DM, DM \setminus DA; R) & \xrightarrow{\Phi} & H_n(DM, (M \setminus A) \cup M'; R) \\
\downarrow & & \downarrow \\
H_n(DM, DM \setminus \{P\}; R) & \xrightarrow{=} & H_n(DM, DM \setminus \{P\}; R).
\end{array}$$

Since all maps are induced by inclusions of pairs of topological spaces we see that the diagram commutes. By definition of $\mu_{DA}$ the left-hand vertical map sends $\mu_{DA}$ to $\alpha_P$. But this implies that the right-hand vertical map sends $\Phi(\mu_{DA})$ to $\alpha_P \in H_n(M, M \setminus \{P\}; R)$.

Now we turn to the proof of the uniqueness of a lift. The following claim is the key to proving uniqueness.

Claim. Let $t \in (0, 1)$. Note that $A_t \subset A\partial$. The two inclusion induced maps

$$\gamma: H_n(M, M \setminus A\partial; R) \to H_n(M, M \setminus A_t; R)$$

$$\delta: H_n(M, M \setminus A\partial; R) \to H_n(DM, DM \setminus A_t; R)$$

are isomorphisms.

It follows immediately from the Excision Theorem 44.10 for topological manifolds that the map $\delta$ is an isomorphism. Regarding the map $\gamma$, note that it follows from the long exact sequence of the triple $(M, M \setminus A_t, M \setminus A\partial)$, see Proposition 43.15 that it suffices to show that $H_i(M \setminus A_t, M \setminus A\partial; R) = 0$ for all $i$. We pick $s \in (t, 1)$. We see that indeed we have

by the Excision Theorem 43.19 where we excise everything in the complement of $([0, s] \times \partial M) \cap A$

$$H_i(M \setminus A_t, M \setminus A\partial; R) \xleftarrow{\cong} H_i(([0, s] \times \partial M) \setminus (K \times [t, s]), ([0, s] \times \partial M) \setminus ((0, s) \times K); R) = 0.$$

follows from Corollary 43.18 since $([0, s] \times \partial M) \setminus ((0, s) \times K)$ is a deformation retract of $((0, s) \times K)$.
Now let $\mu, \nu \in H_\partial(M, M \setminus A_\partial; R)$ be two lifts of the $R$-section $\{\alpha_x\}_{x \in M \setminus \partial M}$. With the same arguments as before one can convince oneself easily of the fact that $\delta^{-1}(\gamma(\mu))$ and $\delta^{-1}(\gamma(\nu))$ are lifts of the $R$-section $\{\alpha_x\}_{x \in \partial M}$. By Theorem 87.10 these two lifts are identical. But then it follows from the claim that also $\mu = \nu$. \hfill \blacksquare

We conclude this long and tiring chapter with the following lemma that is a generalization of Corollary 87.12.

**Lemma 87.31.** Let $M$ be an oriented $n$-dimensional topological manifold and let $R$ be a commutative ring. We suppose that $M$ is equipped with an $R$-orientation. We use the notation from Theorem 87.30:

1. Let $K \subset L \subset M$ be compact subsets that are products close to the boundary. We denote by $f_{KL}: (M, M \setminus L) \to (M, M \setminus K)$ the inclusion map of pairs. The map $f_{KL*}: H_n(M, M \setminus L) \to H_n(M, M \setminus K)$ sends $\alpha^M_L$ to $\alpha^M_K$.
2. Let $U$ be an open subset of $M$ and let $A \subset U$ be a compact subset that is a product close to the boundary. We use Lemma 86.17 to view $U$ as an oriented topological manifold. If $i: U \to M$ denotes the inclusion map, then $i_*(\alpha^U_A) = \alpha^M_A$.

**Proof.** The lemma follows easily from the functoriality of homology groups and the uniqueness statement of Theorem 87.30. \hfill \blacksquare

87.8. **The degree of a map between oriented topological manifolds ($*$).** Recall that on page 1737 we used the fundamental class to define the degree of a map between smooth manifolds. Now that we also managed to introduce the fundamental class for topological manifolds we can generalize the earlier definition to the setting of topological manifolds. More precisely, we have the following definition.

**Definition.** Let $f: M \to N$ be a map between two compact oriented connected non-empty $n$-dimensional topological manifolds. We assume that $f(\partial M) \subset \partial N$. We denote by $\deg(f) \in \mathbb{Z}$ the unique integer with

by Corollary 87.4(3)

$$f_*([M]) = \deg(f) \cdot [N] \in H_n(N, \partial N) \uparrow \downarrow = \mathbb{Z} \cdot [N].$$

since $f(\partial M) \subset \partial N$ we have an induced map $f_*: H_n(M, \partial M) \to H_n(N, \partial N)$

We refer to $\deg(f)$ as the **degree of** $f$. 

**Figure 1237.** Second illustration for the proof of Theorem 87.30.
Remark. For a map \( f : S^n \to S^n \) the above degree is, by definition, exactly the same as the degree that we defined on page 1181. Furthermore, given a map between smooth manifolds it follows from Lemma 87.6 that the above definition of the degree agrees with the definition given on page 1737.

In Propositions 45.23 and 69.7 we already saw that in some settings we can calculate the "global" degree of a map by "local" degrees. To formulate the analogue in our present setting we need the following straightforward definition.

**Definition.** Let \( f : M \to N \) be a map between two oriented \( n \)-dimensional topological manifolds and let \( x \in M \setminus \partial M \) such that \( f(x) \in N \setminus \partial N \). We set \( y := f(x) \). We suppose that there exists an open neighborhood \( U \) of \( x \) such that \( f(z) \neq f(x) \) for every \( z \in U \setminus \{x\} \). We pick an embedding \( \Psi : \mathbb{B}^n \to U \subset M \) with \( \Psi(0) = x \) and we pick an embedding \( \Theta : \overline{\mathbb{B}}^n \to M \) with \( \Theta(0) = y \) and with \( f(\Psi(\mathbb{B}^n)) \subset \Theta(\overline{\mathbb{B}}^n) \). We assume that \( \Psi \) and \( \Theta \) are either both orientation-preserving or they are both orientation-reversing. We define the local degree \( \deg(f, x) \) as follows:

\[
\deg(f, x) := \deg((\Theta^{-1} \circ f \circ \Psi)_* : H_n(\mathbb{B}^n, \mathbb{B}^n \setminus \{0\}) \to H_n(\overline{\mathbb{B}}^n, \overline{\mathbb{B}}^n \setminus \{0\})).
\]

We leave it to the reader to verify that \( \deg(f, x) \) is well-defined.

![Diagram](image)

**Figure 1238**

Remark.

1. It is fairly straightforward to show that for \( M = N = S^n \) the above local degree agrees with the definition given on page 1191.

2. Let \( f : M \to N \) be a map between two oriented \( n \)-dimensional topological manifolds. Let \( x \in M \setminus \partial M \) be a point such that \( f \) is a local homeomorphism around \( x \). It follows easily from the definitions that

\[
\deg(f, x) = \begin{cases} 
+1, & \text{if } f \text{ is orientation-preserving at } x \\
-1, & \text{if } f \text{ is orientation-reversing at } x.
\end{cases}
\]

It follows from the above remark that the following proposition is a generalization of Propositions 45.23 and 69.7.

**Proposition 87.32.** Let \( f : M \to N \) be a map between two closed oriented connected \( n \)-dimensional topological manifolds \( M \) and \( N \) and let \( x \in M \). Let \( y \in N \) such that \( f^{-1}(\{y\}) \) consists of finitely many points \( x_1, \ldots, x_m \). Then

\[
\deg(f : M \to N) = \sum_{i=1}^{m} \deg(f, x_i).
\]

Proof of Proposition 87.32. The proof of the proposition is similar to the proofs of Propositions 45.23 and 69.7. Thus, in a vein attempt to keep these notes concise, we will
not provide a proof. Instead we hope that the reader will take the baton and carry out the proof.

87.9. **Applications.** The results from this chapter makes it possible to read several sections which are placed in the part on simplicial complexes. For example, with the results from this chapter one can now read the following sections:

1. Section 66.3 in which we calculate the homology groups of lens spaces.
2. Section 66.4 in which we construct the Poincaré Homology Sphere.
3. Section 68.5 in which we calculate the homology groups of the connected sum of two closed oriented smooth manifolds.
4. Section 68.6 in which we calculate the homology groups of a knot complement.

Furthermore, using Lemma 87.6 and a little bit of mental agility one can also read Chapter 69, where we introduce and study the degree of a map between closed oriented connected non-empty smooth manifolds. Finally, Chapter 70 in which we discuss the question, which homology classes can be represented by (sub-) manifolds, is now also accessible to the reader.

---

**Exercises for Chapter 87**

**Exercise 87.1.** Let $M$ be a connected $n$-dimensional topological manifold without boundary and let $K$ be a compact subset. Show that there exists an open subset $U \subset M$ that contains $K$ and such that the closure $\overline{U}$ is compact.

**Exercise 87.2.** Let $M$ be a closed orientable connected non-empty topological manifold of dimension $n \geq 3$. Now we know that $H_n(M; \mathbb{Z}) \cong \mathbb{Z}$ and that $H_{n-1}(M; \mathbb{Z})$ is torsion-free. Furthermore we know that $H_0(M; \mathbb{Z}) \cong \mathbb{Z}$. Can we also say something about the other homology groups? More precisely, are there any restrictions on $H_{n-2}(M; \mathbb{Z})$ or can any finitely generated abelian group be isomorphic to $H_{n-2}(M; \mathbb{Z})$ for some such smooth manifold?

**Exercise 87.3.**

(a) Let $M$ be a compact, connected $n$-dimensional topological manifold with non-empty boundary. Show that $H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k$ for some $k \in \mathbb{N}_0$.

*Hint.* You can use that we already obtained some results for closed smooth manifolds, in particular we have a good understanding of $H_{n-1}(D^n; \mathbb{Z})$. You could start with the case that $M$ is orientable and afterwards you could consider the case that $M$ is non-orientable.

(b) Let $M$ be a connected $n$-dimensional topological manifold. Suppose that $M$ is non-compact. Does it follow that $H_{n-1}(M; \mathbb{Z})$ is a free abelian group? It suffices to give a short justification for your answer.

**Exercise 87.4.** Let $X = S^1 \cup \{*\}$ be the topological space that is given by the circle “with two 1’s”, where the topology is defined in the same way as we defined the topology on the “line with two 0’s” on page 95. It is straightforward to see that $X$ is locally homeomorphic to open subsets of $\mathbb{R}$, in fact one can easily find a finite atlas for $X$. Furthermore we
87. THE FUNDAMENTAL CLASS OF TOPOLOGICAL MANIFOLDS

know by Lemma 6.1 (4) that $X$ is second-countable. But $X$ is not a topological manifold since it is not Hausdorff. The argument of Exercise 46.5 shows that $H_1(X; \mathbb{F}_2) \cong \mathbb{F}_2^2$. This shows that in the proof of Theorem 87.2 at some point we must have used that topological manifolds are Hausdorff. Where did we make use of this fact?

Exercise 87.5. Let $X$ be a topological space, let $n \in \mathbb{N}_0$ and let $G$ be an abelian group.

1. A locally finite singular $n$-chain is a (possibly infinite) sum $\sum_{i \in I} a_i \cdot (\sigma_i : \Delta^n \to X)$ with $a_i \in \mathbb{Z}$, such that for every $x \in X$ there exists an open neighborhood $U$ of $x$ such that $\{i \in I | \sigma_i (\Delta^n) \cap U \neq \emptyset \}$ is finite. We define $C_{\text{lf}}^n(X)$ as the abelian group given by all locally finite singular $n$-chains. Note that the usual boundary map defines in an obvious way a boundary map $C_{\text{lf}}^n(X) \otimes G \to C_{\text{lf}}^{n-1}(X) \otimes G$. We define the $n$-th locally finite homology group $H_{\text{lf}}^n(X; G)$ to be the $n$-th homology of the corresponding chain complex.

2. We consider the set $K(X)$ of all compact subsets of $X$. The set $K(X)$ together with the relation “$\subset$” defined by inclusion is a directed set since the union of two compact subsets is again compact. Given any two compact subsets $K \subset L$ we get an induced map $H_n(X, X \setminus L; G) \to H_n(X, X \setminus K; G)$. These homology groups form an inverse system over the directed set $(K(X), \subset)$ and we can form the inverse limit

$$\hat{H}_n(X; G) := \lim_{\leftarrow} H_n(X, X \setminus K; G).$$

In the following we will see that these two types of homology groups are often naturally isomorphic.

(a) Let TopPropMap be the category of topological spaces with proper maps, i.e. the objects are all topological spaces and the morphisms are proper continuous maps, i.e. maps such that preimage of compact sets are compact. Show that both homology groups define a covariant functor from TopPropMap to the category $\text{AbGr}$ of abelian groups.

(b) Give an explicit natural map $H_{\text{lf}}^n(X; G) \to \hat{H}_n(X; G)$ which is the identity for all compact topological spaces.

(c) We assume that there exists a nested sequence $K_1 \subset K_2 \subset \ldots$ of compact subsets of $X$ such that $X = \bigcup_{i \in \mathbb{N}} K_n$. Show that the natural map $H_{\text{lf}}^n(X; G) \to \hat{H}_n(X; G)$ from (b) is an isomorphism.

(d) Let $k \in \mathbb{N}$. Compute $H_{\text{lf}}^n(\mathbb{R}^k; \mathbb{Z})$.

Remark. Locally finite homology is discussed in detail in [HR96, p. 30-34] and [Spa93]. Note that statement (c) is [Spa93, Theorem 10.1], also see [HR96, p 34] for a related result. For completeness sake we note that it follows with some effort from [Bre97, Corollary V.12.21 and pages 288-292] that for suitable topological spaces these two homology groups are naturally isomorphic to Borel-Moore homology.

\[\text{To the best of my knowledge there is no established name for this natural object.}\]
Exercise 87.6. Let $M$ be a connected $n$-dimensional topological manifold with $\partial M = \emptyset$, let $K \subset M$ be a compact subset and let $x_0 \in K$ be a point.

(a) Show that there exists a connected compact subset $L \subset M$ with $K \subset L$.

(b) Show that the map

$$\text{Im}(H_n(M, M \setminus L; \mathbb{Z}) \to H_n(M, M \setminus K; \mathbb{Z})) \to H_n(M, M \setminus \{x_0\}; \mathbb{Z})$$

$$[\sigma] \mapsto [\sigma]$$

is an isomorphism.

*Hint.* Use Corollary 87.11.

Exercise 87.7. Let $M$ be a connected orientable non-empty $n$-dimensional topological manifold such that $\partial M = \emptyset$. As in the above Exercise 87.5 we now consider the group $\bar{H}_n(M; \mathbb{Z}) := \lim_{K \in \mathcal{K}(M)} H_n(M, M \setminus K; \mathbb{Z})$. Show that in our situation this group is naturally isomorphic to $\mathbb{Z}$. We refer to the corresponding natural generator as the fundamental class $[M] \in \bar{H}_n(M; \mathbb{Z})$.

*Hint.* Use Exercise 87.6.
88. The Topological Poincaré Duality Theorem

In Chapter 71 we stated and proved the Simplicial Poincaré Duality Theorem 71.4 and we saw that it gives rise to the Poincaré Duality Theorem 71.5 for closed smooth manifolds. As discussed on page 1783 that approach has its limitations. We will rectify this by proving in this chapter the Poincaré Duality Theorem 88.1 which in particular has the advantage that it also applies to topological manifolds.

88.1. The Poincaré Duality Theorem. The following theorem is by far the most important theorem regarding homology and cohomology groups of topological manifolds.

**Theorem 88.1. (Poincaré Duality Theorem)** Let $M$ be a compact, non-empty $n$-dimensional topological manifold and let $R$ be a commutative ring. We suppose that $M$ is $R$-oriented. We denote by $[M] \in H_n(M, \partial M; R)$ the $R$-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map $^\cong \sigma \mapsto \sigma \cap [M]$

$$H^k(M, A; R) \xrightarrow{\cong} H_{n-k}(M, B; R)$$

is an isomorphism.

![2-dimensional topological manifold M](image)

for all commutative rings $R$ we have

$$H^k(M, A; R) \xrightarrow{\cong} H_{2-k}(M, B; R)$$

**Figure 1240. Illustration of the Poincaré Duality Theorem 88.1**

We proceed as follows: in this section and the next section we discuss several special cases and applications of the Poincaré Duality Theorem 88.1. In the final two sections of the chapter we will then provide a rigorous, but arguably less intuitive proof, of the theorem. In the coming chapters we will then use the Poincaré Duality Theorem 88.1 to prove many more statements.

**Notation.** The isomorphism of the Poincaré Duality Theorem 88.1 is called the Poincaré Duality isomorphism. We denote it and its inverse both by $\text{PD}_M$, i.e. with the notation of

---

Recall that Proposition 74.12 (5) implies that $(M, A, B)$ is an excisive triad. In particular, following the definition of the relative cap product on page 2029 we obtain a relative cap product

$$H^k(M, A; R) \times H_n(M, A \cup B; R) \xrightarrow{\cap [M]} H_{n-k}(X, B; R).$$

This shows that the map in the Poincaré Duality Theorem is in fact defined.
the Poincaré Duality Theorem \[88.1\] we have the isomorphism\[\tag{1260}\]
\[\text{PD}_M \colon H^k(M, A; R) \xrightarrow{\cong} H_{n-k}(M, B; R)\]
together with the inverse
\[\text{PD}_M \colon H_{n-k}(M, B; R) \xrightarrow{\cong} H^k(M, A; R).\]
The isomorphisms \(\text{PD}_M\) thus allow us to go back and forth between homology and cohomology of an \(R\)-oriented topological manifold.

**Remark.** Let \(M\) be a compact \(n\)-dimensional topological manifold.

1. Proposition \[86.13\] says that \(M\) is \(\mathbb{F}_2\)-orientable, i.e. the duality statement holds with \(\mathbb{F}_2\)-coefficients without any further assumptions on \(M\).
2. If \(M\) is in fact orientable, then it follows from Lemma \[86.14\] that \(M\) is \(R\)-orientable for any commutative ring \(R\). In particular the duality statement holds for any commutative ring.
3. The two most important instances of \(A\) and \(B\) are that we have either \(A = \emptyset\) or \(A = \partial M\). Under the hypothesis of the Poincaré Duality Theorem \[88.1\] we then get
   \[H^k(M; R) \xrightarrow{\cong} H_{n-k}(M, \partial M; R)\]
   \(\sigma \mapsto \sigma \cap [M]\)
   and
   \[H^k(M, \partial M; R) \xrightarrow{\cong} H_{n-k}(M; R)\]
   \(\sigma \mapsto \sigma \cap [M]\).
4. For topological manifolds with non-empty boundary the Poincaré Duality Theorem is sometimes also called the *Poincaré-Lefschetz Duality Theorem*.

**Examples.**

1. Let \(P\) be a point in \(M\) and suppose that \(M\) is connected. As we pointed out on page \[2026\] we have \([M]^* \cap [M] = [P] \in H_0(M; \mathbb{Z})\). Therefore we obtain that \(\text{PD}_M([P]) = [M]^*\).
2. Earlier we had already performed several explicit calculations which can be viewed as special case of the Poincaré Duality Theorem \[88.1\]
   (a) On page \[2023\] we saw explicitly that for any surface \(\Sigma\) the map
   \[- \cap [\Sigma] : H^1(\Sigma; \mathbb{Z}) \to H_1(\Sigma; \mathbb{Z})\]
   is an isomorphism. On page \[2024\] we had obtained similar results for \(\mathbb{R}\mathbb{P}^2\) with \(\mathbb{F}_2\)-coefficients.
   (b) On page \[2027\] we saw explicitly that for the annulus \(X = S^1 \times [0, 1]\) the map
   \[- \cap [X] : H^1(X; \mathbb{Z}) \to H_1(X, \partial X; \mathbb{Z})\]
   is an isomorphism.

When \(M\) is understood, then we drop it from the notation.
It is instructive to consider the case $k = 0$ of the Poincaré Duality Theorem \[88.1\]. We obtain for a compact connected non-empty $n$-dimensional topological manifold that

$$H_n(M, \partial M; \mathbb{Z}) \cong H^0(M; \mathbb{Z}) \cong \mathbb{Z} \quad \text{and} \quad H_n(M; \mathbb{Z}) \cong H^0(M, \partial M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } \partial M = \emptyset, \\ 0, & \text{if } \partial M \neq \emptyset. \end{cases}$$

This calculation is consistent with the results from Theorem \[87.1\] and Theorem \[87.3\].

We formulate our last example as a proposition.

**Proposition 88.2.** Let $M$ and $N$ be two compact oriented connected topological manifolds. Furthermore, let $x_0 \in M$ and $y_0 \in N$.

(a) We denote by $p : M \times N \to M$ and $q : M \times N \to N$ the obvious projections.

(b) We denote by $i : M \to M \times N$ and $j : N \to M \times N$ the obvious inclusions.

(c) We equip $M \times N$ with the product orientation introduced in Proposition \[80.10\].

(d) We work with the decomposition $\partial (M \times N) = (\partial M \times N) \cup (M \times \partial N)$.

(e) We write $m = \dim(M)$ and $n = \dim(N)$.

The following equalities hold:

$$PD_{M \times N}(i_*(\llbracket M \rrbracket)) = (\pm 1)^m \cdot q^*(\llbracket N \rrbracket^*) \in H^m(M \times N, M \times \partial N; \mathbb{Z})$$

$$PD_{M \times N}(j_*(\llbracket N \rrbracket)) = p^*(\llbracket M \rrbracket^*) \in H^n(M \times N, M \times \partial N; \mathbb{Z})$$

$$PD_{M \times N}(i_*(\llbracket M \rrbracket)) \cup PD_{M \times N}(j_*(\llbracket N \rrbracket)) = [M \times N]^* \in H^{m+n}(M \times N, \partial (M \times N); \mathbb{Z}).$$

**Proof.** By Proposition \[84.2\](2) we have

$$p^*(\llbracket M \rrbracket^*) \cap [M \times N] = i_*(\llbracket M \rrbracket) \quad \text{and} \quad q^*(\llbracket N \rrbracket^*) \cap [M \times N] = (\pm 1)^m \cdot j_*(\llbracket N \rrbracket).$$

The first two equalities follow from these two calculations and the definition of the Poincaré Duality isomorphisms. The third equality is verified in the following little calculation:

by the first two equalities

$$PD_{M \times N}(i_*(\llbracket M \rrbracket)) \cup PD_{M \times N}(j_*(\llbracket N \rrbracket)) = (\pm 1)^m \cdot q^*(\llbracket N \rrbracket^*) \cup p^*(\llbracket M \rrbracket^*)$$

$$= (\pm 1)^m \cdot (\pm 1)^m \cdot p^*(\llbracket M \rrbracket^*) \cup q^*(\llbracket N \rrbracket^*) = [M \times N]^*.$$
there exists an isomorphism\footnote{It is worth stressing that this isomorphism is not natural.}

\[ H_{n-k}(M, A; \mathbb{Z}) \cong FH_k(M, B; \mathbb{Z}) \oplus \text{Tor}(H_{k-1}(M, B; \mathbb{Z})). \]

given an abelian group \( G \) we denote by \( \text{Tor}(G) \) its torsion-subgroup and we denote by \( F_G := G/\text{Tor}(G) \) the maximal torsion-free quotient

**Proof.** We have the following isomorphisms

\[
\begin{align*}
H_{n-k}(M, A; \mathbb{Z}) & \cong H^k(M, B; \mathbb{Z}) \\
& \cong \text{Hom}(H_1(M, B; \mathbb{Z}), \mathbb{Z}) \oplus \text{Ext}(H_{k-1}(M, B; \mathbb{Z}), \mathbb{Z}) \\
& \cong FH_k(M, B; \mathbb{Z}) \oplus \text{Tor}(H_{k-1}(M, B; \mathbb{Z})).
\end{align*}
\]

follows from Lemma \footnote{It is worth stressing that this isomorphism is not natural.} \ref{lem:5.5} (5) and the fact that by Lemma \ref{lem:64.7} together with Proposition \ref{prop:85.13} (4) we know that the homology groups \( H_i(M, B; \mathbb{Z}) \) are finitely generated abelian groups ■

**Example.** Let \( p, q \in \mathbb{N} \) be coprime. In this example we consider the corresponding lens space \( L(p, q) = S^3/\mathbb{Z}_p \) as defined and discussed on page \ref{p:502}. Note that \( L(p, q) \) is a closed orientable 3-dimensional smooth manifold. In Lemma \ref{lem:66.9} we computed the following homology groups:

\[
\begin{align*}
H_3(L(p, q); \mathbb{Z}) & \cong \mathbb{Z} \\
H_2(L(p, q); \mathbb{Z}) & \cong 0 \\
H_1(L(p, q); \mathbb{Z}) & \cong \mathbb{Z}_p \\
H_0(L(p, q); \mathbb{Z}) & \cong \mathbb{Z}.
\end{align*}
\]

Fortunately this data is indeed consistent with Proposition \ref{prop:88.3}.

The following straightforward corollary to the previous proposition gives in particular a new proof to Theorem \ref{thm:66.6} (2) and Proposition \ref{prop:87.22}.

**Corollary 88.4.** Let \( M \) be a compact orientable \( n \)-dimensional topological manifold and suppose that we are given a decomposition \( \partial M = A \cup B \) where \( A \) and \( B \) are compact \( (n-1) \)-dimensional submanifolds of \( \partial M \) such that \( A \cap B = \partial A = \partial B \). Then the homology groups \( H_{n-1}(M, A; \mathbb{Z}) \) and \( H_{n-1}(M, B; \mathbb{Z}) \) are free abelian groups.

**Proof.** We have

\[
\begin{align*}
H_{n-1}(M, A; \mathbb{Z}) & \cong FH_1(M, B) \oplus \text{Ext}(H_0(M, B; \mathbb{Z}), \mathbb{Z}) \\
& \cong \text{free abelian group} \oplus \text{free abelian group} \\
& = 0 \text{ by Lemma } \ref{lem:5.5}. & \text{free abelian group}
\end{align*}
\]

Let \( X \) be a topological space \( X \) and let \( n \in \mathbb{N}_0 \). Recall that on page \ref{p:1366} we defined the \( n \)-th Betti number of \( X \) as \( b_n(X) := \text{rank}(H_n(X)) \). With this definition we have the following immediate corollary to Proposition \ref{prop:88.3}.

**Corollary 88.5.** Let \( M \) be a closed orientable \( n \)-dimensional topological manifold. Given any \( k \in \mathbb{N}_0 \) we have \( b_{n-k}(M) = b_k(M) \).
Remark. Henri Poincaré [Poi1895, Poi2010, PGL53, Chapter 9], formulated the conclusion of Corollary 88.5 in a distinctly more elegant way: in his seminal paper “analysis situs”, published in 1895, he wrote

“[…] pour une variété fermé les nombres de Betti également distants des extrêmes sont égaux”.

In fact when Henri Poincaré first developed what became known as Poincaré Duality he thought that for any closed orientable connected $n$-dimensional smooth manifold the groups $H_k(M;\mathbb{Z})$ and $H_{n-k}(M;\mathbb{Z})$ are isomorphic. A Danish mathematician, Poul Heegaard [Hee1898], pointed out to him that this is not true in general, for example as we just saw, for the lens space $L(p,q)$ we have by Lemma 66.9 that $H_1(L(p,q);\mathbb{Z}) \cong \mathbb{Z}_p$ but $H_2(L(p,q);\mathbb{Z}) = 0$. Shortly afterwards Henri Poincaré [Poi1900] came up with the correct formulation of Poincaré Duality, namely the one given in Proposition 88.3.

Next let us consider (co-) homology groups with field coefficients. In this context we have the following almost immediate consequence of the Poincaré Duality Theorem 88.1.

**Theorem 88.6.** Let $M$ be a compact $n$-dimensional topological manifold and let $k \in \mathbb{N}_0$.

1. We have

$$\dim_{\mathbb{F}_2}(H_k(M;\mathbb{F}_2)) = \dim_{\mathbb{F}_2}(H_{n-k}(M,\partial M;\mathbb{F}_2))$$

and

$$\dim_{\mathbb{F}_2}(H^k(M;\mathbb{F}_2)) = \dim_{\mathbb{F}_2}(H^{n-k}(M,\partial M;\mathbb{F}_2)).$$

2. If $M$ is orientable, then for any field $\mathbb{F}$ we have

$$\dim_{\mathbb{F}}(H_k(M;\mathbb{F})) = \dim_{\mathbb{F}}(H_{n-k}(M,\partial M;\mathbb{F}))$$

and

$$\dim_{\mathbb{F}}(H^k(M;\mathbb{F})) = \dim_{\mathbb{F}}(H^{n-k}(M,\partial M;\mathbb{F})).$$

**Proof.** Let $M$ be a compact $n$-dimensional topological manifold. We have

$$\dim_{\mathbb{F}_2}(H_k(M;\mathbb{F}_2)) = \dim_{\mathbb{F}_2}(H_{n-k}(M,\partial M;\mathbb{F}_2)) = \dim_{\mathbb{F}_2}(\text{Hom}(H_{n-k}(M,\partial M;\mathbb{F}_2),\mathbb{F}_2))$$

$$\uparrow$$

Theorem 88.1

$$\uparrow$$

Proposition 75.19

$$= \dim_{\mathbb{F}_2}(H_{n-k}(M,\partial M;\mathbb{F}_2)).$$

since Propositions 85.13 (4) and 44.2 (3) and (4) together with Lemma 64.7 imply that $H_{n-k}(M,\partial M;\mathbb{F}_2)$ is finite-dimensional

The proofs of all other statements are basically the same. ■

**Example.** We consider the real projective space $\mathbb{R}P^n$. On page 1420 we had determined that

$$H_k(\mathbb{R}P^n;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0,\ldots,n, \\ 0, & \text{otherwise}. \end{cases}$$

So the homology groups with $\mathbb{F}_2$-coefficients are in particular symmetric, which is exactly what the above Poincaré Duality Theorem 88.6 with $\mathbb{F}_2$-coefficients predicts.

---

The statement implies of course that $H^k(M;\mathbb{F})$ and $H^{n-k}(M,\partial M;\mathbb{F})$ are isomorphic. We prefer to state the result in terms of dimensions to stress that the isomorphism is not natural.
Remark. Let $M$ be a compact $n$-dimensional topological manifold and let $\mathbb{F}$ be a field. In Proposition 85.13 (4) we had mentioned that all homology groups $H_k(M; \mathbb{F})$ are finite-dimensional. But this proof relied on the slightly mysterious Theorem 85.12. Now we can give an alternative argument if $M$ is closed and orientable. Indeed, we have

$$H_k(M; \mathbb{F}) \cong H^{n-k}(M; \mathbb{F}) \cong H_{n-k}(M; \mathbb{F})^* \cong H^k(M; \mathbb{F})^* \cong (H_k(M; \mathbb{F}))^*.$$  

(Here, as always given an $\mathbb{F}$-vector space $V$ we denote by $V^* = \text{Hom}_\mathbb{F}(V, \mathbb{F})$ its dual vector space.) But by [Jacb53] p. 244-248 (see also [DF04] Chapter 11.4) a vector space $V$ is isomorphic to its double dual $(V^*)^*$ if and only if the vector space is finite-dimensional.

Using Theorem 88.6 we obtain the following pretty proposition.

**Proposition 88.7.** For every compact odd-dimensional topological manifold $M$ we have

$$\chi(M) = \frac{1}{2}\chi(\partial M).$$

In particular if $M$ is closed, then $\chi(M) = 0$.

**Remark.** In Corollary 106.5 we will use handle decompositions to give an alternative proof of Proposition 88.7 in the setting of closed smooth manifolds.

**Proof.** Let $M$ be a compact topological manifold of dimension $2n + 1$. Then

$$\chi(M) = \sum_{i=0}^{2n+1} (-1)^i \cdot \dim_{\mathbb{F}_2}(H_i(M; \mathbb{F}_2))$$

by Proposition 85.34 (4) and Theorem 88.6

$$= -\sum_{j=0}^{2n+1} (-1)^j \cdot \dim_{\mathbb{F}_2}(H_j(M, \partial M; \mathbb{F}_2))$$

follows from the substitution $j = 2n + 1 - i$ and Proposition 85.34 (4) together with the fact that $(-1)^{2n+1} = -1$

Summarizing we have shown that $\chi(M) = -\chi(M) + \chi(\partial M)$. The desired equality follows from solving for $\chi(M)$.  

Proposition 88.7 raises the following question: what can we say about Euler characteristics of closed even-dimensional topological manifolds. By the classification of closed oriented connected 2-dimensional topological manifolds, see the Surface Classification Theorem 23.4 we know that the Euler characteristic of such a topological manifold is even. In higher dimensions there is evidently much more freedom for constructing topological manifolds.

**Question 88.8.** Let $n \geq 4$ be even. Is every integer the Euler characteristic of a closed orientable connected $n$-dimensional topological manifold?

Using Proposition 88.7 we easily obtain the following surprising (?) corollary.

**Corollary 88.9.** The 2-dimensional topological manifold $\mathbb{R}P^2$ is not the boundary of a compact 3-dimensional topological manifold.
88. THE TOPOLOGICAL POINCARÉ DUALITY THEOREM

Proof. Suppose there was a compact 3-dimensional topological manifold \( M \) with \( \partial M = \mathbb{R}P^2 \). We would obtain that
\[
\chi(M) = \frac{1}{2} \chi(\partial M) = \frac{1}{2} \chi(\mathbb{R}P^2) = \frac{1}{2}.
\]

But the Euler characteristic of a compact topological manifold is by definition an integer.

Remark. In Exercise 88.5 we will study the question, whether the Klein bottle is the boundary of a compact 3-dimensional topological manifold \( M \). It follows from the CW-structure on page 934 that the Euler characteristic of the Klein bottle \( K \) is zero, therefore Proposition 88.7 does not obstruct the existence of such an \( M \).

Clearly non-orientable topological manifolds exhibit some unusual behavior. So the following question arises.

**Question 88.10. Is every closed orientable topological manifold the boundary of a compact topological manifold?**

Note that in Corollary 17.4 we showed that if \( N \) is a non-orientable topological manifold, then \( \pi_1(N) \) admits an epimorphism onto \( \mathbb{Z}_2 \). It follows from the Hurewicz Theorem 52.5 that there exists also an epimorphism \( H_1(N;\mathbb{Z}) \rightarrow \mathbb{Z}_2 \). For closed 3-dimensional topological manifolds the following Lemma 88.11 is thus a considerable strengthening of Corollary 17.4.

**Lemma 88.11.** Let \( M \) be a connected closed 3-dimensional topological manifold. If \( M \) is non-orientable, then \( H_1(M;\mathbb{Z}) \) is infinite.

Proof. Let \( M \) be a connected closed 3-dimensional topological manifold. We have
\[
0 = \chi(M) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot b_n(M) = b_0(M) - b_1(M) + b_2(M) = 1 - b_1(M) + b_2(M).\]
This equality can only hold if \( b_1(M) > 0 \), i.e. if \( H_1(M;\mathbb{Z}) \) is infinite.

**Definition.** Let \( f : M \rightarrow N \) be a map between closed, oriented connected non-empty \( n \)-dimensional topological manifolds. We consider the following diagram of maps:
\[
\begin{array}{ccc}
H_k(M;\mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{n-k}(M;\mathbb{Z}) \\
\cap [M] & \searrow \downarrow f^* & \searrow \downarrow f^* \\
H_k(N;\mathbb{Z}) & \xleftarrow{\text{PD}_N} & H^{n-k}(N;\mathbb{Z})
\end{array}
\]

We refer to\footnote{If in the proof of Corollary 17.4 we replace Proposition 17.3 by Proposition 86.15 we see that the statement also holds for non-orientable topological manifolds.} **f**: \( H_k(N;\mathbb{Z}) \rightarrow H_k(M;\mathbb{Z}) \) and \( \sigma \mapsto f^*(\text{PD}_N(\sigma)) \cap [M] \).
as the Umkehr map of $f$.

The following lemma shows that in some circumstances the Umkehr map is just the transfer map that we introduced on page 1445.

**Lemma 88.12.** Let $p: \tilde{N} \to N$ be a finite cover of a closed, oriented, non-empty $n$-dimensional topological manifold. If we equip $\tilde{N}$ with the orientation given by Lemma 86.17 (3), then for any $k \in \mathbb{N}_0$ the Umkehr map $p^*: H_k(N; \mathbb{Z}) \to H_k(\tilde{N}; \mathbb{Z})$ equals the transfer map $p^*$.

**Proof.** We start our proof with the following claim.

**Claim.** Let $r \leq s$. Given any singular simplex $\sigma: \Delta^s \to N$ and any cochain $\phi \in C^r(N; \mathbb{Z})$ we have

$$p^*(\phi) \cap p^*(\sigma) = p^*(\phi \cap \sigma).$$

We write $m = [\tilde{N} : N]$. We denote by $\tilde{\sigma}_1, \ldots, \tilde{\sigma}_m$ the lifts of $\sigma$. Then

$$p^*(\phi) \cap p^*(\sigma) = p^*(\phi) \cap \sum_{i=1}^m \tilde{\sigma}_i = \sum_{i=1}^m p^*(\phi)(\tilde{\sigma}_i \circ [v_0, \ldots, v_r]) \cdot \tilde{\sigma}_i \circ [v_r, \ldots, v_s]$$

$$= \sum_{i=1}^m \phi((p_* \circ \sigma) \circ [v_0, \ldots, v_r]) \cdot \sigma \circ [v_r, \ldots, v_s]$$

$$= p^*(\phi(\sigma \circ [v_0, \ldots, v_r]) \cdot \sigma \circ [v_r, \ldots, v_s]) = p^*(\phi \cap \sigma)$$

since $p_* \circ \sigma = \sigma$ and since $\tilde{\sigma}_i \circ [v_0, \ldots, v_r]$, $i = 1, \ldots, m$ are the lifts of $\sigma \circ [v_0, \ldots, v_r]$.

Now we turn to the actual proof of the lemma. We pick an $n$-cycle $\tau$ that is a representative for the fundamental class $[N] \in H_n(N; \mathbb{Z})$ of $N$. By Proposition 87.25 we know that $p^*(\tau)$ represents the fundamental class of $\tilde{N}$. By definition of the Umkehr map it suffices to prove the following claim.

**Claim.** For any cocycle $\phi \in C^r(N; \mathbb{Z})$ we have

$$f^*(\phi) \cap p^*(\tau) = p^*(\phi \cap \tau).$$

The claim is an immediate consequence of the first claim. □

We continue with the following useful and typical application of the Poincaré Duality Theorem 88.1.

**Proposition 88.13.** Let $n \geq 2$. Give a closed connected $n$-dimensional topological manifold $X$ the following statements are equivalent:

1. $X$ is $\lfloor \frac{n}{2} \rfloor$-connected,
2. $X$ is $(n - 1)$-connected,
3. $\pi_1(X)$ is trivial and $H_i(X; \mathbb{Z}) = 0$ for $i = 2, \ldots, n - 1$,
4. $\pi_1(X)$ is trivial and $H_i(X; \mathbb{Z}) = 0$ for $i = 2, \ldots, \lfloor \frac{n}{2} \rfloor$.

---

1264 This map is indeed called “Umkehr map” in English. The name stems from the fact that it is a map on homology that “goes the wrong way”.

1265 Wikipedia writes: “In category theory [...] certain unusual functors are denoted $f^!$ and $f_!$, with the exclamation mark used to indicate that they are exceptional in some way. They are thus accordingly sometimes called shriek maps, with ‘shriek’ being slang for an exclamation mark [...]”
Definition. A closed connected $n$-dimensional topological manifold $M$ that satisfies any of the four equivalent statements in Proposition 88.14 is called an homotopy $n$-sphere. If $M$ is actually a smooth manifold, then we refer to $M$ as a smooth homotopy $n$-sphere.

Remark. In Corollaries 111.15 and Proposition 88.14 we will give alternative characterizations of homotopy spheres.

Proof. We have (1) $\Rightarrow$ (4) by Corollary 53.7. We can easily show that (4) $\Rightarrow$ (3) by applying the Poincaré Duality Theorem 88.1 (here we use that $X$ is orientable by Corollary 86.16) and the Universal Coefficient Theorem 75.13 for Cohomology Groups. The conclusion (3) $\Rightarrow$ (2) is again Corollary 53.7 and finally (2) $\Rightarrow$ (1) is trivial.

Finally we want to study degree-one maps between topological manifolds. We recall that on page 1737 we defined the degree of a map $f : M \to N$ between closed, oriented connected non-empty $n$-dimensional topological manifolds to be the unique integer $\deg(f) \in \mathbb{Z}$ with $f_*(\mathbb{Z}) = \deg(f) \cdot \mathbb{Z}$. We had obtained the following results:

(1) In Proposition 69.3 we showed that for any closed oriented non-empty $n$-dimensional topological manifold $M$ there exists a degree-one map $M \to S^n$.

(2) In Proposition 69.9 we saw that if $\deg(f) = \pm 1$, then $f_* : \pi_1(M) \to \pi_1(N)$ is an epimorphism.

(3) In Lemma 84.5 we had used cup products to show that there does not exist a map $f : S^4 \to \mathbb{R}^2 \times S^2$ of non-zero degree.

Now we add the following proposition to our list on results on the non-existence of degree-one maps.

Proposition 88.14. Let $f : M \to N$ be a map between closed oriented non-empty $n$-dimensional topological manifolds. For every $k \in \mathbb{N}$ the following statements hold:

(1) The map $f_* \circ f^!$ is multiplication by $\deg(f)$.

(2) Suppose that $f$ is a map of degree $\pm 1$.

(a) The map $f^! : H_k(N; \mathbb{Z}) \to H_k(M; \mathbb{Z})$ splits.

(b) The image $f^!(H_k(N; \mathbb{Z}))$ is a subsummand of $H_k(M; \mathbb{Z})$, i.e. there exists a subgroup $Q$ of $H_k(M; \mathbb{Z})$ such that $H_k(M; \mathbb{Z}) = f^!(H_k(N; \mathbb{Z})) \oplus Q$.

(c) There exists an isomorphism $H_k(M; \mathbb{Z}) \cong H_k(N; \mathbb{Z}) \oplus Q$ for some finitely generated abelian group $Q$.

Proof. Let $f : M \to N$ be a between closed oriented non-empty $n$-dimensional topological manifolds. We write $d = \deg(f)$. Let $\sigma \in H_k(N; \mathbb{Z})$. We have

$$ (f_* \circ f^!)(\sigma) = f_*(f^*(PD_N(\sigma)) \cap [M]) = PD_N(\sigma) \cap f_*([M]) = d \cdot PD_N(\sigma) \cap [N] = d \cdot \sigma. $$

The second statement of the lemma follows from combining the first statement with the Splitting Lemma 46.2.

\[ \text{Note that the proof of (4) $\Rightarrow$ (3) is almost identical to the proof of Lemma 88.14.} \]

\[ \text{Basically the same proof, together with say Theorem 87.1 (4) and an excision argument, shows that the same statement also holds for topological manifolds. We leave it to the reader to fill in the details.} \]
It follows from remark (2) above that there is no degree-one map from $\mathbb{R}P^3$ to $S^1 \times S^2$. In Question 69.12 we had asked whether there exists a degree-one map from $S^1 \times S^2$ to $\mathbb{R}P^3$. Now we can give a negative answer.

**Corollary 88.15.** There is no degree-one map from $S^1 \times S^2$ to $\mathbb{R}P^3$.

**Proof.** The corollary follows immediately from Proposition 88.14 and the observation that the group $H_1(\mathbb{R}P^3; \mathbb{Z}) \cong \mathbb{Z}_2$ is not a subsummand of $H_1(S^1 \times S^2; \mathbb{Z}) \cong \mathbb{Z}$.

We conclude this long list of applications of the Poincaré Duality Theorem 88.1 with the following result.

**Corollary 88.16.** Let $n \in \mathbb{N}_{\geq 2}$ and let $M$ be a closed oriented connected $n$-dimensional topological manifold. If there exists a degree one map $f : S^n \to M$, then $M$ is a homotopy $n$-sphere.

**Proof.** Let $f : S^n \to M$ be a degree one map. Recall that by Proposition 69.9 we know that $f_* : \pi_1(S^n) \to \pi_1(M)$ is an epimorphism. Thus we see that $M$ is simply connected. Furthermore it follows from Proposition 88.14 that for $i = 2, \ldots, n - 1$ the homology group $H_i(M; \mathbb{Z})$ is isomorphic to a subgroup of $H_i(S^n; \mathbb{Z})$. Since the latter is zero we obtain from Proposition 88.13 that $M$ is indeed a homotopy sphere.

### 88.3. The proof of the Poincaré Duality Theorem 88.1 for topological manifolds without boundary.

In this section we will prove the Poincaré Duality Theorem 88.1 for closed topological manifolds. More precisely, we will prove the following theorem.

**Theorem 88.17.** Let $M$ be a closed, non-empty $n$-dimensional topological manifold and let $R$ be a commutative ring. We suppose that $M$ is $R$-oriented. We denote by $[M] \in H_n(M; R)$ the $R$-fundamental class. Then for each $k \in \mathbb{N}_0$ the map

$$
PD_M : H^k(M; R) \cong H_{n-k}(M; R)
$$

$$
\sigma \mapsto \sigma \cap [M]
$$

is an isomorphism.

In order to simplify the notation a little bit we will work throughout the section with $R = \mathbb{Z}$. The proof for other commutative rings is verbatim the same.

The key idea is somewhat similar to the strategy of the proof of Theorem 87.10. More precisely, using a Mayer–Vietoris argument and a limit argument we want to reduce the proof eventually to the fairly trivial case of an open ball in $\mathbb{R}^n$.

To carry out the above strategy we need a version of Poincaré Duality for every topological manifold (not necessarily compact) with empty boundary. Formulating this generalized Poincaré Duality Theorem requires some preparations. First we recall some definitions and results from earlier on:

1. Given a topological space $X$ we denote by $\mathcal{K}(X)$ the set of all compact subsets of $X$. Let $k \in \mathbb{N}_0$. By Proposition 77.4 we have an identification

$$
\lim_{\substack{\longrightarrow \; \kappa \in \mathcal{K}(X) \; \kappa \in \mathcal{K}(X)}} H^k(X, X \setminus K) = H^k_c(X).
$$
(2) Let $M$ be an $n$-dimensional topological manifold with empty boundary. If $M$ is equipped with an orientation $\{\mu_x\}_{x \in M}$, then we saw in Theorem 87.10 (i) that given any compact subset $K$ of $M$ there exists a unique class $\mu^M_K \in H_n(M, M \setminus K)$ such that for any $x \in K$ the image of $\mu^M_K$ under the map

$$H_n(M, M \setminus K) \to H_n(M, M \setminus \{x\})$$

equals the given orientation $\mu_x$ at $x$. If $M$ is understood, then we drop it from the notation, i.e. we just write $\mu_K$ instead of $\mu^M_K$.

**Lemma 88.18.** Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary.

1. Let $K \subset L \subset M$ be compact subsets. We denote by $f_{KL} : (M, M \setminus L) \to (M, M \setminus K)$ the inclusion map of pairs.
   - (a) The map $f_{KL}^* : H^k(M, M \setminus L) \to H^k(M, M \setminus K)$ sends $\mu_L$ to $\mu_K$.
   - (b) For any $k \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
H^k(M, M \setminus L) & \xrightarrow{\cap \mu_K} & H^k_{c}(M) \\
\downarrow f_{KL}^* & & \downarrow \mu_K \\
H^k(M, M \setminus K) & \xrightarrow{\cap \mu_L} & H^k_{c}(M) \\
\end{array}
$$

2. For any $k \in \mathbb{N}_0$ there exists a unique map

$$PD_M : H^k_c(M) \to H^k_{c}(M)$$

such that for each compact subset $K \subset M$ the following diagram commutes:

$$
\begin{array}{ccc}
H^k(M, M \setminus K) & \xrightarrow{\cap \mu_K} & H^k_{c}(M) \\
\downarrow & & \downarrow PD_M \\
H^k_{c}(M) & \xrightarrow{\cap \mu_K} & H^k_{c}(M) \\
\end{array}
$$

**Proof.** Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary.

1. (a) This is precisely Corollary 87.12 (1).
   - (b) Let $\varphi \in H^k_c(M, M \setminus K)$. We see that

$$\varphi \cap \mu_K = \varphi \cap f_{KL}^*(\mu_L) = f_{KL}^*(\varphi) \cap \mu_L.$$  

But this means precisely that the diagram under consideration commutes.

2. This statement follows immediately from (1b) and the universal property of the direct limit.

Throughout the remainder of this section we use the following notation.

---

Note that for a class $\varphi \in H^k_c(M, M \setminus K)$ and $\mu_K \in H_n(M, M \setminus K)$ the cap product $\varphi \cap \mu_K$ does indeed lie in $H_{n-k}(M)$. 

---
Notation. Let $k \in \mathbb{N}_0$ and let $X$ be a topological space.

(1) Given any subset $A$ of $X$ we denote by $i_* : H_k(A) \to H_k(X)$ and $i^* : H_k(X) \to H_k(A)$ the inclusion induced map.

(2) Suppose that $X$ is Hausdorff and that $U$ is an open subset of $X$. Then we denote by $i : H^k_c(U) \to H^k_c(X)$ the map defined by

$$H^k_c(U) = \lim_{K \in \mathcal{K}(U)} H^k(U, U \setminus K) \cong \lim_{K \in \mathcal{K}(U)} H^k(X, X \setminus K) \to \lim_{K \in \mathcal{K}(X)} H^k(X, X \setminus K) = H^k_c(X).$$

We refer to Lemma 77.5 for the proof that these inclusion maps are covariantly functorial with respect to compositions of inclusions.

We will prove the following generalization of Theorem 88.17. This more general version of Poincaré Duality will not only be useful for the divide-et-impera approach to the proof of Theorem 88.17, but it will also be of interest in its own right later on.

**Theorem 88.19.** Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary. Then for each $k \in \mathbb{N}_0$ the map

$$PD_M : H^k_c(M) \cong H_{n-k}(M)$$

from Lemma 88.18 is an isomorphism.

**Example.** Let $M$ be an oriented connected, non-empty $n$-dimensional topological manifold with empty boundary. Then

$$H_n(M; \mathbb{Z}) \cong H^0_c(M; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ is compact}, \\ 0, & \text{if } M \text{ is non-compact}. \end{cases}$$

This calculation is consistent with the results obtained in Theorems 87.1 and 87.3.

**Remark.**

(1) Let $M$ be an oriented connected, non-empty $n$-dimensional topological manifold with empty boundary. Following the convention introduced on page 2153 we denote the inverse of the isomorphism $PD_M : H^k_c(M) \cong H_{n-k}(M)$ also by $PD_M$.

(2) Given a possibly non-compact oriented topological manifold without boundary Theorem 88.19 allows us to relate singular homology to cohomology with compact support. There is also a different version of Poincaré Duality that relates singular cohomology to a different flavor of homology, namely Borel-Moore homology. We refer to [Greenb67], [Bre97] Chapter V.9 and [PS08] p. 332 for details.

As a warm up for the proof of Theorem 88.19 we will deal with the case $M = B^n$ by hand. More precisely, we will prove the following lemma.

---

\[^{1209}\text{Why is it a generalization of Theorem 88.17?}\]

\[^{1270}\text{We use the convention that any } n\text{-dimensional submanifold of } \mathbb{R}^n \text{ is equipped with the orientation induced from the standard orientation of } \mathbb{R}^n, \text{ see Lemma 86.17.}\]
Lemma 88.20. For each $k \in \mathbb{N}_0$ the map
\[ \text{PD}_{B^n} : H_c^k(B^n) \xrightarrow{\cong} H_{n-k}(B^n) \]
is an isomorphism.

Proof. Let $k \in \mathbb{N}_0$. Given any $s \in (0, 1)$ we write $\overline{B}^n_s := \{ x \in \mathbb{R}^n | ||x|| \leq s \}$ and we also write $S^{n-1}_s := \partial \overline{B}^n_s$. For the remainder of the proof we fix $0 < r < s < 1$. We denote by $i : (\overline{B}^n_s, S^n_s) \to (B^n, B^n \setminus \overline{B}^n_r)$ the inclusion map of pairs.

We consider the following diagram:

\[
\begin{array}{ccc}
H^k(\overline{B}^n_s, S^n_s) & \xleftarrow{i^*} & H^k(B^n, B^n \setminus \overline{B}^n_r) \\
\downarrow \cap [\overline{B}^n_s] & & \downarrow \cap [\mu_{\overline{B}^n_r}] \\
H_{n-k}(\overline{B}^n_s) & \xrightarrow{i_*} & H_{n-k}(B^n) \\
\downarrow \text{PD}_{B^n} & & \downarrow \text{PD}_{B^n}
\end{array}
\]

The lemma is an immediate consequence of the following claim.

Claim.

1. The diagram commutes,
2. the left vertical map is an isomorphism, and
3. all horizontal maps are isomorphisms.

We turn to the proof of the three statements.

1. The square on the right commutes by definition of $\text{PD}_{B^n}$. So it remains to show that the square on the left commutes. Thus let $\varphi \in H^k(B^n, B^n \setminus \overline{B}^n_r)$. We have
\[ i_* \left( i^* \varphi \cap [\overline{B}^n_s] \right) = \varphi \cap i_* ([\overline{B}^n_s]) = \varphi \cap \mu_{\overline{B}^n_r} \in H_{n-k}(B^n). \]

Lemma 83.8 since the images of $[\overline{B}^n_s]$ and $\mu_{\overline{B}^n_r}$ in $H_n(B^n, B^n \setminus \{0\})$ agree

2. We consider the left vertical map of the diagram. Clearly both groups are zero for $k \neq n$. Evidently a generator for $H^n(\overline{B}^n_s, S^n_s)$ is given by the dual fundamental class $[\overline{B}^n_s]^*$. Since $\overline{B}^n_s$ is path-connected we see, following the discussion on page 2026, that $[\overline{B}^n_s]^* \cap [\overline{B}^n_s] = \langle [\overline{B}^n_s]^*, [\overline{B}^n_s] \rangle = 1 \in H_0(\overline{B}^n_s) = \mathbb{Z}$. In particular the left vertical map is an isomorphism.

Figure 1241. Illustration for the proof of Lemma 88.20.
(3) It follows easily from Corollary 43.18 and Lemma 73.13 that the left horizontal maps are isomorphisms. It remains to show that the top right horizontal map is an isomorphism. We consider the following commutative diagram

$$
\begin{align*}
H^k(B^n, B^n \setminus B^n_r) & \xrightarrow{\lim_{K \in K(B^n)}} \lim_{k \in K(B^n)} H^k(B^n, B^n \setminus B^n_r) \\
\lim_{t \in (0,1)} H^k(B^n, B^n \setminus B^n_t) & \xrightarrow{\lim_{K \in K(B^n)}} H^k(B^n, B^n \setminus B^n_r)
\end{align*}
$$

We make the following two observations:

(a) Every compact subset of $B^n$ is contained in a closed ball $B^n_t$ with $t \in (0,1)$. Therefore it follows from Lemma 76.3 that the right diagonal map is an isomorphism.

(b) It follows easily from Lemmas 73.13 and 76.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.

In the proof of Theorem 88.19 we will need the following two lemmas.

**Lemma 88.21.** Let $M$ be a topological manifold and let $U, V$ be open subsets such that $M = U \cup V$. Then given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.

![Figure 1242. Illustration of Lemma 88.21](image)

**Proof.** Let $M$ be an $n$-dimensional topological manifold and let $U, V$ be open subsets with $M = U \cup V$. Furthermore let $C$ be a compact subset of $M$. Using charts one can easily show that given any point $x \in C$ there exists a compact set $A_x$ with the following properties:

1. the point $x$ lies in the interior of $A_x$,
2. if $x \in U$ then the set $A_x$ is contained in $U$,
3. if $x \in V$ then the set $A_x$ is contained in $V$.

It follows from (1), the fact that the sets $A_x$ cover all of $C$ together with the hypothesis that $C$ is compact that there exist finitely many $y_1, \ldots, y_r \in C$ with $C \subset \overset{\circ}{A}_{y_1} \cup \cdots \cup \overset{\circ}{A}_{y_r}$. One can now easily verify that $K := \bigcup_{y_i \in U \cap C} (A_{y_i} \cap C)$ and $L := \bigcup_{y_i \in V \setminus C} (A_{y_i} \cap C)$ have the desired properties.
Lemma 88.22. Let $M$ be a compact oriented $n$-dimensional topological manifold and let $U,V$ be open subsets such that $M = U \cup V$ and let $K \subset U$ and $L \subset V$ be compact subsets. Then there exist singular $n$-chains $\alpha_{U \setminus L}$, $\alpha_{U \cap V}$ and $\alpha_{V \setminus K}$ in $U \setminus L$, $U \cap V$ and $V \setminus K$ such that the following three equalities hold:

\begin{align*}
(a) \quad \mu^M_{K \cup L} &= [\alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K}] \quad \text{in } H_n(M, M \setminus (K \cup L)) \\
(b) \quad \mu^M_{K \cap V} &= [\alpha_{U \cap V}] \quad \text{in } H_n(U \cap V, U \cap V \setminus (K \cap L)) \\
(c) \quad \mu^U_K &= [\alpha_{U \setminus L} + \alpha_{U \cap V}] \quad \text{in } H_n(U, U \setminus K).
\end{align*}

\[\text{Figure 1243. Illustration of Lemma 88.22}\]

Proof. We pick a representative $\alpha \in C_n(M)$ for $\mu^M_{K \cup L}$. Note that the open sets $U \setminus L, U \cap V$ and $V \setminus K$ cover $M$. It follows from Lemmas 43.28 and 43.31 that there exist singular chains $\alpha_{U \setminus L}, \alpha_{U \cap V}$ and $\alpha_{V \setminus K}$ in $U \setminus L, U \cap V$ and $V \setminus K$ such that $\alpha$ is homologous in $C_k(M)$ to $\alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K}$. The chains are in particular homologous in $C_k(M, M \setminus (K \cup L))$ which implies that (a) holds.\[\text{\textsuperscript{1271}}\]

Next note that we have

$$\mu^M_{K \cap L} \overset{\uparrow}{=} \text{image of } \mu^M_{K \cup L} = [\alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K}] = [\alpha_{U \cap V}] \in H_n(M, M \setminus (K \cap L)).$$

Lemma 88.18 since $\alpha_{U \setminus L}, \alpha_{V \setminus K}$ lie in $C_n(M \setminus (K \cap L))$.

But $\alpha_{U \cap V}$ lies in $U \cap V$, therefore it follows from Corollary 87.12 (2) that $\mu^U_{K \cap V} = [\alpha_{U \cap V}]$ in $H_n(U \cap V, U \cap V \setminus (K \cap L))$. We have thus verified (b).

Finally the proof of equality (c) is basically the same as the proof of equality (b). \[\blacksquare\]

We recall the following notation and convention:

Convention. Let $X$ be a topological space, let $A$ be a subset and let $k \in \mathbb{N}_0$. As on page 2003 we make the identification

$$C^k(X, A) \xrightarrow{\sim} \text{all homomorphisms } C_k(X) \rightarrow \mathbb{Z} \text{ that vanish on } C_k(A).$$

Furthermore, given another subset $B$ of $X$ we write

$$C^k(X, \{A, B\}) := \text{all homomorphisms } C_k(X) \rightarrow \mathbb{Z} \text{ that vanish on } C_k(A) \text{ and on } C_k(B).$$

If $A$ and $B$ are open subsets of $X$ then we use the isomorphism

$$H^k(X, A \cup B) \xrightarrow{\sim} H^k(X, \{A, B\})$$

from Lemma 82.1 to identify the two groups.

\[\text{\textsuperscript{1271}}\text{Why is } \alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K} \text{ a cycle in } C_n(M, M \setminus (K \cup L))?\]
In the proof of Theorem 88.19 we will also need the following “inverted” Mayer–Vietoris Theorem, which is very similar to Theorem 46.7.

**Theorem 88.23.** (The inverted Mayer–Vietoris Theorem for Cohomology groups) Let $X$ be a topological space and let $A$ and $B$ be open subsets.

1. For every $n \in \mathbb{N}_0$ and every cochain $\varphi \in C^n(X, A \cup B)$ there exist $\varphi_A \in C^n(X, A)$ and $\varphi_B \in C^n(X, B)$ such that $\varphi_A + \varphi_B = \varphi$.
2. For all $n \in \mathbb{N}_0$ there exists a unique homomorphism $\delta: H^n(X, A \cap B) \to H^{n+1}(X, A \cup B)$ which has the following property: for every $\varphi_A \in C^n(X, A)$ and $\varphi_B \in C^n(X, B)$ such that $\varphi_A + \varphi_B$ is a cocycle in $C^n(X, A \cap B)$ we have $\delta([\varphi_A + \varphi_B]) = [\delta \varphi_A] = -[\delta \varphi_B] \in H^n(X, \{A, B\}) = H^n(X, A \cup B)$.
3. The sequence
   \[
   \ldots \to H^n(X, A \cup B) \xrightarrow{i^* \oplus -i^*} H^n(X, A) \oplus H^n(X, B) \xrightarrow{i^* \oplus i^*} H^n(X, A \cap B) \to \ldots
   \]
   is exact.

**Proof.** We start out with the following two observations:

1. It is straightforward to verify that the following sequence of cochain maps between cochain complexes is exact:
   \[
   0 \to C^\ast(X, \{A, B\}) \xrightarrow{i^* \oplus -i^*} C^\ast(X, A) \oplus C^\ast(X, B) \xrightarrow{i^* \oplus i^*} C^\ast(X, A \cap B) \to 0.
   \]
2. Since the subsets $A$ and $B$ are open we know from Proposition 74.12 (4) that the triad $(X, A, B)$ is excisive. Therefore it follows from Lemma 82.1 that the obvious map $C^\ast(X, A \cup B) \to C^\ast(X, \{A, B\})$ induces for every $n \in \mathbb{N}_0$ an isomorphism $H^n(X, A \cup B) \xrightarrow{\cong} H^n(X, \{A, B\})$.

With these two observations it is straightforward to modify the proof of Theorem 46.7 to obtain the theorem. We leave it to the reader to fill in the details. \(\blacksquare\)

**Lemma 88.24.** Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary that is the union of two open sets $U$ and $V$. Then there exists a diagram

\[
\begin{array}{ccccccc}
\ldots & \to & \mathrm{H}_k^c(U \cap V) & \xrightarrow{i^* \oplus -i^*} & \mathrm{H}_k^c(U) \oplus \mathrm{H}_k^c(V) & \xrightarrow{i^* + i^*} & \mathrm{H}_k^c(M) & \xrightarrow{i^*} & \mathrm{H}_{k+1}^c(U \cap V) & \to & \ldots \\
\mid_{\mathrm{PD}_{U \cap V}} & & \mid_{\mathrm{PD}_U \oplus \mathrm{PD}_V} & & \mid_{\mathrm{PD}_M} & & \mid_{\mathrm{PD}_{U \cap V}} \\
\ldots & \to & \mathrm{H}_n-k(U \cap V) & \xrightarrow{i^* \oplus -i^*} & \mathrm{H}_{n-k}(U) \oplus \mathrm{H}_{n-k}(V) & \xrightarrow{i^* + i^*} & \mathrm{H}_{n-k}(M) & \to & \mathrm{H}_{n-k-1}(U \cap V) & \to & \ldots
\end{array}
\]

with the following properties:

1. the first two squares commute, the third square commutes up to the sign $(-1)^{k+1}$,
2. the lower exact sequence is the long exact Mayer–Vietoris sequence for $M = U \cup V$,
3. the upper horizontal sequence is also exact.
Proof. Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary. Throughout the proof, given any two subsets $X \subset Y$ and $i \in \mathbb{N}_0$ we write as before $H^i(Y|X) := H^i(Y, Y \setminus X)$. We note that if $U$ is open and $K \subset U$ is compact we obtain a map

$$ - \cap \mu^U_K : H^k(U|K) \to H_{n-k}(U). $$

Now let let $U$ and $V$ be open subsets with $M = U \cup V$. Furthermore let $K \subset U$ and $L \subset V$ be compact subsets. We consider the following diagram

$$ \cdots \to H^k(M|K \cap L) \to H^k(M|K) \oplus H^k(M|L) \to H^k(M|K \cup L) \xrightarrow{\delta_k} H^{k+1}(M|K \cap L) \to \cdots $$

$$ \cong \downarrow \cong \quad \cong \downarrow \cong $$

$$ H^k(U \cap V|K \cap L) \quad H^k(U|K) \oplus H^k(V|L) \quad \cap \mu^U_{K,L} \quad \cong H^k(U \cap V|K \cap L) $$

$$ \cong \downarrow \cong \quad \cong \downarrow \cong $$

$$ \cdots \to H_{n-k}(U \cap V) \to H_{n-k}(U) \oplus H_{n-k}(V) \to H_{n-k}(M) \xrightarrow{\partial} H_{n-k-1}(U \cap V) \to \cdots $$

which we now explain in more detail:

(1) We write $A = M \setminus K$ and $B = M \setminus L$. The upper horizontal sequence is the inverted Mayer–Vietoris Sequence for cohomology groups from Theorem 88.23.

(2) The lower horizontal sequence is the Mayer–Vietoris sequence coming from Theorem 46.5, corresponding to the decomposition $M = U \cup V$.

(3) The three vertical maps on the top are induced by inclusions of pairs of topological spaces, they are isomorphisms by the Excision Theorem 43.20 (2).

The following is the key claim of the proof.

Claim. The first two rectangles commute and the third rectangle commutes up to the sign $(-1)^{k+1}$.

\[ M = U \cup V \]

\[ K \quad L \]

\[ V \]

\[ U \]

\[ \text{Figure 1244} \]

Before we prove the claim we show that it implies Theorem 88.19. For each group appearing in the above diagram we take the direct limit over the directed set \[ I = \{(K, L) \mid K \text{ compact subset of } U \text{ and } L \text{ compact subset of } V\} \]

\[ \text{1272} \] We view $I$ as a directed set given by the relation $(K, L) \leq (K', L')$ if $K \subset K'$ and $L \subset L'$. It is clear that each of the groups in the diagram forms a direct system with respect to this directed set.
and we consider the induced maps of direct limits that were introduced on page 1243. We make the following remarks regarding this new diagram:

(1) Using Lemma 76.4 one can show that the groups that we obtain taking the direct limit over $I$ are naturally isomorphic to the corresponding cohomology groups with compact support. We carry out the argument for two groups:

$$\lim_{(K,L) \in I} H^k(U \cap V|K \cap L) = \lim_{C \in K(U \cap V)} H^k(U \cap V).$$

we apply Lemma 76.4 to the cofinal morphism of directed sets given by $(K, L) \mapsto K \cap L$

and

$$\lim_{(K,L) \in I} H^k(M|K \cup L) = \lim_{C \in K(M)} H^k(M).$$

we apply Lemma 76.4 to the morphism of directed sets given by $(K, L) \mapsto K \cup L$, this morphism is cofinal by Lemma 88.21

All other cases are treated in a very similar fashion.

(2) By the functoriality of direct limits, and since the signs in the commutativity do not depend on $K$ and $L$, the new diagram also commutes (up to the same signs).

(3) Using (2) and the definition of the “PD-maps” in Lemma 88.18 one can easily verify that the direct limit of the diagram does indeed give rise to the diagram specified in the statement of the lemma.

(4) Proposition 47.2 says that the direct limit of exact sequences is again exact.

All these remarks put together show that the direct limit of the above diagram gives rise precisely to the diagram that we claimed exists and that all claimed statements are satisfied. This concludes the proof that the claim implies the lemma.

We turn to the proof of the claim. We show in three separate subclaims that the three rectangles commute. The proof of the first two subclaims consists of a clever usage of Lemma 83.8. The proof of the third subclaim is much more sophisticated since it relies on understanding the connecting homomorphisms in the Mayer-Vietoris sequences in (co-)homology.

**Subclaim.** The first rectangle of the diagram on page 2169 commutes.

So we need to show that the following diagram commutes:

$$\begin{array}{ccc}
H^k(M, M \setminus K \cap L) & \xrightarrow{i \oplus -i} & H^k(M, M \setminus K) \oplus H^k(M, M \setminus L) \\
| & & | \\
\cong & & \cong \\
H^k(U \cap V, U \cap V \setminus K \cap L) & \xrightarrow{\cap \mu^U_{K \cap L}} & H^k(U, U \setminus K) \oplus H^k(V, V \setminus L) \\
| & & | \\
H_{n-k}(U \cap V) & \xrightarrow{i \oplus -i} & H_{n-k}(U) \oplus H_{n-k}(V).
\end{array}$$

Evidently the triangle commutes. We note that the remaining pentagon breaks up into the “direct sum” of two diagrams. By symmetry reasons it suffices to consider the left-hand
summands. So let \( \phi \in H^k(M, M \setminus K \cap L) \). We consider the following diagram of maps between pairs of topological spaces

\[
(U \cap V, U \cap V \setminus K \cap L) \xrightarrow{\alpha} (U, U \setminus K \cap L) \\
\downarrow_{f \circ \alpha} \xrightarrow{f} \\
(M, M \setminus K \cap L) \xleftarrow{(U, U \setminus K).}
\]

With this notation we need to show that

\[
\alpha_*((f \circ \alpha)^*(\phi) \cap \mu_{K \cap L}^{U \cap V}) = (f \circ \beta)^*(\phi) \cap \mu_{K}^U.
\]

But this is indeed the case, since

\[
\alpha_*((f \circ \alpha)^*(\phi) \cap \mu_{K \cap L}^{U \cap V}) = f^*(\phi) \cap \alpha_*((\mu_{K \cap L}^{U \cap V}) = f^*(\phi) \cap \mu_{K \cap L}^U.
\]

Lemma 88.3 by Corollary 87.12 we have \( \alpha_*((\mu_{K \cap L}^{U \cap V}) = \mu_{K}^U \)

\[
\beta_*((f \circ \beta)^*(\phi) \cap \mu_{K}^U) = (f \circ \beta)^*(\phi) \cap \mu_{K}^U
\]

same argument backwards since \( \beta \) on the first coordinate is the identity

This concludes the proof of the subclaim.

Subclaim. The second rectangle of the diagram on page 2169 commutes.

The proof of that subclaim is very similar to the proof of the previous subclaim. Thus we leave it to the reader to fill in the details.

Subclaim. The third rectangle of the diagram on page 2169 commutes up to the sign \((-1)^{k+1}\).

As a reminder, we need to show that the following diagram commutes up to the sign \((-1)^{k+1}\):

\[
H^k(M, M \setminus K \cup L) \xrightarrow{\delta} H^{k+1}(M, M \setminus K \cap L) \xrightarrow{\cong} H^{k+1}(U \cap V, U \cap V \setminus K \cap L) \\
\downarrow_{\cap \mu_{K \cup L}^U} \xrightarrow{\partial} H_{n-k}(M) \xrightarrow{\cap \mu_{K \cap L}^U} H_{n-k-1}(U \cap V).
\]

So let \([\varphi] \in H^k(M, M \setminus K \cup L) = H^k(M, A \cap B)\). We start out with the following preparations:

1. By Theorem 88.23 (1) we can find \( \varphi_A \in C^k(M, A) \) and \( \varphi_B \in C^k(M, B) \) such that \( \varphi = \varphi_A + \varphi_B \).
2. By Lemma 88.22 there exist singular chains \( \alpha_{U \setminus L} \), \( \alpha_{U \cap V} \) and \( \alpha_{V \setminus K} \) in \( U \setminus L, U \cap V \) and \( V \setminus K \) such that the following three equalities hold:

\[
(2a) \quad \mu_{K \setminus L} = [\alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K}] \quad \text{in } H_n(M, M \setminus (K \cup L))
\]

\[
(2b) \quad \mu_{K \setminus L}^U = [\alpha_{U \cap V}] \quad \text{in } H_n(U \cap V, U \cap V \setminus (K \cap L))
\]

\[
(2c) \quad \mu_K^U = [\alpha_{U \setminus L} + \alpha_{U \cap V}] \quad \text{in } H_n(U, U \setminus K).
\]
After these preparations we obtain the following equalities in $H_{n-k-1}(U \cap V)$:

maps in the rectangle applied clockwise to $[\varphi] = \delta[\varphi] \cap \mu_{K \cap L}^{U \cap V}$
$$= [\varphi_A \cap \partial \alpha_{U \cap V}] = [\varphi_A \cap \partial \alpha_{U \cap V} - \varphi_A \cap \partial (\alpha_{U \cap V} + \alpha_{U \setminus L})] = [-\varphi_A \cap \partial \alpha_{U \setminus L}]$$

Lemma 88.24 (1). Since the maps $PD$ actually contains an interesting and useful statement which is worth jotting down separately.

Lemma 88.25. Let $M$ be an oriented $n$-dimensional topological manifold with empty boundary and let $U$ be an open subset of $M$. We denote by $i: U \to M$ the inclusion. For any $k \in \mathbb{N}_0$ the following two diagrams commute:

$$
\begin{array}{ccc}
H^k_c(U) & \xrightarrow{i_*} & H^k_c(M) \\
\downarrow\text{PD}_U & & \downarrow\text{PD}_M \\
H_{n-k}(U) & \xrightarrow{i_*} & H_{n-k}(M)
\end{array}
\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \frac{1273}{1273}\text{The maps } \delta \text{ and } \partial \text{ written in blue are the connecting homomorphisms in the Mayer–Vietoris sequences.}
\end{array}
$$

Proof. The statement that the diagram on the left commutes for any $k$ is contained in Lemma 88.24 (1). Since the maps PD$_U$ and PD$_M$ are isomorphisms the statement that the diagram on the right commutes is just a reformulation of the fact that the diagrams on the left commutes.

Now we turn to the actual proof of Theorem 88.19

Proof of Theorem 88.19. We fix a dimension $n$. Throughout this proof by a “manifold” we mean an oriented $n$-dimensional topological manifold without boundary. We say Poincaré Duality holds for a topological manifold $M$ if for each $k \in \mathbb{N}_0$ the map
$$PD_M : H^k_c(M) \to H_{n-k}(M)$$
from Lemma 88.18 is an isomorphism. Our goal is to show that Poincaré Duality holds for all topological manifolds.

We start out with the following claim.

Claim. Let $W$ be a topological manifold.

(A) If Poincaré Duality holds for $W$ equipped with an orientation, then it also holds for any other orientation of $W$.

(B) If $W$ is homeomorphic to a topological manifold for which Poincaré Duality holds, then Poincaré Duality also holds for $W$.

(C) Suppose that $W$ is the union of two open subsets $U$ and $V$. If Poincaré Duality holds for $U$, $V$ and $U \cap V$, then it also holds for $W$.

(D) If $W$ is the union of a nested sequence $U_1 \subset U_2 \subset \ldots$ of open subsets such that Poincaré Duality holds for each $U_i$, then it also holds for $W$.

So let $W$ be a topological manifold.

(A) Clearly it suffices to consider the case that $W$ is path-connected. By Lemma 86.10 the path-oriented connected topological manifold $W$ admits only one other orientation, namely the reverse orientation. Evidently Poincaré Duality also holds for that orientation.

(B) This statement is obvious.

(C) If all maps $PD_U$, $PD_V$ and $PD_{U \cap V}$ are isomorphisms, then it follows immediately from Lemma 88.24 and the Five Lemma 43.12 that also each $PD_W$ is an isomorphism, i.e. Poincaré Duality holds for $W = U \cup V$.

(D) Let $k \in \mathbb{N}_0$. We suppose that for every $i \in \mathbb{N}$ the map $PD_{U_i} : H^k_c(U_i) \to H_{n-k}(U_i)$ is an isomorphism. Using Lemmas 83.8 and 88.18 it is straightforward to verify that for any $i \leq j$ the following diagram commutes:

\[
\begin{array}{ccc}
H^k_c(U_i) & \xrightarrow{PD_{U_i}} & H_{n-k}(U_i) \\
\downarrow & & \downarrow \\
H^k_c(U_j) & \xrightarrow{PD_{U_j}} & H_{n-k}(U_j).
\end{array}
\]

We obtain isomorphisms

\[
H^k_c(W) = \lim_{\longrightarrow} H^k_c(U_i) \xrightarrow{\lim_{\longrightarrow} PD_{U_i}} \lim_{\longrightarrow} H_{n-k}(U_i) = H_{n-k}(W).
\]

We leave it to the reader to verify that the map from left to right is indeed given by $PD_W$.

The following claim completes the proof of the theorem.

Claim.

(1) Poincaré Duality holds for every open bounded convex subset of $\mathbb{R}^n$.  

(2) For every \( m \in \mathbb{N} \) Poincaré Duality holds for the union of \( m \) open bounded convex subsets of \( \mathbb{R}^n \).
(3) Poincaré Duality holds for every open subset of \( \mathbb{R}^n \).
(4) For every \( m \in \mathbb{N} \) Poincaré Duality holds for all topological manifolds that admit an atlas with \( m \) charts.
(5) Poincaré Duality holds for all topological manifolds.

Now we provide the proof of the claim.

(1) Let \( M \) be an open bounded convex subset of \( \mathbb{R}^n \). By Proposition 2.52 (1) there exists a homeomorphism \( M \to B^n \). It follows from Lemma 88.20 and (B) that Poincaré Duality also holds for \( M \).

(2) We prove the claim by induction on \( m \). By (1) we know that the statement holds for \( m = 1 \). Now suppose it holds for all unions of \( m - 1 \) open bounded convex subsets of \( \mathbb{R}^n \). Let \( M \) be the union of \( m \) open bounded convex subsets \( U_1, \ldots, U_m \). We set \( V = U_1 \cup \cdots \cup U_{m-1} \). By our hypothesis and by induction the statement holds for \( U_m \), for \( V \) and also for \( V \cap U_m = (U_1 \cap U_m) \cup \cdots (U_{m-1} \cap U_m) \), which is the union of \( (m - 1) \) open bounded convex subsets. Hence by (C) the statement also holds for \( M = V \cup U_m = (U_1 \cup \cdots \cup U_{m-1}) \cup U_m \).

(3) Let \( M \) be an arbitrary open subset of \( \mathbb{R}^n \). By Lemma 2.7 we can write \( M \) as the union of countably many open balls \( B_i, i \in \mathbb{N} \). For \( i \in \mathbb{N} \) we set \( U_i := \bigcup_{j \leq i} B_j \). By (2) Poincaré Duality holds for each \( U_i \in \mathbb{N} \). But then it follows from (D) that Poincaré Duality also holds for \( M \).

(4) We prove this statement by induction on \( m \). The case \( m = 1 \) is taken care of by (3) and (B). Now suppose Poincaré Duality holds for all topological manifolds that admit an atlas with \( m - 1 \) charts. Let \( M \) be a topological manifold that admits an atlas \( \{ \phi_i : U_i \to V_i \}_{i=1,\ldots,m} \) with \( m \) charts. We write \( U = U_1 \cup \cdots \cup U_{m-1} \) and \( V = U_m \). Both are open subsets of a topological manifold, hence they are also topological manifolds. Furthermore \( U \) and \( V \) are topological manifolds that admit an atlas with \( m - 1 \) charts respectively one chart. Similarly \( U \cap V = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m) \) is a topological manifold that admits an atlas with \( m - 1 \) charts. By induction Poincaré Duality holds for \( U \), \( V \) and \( U \cap V \). Thus by (C) Poincaré Duality also holds for \( M \) itself.

(5) Finally let \( M \) be any topological manifold. We saw in Exercise 6.19 (1), using the fact that \( M \) is second-countable and using Lemma 2.25 that \( M \) admits a countable atlas \( \{ \Phi_j : U_j \to V_j \}_{j \in \mathbb{N}} \). For \( i \in \mathbb{N} \) we set \( X_i := \bigcup_{j \leq i} U_j \). By (4) Poincaré Duality holds for each \( X_i \). It follows from (D) that Poincaré Duality also holds for \( M \). ■

88.4. The proof of Poincaré Duality for topological manifolds with boundary.
Now we will finally prove the general statement of the Poincaré Duality Theorem 88.1. For the reader’s convenience we recall the statement.

---

1274 Here we once again use the convenient fact that the intersection of two convex sets is convex.
Theorem 88.1 (Poincaré Duality Theorem) Let $M$ be a compact, non-empty $n$-dimensional topological manifold and let $R$ be a commutative ring. We suppose that $M$ is $R$-oriented. We denote by $[M] \in H_0(M, \partial M; R)$ the $R$-fundamental class. Furthermore, suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map

$$H^k(M, A; R) \xrightarrow{\cong} H_{n-k}(M, B; R)$$

$$\sigma \mapsto \sigma \cap [M]$$

is an isomorphism.

Proof of Theorem 88.1 For $A = \partial M$ and $B = \emptyset$. In this proof we consider the case that $A = \partial M$ and $B = \emptyset$. To simplify the notation we will once again only consider the case that $R = \mathbb{Z}$. The proof of the general case is basically the same. We introduce the following objects:

1. From the Topological Collar Neighborhood Theorem 44.5 we obtain a collar neighborhood $[-1, 0] \times \partial M$ of $\partial M = \{0\} \times M$. We refer to it as the “internal collar”.

2. We define

$$W := M \cup ([0, 1) \times \partial M) / \sim$$

with $x \sim (x, 0)$ for every $x \in \partial M$. Sometimes $[0, 1) \times \partial M$ is called an external collar of $M$. Furthermore, given any $t \in [-1, 1)$ we write

$$K_t := (M \setminus [-1, 0] \times \partial M) \cup ([-1, t] \times \partial M) / \sim.$$

By elementary arguments and using Proposition 44.2 (1) one can easily show the following statements:

(A) $W$ is an $n$-dimensional topological manifold with empty boundary,

(B) $W$ admits an orientation such that $M$ is a submanifold and such that $M \to W$ is orientation-preserving,

(C) every $K_t$ is a compact subset of $W$ and given any compact subset $K$ of $W$ there exists a $t \in [-1, 1)$ with $K \subset K_t$. 

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1245.png}
\caption{Figure 1245}
\end{figure}
We denote by $i: (M, \partial M) \to (W, W \setminus K_{-1})$ the obvious inclusion map. We obtain the following diagram:

$$
\begin{array}{c}
H^k(M, \partial M) \xleftarrow{i^*} H^k(W, W \setminus K_{-1}) \xrightarrow{\cup [M]} H_c^k(W) \\
\downarrow \cup [W] \quad \downarrow \cup [K_t] \quad \downarrow \text{PD}_W \\
H_{n-k}(M) \xrightarrow{i^*} H_{n-k}(W) \xrightarrow{=} H_{n-k}(W).
\end{array}
$$

It remains to prove the following claim which resembles closely the claim in the proof of Lemma 88.20.

**Claim.** The following three statements hold:

1. The diagram commutes,
2. the right vertical map is an isomorphism, and
3. all horizontal maps are isomorphisms.

We turn to the proof of the claim.

1. The right-hand square commutes by definition of PD$_W$. Using (B) we can apply the same argument as in the proof of the claim in Lemma 88.20 to show that the left-hand square commutes.
2. Theorem 88.19 implies that the right vertical map is an isomorphism.
3. It follows easily from Corollary 43.18 and Lemma 73.13 that the left horizontal maps are isomorphisms. It remains to show that the top right horizontal map is an isomorphism. Similar to the proof of Lemma 88.20 we consider the following commutative diagram

$$
\begin{array}{c}
H^k(W, W \setminus K_{-1}) \xrightarrow{i^*} H^k(W, W \setminus K_{-1}) \xrightarrow{\lim_{K \in C(W)}} H^k(W, W \setminus K) = H_c^k(W).
\end{array}
$$

We make the following two observations:

(a) By (C) every compact subset of $W$ is contained in some $K_t$. Therefore it follows from Lemma 76.3 that the right diagonal map is an isomorphism.

(b) It follows easily from Lemmas 73.13 and 76.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.

This concludes the proof of the claim and it concludes the proof of Theorem 88.1 in the special case that $A = \partial M$ and $B = \emptyset$.

**Proof of Theorem 88.1 for the general case.** Now we finally consider the general case of Theorem 88.1. So we suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. We recall that by Proposition 74.12 (5) we know that the triad $(M, A, B)$
is excisive. In this proof, once again we simplify the notation and we only work with $\mathbb{Z}$-coefficients.

We equip $\partial M$ and then also $B$ with the orientations coming from Proposition $86.19$ and Lemma $86.17$. We consider the following diagram

$$
\cdots \longrightarrow H^k(M, \partial M) \longrightarrow H^k(M, A) \longrightarrow H^k(\partial M, A) \overset{\delta}{\longrightarrow} H^{k+1}(M, \partial M) \longrightarrow \cdots
$$

$$
\begin{array}{ccc}
\cong & \cong & \\
-\cap[M] & -\cap[M] & \cong \cap[M] \\
\downarrow & \downarrow & \cong \downarrow \\
\cdots \longrightarrow H_{n-k}(M) \longrightarrow H_{n-k}(M, B) \overset{\partial}{\longrightarrow} H_{n-k-1}(B) \longrightarrow H_{n-k-1}(M) \longrightarrow \cdots
\end{array}
$$

We make the following observations:

1. The top horizontal sequence is the long exact sequence in cohomology of the triple $(M, \partial M, A)$ provided by Lemma $73.15$.
2. The bottom horizontal sequence is the long exact sequence in homology of the pair $(M, B)$ provided by Corollary $43.16$.
3. The above vertical map $i^*: H^k(\partial M, A) \to H^k(B, \partial B)$ is induced by the inclusion $i: (B, \partial B) \to (\partial M, A)$. It is an isomorphism by Proposition $74.12$ (5) together with Lemma $74.13$ (3).
4. The other maps decorated with “$\cong$” are isomorphisms by the special case of the Poincaré Duality Theorem $88.1$ that we have already dealt with.

By the Five Lemma $43.12$ it remains to prove the following claim.

**Claim.** The above diagram commutes up to signs, more precisely:

1. The first rectangle commutes,
2. The second rectangle commutes up to the sign $(-1)^k$,
3. The third rectangle commutes.

We consider the three rectangles separately.

1. We consider the following diagram:

$$
\begin{array}{ccc}
H^k(M, \partial M) \times H_n(M, \partial M) & \longrightarrow & H_{n-k}(M) \\
\uparrow & & \downarrow \\
H^k(M, \partial M) \times H_n(M, \partial M) & \longrightarrow & H_{n-k}(M, B) \\
\downarrow & & \uparrow \\
H^k(M, A) \times H_n(M, \partial M) & \longrightarrow & H_{n-k}(M, B).
\end{array}
$$

We can convince ourselves that the diagram commutes by applying Lemma $83.8$ to the maps $(M, \partial M, \emptyset) \to (M, \partial M, B)$ and $(M, A, B) \to (M, \partial M, B)$ of excisive triads.

It follows easily from this observation that the first rectangle of the claim commutes.

Before we continue with the discussion of the other two rectangles we need to make one remark. We denote by $j: (B, \partial B) \to (\partial M, A)$ the inclusion map and we denote by $\partial: H_n(M, \partial M) \to H_{n-1}(\partial M, A)$ the connecting homomorphism in the long exact sequence
of the triple \((M, \partial M, A)\). It follows from Proposition 87.27 (1), Lemma 87.24 and the remark on page 1125 that the following equality holds

\[(*) \quad i_*([B]) = \partial [M] \in H_{n-1}(\partial M, A).\]

Now we continue with the proof of the claim.

(2) We apply Lemma 83.10 (2) to the excisive triad \((M, A, B)\). (Recall that \(A \cup B = \partial M\) and \(A \cap B = \partial B\).) We obtain that for any \(k \in \mathbb{N}_0\) the following diagram commutes up to the sign \((-1)^k\):

\[
\begin{array}{ccc}
H^k(M, A) \times H_n(M, \partial M) & \xrightarrow{\wedge} & H_{n-k}(M, B) \\
\downarrow i^* & & \downarrow \partial \\
H^k(\partial M, A) \times H_{n-1}(\partial M, A) & \xrightarrow{\wedge} & H_{n-k-1}(\partial M, A) \\
\downarrow j^* \cong (j_*^{-1}) \downarrow & & \downarrow \partial \\
H^k(B, \partial B) \times H_{n-1}(B, \partial B) & \xrightarrow{\wedge} & H_{n-k-1}(B).
\end{array}
\]

Together with (*) we obtain that the second rectangle of the claim does indeed commute up to the sign \((-1)^k\).

(3) We consider the following diagram:

\[
\begin{array}{ccc}
H^k(B, \partial B) \times H_{n-1}(B, \partial B) & \xrightarrow{\wedge} & H_{n-k-1}(B) \\
\downarrow i_*^* \uparrow i_* & & \downarrow i_* \\
H^k(\partial M, A) \times H_{n-1}(\partial M, A) & \xrightarrow{\wedge} & H_{n-k-1}(\partial M) \\
\downarrow \delta & & \downarrow \delta \\
H^{k+1}(M, \partial M) \times H_n(M, \partial M) & \xrightarrow{\wedge} & H_{n-k-1}(M).
\end{array}
\]

The upper part of this diagram commutes by Lemma 83.8 applied to the map \((B, \partial B, \emptyset) \to (\partial M, A, \emptyset)\) between excisive triads. The lower part commutes by Lemma 83.10 (1) applied to the triple \((M, \partial M, A)\). This discussion, together with (*), implies that the third rectangle of the diagram in the claim commutes.

This concludes the proof of the claim and thus also of the Poincaré Duality Theorem 88.1.

\[\blacksquare\]

Remark. It follows from the Poincaré Duality Theorem 88.1 and Corollary 81.12 that if \(X\) is a topological space that is homotopy equivalent to a closed orientable \(n\)-dimensional topological manifold, then there exists a \(\phi \in H_n(X; \mathbb{Z})\) such that for any \(k \in \mathbb{N}_0\) the map

\[
- \wedge \phi : H^k(X; \mathbb{Z}) \to H_{n-k}(X; \mathbb{Z})
\]

is an isomorphism. One can ask to what degree the converse holds. Namely, if say a CW-complex \(X\) admits such a \(\phi\), is \(X\) homotopy equivalent to a closed orientable topological manifold? We will discuss this question on page ??.

We conclude this section with two propositions that relate Poincaré duality on a manifold to Poincaré duality on its boundary.
Proposition 88.26. Let $M$ be a compact $n$-dimensional topological manifold with non-empty boundary. Let $R$ be a commutative ring. We suppose that $M$ is $R$-oriented. We equip the boundary $\partial M$ with the $R$-orientation given by Proposition 86.19. As usual we denote by $[M] \in H_n(M, \partial M; R)$ and $[\partial M] \in H_{n-1}(\partial M; R)$ the corresponding $R$-fundamental classes. We consider the following diagram:

\[ \ldots \rightarrow H^k(M, \partial M; R) \rightarrow H^k(M; R) \rightarrow H^k(\partial M; R) \xrightarrow{\delta} H^{k+1}(M, \partial M; R) \rightarrow \ldots \]

where the horizontal sequences are the long exact sequences in (co-) homology of the pair $(M, \partial M)$. (Note that the vertical maps are isomorphisms by Theorem 88.1.) The first and the third squares commute, furthermore the second square commutes up to the sign $(-1)^k$.

Proof. We had implicitly proved the proposition in the above proof of the Poincaré Duality Theorem 88.1 applied to the special case that $A = \emptyset$ and $B = \partial M$.

Finally we have the following proposition.

Proposition 88.27. Let $M$ be a compact, non-empty $n$-dimensional topological manifold and let $R$ be a commutative ring. We suppose that $M$ is $R$-oriented. We denote by $[M] \in H_n(M, \partial M; R)$ the $R$-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. We consider the following two diagrams:

\[ \begin{array}{ccc}
H_k(M, A; R) & \xrightarrow{\partial} & H_k(A; R) \\
\xrightarrow{PD_M} & & \xrightarrow{PD_A} \\
H^{n-k}(M, B; R) & \xrightarrow{w_*} & H^{n+1-k}(A, \partial A; R) \\
\end{array} \quad \begin{array}{ccc}
H_k(A, \partial A; R) & \xrightarrow{w_*} & H_k(M, B; R) \\
\xrightarrow{PD_A} & & \xrightarrow{PD_M} \\
H^{n-k}(A; R) & \xrightarrow{\delta} & H^{n+1-k}(M, A; R). \\
\end{array} \]

The first diagram commutes up to multiplication by $(-1)^k$ whereas the second commutes as it is.

Proof. We already showed on page 2178 that the first diagram commutes up to multiplication by $(-1)^k$. The fact that the second diagram commutes is a fairly straightforward consequence of Lemma 83.10. We leave it to the reader to fill in the details.

Exercises for Chapter 88

Exercise 88.1. Let $M$ be a closed 0-connected $n$-dimensional topological manifold. We suppose there exists an $(n+1)$-dimensional topological manifold $N$ such that for every $i \in \{1, \ldots, n\}$ we have $\tilde{H}_i(N) \cong H_{i-1}(M)$. Show that $M$ is a homology $n$-sphere, i.e. show that $H_1(M) \cong H_1(S^n)$ for all $i \in \mathbb{N}_0$.

Remark. In view of Proposition 45.7, this exercise can be viewed as a variation on Exercise 45.8.
Exercise 88.2. Let $M$ and $N$ be two closed orientable connected non-empty 3-dimensional topological manifolds such that $\pi_1(M)$ is isomorphic to $\pi_1(N)$. Show that for all $i \in \mathbb{N}_0$ there exists an isomorphism $H_i(M; \mathbb{Z}) \cong H_i(N; \mathbb{Z})$.

Remark. This exercise is almost identical to Exercise 71.4.

Exercise 88.3.

(a) Let $M$ be an $n$-dimensional closed orientable connected topological manifold such that $\pi_1(M)$ is isomorphic to the permutation group $S_5$. What can you say about $H^{n-1}(M; \mathbb{Z})$? Does the answer depend on whether or not $M$ has boundary?

(b) Let $M$ be a non-compact orientable topological manifold. Show that the group $H_{n-1}(M, \partial M; \mathbb{F}_2)$ is non-zero.

Exercise 88.4. Let $p: \tilde{N} \to N$ be a finite covering of a closed, oriented $n$-dimensional topological manifold. We equip $\tilde{N}$ with the orientation given by Lemma 86.17

(a) Let $r \leq s$. Show that given any singular simplex $\sigma: \Delta^s \to N$ and any cochain $\phi \in C^r(N; \mathbb{Z})$ we have

$$p^*(\phi) \cap p^*(\sigma) = p^*(\phi \cap \sigma).$$

Here $p^*$ for homology classes denotes the transfer map.

(b) Show that for any $k \in \mathbb{N}_0$ the Umkehr map $p^*: H_k(N; \mathbb{Z}) \to H_k(\tilde{N}; \mathbb{Z})$ equals the transfer map $p^*$.

Hint. Proposition 87.25 might be useful.

Exercise 88.5. Is the Klein bottle the boundary of a compact 3-dimensional topological manifold?

Exercise 88.6.

(a) Let $M$ be a topological manifold and let $U, V$ be open subsets such that $M = U \cup V$. Show that given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.

(b) Does statement (a) hold for any topological space?

Exercise 88.7. Let $M$ be a closed connected 4-dimensional topological manifold that is simply connected and with $\chi(M) = 2$. What can you say about the homeomorphism type of $M$?

Exercise 88.8.

(a) Let $W$ be a closed orientable connected 4-dimensional topological manifold with $\chi(W) = -3$. Show that $W$ admits a finite connected covering $\tilde{W}$ with $\chi(\tilde{W}) < -27$.

(b) Is the hypothesis in (a) that $W$ is orientable necessary?

Remark. This exercise is almost identical to Exercise 71.5.

Exercise 88.9. Let $M$ be a closed 4-dimensional topological manifold.

(a) Show that if $M$ is simply connected, then there exist at most finitely many isomorphism classes of finite groups which can act discretely on $M$.

(b) Is the hypothesis in (a) that $M$ is simply connected necessary?
Exercise 88.10. Let $M$ be a compact orientable 4-dimensional topological manifold with $\partial M = \partial A \sqcup B$ where $A$ and $B$ are two connected 3-dimensional topological manifolds with $H_1(A; \mathbb{Z})$ finite. We suppose that the inclusion induced map $H_1(A; \mathbb{Z}) \to H_1(M; \mathbb{Z})$ is an epimorphism. Show that the inclusion induced map $H_1(B; \mathbb{Z}) \to H_1(M; \mathbb{Z})$ is a monomorphism.

Exercise 88.11. Let $M$ be a closed orientable connected odd-dimensional topological manifold and let $f: M \to M$ be a map such that the induced map $f_*: H_n(M) \to H_n(M)$ is an isomorphism. Show that the Lefschetz number

$$\Lambda(\varphi) = \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(\varphi_*: H_n(M) \to H_n(M)),$$

equals zero.

Remark. This exercise is almost identical to Exercise 71.6.

Exercise 88.12. Let $M$ be a closed oriented connected $n$-dimensional topological manifold. Furthermore let $i \in \{0, \ldots, n\}$ and let $v_1, \ldots, v_m$ be a basis of $FH^i(M; \mathbb{Z})$. Show that there exists a basis $\tilde{v}_1, \ldots, \tilde{v}_m$ of $FH^{n-i}(M; \mathbb{Z})$ such that for any $k, l \in \{1, \ldots, m\}$ we have $\langle v_k \cup \tilde{v}_l, [M] \rangle = \delta_{kl}$.

Exercise 88.13. Let $M$ be a compact oriented connected $n$-dimensional topological manifold. We say $M$ is an $n$-dimensional homotopy ball if $\pi_i(M) = 0$ for $i \geq 1$ and if $\pi_1(\partial M) = \{e\}$. Show that if $M$ is an $n$-dimensional homotopy ball, then $\partial M$ is a homotopy $(n-1)$-sphere, as defined in Exercise 88.13.

Exercise 88.14. Let $n \in \mathbb{N}_{\geq 2}$ and let $M$ be a compact oriented connected $n$-dimensional topological manifold. Suppose that there exists a degree one map $f: (B^n, S^{n-1}) \to (M, \partial M)$. Show that $M$ is an $n$-dimensional homotopy ball.

Exercise 88.15. Let $M$ be a compact oriented connected $n$-dimensional topological manifold. Let $Y$ be a boundary component of $M$ which is homeomorphic to $S^{n-1}$. Show that either $[Y] \neq 0 \in \pi_{n-1}(M)$ or $M$ is a homotopy ball, as defined in Exercise 88.13.

Hint. Show that if $[Y] = 0$, then there exists a degree one map $(B^n, S^{n-1}) \to (M, Y)$. Now use Exercise 88.14.

Exercise 88.16. Let $f: M \to N$ be a homeomorphism between two compact oriented connected $n$-dimensional topological manifolds and let $A, B$ be two compact $(n-1)$-dimensional submanifolds of $\partial M$ with $A \cup B = \partial M$, $A \cap B = \partial A = \partial B$. Show that for any $\sigma \in H_k(M, A)$ we have

$$f^*(\text{PD}_N(f_*(\sigma))) = \begin{cases} \text{PD}_M(\sigma), & \text{if } \sigma \text{ is orientation-preserving}, \\ -\text{PD}_M(\sigma), & \text{if } \sigma \text{ is orientation-reversing}. \end{cases}$$

Remark. This exercise consists mostly of collecting fairly standard facts.

Exercise 88.17. Let $M$ be an oriented connected non-empty $n$-dimensional topological manifold. As in Exercise 87.5 we consider the group $\overline{H}_n(M; \mathbb{Z}) := \lim_{\leftarrow} H_n(M, M \setminus K; G)$.

In Exercise 87.7 we showed that $\overline{H}_n(M; \mathbb{Z})$ is isomorphic to $\mathbb{Z}$ and we showed that there exists a natural generator $[M]$. Let $k \in \mathbb{N}_0$. 

88. THE TOPOLOGICAL Poincaré DUALITY THEOREM 2181
(a) Let \( \cap: H^{n-k}_c(M;\mathbb{Z}) \times \overset{\leftarrow}{H}_k(M;\mathbb{Z}) \to H_k(M;\mathbb{Z}) \) be the natural cap product that we introduced in Exercise 83.4. Show that the map \( H^{n-k}_c(M;\mathbb{Z}) \to H_k(M;\mathbb{Z}) \) given by capping with \([M]\) defines an isomorphism.

Remark. Use Lemma 88.18.

(b) Now let \( f: M \to N \) be a proper map between two connected orientable non-empty \( n \)-dimensional topological manifolds. Since \( f \) is proper we obtain by Exercise 87.5 an induced map \( f_*: H_k(M;\mathbb{Z}) \to H_k(N;\mathbb{Z}) \). We define \( \deg(f) \in \mathbb{Z} \) via the equality \( f_*([M]) = \deg(f) \cdot [N] \). Furthermore, using (a), we can define the Umkehr map \( f^!: H_k(N;\mathbb{Z}) \to H_k(M;\mathbb{Z}) \). Show that the map \( f^! \circ f_*: H_k(M;\mathbb{Z}) \to H_k(M;\mathbb{Z}) \) is given by multiplication by \( \deg(f) \).

Remark. The goal of this exercise is to generalize the ideas and concepts behind Proposition 88.14 to the setting of non-compact topological manifolds.

Exercise 88.18. Recall that given a topological space \( X \) we defined on page 2015 its cup length \( \text{cl}(X) \in \mathbb{N}_0 \cup \{\infty\} \) as follows:

\[
\text{cl}(X) := \max \left\{ n \in \mathbb{N}_0 \mid \text{there exists a commutative ring } R \text{ and } R\text{-cohomology classes } x_1, \ldots, x_n \text{ in degrees } \geq 1 \text{ with } x_1 \cup \cdots \cup x_n \neq 0 \right\}
\]

Let \( M \) and \( N \) be two closed oriented connected \( n \)-dimensional topological manifolds. Show that if there exists a map \( f: M \to N \) of degree one, then \( \text{cl}(M) \geq \text{cl}(N) \).

Remark. At least in spirit this exercise is related to the Rudyak Conjecture 82.13.

Exercise 88.19. Let \( M \) be a closed simply connected 4-dimensional topological manifold. Show that \( H_1(M;\mathbb{Z}) = 0, H_3(M;\mathbb{Z}) = 0 \) and show that that \( H_2(M;\mathbb{Z}) \) is torsion-free.

Exercise 88.20. Let \( X \) and \( Y \) be compact oriented connected non-empty \( n \)-dimensional topological manifolds and let \( f: X \to Y \) be a map of degree one. Does it follow that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(X;\mathbb{Z}) & \xrightarrow{f_*} & H_k(Y;\mathbb{Z}) \\
\text{PD}_X & \cong & \text{PD}_Y \\
H^{n-k}(X;\mathbb{Z}) & \leftarrow & H^{n-k}(Y;\mathbb{Z})
\end{array}
\]

Exercise 88.21. Let \( M \) be a compact orientable \( n \)-dimensional topological manifold. Determine the homology groups of the double \( D\mathbb{M} \) in terms of the homology groups of \( M \).

Remark. It is tempting to use Mayer–Vietoris sequences, but this will most likely not lead very far. At some stage in the calculation it will be helpful to use the Poincaré Duality Theorem 88.1.
89. Poincaré duality and codimension-zero submanifolds (*)

In this short chapter we will study the interplay between Poincaré Duality on a given compact topological manifold $M$ and on a given codimension-zero submanifold $W$ of $M$. Later on, in the applications of this chapter’s results, we will also deal with submanifolds with corner, so we will use this opportunity to finally introduce the notion of a submanifold with corner. The results and concepts of this chapter will be used on several occasions. Nonetheless it is safe to skip this chapter and to move on to the next, significantly more entertaining, chapter.

89.1. Submanifolds with corner. Recall that on page 270 we defined what it means for a subset $W$ of a manifold $M$ to be a submanifold, namely it means that given any $P \in W$ there is a chart for $M$ of one of the three types $(\alpha)$, $(\beta)$ and $(\gamma)$ that are defined properly on page 270 and that are sketched in Figure 1246.

![Figure 1246](image)

**Figure 1246**

Now we introduce the more general notion of a submanifold with corner.

**Definition.** Let $M$ be an $n$-dimensional topological manifold. We say a subset $W \subset M$ is a $k$-dimensional submanifold with corner if for every $P \in W$ there exists a chart of the type $(\alpha)$, $(\beta)$ and $(\gamma)$ from page 270 or if

$(\delta)$ there exists a chart $\Phi: U \to V$ of type $(\text{ii})^{1276}$ for $M$ such that

$$\Phi(U \cap W) \subset \{(0, \ldots, 0, x_1, \ldots, x_k) | x_1, \ldots, x_k \in \mathbb{R} \text{ with } x_{k-1} \geq 0 \text{ and } x_k \geq 0 \}$$

and with $\Phi(P) \in \{(0, \ldots, 0, x_1, \ldots, x_{k-2}, 0, 0) | x_1, \ldots, x_{k-2} \in \mathbb{R} \}$.

If $M$ is an $n$-dimensional smooth manifold, then we demand that the charts come from the maximal smooth atlas. We refer to the set of points in $W$ that admit a chart of type $(\delta)$ as the *corner set of $W$* and we denote it by $\partial_c W$.

**Remark.** Throughout these lecture notes we will only consider submanifolds with corner of codimension zero. But the concept can of course also play a role for other codimensions.

The following lemma also introduces a notation that we will use throughout these notes.

---

1275 Often in the literature such objects are called “submanifold with corners”. Following [Wall16, p. 30] we write “submanifold with corner” instead.

1276 See page 261 for the definition of a chart of type (ii).
Lemma 89.1. Let $M$ be an $n$-dimensional topological manifold and let $W$ be a compact codimension-zero submanifold with corner. We write

$$\partial_0 W := W \cap M \setminus \mathring{W} \quad \text{and} \quad \partial_1 W := W \cap \partial M.$$ 

The following five statements hold:

1. The subset $W$ itself is an $n$-dimensional topological manifold.
2. The boundary of the topological manifold $W$ equals $\partial_0 W \cup \partial_1 W$. Furthermore $\partial_0 W$ and $\partial_1 W$ are $(n-1)$-dimensional submanifolds of the boundary $\partial W$ such that $\partial_0 W \cap \partial_1 W = \partial(\partial_0 W) = \partial(\partial_1 W) = \partial_c W$.
3. The set $\hat{W} := W \setminus \partial_0 W$ is the interior of $W$ in $M$, in particular $\hat{W}$ is an open subset of $M$.
4. The subset $M \setminus \hat{W}$ is a codimension-zero submanifold of $M$ with corner given by $\partial_c(M \setminus \hat{W}) = \partial_c W$. Furthermore $\partial_0(M \setminus \hat{W}) = \partial_0 W$ and $\partial_1(M \setminus \hat{W}) = \partial_1 W$.
5. $\partial_0 W$ is a proper submanifold of $M$, in the sense of the definition on page 270.

The analogous statements also hold if we replace “topological” by “smooth”.

Remark. Let $M$ be a topological manifold and let $W$ be a submanifold in the sense of the definition on page 270. Evidently it is also a submanifold with corner. Furthermore note that it follows from Proposition 14.3 (1) together with Lemma 89.1 that $\partial_c W = \emptyset$.

Sketch of proof. In the proof that $W$ itself is a (topological) manifold we only have to worry about the corners. But for these we can use the approach taken in Proposition 80.9 to find a (smooth) atlas. The remaining statements follow reasonably easily from Proposition 14.2 and the definitions. We leave the slightly annoying task of filling in the details to the reader.

In the following we will generalize a few results on codimension-zero submanifolds to codimension-zero submanifolds with corner. It is unlikely that the reader’s pulse will quicken while reading the remainder of this section.
First we have the following variation on the Excision Theorem \[44.10\] for Topological Manifolds.

**Theorem 89.2. (Excision Theorem for Submanifolds with Corner)** Let \( M \) be an \( n \)-dimensional topological manifold and let \( W \) be a compact codimension-zero submanifold of \( M \) with corner. We write \( \hat{W} := W \setminus \partial W \). For every \( k \in \mathbb{N}_0 \) and every abelian group \( G \) the inclusion induced maps

\[
\begin{align*}
(a) \quad & H_k(W, \partial W; G) \xrightarrow{\cong} H_k(M, M \setminus \hat{W}; G) \\
(b) \quad & H_k(W, \partial W; G) \xrightarrow{\cong} H_k(M, (M \setminus \hat{W}) \cup \partial M; G) \\
(c) \quad & H_k(W, \partial_1 W; G) \xrightarrow{\cong} H_k(W \cup \partial M, \partial_1 W; G)
\end{align*}
\]

are isomorphisms. Similarly, all maps in cohomology “in the other direction” are also isomorphisms.

**Proof.** We will prove the statements on homology groups with \( \mathbb{Z} \)-coefficients in Exercise \[89.2\]. The statement for homology with \( G \)-coefficients and the statement for cohomology with \( G \)-coefficients are an immediate consequence of the above together with Corollaries \[57.20\] and \[73.20\].

We turn to the topic of orientations and fundamental classes. First we have the following lemma which generalizes Lemma \[86.17\] (2).

**Lemma 89.3.** Let \( R \) be a commutative ring and let \( M \) be a topological manifold that is equipped with an \( R \)-orientation. If \( W \) is a codimension-zero submanifold of \( M \) with corner, then \( W \) admits a unique \( R \)-orientation such that the inclusion map \( N \to M \) is orientation-preserving.

**Proof.** This statement follows immediately from Lemma \[86.17\] (1).

**Convention.** Let \( M \) be a topological manifold and let \( W \) be a codimension-zero submanifold with corner. If \( M \) is oriented, then we equip \( W \) with the orientation coming from Lemma \[89.3\].

The following lemma is a generalization of Lemma \[87.24\].

**Lemma 89.4.** Let \( M \) be a compact oriented \( n \)-dimensional topological manifold. Furthermore let \( W \subset M \) be a compact non-empty codimension-zero submanifold with corner. We write \( \hat{W} = W \setminus \partial W \). The following two statements hold:

1. The inclusion induced map \( H_n(W, \partial W; \mathbb{Z}) \to H_n(M, (M \setminus \hat{W}) \cup \partial_1 W; \mathbb{Z}) \) is an isomorphism.

2. The image of the fundamental classes \([M] \in H_n(M, \partial M; \mathbb{Z})\) and \([W] \in H_n(W, \partial W; \mathbb{Z})\) under the maps

\[
\begin{align*}
H_n(M, \partial M; \mathbb{Z}) & \to H_n(M, (M \setminus \hat{W}) \cup \partial_1 W; \mathbb{Z}) \\
\uparrow & \quad \downarrow
\end{align*}
\]

isomorphism by the Excision Theorem \[89.2\] (2).
Proof. The proof of Lemma 89.4 is basically identical to the proof of Lemma 87.24. □

89.2. Poincaré duality and codimension-zero submanifolds. The following lemma says that given a homology class in a codimension-zero submanifold $W$ of some topological manifold $M$ we can apply Poincaré duality in $M$ or $W$ and essentially we end up with the same result.

Lemma 89.5. Let $M$ be a compact oriented $n$-dimensional topological manifold and let $W$ be a compact codimension-zero with corner. We equip $W$ with the induced orientation from Lemma 86.17. We denote by $\hat{W} = W \setminus \partial W$. Furthermore let $A$ and $B$ be disjoint unions of components of $\partial M$ with $\partial M = A \cup B$ and $\partial_1 W \subset A$. We fix the following notation:

1. We denote by $w$ the obvious map $(W, \partial_1 W) \to (M, A)$ and also the obvious map $(W, \partial_0 W) \to (M, M \setminus \hat{W})$.
2. We denote by $p: (M, B) \to (M, M \setminus \hat{W})$ the obvious map.

Then for every $k \in \mathbb{N}_0$ the following diagram commutes:

\[
\begin{array}{ccc}
H_k(W, \partial_1 W; \mathbb{Z}) & \xrightarrow{\text{PD}_W} & H^{n-k}(W, \partial_0 W; \mathbb{Z}) \\
\downarrow w_* & & \downarrow (w^*)^{-1} \\
H_k(M, A; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{n-k}(M, B; \mathbb{Z}).
\end{array}
\]

Figure 1249. Illustration of Lemma 89.5

In the proof of Lemmas 89.5 and 89.6 will use the full force of Lemma 83.8 applied to excisive triads. Since this can be seriously confusing we recall the general statement of the lemma, before we provide the proof of Lemma 89.5.

---

\[1277\] Recall that by Proposition 44.3 the set $\hat{W} = W \setminus \partial W$ is indeed the interior of $W$ in $M$.

\[1278\] Here we use that by the Excision Theorem 89.2 we know that $w: (W, \partial_0 W) \to (M, M \setminus \hat{W})$ induces an isomorphism on cohomology groups.

\[1279\] Note that by Lemma 89.1 we can apply the Poincaré Duality Theorem 88.1 to obtain that $\cap[W]: H^{n-k}(W, \partial_1 W; \mathbb{Z}) \to H_k(W, \partial_0 W; \mathbb{Z})$ is an isomorphism. We denote its inverse by $\text{PD}_W$. 

Lemma 83.8. Let $f: (X, A, B) \rightarrow (\widetilde{X}, \widetilde{A}, \widetilde{B})$ be a map between two excisive triads. Then for any choice of $\varphi \in H^{n-k}(\widetilde{X}, \widetilde{A}; Z)$ and $\sigma \in H_m(X, A \cup B; Z)$ we have

$$f_*: H_m(X, A \cup B) \rightarrow H_m(\widetilde{X}, \widetilde{A} \cup \widetilde{B}) \quad f^*: H^{n-k}(\widetilde{X}, \widetilde{A}) \rightarrow H^{n-k}(X, A)$$

\[ \varphi \cap f_*(\sigma) = f_*(f^*(\varphi) \cap \sigma) \in H_k(\widetilde{X}, \widetilde{B}; Z). \]

Proof of Lemma 89.5. By definition of the isomorphisms $PD_W$ and $PD_M$, proving the lemma is equivalent to proving that the following diagram commutes:

$$\begin{array}{ccc}
H_k(W, \partial_1 W; Z) & \xleftarrow{\cong} & H^{n-k}(W, \partial_0 W; Z) \\
\downarrow w_* & & \downarrow p_* \\
H_k(M, A; Z) & \xleftarrow{\cong} & H^{n-k}(M, M \setminus \hat{W}; Z).
\end{array}$$

In the following we use the following notation:

1. We write $\hat{W} := W \setminus \partial W$.
2. We denote the map $(W, \partial W) \rightarrow (M, M \setminus \hat{W})$ by $w$ as well.
3. We denote the map $(M, \partial M) \rightarrow (M, M \setminus \hat{W})$ by $p$ as well.

Now let $\beta \in H^{n-k}(M, M \setminus \hat{W}; Z)$. We have the following equality in $H_k(M, A; Z)$:

$$w_*(w^*(\beta) \cap [W]) = \beta \cap w_*(\beta) \in H_k(M, M \setminus \hat{W}; Z).$$

Lemma 83.8 applied to the map $w: (W, \partial_0 W, \partial W) \rightarrow (M, (M \setminus \hat{W}) \setminus \hat{W})$ and $p: (M, B, A) \rightarrow (M, (M \setminus \hat{W}) \cup \hat{W})$ we have $p_* = \text{id}$.

We have thus shown that the above diagram does indeed commute.

We conclude this short introduction to submanifolds with corner with the following lemma that also relates Poincaré Duality in a topological manifold $M$ to Poincaré Duality in a compact submanifold $W$ with corner.

Lemma 89.6. Let $M$ be a compact oriented $n$-dimensional topological manifold and let $W$ be a compact codimension-zero submanifold with corner. Furthermore let $A$ and $B$ be disjoint unions of components of $\partial M$ with $\partial M = A \cup B$. We fix the following notation:

1. we set $C := \partial_1 W \cap A$ and $D := (\partial_1 W \cap B) \cup \partial_0 W$,
2. we set $\hat{W} := W \setminus \partial_0 W$,
3. the obvious maps $(W, C) \rightarrow (M, A)$ and $(W, D) \rightarrow (M, (M \setminus \hat{W}) \cup B)$ are denoted by $w$, and
4. we denote by $p: (M, B) \rightarrow (M, M \setminus \hat{W})$ the obvious map.
Then for every \( k \in \mathbb{N}_0 \) the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M, B; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{n-k}(M, A; \mathbb{Z}) \\
\downarrow^{p_*} & & \downarrow^{w^*} \\
H_k(M, (M \setminus \hat{W}) \cup B; \mathbb{Z}) & \xrightarrow{(w_*)^{-1}} & H_k(W, D; \mathbb{Z}) \xrightarrow{\text{PD}_W} H^{n-k}(W, C; \mathbb{Z}).
\end{array}
\]

**Example.** We continue with the notation from the previous lemma. If we set \( A := \partial M \) and \( B := \emptyset \), then \( C = \partial_1 W \) and \( D = \partial_0 W \) and we obtain that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{n-k}(M, \partial M; \mathbb{Z}) \\
\downarrow^{p_*} & & \downarrow^{w^*} \\
H_k(M, M \setminus \hat{W}; \mathbb{Z}) & \xrightarrow{(w_*)^{-1}} & H_k(W, \partial_0 W; \mathbb{Z}) \xrightarrow{\text{PD}_W} H^{n-k}(W, \partial_1 W; \mathbb{Z}).
\end{array}
\]

Furthermore, if we set \( A := \emptyset \) and \( B := \partial M \), then \( C = \emptyset \) and \( D = \partial W \), and we see that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M, \partial M; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{n-k}(M; \mathbb{Z}) \\
\downarrow^{p_*} & & \downarrow^{w^*} \\
H_k(M, (M \setminus \hat{W}) \cup \partial M; \mathbb{Z}) & \xrightarrow{(w_*)^{-1}} & H_k(W, \partial W; \mathbb{Z}) \xrightarrow{\text{PD}_W} H^{n-k}(W; \mathbb{Z}).
\end{array}
\]

These two important special cases are illustrated in Figure 1250.

---

**Proof.** We set \( \hat{W} := W \setminus (\partial_0 W \cup C) \). Note that \( M \setminus \hat{W} = (M \setminus \hat{W}) \cup B \). By definition of the isomorphisms \( \text{PD}_W \) and \( \text{PD}_M \), proving the lemma is equivalent to proving that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M, B; \mathbb{Z}) & \xrightarrow{\cap [M]} & H^{n-k}(M, A; \mathbb{Z}) \\
\downarrow^{p_*} & & \downarrow^{w^*} \\
H_k(M, M \setminus \hat{W}; \mathbb{Z}) & \xrightarrow{w_*} & H_k(W, D; \mathbb{Z}) \xleftarrow{\cup [W]} H^{n-k}(W, C; \mathbb{Z}).
\end{array}
\]

\[\text{We use that } w: (W, D) \to (M, (M \setminus \hat{W}) \cup B) \text{ induces an isomorphism on cohomology. This follows from a slight generalization of the Excision Theorem 89.2.}\]
So let $\beta \in H^{n-k}(M, A; \mathbb{Z})$. We have the following equalities in $H_k(M, M \setminus \hat{W}; \mathbb{Z})$:

$$p_* (\beta \cap [M]) = \beta \cap p_* ([M]) = \beta \cap w_* ([W]) = w_*(w^*(\beta) \cap [W]).$$

*Lemma 83.3* applied to the map $p: (M, A, B) \to (M, A, M \setminus \hat{W})$ of excisive triads

*by Lemma 89.4* we have $p_*([M]) = w_*([W])$ in $H_n(M, (M \setminus \hat{W}) \cup \partial M)$

*Lemma 83.3* applied to the map $w: (W, C, D) \to (M, A, M \setminus \hat{W})$ of excisive triads

---

**Exercises for Chapter 89**

**Exercise 89.1.** Let $M$ be an $n$-dimensional topological manifold and let $W$ be a compact codimension-zero submanifold of $M$ with corner. Show that there exists an embedding $\varphi: [0, 1] \times \partial_0 W \to W$ with the following two properties:

1. For every $x \in \partial_0 W$ we have $\varphi(0, x) = x$.
2. For every $t \in [0, 1]$ and every $x \in \partial_0 W = \partial (\partial_0 W)$ we have $\varphi(t, x) \in \partial_1 W$.

*Hint.* Adapt the proof of the Topological Collar Neighborhood Theorem 44.3

**Exercise 89.2.** Let $M$ be an $n$-dimensional topological manifold and let $W$ be a compact codimension-zero submanifold of $M$ with corner. We write $\hat{W} := W \setminus \partial_0 W$. Show that for every $k \in \mathbb{N}_0$ the inclusion induced maps

(a) $H_k(W, \partial_0 W) \xrightarrow{\sim} H_k(M, M \setminus \hat{W})$

(b) $H_k(W, \partial W) \xrightarrow{\sim} H_k(M, (M \setminus \hat{W}) \cup \partial M)$

(c) $H_k(W, \partial_1 W) \xrightarrow{\sim} H_k(W \cup \partial M, \partial M)$

are isomorphisms.

*Remark.* This exercise is a variation on the Excision Theorem 44.10 for Topological Manifolds. You might want to use Exercise 89.1

Part X

Applications of Poincaré Duality
90. THE CUP PRODUCT OF PROJECTIVE SPACES

In this chapter we will use the Poincaré Duality Theorem [88.1] to determine the cup product on \(H^*(\mathbb{C}P^n; \mathbb{Z})\) and \(H^*(\mathbb{R}P^n; \mathbb{F}_2)\). These calculations will allow us to prove several interesting consequences which at first glance have very little to do with cup products.

90.1. Non-singular pairings and the cup product. Before we start drawing more conclusions from the Poincaré Duality Theorem [88.1] we need to introduce some purely algebraic definitions.

**Definition.** Let \(R\) be a commutative ring and let \(V, W\) and \(S\) be \(R\)-modules.

1. A pairing on \(V \times W\) is a map
   \[
   V \times W \to S
   \]
   that is \(R\)-bilinear, i.e. that is \(R\)-linear in \(V\) and that is \(R\)-linear in \(W\).

2. We say that a pairing \(\langle \ , \rangle: V \times W \to S\) is non-singular if the induced maps
   \[
   V \to \text{Hom}_R(W, S) \quad \text{and} \quad W \to \text{Hom}_R(V, S)
   \]
   are isomorphisms.

We start out with the following elementary lemma.

**Lemma 90.1.** Let \(R\) be a commutative ring. Let \(V\) and \(W\) be free \(R\)-modules of the same finite rank and let
\[
\langle \ , \rangle: V \times W \to R
\]
be a pairing.

1. We denote by \(n\) the rank of \(V\). Let \(v_1, \ldots, v_n\) be a basis for \(V\) and let \(w_1, \ldots, w_n\) be a basis for \(W\). Then the following statement holds:
   the pairing \(\langle \ , \rangle\) is non-singular \(\iff\) \(\det(\langle v_i, w_j \rangle)_{i,j=1,\ldots,n}\) is a unit of \(R\).

2. Suppose \(V\) and \(W\) are of rank one. If \(v\) and \(w\) are generators of \(V\) respectively \(W\), then the following statement holds:
   the pairing \(\langle \ , \rangle\) is non-singular \(\iff\) \(\langle v, w \rangle\) is a unit of the ring \(R\).

**Proof.** The second statement is evidently just a special case of the first statement. So it suffices to prove the first statement. Let \(v_1, \ldots, v_n\) be a basis for \(V\) and let \(w_1, \ldots, w_n\) be a basis for \(W\). We denote by \(v_1^*, \ldots, v_n^* \in \text{Hom}(V, R)\) and \(w_1^*, \ldots, w_n^* \in \text{Hom}(W, R)\) the dual bases. We consider the maps
\[
V \to \text{Hom}_R(W, R) \quad \text{and} \quad W \to \text{Hom}_R(V, R)
\]
\[
v \mapsto \left( \begin{array}{c} W \to R \\ w \mapsto \langle v, w \rangle \end{array} \right) \quad \text{and} \quad w \mapsto \left( \begin{array}{c} V \to R \\ v \mapsto \langle v, w \rangle \end{array} \right).
\]

\[\text{In most examples we will be interested in } S = R, \text{ but later on we will, oddly enough, also develop a fondness for } R = \mathbb{Z} \text{ and } S = \mathbb{Q}/\mathbb{Z}.\]
Since \((\ ,\ )\) is \(R\)-bilinear both maps are \(R\)-homomorphisms. Furthermore, it is straightforward to show that with respect to these bases both the \(R\)-homomorphisms are represented by the transpose of the matrix \(\langle v_i, w_j \rangle_{i,j=1,...,n}\). The lemma is an immediate consequence of this observation. ■

Remark. The proof of Lemma 90.1 shows that if \(V\) and \(W\) are free \(R\)-modules of finite rank, then the pairing is non-singular if and only if either of the two maps \(V \to \text{Hom}(W, R)\) or \(W \to \text{Hom}(V, R)\) is an isomorphism. 1282

Now we return to topology.

**Proposition 90.2.** Let \(M\) be a closed \(n\)-dimensional topological manifold and let \(k \in \mathbb{N}_0\).

1. Suppose \(M\) is oriented with fundamental class \([M]\). If \(H_{k-1}(M; \mathbb{Z})\) and \(H_{n-k-1}(M; \mathbb{Z})\) are torsion-free, then the cup product pairing
   \[ H^k(M; \mathbb{Z}) \times H^{n-k}(M; \mathbb{Z}) \to \mathbb{Z} \]
   \[ (\varphi, \psi) \mapsto \langle \varphi \cup \psi, [M] \rangle \]
   is non-singular.

2. Let \(F\) be a field. If \(M\) is \(F\)-oriented with fundamental class \([M]\), then for any \(k \in \mathbb{N}_0\) the cup product pairing
   \[ H^k(M; F) \times H^{n-k}(M; F) \to F \]
   \[ (\varphi, \psi) \mapsto \langle \varphi \cup \psi, [M] \rangle \]
   is non-singular.

**Proof.** Let \(M\) be a closed \(n\)-dimensional topological manifold and let \(k \in \mathbb{N}_0\).

1. We suppose that \(M\) is oriented with fundamental class \([M]\) and we suppose that \(H_{k-1}(M; \mathbb{Z})\) and \(H_{n-k-1}(M; \mathbb{Z})\) are torsion-free. It follows from Proposition 85.13 (4), our hypothesis on \(H_{k-1}(M; \mathbb{Z})\) and \(H_{n-k-1}(M; \mathbb{Z})\), the classification of finitely generated abelian groups, Lemma 75.5 (3) and the Universal Coefficient Theorem 75.13 that \(H_{k-1}(M; \mathbb{Z})\), \(H_{n-k-1}(M; \mathbb{Z})\), \(H^k(M; \mathbb{Z})\) and \(H^{n-k}(M; \mathbb{Z})\) are finitely generated free abelian groups. Therefore by the remark on page 2193 it suffices to show that the map
   \[ \Omega: H^{n-k}(M; \mathbb{Z}) \to \text{Hom}(H^k(M; \mathbb{Z}), \mathbb{Z}) \]
   \[ \psi \mapsto (\varphi \mapsto \langle \varphi \cup \psi, [M] \rangle) \]
   is an isomorphism. We start out with the following claim.

   **Claim.** The following diagram commutes:
   \[ \begin{array}{ccc}
   H^{n-k}(M; \mathbb{Z}) & \xrightarrow{\Omega} & \text{Hom}(H^k(M; \mathbb{Z}), \mathbb{Z}) \\
   \text{ev} & \downarrow & \bigcirc ([M])^* \\
   \text{Hom}_{\mathbb{Z}}(H_{n-k}(M; \mathbb{Z}), \mathbb{Z}) & \xrightarrow{\langle \cdot, [M] \rangle} & H_{n-k}(M; \mathbb{Z}).
   \end{array} \]

---

1282 Is the hypothesis on \(V\) and \(W\) necessary to draw this conclusion? 1283 The right diagonal is the dual map corresponding to the map \(H^k(M; \mathbb{Z}) \xrightarrow{\langle [M] \rangle} H_{n-k}(M; \mathbb{Z}).\)
Note that for any $\psi \in H^{n-k}(M; \mathbb{Z})$ and any $\varphi \in H^k(M; \mathbb{Z})$ the following equalities hold in $\mathbb{Z}$:

$$\Omega(\psi)(\varphi) = (\varphi \cup \psi) \cap [M] = \varphi \cap (\psi \cap [M]) = \langle \psi, \varphi \cap [M] \rangle = \ev(\psi)(\varphi \cap [M]).$$

by definition of $\Omega$

and Lemma 83.7  Lemma 83.4

But this observation immediately shows that the diagram commutes.

We need to show that in the above diagram the horizontal map is an isomorphism. By the claim it suffices to show that the two diagonal maps are isomorphisms. The left diagonal map is an isomorphism by the Universal Coefficient Theorem 75.13 for Cohomology Groups together with Lemma 75.5 (3) and the fact, pointed out above, that $H_{n-k-1}(M; \mathbb{Z})$ is free abelian. Furthermore the second map is an isomorphism by the Poincaré Duality Theorem 88.1.

(2) Now let $F$ be a field. We suppose that $M$ is $F$-oriented with corresponding fundamental class $[M]$. By Proposition 75.19 the map

$$\ev : H^k(M; F) \rightarrow \Hom_F(H_k(M; F), F)$$

$$\varphi \mapsto \left( H_k(M; F) \rightarrow F, \sigma \mapsto \langle \varphi, \sigma \rangle \right)$$

is a natural isomorphism of $F$-vector spaces. The proof of (2) is now basically the same as the proof of (1).

The following corollary will be surprisingly effective in determining cup products on topological manifolds.

**Corollary 90.3.** Let $M$ be a closed connected $n$-dimensional topological manifold and let $k \in \mathbb{N}_0$.

1. Suppose that $M$ is oriented and that $H_{k-1}(M; \mathbb{Z})$ and $H_{n-k-1}(M; \mathbb{Z})$ are torsion-free. Furthermore suppose that $H^k(M; \mathbb{Z}) \cong \mathbb{Z}$ and $H^{n-k}(M; \mathbb{Z}) \cong \mathbb{Z}$. If $\varphi \in H^k(M; \mathbb{Z})$ and $\psi \in H^{n-k}(M; \mathbb{Z})$ are generators, then

$$\varphi \cup \psi = \epsilon \cdot [M]^* \in H^n(M; \mathbb{Z})$$

for some $\epsilon \in \{-1, 1\}$.

2. Let $F$ be a field such that $M$ is $F$-orientable. Suppose that $H^k(M; F) \cong F$ and $H^{n-k}(M; F) \cong F$. If $\varphi \in H^k(M; F)$ and $\psi \in H^{n-k}(M; F)$ are non-zero, then $\varphi \cup \psi$ is non-zero in $H^n(M; F) \cong F$.

**Proof.** Let $M$ be a closed connected $n$-dimensional topological manifold and let $k \in \mathbb{N}_0$.

1. By our hypothesis and by Proposition 90.2 (1) the cup product pairing

$$H^k(M; \mathbb{Z}) \times H^{n-k}(M; \mathbb{Z}) \rightarrow \mathbb{Z},$$

$$(\varphi, \psi) \mapsto \langle \varphi \cup \psi, [M] \rangle$$

is non-singular. It follows from this fact and Lemma 90.1 (2) that $\langle \varphi \cup \psi, [M] \rangle = \pm 1$. But by Lemma 75.16 this just means that $\varphi \cup \psi \in H^n(M; \mathbb{Z})$ is a generator.
(2) This proof is almost identical to the proof of (1), we just need to replace Proposition 90.2 (1) by Proposition 90.2 (2).

\[ \text{Example.} \] Let \( m \neq n \in \mathbb{N} \). As on many earlier occasions we denote by \( p: S^m \times S^n \rightarrow S^m \) and by \( q: S^m \times S^n \rightarrow S^n \) the two obvious projection maps. Let \( 1 \in H^0(S^m \times S^n; \mathbb{Z}) \) be the neutral element from Proposition 81.7. In Lemma 84.3 we showed that the cohomology of \( S^m \times S^n \) is given as follows:

\[
H^*(S^m \times S^n; \mathbb{Z}) = \mathbb{Z} \cdot 1 \oplus \mathbb{Z} \cdot p^*([S^m]^*) \oplus \mathbb{Z} \cdot q^*([S^n]^*) \oplus \mathbb{Z} \cdot [S^m \times S^n]^*.
\]

It follows from Corollary 90.3 (1)\(^{1284}\) that \( p^*([S^m]^*) \cup q^*([S^n]^*) = \pm [S^m \times S^n]^* \). This result recovers (up to the sign indeterminacy) the calculation of the non-trivial cup product on \( S^m \times S^n \) that we had initially performed in Lemma 84.3 using the somewhat mysterious Product Theorem 84.1. In Exercise 90.3 we will see, that with slightly more effort, one can also prove the same type of result for \( m = n \).

Next we consider the topological spaces \( S^2 \vee S^4 \) and \( \mathbb{C}P^2 \). It follows from Propositions 14.14 and 20.3 and the discussion on page 997 that \( S^2 \vee S^4 \) and \( \mathbb{C}P^2 \) are both simply connected. Furthermore it follows from Propositions 43.4 and 47.8 the calculation on page 1262 and the Universal Coefficient Theorem 75.13 for Cohomology Groups that for any \( k \in \mathbb{N}_0 \) we have

\[
H_k(S^2 \vee S^4; \mathbb{Z}) \cong H^k(S^2 \vee S^4; \mathbb{Z}) \cong H^k(\mathbb{C}P^2; \mathbb{Z}) \cong H_k(\mathbb{C}P^2; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \\ 0, & \text{otherwise.} \end{cases}
\]

We can thus view \( S^2 \vee S^4 \) as a (co-) homological doppelgänger to \( \mathbb{C}P^2 \).

Using Corollary 90.3 (1) we can easily prove the following lemma which implies in particular that \( S^2 \vee S^4 \) is not homotopy equivalent to \( \mathbb{C}P^2 \).

**Lemma 90.4.** The topological space \( S^2 \vee S^4 \) is not homotopy equivalent to any closed topological manifold.

**Proof.** Let \( X \) be a closed topological manifold whose homology and cohomology groups are isomorphic to the corresponding groups of \( S^2 \vee S^4 \). It follows from the above calculation of homology groups, our hypothesis that \( X \) is compact, from Propositions 41.5 and 87.22 and Theorems 87.1 and 87.3 that \( X \) is a closed oriented closed connected 4-dimensional topological manifold. But then Corollary 90.3 (1) implies that the cup product

\[
H^2(X; \mathbb{Z}) \times H^2(X; \mathbb{Z}) \rightarrow H^4(X; \mathbb{Z})
\]

is non-zero.

On the other hand in Lemma 81.11 we saw that the cup product

\[
\cup: H^2(S^2 \vee S^4; \mathbb{Z}) \times H^2(S^2 \vee S^4; \mathbb{Z}) \rightarrow H^4(S^2 \vee S^4; \mathbb{Z})
\]

is the zero-map. By Corollary 81.12 and the above calculation of the cup product of \( X \) this implies that \( S^2 \vee S^4 \) and \( X \) are not homotopy equivalent. \( \blacksquare \)

\(^{1284}\) Of course here we also use the fact, with which we are very familiar by now, that the homology groups of \( S^m \times S^n \) are torsion-free.
Remark. One can ask whether the adjective “closed” in Lemma 90.4 is necessary. It turns out that this is the case. In fact every wedge of finitely many spheres can be viewed as a deformation retract of an open subset of a sufficiently high-dimensional $\mathbb{R}^n$. For the wedge $S^1 \vee S^1$ we sketch the argument in Figure 1252. With slightly more care one can also show that this wedge of finitely many spheres is also a deformation retract of some compact $n$-dimensional smooth manifold of $\mathbb{R}^n$. We leave it to the reader to provide a formal proof for these statements.

We conclude this section with the following application to de Rham cohomology. We will not make use of it later on.

Corollary 90.5. If $M$ is a closed oriented $n$-dimensional smooth manifold, then for any $k \in \mathbb{N}_0$ the pairing

$$H^k_{\text{dR}}(M) \times H^{n-k}_{\text{dR}}(M) \to \mathbb{R}$$

$$([\varphi], [\psi]) \mapsto \int_M \varphi \wedge \psi$$

is non-singular.

Since there is no “de Rham homology” the above corollary is usually called the Poincaré Duality Theorem for de Rham cohomology.

Remark. Evidently there are also more direct proofs of Corollary 90.5 that take place within the setting of de Rham cohomology. We refer to [BoT82, p. 44] or alternatively [War83, Theorem 6.13] for such a proof.

Proof. It is straightforward to see that it suffices to deal with the case that $M$ is connected. Theorem 81.19 and Proposition 79.7 give us the following commutative diagram with vertical isomorphisms:

$$
\begin{array}{ccc}
H^k_{\text{dR}}(M) \times H^{n-k}_{\text{dR}}(M) & \to & \mathbb{R} \\
\cong & & = \\
H^k(M; \mathbb{R}) \times H^{n-k}(M; \mathbb{R}) & \to & \mathbb{R}
\end{array}
$$

By Proposition 90.2 (2) the pairing on the bottom is non-singular. Thus the pairing on the top is also non-singular.

90.2. The cup product of $\mathbb{C}P^n$ and applications. In this section we apply our acquired wisdom to the complex projective spaces $\mathbb{C}P^n$. Recall that in Lemma 12.5 we showed that
\(\mathbb{CP}^n\) is a closed \(2n\)-dimensional smooth manifold that comes with a canonical orientation. Thus we will always view \(\mathbb{CP}^n\) as an oriented smooth manifold. In particular \(\mathbb{CP}^n\) comes with a canonical fundamental class \([\mathbb{CP}^n] \in H_{2n}(\mathbb{CP}^n; \mathbb{Z})\) and a canonical dual fundamental class \([\mathbb{CP}^n]^* \in H^{2n}(\mathbb{CP}^n; \mathbb{Z})\).

An astute observer might already have noticed that Corollary 90.3 (1) can be used to compute the cup product on \(H^*(\mathbb{CP}^2; \mathbb{Z})\). In fact in this section we will use Corollary 90.3 (1) and the naturality of the cup product to compute the cohomology ring of any complex projective space \(\mathbb{CP}^n\). Throughout this section, given \(m \leq n\) we will view \(\mathbb{CP}^m\) as a submanifold of \(\mathbb{CP}^n\) via the smooth embedding

\[
i : \mathbb{CP}^m \to \mathbb{CP}^n \quad [z_0 : \cdots : z_m] \mapsto [z_0 : \cdots : z_m : 0 : \cdots : 0].
\]

We prepare the ground with the following elementary lemma.

**Lemma 90.6.**

1. For every \(n \in \mathbb{N}\) and every \(k \in \mathbb{N}_0\) we have

\[
H_k(\mathbb{CP}^n; \mathbb{Z}) \cong H^k(\mathbb{CP}^n; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise}. \end{cases}
\]

2. Let \(m \leq n\). We denote by \(i : \mathbb{CP}^m \to \mathbb{CP}^n\) the inclusion map. For any \(k \leq 2m\) the induced maps \(i_* : H_k(\mathbb{CP}^m; \mathbb{Z}) \to H_k(\mathbb{CP}^n; \mathbb{Z})\) and \(i^* : H^k(\mathbb{CP}^n; \mathbb{Z}) \to H^k(\mathbb{CP}^m; \mathbb{Z})\) are isomorphisms.

**Proof (\(*\)).** First we recall that in Lemma 36.1 we showed that we can view \(\mathbb{CP}^n\) as a CW-complex which admits exactly one cell in dimensions \(0, 2, \ldots, 2n\) and which admits no cells in any other dimension. Furthermore we saw that the CW-structure can be chosen in such a way that for \(k \in \{0, \ldots, n\}\) the \((2k+1)\)-skeleton on \(\mathbb{CP}^n\) equals \(\mathbb{CP}^k\).

Furthermore recall that by Propositions 48.4 we know that singular and cellular homology are naturally isomorphic. Together with the above discussion of the CW-structures it follows that for every \(n \in \mathbb{N}\) and every \(k \in \mathbb{N}_0\) we have

\[
H_k(\mathbb{CP}^n; \mathbb{Z}) \cong H^k_{\text{CW}}(\mathbb{CP}^n; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise} \end{cases}
\]

and that for every \(m \leq n\) the inclusion induced maps \(i_* : H_k(\mathbb{CP}^m; \mathbb{Z}) \to H_k(\mathbb{CP}^n; \mathbb{Z})\) are isomorphisms for \(k \leq 2m\).

In Proposition 4.4 we had also seen that singular and cellular cohomology are naturally isomorphic. So the same logic applies to cohomology groups.

We also introduce the following notation.

**Notation.**

1. Let \(X\) be a topological space, let \(R\) be a commutative ring and let \(\varphi \in H^k(X; R)\). We define \(\varphi^0 = 1_X\) and given any \(n \in \mathbb{N}\) we define

\[
\varphi^n = \underbrace{\varphi \cup \cdots \cup \varphi}_{n \text{ times}} \in H^{kn}(X; R).
\]
(2) Recall that we denote by \([\mathbb{CP}^1]^*\) ∈ \(H^2(\mathbb{CP}^1; Z)\) the dual fundamental class of \(\mathbb{CP}^1\). For any \(n \geq 1\) we denote by \(i: \mathbb{CP}^1 \to \mathbb{CP}^n\) the above inclusion map. By Lemma 90.6 we can define \(x := (i^*)^{-1}([\mathbb{CP}^1]^*) \in H^2(\mathbb{CP}^n; Z)\). We refer to \(x \in H^2(\mathbb{CP}^n; Z)\) as the **standard generator**.

Now we have the tools to determine the cup product of all complex projective spaces.

**Proposition 90.7.** Let \(n \in \mathbb{N}\).

1. For every \(k \in \{0, \ldots, n\}\) the \(k\)-th power \(x^k \in H^{2k}(\mathbb{CP}^n; Z) \cong \mathbb{Z}\) is a generator.
2. If we view \([x]/(x^{n+1})\) as a superalgebra by equipping the ring with the grading determined by \(\deg(x) = 2\), then the obvious map
   \[Z[x]/(x^{n+1}) \to (H^*(\mathbb{CP}^n; Z), \cup)\]

   is an isomorphism of superalgebras.

**Proof.** It follows immediately from the definitions and Proposition 81.8 that the map in (2) is a homomorphism of superalgebras. This observation, together with Lemma 90.6 shows that (2) is a consequence of (1). Thus it remains to prove (1)

We prove (1) by induction on \(n\). Evidently the statement holds for \(n = 1\). Now suppose it holds for some \(n - 1\) with \(n \geq 2\). We denote by \(i: \mathbb{CP}^{n-1} \to \mathbb{CP}^n\) the inclusion map. Note that \(i^*(x) = x \in H^2(\mathbb{CP}^{n-1}; Z)\). It follows easily from Lemma 90.6 together with Lemma 81.10 and our induction hypothesis that for each \(k \in \{1, \ldots, n-1\}\) the cohomology class \(x^k \in H^{2k}(\mathbb{CP}^n; Z)\) is a generator. It remains to show that \(x^n \in H^{2n}(\mathbb{CP}^n; Z)\) is also a generator. This is an immediate consequence of Corollary 90.3 (1), applied to the generator \(\varphi := x \in H^2(\mathbb{CP}^n; Z) \cong \mathbb{Z}\) and the generator \(\psi := x^{-1} \in H^{2(n-1)}(\mathbb{CP}^n; Z) \cong \mathbb{Z}\).

The previous proof leaves it open whether or not \(x^n \in H^{2n}(\mathbb{CP}^n; Z)\) equals the dual fundamental class \([\mathbb{CP}^n]^*\). We formulate this as a question which we will answer later in Proposition 94.11, when we will have obtained more tools for calculating cup products.

**Question 90.8.** Let \(n \in \mathbb{N}\). Does the \(n\)-th power \(x^n \in H^{2n}(\mathbb{CP}^n; Z)\) equal the dual fundamental class \([\mathbb{CP}^n]^*\)?

In Lemma 90.4 we had in particular shown that \(\mathbb{CP}^2\) is not homotopy equivalent to its (co-) homological doppelgänger \(S^2 \vee S^4\). On page 442 we pointed out that \(S^2 \times S^4\) and \(\mathbb{CP}^3\) is another example of a pair of topological spaces that cannot be distinguished using the fundamental group and using homology groups. This motivated us to ask in Question 58.9 whether the topological spaces \(S^2 \times S^4\) and \(\mathbb{CP}^3\) are homeomorphic. Now we can answer the question in the negative, in fact we can prove an even stronger result.

**Corollary 90.9.** The topological spaces \(S^2 \times S^4\) and \(\mathbb{CP}^3\) are not homotopy equivalent.

**Proof.** In Lemma 84.3 we saw that the cup product
\[H^2(S^2 \times S^4; Z) \times H^2(S^2 \times S^4; Z) \to H^4(S^2 \times S^4; Z)\]
is zero, whereas we saw in Proposition 90.7 that the cup product
\[H^2(\mathbb{CP}^3; Z) \times H^2(\mathbb{CP}^3; Z) \to H^4(\mathbb{CP}^3; Z)\]
is non-zero. It follows from Corollary 81.12 that \(S^2 \times S^4\) and \(\mathbb{CP}^3\) are not homotopy equivalent.
We recall the following definition from page 1808.

**Definition.** Let \( M \) be a compact oriented topological manifold. We say that \( M \) is **amphichiral** if \( M \) admits an orientation-reversing self-homeomorphism, otherwise we say that \( M \) is **chiral**.

On page 1811 we saw that many smooth manifolds are amphichiral, for example we showed that all compact oriented 2-dimensional topological manifolds are amphichiral.

In Question 72.5 we had asked whether there exist compact oriented topological manifolds that are chiral. Now we will see that the complex projective space \( \mathbb{C}P^2 \) is chiral. This gives an affirmative answer to Question 72.5. Note that the following corollary also gives a negative answer to Question 69.13 (3).

**Corollary 90.10.** The smooth manifold \( \mathbb{C}P^2 \) is chiral, i.e. there does not exist a self-homeomorphism \( f : \mathbb{C}P^2 \to \mathbb{C}P^2 \) with \( f_*([\mathbb{C}P^2]) = -[\mathbb{C}P^2] \).

**Remark.** In Exercise 90.4 we will discuss for which \( n \in \mathbb{N} \) the complex projective space \( \mathbb{C}P^n \) is chiral.

**Proof.** As usual we denote by \( x \in H^2(\mathbb{C}P^2; \mathbb{Z}) \) the standard generator. By Proposition 90.7 we know that \( x \cup x \in H^4(\mathbb{C}P^2; \mathbb{Z}) \) is a generator. This implies that \( x \cup x = \epsilon \cdot [\mathbb{C}P^2]^* \) for some \( \epsilon \in \{-1, 1\} \).

Now let \( f : \mathbb{C}P^2 \to \mathbb{C}P^2 \) be a self-homeomorphism. Since we want to show that \( \mathbb{C}P^2 \) is chiral we need to show that \( f_*([\mathbb{C}P^2]) = [\mathbb{C}P^2] \) \( \in \) \( H_4(\mathbb{C}P^2; \mathbb{Z}) \), or equivalently, that \( f^*([\mathbb{C}P^2]^*) = [\mathbb{C}P^2]^* \) \( \in \) \( H^4(\mathbb{C}P^2; \mathbb{Z}) \).

Now we see that
\[
\begin{align*}
 f^*([\mathbb{C}P^2]^*) &= \epsilon \cdot f^*(x \cup x) \\
 &= \epsilon \cdot (f^*(x) \cup f^*(x)) \\
 &\uparrow \text{Lemma 81.10} \\
 &= \epsilon \cdot (\eta \cdot x \cup \eta \cdot x) \\
 &= \epsilon \cdot \eta^2 \cdot (x \cup x) \\
 &\uparrow \text{Lemma 81.10} \quad \text{f}^*(x) \text{ is also a generator of } H^2(\mathbb{C}P^4; \mathbb{Z}) \\
 &= \epsilon \cdot (x \cup x) = [\mathbb{C}P^2]^*.
\end{align*}
\]

\( \cup \) is bilinear since \( \eta \in \{-1, 1\} \)

Next we turn to the calculation of the cohomology ring of the infinite-dimensional complex projective space \( \mathbb{C}P^\infty = \lim \mathbb{C}P^n \).

**Lemma 90.11.**

1. For every \( k \in \mathbb{N} \) we have
\[
H^k(\mathbb{C}P^\infty; \mathbb{Z}) \cong H_k(\mathbb{C}P^\infty; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}, & \text{if } k \text{ is even}, \\
0, & \text{if } k \text{ is odd}.
\end{cases}
\]

2. Let \( n \in \mathbb{N} \). We denote by \( i : \mathbb{C}P^n \to \mathbb{C}P^\infty \) the inclusion map. For any \( k \leq 2n \) the induced maps \( i_* : H_k(\mathbb{C}P^n; \mathbb{Z}) \to H_k(\mathbb{C}P^\infty; \mathbb{Z}) \) and \( i^* : H^k(\mathbb{C}P^\infty; \mathbb{Z}) \to H^k(\mathbb{C}P^n; \mathbb{Z}) \) are isomorphisms.

**Proof.** The statements in (1) and (2) regarding homology groups follow from the discussion on page 1263. The statements in (1) and (2) regarding cohomology groups then follow from the Universal Coefficient Theorem 75.13 for Cohomology Groups.
Remark. One could also prove the lemma using Lemma \ref{Lemma:90.6} and a suitable generalization of Proposition \ref{Prop:76.12}.

Notation. We denote by $i: \mathbb{C}P^1 \to \mathbb{C}P^\infty$ the inclusion map. By Lemma \ref{Lemma:90.11} we can set $x := (i^*)^{-1}([\mathbb{C}P^1]^*) \in H^2(\mathbb{C}P^\infty; \mathbb{Z})$. We refer to $x$ as the standard generator of $H^2(\mathbb{C}P^\infty; \mathbb{Z})$.

**Proposition 90.12.**

1. For every $k \in \mathbb{N}$ the $k$-th power $x^k \in H^{2k}(\mathbb{C}P^\infty; \mathbb{Z}) \cong \mathbb{Z}$ is a generator.
2. If we view $\mathbb{Z}[x]$ as a superalgebra by equipping the ring with the grading determined by deg($x$) = 2, then the obvious map

$$\mathbb{Z}[x] \to (H^*(\mathbb{C}P^\infty; \mathbb{Z}), \cup)$$

is an isomorphism of superalgebras.

**Proof.** Exactly as in the proof of Proposition \ref{Prop:90.7} we see that (2) is a consequence of (1). Thus it remains to prove (1). So let $k \in \mathbb{N}$. We consider the inclusion map $j: \mathbb{C}P^k \to \mathbb{C}P^\infty$. By Proposition \ref{Prop:90.7} and Lemma \ref{Lemma:81.10} we know that $j^*(x^k) = j^*(x)^k = x^k \in H^{2k}(\mathbb{C}P^k; \mathbb{Z})$ is a generator. It follows from Lemma \ref{Lemma:90.11} that $x^k \in H^{2k}(\mathbb{C}P^\infty; \mathbb{Z})$ is also a generator. \hfill \Box

Remark. It follows from Proposition \ref{Prop:84.21} and the discussion on page \pageref{Page:2055} that for each $k \in \mathbb{N}$ we also have an isomorphism

$$(H^*(\mathbb{C}P^\infty \times \ldots \times \mathbb{C}P^\infty; \mathbb{Z}), \cup) \cong \mathbb{Z}[x_1, \ldots, x_k]$$

of superalgebras. Here $x_1, \ldots, x_k$ are given by preimages of the standard generator of the group $H^2(\mathbb{C}P^\infty; \mathbb{Z})$ under the $k$ obvious projection maps.

The fact that so far we worked with $\mathbb{Z}$-coefficients was mostly irrelevant. In fact most of the results carry over, with obvious modifications, to the cohomology groups $H^*(\mathbb{C}P^n; R)$ where $R$ is an arbitrary commutative ring. For future reference we state the following proposition.

**Proposition 90.13.** Let $n \in \mathbb{N}$.

1. For every every $k \in \mathbb{N}_0$ we have

$$H_k(\mathbb{C}P^n; \mathbb{Z}_2) \cong H^k(\mathbb{C}P^n; \mathbb{Z}_2) \cong \begin{cases} \mathbb{Z}_2, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

2. We denote by $x \in H^2(\mathbb{C}P^n; \mathbb{Z}_2)$ the unique non-trivial element. If we view the ring $\mathbb{Z}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by deg($x$) = 2, then the obvious map

$$\mathbb{Z}_2[x]/(x^{n+1}) \to (H^*(\mathbb{C}P^n; \mathbb{Z}_2), \cup)$$

is an isomorphism of superalgebras. The obvious analogues for $\mathbb{C}P^\infty$ also hold.
90. THE CUP PRODUCT OF PROJECTIVE SPACES

Proof. This proposition can be proved in an almost identical way as Proposition 90.12. Alternatively, we can deduce the proposition from Proposition 90.12, the Universal Coefficient Theorem 75.26, Lemma 75.30, and Proposition 82.4 (2). We leave it to the impeccably conscientious reader to fill in the details.

Towards the end of this section we recall the definition of a retract. Thus let $A$ be a subset of a topological space $X$. We denote by $i: A \rightarrow X$ the inclusion map. Recall that we say that $A$ is a retract of $X$ if there exists a map $r: X \rightarrow A$ such that $r \circ i = id_A$. It follows immediately from the functoriality of homology groups and Splitting Lemma 46.2 that for each $k$ the group $H_k(A; \mathbb{Z})$ is a subsummand of $H_k(X; \mathbb{Z})$.

Let $m < n$. In Question 53.4 we had asked whether $\mathbb{C}P^m \subset \mathbb{C}P^n$ is a retract of $\mathbb{C}P^n$. Note that Lemma 90.6 shows that a study of homology groups does not preclude that for $m < n$ the complex projective space $\mathbb{C}P^m$ is a retract of $\mathbb{C}P^n$. Nonetheless, the final result of the section gives a negative answer to Question 53.4, i.e., we show that $\mathbb{C}P^m$ is not a retract of $\mathbb{C}P^n$.

Proposition 90.14. If $1 \leq m < n$, then $\mathbb{C}P^m \subset \mathbb{C}P^n$ is not a retract of $\mathbb{C}P^n$.

Proof. Let $1 \leq m < n$. We denote by $i: \mathbb{C}P^m \rightarrow \mathbb{C}P^n$ the inclusion map. Suppose there exists a retraction $r: \mathbb{C}P^n \rightarrow \mathbb{C}P^m$. We denote by $x \in H^2(\mathbb{C}P^n; \mathbb{Z})$ the standard generator. We have

$$x^2 = (r^*i^*(x))^2 = r^*(i^*(x))^2 = r^*(0) = 0 \in H^2(\mathbb{C}P^n; \mathbb{Z}).$$

But this contradicts the fact shown in Proposition 90.7 that $x^n \neq 0$.

90.3. The cup product of $\mathbb{R}P^n$ and applications. In this section we intend to determine the cup product of the real projective space $\mathbb{R}P^n$ with $\mathbb{F}_2$-coefficients. Evidently the approach will be very similar to the one taken in the previous section. First we recall that on page 287 we saw that the real projective space $\mathbb{R}P^n$ is a closed $n$-dimensional smooth manifold. Given $m \leq n$ we will view $\mathbb{R}P^m$ as a submanifold of $\mathbb{R}P^n$ via the smooth embedding

$$i: \mathbb{R}P^m \rightarrow \mathbb{R}P^n,$$

$$[x_0 : \cdots : x_m] \mapsto [x_0 : \cdots : x_m : 0 : \cdots : 0].$$

The following lemma plays the role of Lemma 90.6.

Lemma 90.15.

1. For every $n \in \mathbb{N}$ we have

$$H^k(\mathbb{R}P^n; \mathbb{F}_2) \cong H_k(\mathbb{R}P^n; \mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0, 1, \ldots, n, \\ 0, & \text{otherwise}. \end{cases}$$

2. Let $m \leq n$. For any $k \leq m$ the induced maps $i_*: H_k(\mathbb{R}P^m; \mathbb{F}_2) \rightarrow H_k(\mathbb{R}P^n; \mathbb{F}_2)$ and $i^*: H^k(\mathbb{R}P^n; \mathbb{F}_2) \rightarrow H^k(\mathbb{R}P^m; \mathbb{F}_2)$ are isomorphisms.
**Proof.** The calculation of the isomorphism types of the (co-) homology groups and of the induced maps on homology is basically the same as in the proof of Lemma 90.15. The argument that determines the induced map on $\mathbb{F}_2$-cohomology is slightly different. This time we use Proposition 75.19 which gives us the following commutative diagram:

$$
\begin{array}{ccc}
H^k(\mathbb{R}P^n; \mathbb{F}_2) & \xrightarrow{ev} & \text{Hom}(H_k(\mathbb{R}P^n; \mathbb{F}_2), \mathbb{F}_2) \\
\downarrow i^* & & \downarrow i^* \\
H^k(\mathbb{R}P^m; \mathbb{F}_2) & \xrightarrow{ev} & \text{Hom}(H_k(\mathbb{R}P^m; \mathbb{F}_2), \mathbb{F}_2).
\end{array}
$$

As we had just pointed out, the maps on the right are isomorphisms for $k \leq m$. It follows that the maps on the left are also isomorphisms for $k \leq m$. ■

**Notation.** Given $n \in \mathbb{N}$ we denote by $x \in H^1(\mathbb{R}P^n; \mathbb{F}_2)$ the unique non-trivial element.

The following proposition is the analogue of Propositions 90.7 and 90.12.

**Proposition 90.16.** Let $n \in \mathbb{N}$.

1. For every $k \in \{0, \ldots, n\}$ the $k$-th power $x^k \in H^k(\mathbb{R}P^n; \mathbb{F}_2) \cong \mathbb{F}_2$ is non-trivial.
2. If we view $\mathbb{F}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map

$$
\mathbb{F}_2[x]/(x^{n+1}) \rightarrow (H^*(\mathbb{R}P^n; \mathbb{F}_2), \cup)
$$

is an isomorphism of superalgebras.
3. If we view $\mathbb{F}_2[x]$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map

$$
\mathbb{F}_2[x] \rightarrow (H^*(\mathbb{R}P^\infty; \mathbb{F}_2), \cup)
$$

is an isomorphism of superalgebras.

**Proof.** First recall that Proposition 86.13 implies that any topological manifold, in particular $\mathbb{R}P^n$, is $\mathbb{F}_2$-orientable. With this observation the proof of the proposition is basically identical to the proofs of Proposition 90.7 and 90.12. We just need to replace Lemma 90.15 by Lemma 90.16 and we need to replace Corollary 90.3 (1) by Corollary 90.3 (2). ■

**Remark.**

1. In principle one could have tried to compute the cup product on $\mathbb{R}P^n$ using the same approach that we had taken in Section 81.5. More precisely, suppose one has found an explicit $\mathbb{F}_2$-fundamental class $\sigma$ for $\mathbb{R}P^n$. We denote by $\varphi \in C^1(\mathbb{R}P^2; \mathbb{F}_2)$ the 1-cocycle from page 1998. Now we know from Proposition 90.16 that $\langle \varphi^n, \sigma \rangle = 1$. But more interestingly, if one shows with an explicit calculation that $\langle \varphi^n, \sigma \rangle = 1$, then this gives a new and elementary proof of Proposition 90.16.
2. We have just computed the cup product on $H^*(\mathbb{R}P^n; \mathbb{F}_2)$. We leave it as a highly instructive exercise to use the same approach to determine the cup product on $H^*(\mathbb{R}P^n; \mathbb{Z})$. This cup product is also determined, using a somewhat different approach, in [Hat02] p. 214.
(3) In Corollary 88.15 we showed that there is no map \( S^1 \times S^2 \) to \( \mathbb{R}^3 \) of degree one, thus giving a negative answer to Question 69.12. On page 2037 and in Proposition 90.16 we had determined the cup product of \( S^1 \times S^2 \) and \( \mathbb{R}^3 \) on cohomology with \( \mathbb{F}_2 \)-coefficients. Using an argument similar to the proof of Lemma 84.5 one can easily give an alternative proof of Corollary 88.15.

For completeness’ sake we mention the following analogue of Proposition 90.14.

**Proposition 90.17.** If \( 1 \leq m < n \), then \( \mathbb{R}^m \subset \mathbb{R}^n \) is not a retract of \( \mathbb{R}^n \).

**Proof.** The proof is totally analogous to the proof of Proposition 90.14. In the proof we just need to replace Lemma 90.6 by Lemma 90.15. \( \square \)

**Remark.** We can also give an alternative proof of Proposition 90.17 using higher homotopy groups. More precisely, let \( 1 \leq m < n \). By Proposition 40.10 together with Proposition 40.13 we know that \( \pi_m(S^n) = 0 \). Furthermore by Lemma 53.2 together with Proposition 40.13 we know that \( \pi_m(S^m) \neq 0 \). Since higher homotopy groups are functorial, see Proposition 40.6, we can use the standard argument, see e.g. the proof of Lemma 15.7 to show that \( \mathbb{R}^m \subset \mathbb{R}^n \) is not a retract of \( \mathbb{R}^n \).

One of the many consequences of our calculations from this chapter is that we can now calculate the Lusternik-Schnirelmann category for \( \mathbb{R}P^n \) and \( \mathbb{C}P^n \). More precisely, we have the following proposition that gives a complete answer to Question 82.10.

**Proposition 90.18.** For any \( n \in \mathbb{N}_0 \) we have \( \text{cat}(\mathbb{R}P^n) = \text{cat}(\mathbb{C}P^n) = n \).

**Proof.** Given any \( n \in \mathbb{N}_0 \) we have

\[
\begin{align*}
\text{cat}(\mathbb{R}P^n) \geq & \text{cup length cl}(\mathbb{R}P^n) \geq n. \\
\text{see page } 2014 \text{ for the definition} \\
\text{see page } 1413 \text{ by Proposition } 82.11 \text{ by Proposition } 90.16
\end{align*}
\]

The same argument also works for \( \mathbb{C}P^n \), we just need to replace Propositions 90.16 by Propositions 90.17. \( \square \)

We conclude this section with an alternative proof for the Borsuk-Ulam Theorem. First we recall the statement of the Borsuk-Ulam Theorem.

**Theorem 59.3 (Borsuk-Ulam)** For every map \( f: S^n \to \mathbb{R}^n \) there exists a pair of antipodal points \( x \) and \(-x\) on \( S^n \) with \( f(x) = f(-x) \).

![Figure 1253. Illustration of the Borsuk-Ulam Theorem.](image-url)
Remark. We remind that the reader that in Section 59.4 and Section 59.5 we collected several interesting consequences of the Borsuk-Ulam Theorem 59.3.

In the new proof of the Borsuk-Ulam Theorem below we will need the following Lemma.

**Lemma 90.19.**

1. Let \( k \geq 2 \). As usual we denote by \( p: S^k \to \mathbb{R}P^k \) the obvious projection map. If \( \gamma: [0,1] \to S^k \) is a path with \( \gamma(1) = -\gamma(0) \), then \( p \circ \gamma \) represents the unique non-trivial element in \( \pi_1(\mathbb{R}P^k) \).

2. Let \( k,l \geq 2 \). Furthermore let \( h: \mathbb{R}P^k \to \mathbb{R}P^l \) be a map. If \( h_*: \pi_1(\mathbb{R}P^k) \to \pi_1(\mathbb{R}P^l) \) has non-trivial image, then the induced maps \( h_*: H_1(\mathbb{R}P^k; F_2) \to H_1(\mathbb{R}P^l; F_2) \) and \( h^*: H^1(\mathbb{R}P^l; F_2) \to H^1(\mathbb{R}P^k; F_2) \) are also isomorphisms.

\[
\gamma(1) = -\gamma(0)
\]

**Figure 1254. Illustration of Lemma 90.19**

**Proof of Lemma 90.19.** First we recall that for \( k \geq 2 \) we know from Corollary 16.18 that \( \pi_1(\mathbb{R}P^k) \cong \mathbb{Z}_2 \).

1. The first statement is an immediate consequence of Lemma 16.15 (1) and the fact that \( \pi_1(\mathbb{R}P^n) \cong \mathbb{Z}_2 \).

2. Since \( k,l \geq 2 \) both fundamental groups are isomorphic to \( \mathbb{Z}_2 \). In particular if \( h_*: \pi_1(\mathbb{R}P^k) \to \pi_1(\mathbb{R}P^l) \) has non-trivial image, then this map is already an isomorphism. It follows from the naturality of the Hurewicz homomorphism, see Proposition 52.2 (4), together with the Hurewicz Theorem 52.5 that the induced map \( h_*: H_1(\mathbb{R}P^k; F_2) \to H_1(\mathbb{R}P^l; F_2) \) is also an isomorphism. Finally note that it follows from the naturality of the isomorphisms in Proposition 75.18 that the induced map \( h^*: H^1(\mathbb{R}P^l; F_2) \to H^1(\mathbb{R}P^k; F_2) \) is also an isomorphism.

**Proof of the Borsuk-Ulam 59.3 for \( n \geq 2 \).** Let us suppose that there exists a map \( f: S^n \to \mathbb{R}^n \) such that for any \( x \in S^n \) we have that \( f(x) \neq f(-x) \). We consider the map

\[
g: S^n \to S^{n-1},
\]

\[
x \mapsto \frac{f(x) - f(-x)}{||f(x) - f(-x)||}.
\]

By our hypothesis this map is defined. It is clear that \( g(-x) = -g(x) \) for all \( x \in S^n \). Therefore this map \( g \) descends to a map

\[
h: \mathbb{R}P^n \to \mathbb{R}P^{n-1}
\]

\[
[x] \mapsto [g(x)]
\]
90. THE CUP PRODUCT OF PROJECTIVE SPACES 2205

i.e. we get the following commutative diagram

\[
\begin{array}{ccc}
S^n & \xrightarrow{g} & S^{n-1} \\
\downarrow p & & \downarrow q \\
\mathbb{RP}^n & \xrightarrow{[x] \mapsto h(x) := [g(x)]} & \mathbb{RP}^{n-1}
\end{array}
\]

where \( p \) and \( q \) denote the obvious projection maps.

Claim. The map \( h^*: H^1(\mathbb{RP}^{n-1}; \mathbb{F}_2) \to H^1(\mathbb{RP}^n; \mathbb{F}_2) \) is an isomorphism.

By Lemma 90.19 (2) we only have to show that \( h^*: \pi_1(\mathbb{RP}^n) \to \pi_1(\mathbb{RP}^{n-1}) \) has non-trivial image. Let \( \gamma: [0, 1] \to S^n \) be a path with \( \gamma(1) = -\gamma(0) \). Note that \( p \circ \gamma: [0, 1] \to \mathbb{RP}^n \) is a loop. We calculate that

\[
h^*([p \circ \gamma]) = [h \circ p \circ \gamma] = [g \circ (g \circ \gamma)] \neq e \in \pi_1(\mathbb{RP}^{n-1}).
\]

by the above commutative diagram

We denote by \( y \in H^1(\mathbb{RP}^{n-1}; \mathbb{F}_2) \) and \( x \in H^1(\mathbb{RP}^n; \mathbb{F}_2) \) the unique non-trivial elements. We have the following equality in \( H^n(\mathbb{RP}^n; \mathbb{F}_2) \):

\[
0 \neq x^n = (h^*(y))^n = h^*(y^n) = h^*(0) = 0.
\]

by the above commutative diagram

We have thus obtained the desired contradiction.

90.4. The cup product of quaternionic and octonionic projective spaces \((*)\). In this very short section we discuss the cup product of the quaternionic projective spaces \( \mathbb{HP}^n \) that we introduced on page 1472. We will also calculate the cup product of the octonionic projective plane \( \mathbb{OP}^2 \) that we defined on page 1473. These calculations might not sound all that interesting, but later in Chapter 91 we will use them to show that certain homotopy groups of spheres are non-trivial.

The following proposition is the only, and thus also the most interesting, result of this section. The statement is of course, in light of Proposition 90.7, entirely predictable.

**Proposition 90.20.**

1. Given any \( n \in \mathbb{N} \) there exists an isomorphism

\[
\mathbb{Z}[z]/(z^{n+1}) \to (H^*(\mathbb{HP}^n; \mathbb{Z}), \cup)
\]

of superalgebras, where \( z \) is an element of degree 4.

2. There exists an isomorphism

\[
\mathbb{Z}[z]/(z^{3}) \to (H^*(\mathbb{OP}^2; \mathbb{Z}), \cup)
\]

of superalgebras, where \( z \) is an element of degree 8.
In both cases the obvious analogues with \( \mathbb{Z} \) replaced by \( \mathbb{Z}_2 \) also hold.

**Proof.**

(1) Let \( n \in \mathbb{N}_0 \). By Lemma 60.9 we know that \( \mathbb{H}P^n \) is a \( 4n \)-dimensional closed orientable smooth manifold which admits a CW-structure that has exactly one cell in the dimensions \( 0, 4, 8, \ldots, 4n \). The proof of Proposition 90.7 can be used, with very minor modifications, to prove the desired result.

(2) In Proposition 60.10 (3) we showed that the octonionic projective plane \( \mathbb{O}P^2 \) is a closed orientable 16-dimensional smooth manifold which admits a CW-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Once again the proof of Proposition 90.7 clinches the deal.

Propositions 90.7 and 90.20 do raise a few questions, which can be viewed as a more specific versions of Question 84.19.

The first question asks whether we can realize polynomial rings in other degrees.

**Question 90.21.** Let \( m \) be an even number and \( n \in \mathbb{N} \). Does there exist a topological space \( X \) such that \( (\mathbb{H}^*(X; \mathbb{Z}), \cup) \) is isomorphic to \( \mathbb{Z}[z]/(z^{n+1}) \) where \( z \) is now an element of degree \( m \)?

The following question is even more specific, it asks whether there exists a “cohomological \( \mathbb{O}P^3 \).

**Question 90.22.** Does there exist a topological space \( X \) such that \( (\mathbb{H}^*(X; \mathbb{Z}), \cup) \) is isomorphic to \( \mathbb{Z}[z]/(z^4) \) where \( z \) is now an element of degree 8?

It will not take the reader very long to see that a negative answer to Question 90.22 would also tragically give a negative answer to Question 84.19.

90.5. **Division algebras.** We recall that on page 1461 we defined a real division algebra to be an algebra over \( \mathbb{R} \) such that for all \( a \neq 0 \) and \( b \in A \) there exists an \( x \in A \) with \( a \cdot x = b \) and a \( y \in A \) with \( y \cdot a = b \). In Section 60.1 we gave several examples of real division algebras, namely \( \mathbb{R} \), the complex numbers \( \mathbb{C} \), the quaternions \( \mathbb{H} \) (which are not commutative) and the Cayley Octonions \( \mathbb{O} \) (which are neither commutative nor associative). These real division algebras are defined over \( \mathbb{R}^n \) with \( n = 1, 2, 4 \) and 8.

These dimensions are powers of 2 and the following theorem, which was first proved by Heinz Hopf [Hopf40a] in 1940, shows that this is not a coincidence.

**Theorem 90.23. (Hopf 1940)** If \( \mathbb{R}^n \) admits the structure of a real division algebra, then \( n \) is a power of 2.

In the proof of Theorem 90.23 we will need the following lemma which is interesting in its own right.

**Lemma 90.24.** Let \( k \in \mathbb{N} \). We denote by \( \varphi \in H^1(\mathbb{R}P^k; \mathbb{F}_2) \) the unique non-trivial element. We denote by \( p \) and \( q \) the two obvious projection maps \( \mathbb{R}P^k \times \mathbb{R}P^k \rightarrow \mathbb{R}P^k \) and we write \( \alpha = p^*(\varphi) \) and \( \beta = q^*(\varphi) \). Then the obvious homomorphism

\[
\mathbb{F}_2[\alpha, \beta]/(\alpha^{k+1}, \beta^{k+1}) \rightarrow H^*(\mathbb{R}P^k \times \mathbb{R}P^k; \mathbb{F}_2)
\]
of superalgebras is an isomorphism.

**Proof.** The lemma is an immediate consequence of Propositions 90.16 and 84.24 and the discussion on page 2055.

Now we can provide the proof of Theorem 90.23.

**Proof of Theorem 90.23.** Let “∗” be a real division algebra structure on \( \mathbb{R}^n \). We want to show that \( n \) is a power of 2. Since 1 and 2 are powers of 2 we can assume that \( n \geq 3 \).

As in the proof of Theorem 60.4 we consider the map
\[
\tilde{f}: S^{n-1} \times S^{n-1} \to S^{n-1}
\]
\[
(x, y) \mapsto \tilde{f}(x, y) := \frac{x \ast y}{\|x \ast y\|}.
\]

We make the following observations:

1. In the proof of Theorem 60.4 we already showed, using the hypothesis that “∗” defines a division algebra, that this map is well-defined, i.e. that we never divide by zero.
2. In the proof of Theorem 60.4 we had also shown that the map \( \tilde{f} \) is continuous.
3. Since “∗” defines in particular an algebra we have
\[
\tilde{f}(-x, y) = -\tilde{f}(x, y) \quad \text{and} \quad \tilde{f}(x, -y) = -\tilde{f}(x, y)
\]
for any \( x, y \in S^{n-1} \).

From (3) it follows that the above map \( \tilde{f} \) descends to a map
\[
f: \mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1} \to \mathbb{R}P^{n-1}
\]
\[
[x], [y] \mapsto [\tilde{f}(x, y)].
\]

We pick a point \( z \in S^{n-1} \). We consider the inclusion maps
\[
i: \mathbb{R}P^{n-1} \to \mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}
\]
\[
x \mapsto (x, [z])
\]
and
\[
j: \mathbb{R}P^{n-1} \to \mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}
\]
\[
x \mapsto ([z], x).
\]

Our first goal is to prove the following claim.

**Claim 1.** The map
\[
(f \circ i)_*: H_1(\mathbb{R}P^{n-1}; \mathbb{F}_2) \to H_1(\mathbb{R}P^{n-1}; \mathbb{F}_2)
\]
is an isomorphism. The same conclusion holds with \( i_* \) replaced by \( j_* \).

We provide the proof for the first statement. The proof with \( i_* \) replaced by \( j_* \) is basically the same. By Lemma 90.19 (2) it suffices to show that the map
\[
(f \circ i)_*: \pi_1(\mathbb{R}P^{n-1}) \to \pi_1(\mathbb{R}P^{n-1})
\]
has non-trivial image. We introduce the following notation:

1. We denote by \( \pi: S^{n-1} \to \mathbb{R}P^{n-1} \) the obvious projection map.
2. We pick a path \( \gamma: [0, 1] \to S^{n-1} \) with \( \gamma(1) = -\gamma(0) \). Note that \( \pi \circ \gamma: [0, 1] \to \mathbb{R}P^{n-1} \) is a loop.
3. We denote by \( \tilde{i} \) the inclusion map \( S^{n-1} \to S^{n-1} \times S^{n-1} \) that is given by \( \tilde{i}(x) = (x, z) \).

\([1287] \) The argument of Footnote [1285] shows that \( f \) is continuous.
Note that we get the following commutative diagram

\[
\begin{array}{ccc}
[0, 1] & \xrightarrow{\gamma} & S^{n-1} \\
\downarrow{\pi} & & \downarrow{\pi \times \pi} \\
\mathbb{R}P^{n-1} & \xrightarrow{i} & \mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}
\end{array}
\]

Finally we note that

by the above commutative diagram

\[(f \circ i)_*(\pi \circ \gamma) = [f \circ i \circ \pi \circ \gamma] = [\pi \circ (f \circ \tilde{i} \circ \gamma)] \neq e \in \pi_1(\mathbb{R}P^{n-1}).\]

this follows from Lemma 90.19 (1) since the following equality holds:

\[(f \circ \tilde{i} \circ \gamma)(1) = f(\gamma(1), z) = f(-\gamma(0), z) = -\tilde{f}(\gamma(0), z) = -(f \circ \tilde{i} \circ \gamma)(0) \]

We denote by \(\varphi \in H^1(\mathbb{R}P^{n-1}; F_2)\) the unique non-trivial element. Furthermore, as often we denote by \(p\) and \(q\) the two obvious projection maps \(\mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1} \rightarrow \mathbb{R}P^{n-1}\). Finally we write \(\alpha = p^*(\varphi)\) and \(\beta = q^*(\varphi) \in H^1(\mathbb{R}P^{n-1}; F_2)\).

**Claim 2.** The following equality holds

\[f^*(\varphi) = \alpha + \beta \in H^1(\mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}; F_2).\]

We start out the proof of the claim with the following three observations:

(1) Proposition 75.19 says that for any topological space \(W\) the map

\[
ev: H^1(W; F_2) \rightarrow \text{Hom}(H_1(W; F_2), F_2) \\
\psi \mapsto (\sigma \mapsto \langle \psi, \sigma \rangle)
\]

is an isomorphism.

(2) Let \(x \in H_1(\mathbb{R}P^{n-1}; F_2)\) be the unique non-trivial element. By the discussion on page 1965 the map

\[H_1(\mathbb{R}P^{n-1}; F_2) \oplus H_1(\mathbb{R}P^{n-1}; F_2) \rightarrow H_1(\mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}; F_2) \\
a \oplus b \mapsto i_*(a) \oplus j_*(b)
\]

is an isomorphism. In particular we see that \(H_1(\mathbb{R}P^{n-1} \times \mathbb{R}P^{n-1}; F_2)\) is generated by \(i_*(x)\) and \(j_*(x)\).

(3) Since \(H^1(\mathbb{R}P^{n-1}; F_2)\) and \(H_1(\mathbb{R}P^{n-1}; F_2)\) both contain a unique non-trivial element, namely \(\varphi\) and \(x\), we obtain from Observation (1) that \(\ev(\varphi)(x) = \langle \varphi, x \rangle = 1\).

It follows from (1) and (2) that it suffices to show that \(\ev(f^*(\varphi))\) and \(\ev(\alpha + \beta)\) agree on \(i_*(x)\) and \(j_*(y)\). In fact we have

\[\ev(f^*(\varphi))(i_*(x)) = \langle f^*(\varphi), i_*(x) \rangle = \langle \varphi, f_*(i_*(x)) \rangle = \langle \varphi, x \rangle = 1.
\]

by definition \(\text{Lemma 74.6 (3)}\) by Claim 1 since \(x\) is the unique non-zero element of \(H_1(\mathbb{R}P^{n-1}; F_2)\)
We also calculate that
\[
ev(\alpha + \beta)(i_*(x)) = (p^*\varphi + q^*\varphi, i_*(x)) = \langle \varphi, p_*(i_*(x)) \rangle + \langle \varphi, q_*(i_*(x)) \rangle = \langle \varphi, x \rangle = 1.
\]
by definition \[\text{Lemma 74.6 (3)}\] since \(p \circ i = \text{id}\) and \(q \circ i\) is a constant map.

We have thus shown that \(\ev(f^*(\varphi))\) and \(\ev(\alpha + \beta)\) agree on \(i_*(x)\). The same argument also works with \(i_*(x)\) replaced by \(j_*(y)\).

Using \[\text{Lemma 90.24}\] we can and will make the identification
\[
H^*(\mathbb{RP}^{n-1} \times \mathbb{RP}^{n-1}; \mathbb{F}_2) = \mathbb{F}_2[\alpha, \beta]/(\alpha^n, \beta^n).
\]
Using this identification we see that
\[
0 = f^*(0) = f^*(\varphi^n) = (f^*(\varphi))^n = (\alpha + \beta)^n = \sum_{k=0}^{n} \binom{n}{k} \cdot \alpha^k \beta^{n-k} = \sum_{k=1}^{n-1} \binom{n}{k} \cdot \alpha^k \beta^{n-k}.
\]
by \[\text{Proposition 90.16}\] \[\text{Lemma 81.10}\] by the previous claim since \(\alpha^n = \beta^n = 0\)

This equality holds in the polynomial ring \(\mathbb{F}_2[\alpha, \beta]/(\alpha^n, \beta^n)\). In this ring the \(n-1\) monomials \(\alpha \beta^{n-1}, \alpha^2 \beta^{n-2}, \ldots, \alpha^{n-1} \beta\) are linearly independent over the field \(\mathbb{F}_2\). This implies that for \(k = 1, \ldots, n-1\) we have \(\binom{n}{k} \equiv 0 \mod 2\). Thus it remains to prove the following purely algebraic claim.

**Claim.** If \(n \in \mathbb{N}\) satisfies that \(\binom{n}{k} \equiv 0 \mod 2\) for \(k = 1, \ldots, n-1\), then \(n\) is a power of 2.

We can and will write \(n\) as a sum \(n = n_1 + \cdots + n_r\) where each \(n_i\) is a power of 2 and with \(n_1 < \cdots < n_r\). In the polynomial ring \(\mathbb{F}_2[x]\) we obtain that

\[
1 + x^n = \sum_{k=0}^{n} \binom{n}{k} x^k = (1 + x)^n = (1 + x)^{n_1} \cdots (1 + x)^{n_r}
\]
by our hypothesis since \(n = n_1 + \cdots + n_r\)

\[
= (1 + x^{n_1}) \cdots (1 + x^{n_r}) = 1 + x^{n_1} + \text{higher powers.}
\]
since each \(n_i\) is a power of 2 and \(n_1 < \cdots < n_r\)

But this is only possible if \(n = n_1\), i.e. if \(n\) itself is a power of 2.

In fact, with more fancy topological methods one can actually strengthen the previous theorem to obtain the following theorem which gives a complete answer to Question 60.7. Unfortunately the proof is well beyond the scope of these modest lecture notes.

**Theorem 90.25. (Bott–Kervaire–Milnor 1958)** Every finite-dimensional division algebra over \(\mathbb{R}\) is of dimension 1, 2, 4 or 8.

**Proof.** The theorem was first proved using topological methods by Michel Kervaire [Kerv58] and John Milnor [Miln58a, Corollary 1], building on the “Bott Periodicity Theorem” proved by Raoul Bott [Bot57, Bot59]. Full details for the proof can also be found...
Remark. One might ask whether any finite-dimensional division algebra over \( \mathbb{R} \) is isomorphic to \( \mathbb{R}, \mathbb{C}, \mathbb{H} \) or \( \mathbb{O} \). The statement holds under the stronger hypothesis that the algebra is “normed” or “alternative”. We refer to [BD73, p. 73], [EHHKMNPR91, p. 262] and [Bae01] for results in this direction. As is shown in [Hat02, p. 59], [Bruc44, Osb62], without any extra hypotheses one cannot expect a uniqueness statement.

Exercises for Chapter 90

Exercise 90.1. Let \( V \) and \( W \) be free \( \mathbb{Z} \)-modules of finite rank, i.e. \( V \) and \( W \) are free abelian groups. Furthermore let \( \varphi : V \times W \to \mathbb{Z} \) be a pairing.

(a) Let \( v_1, \ldots, v_n \) be a basis for \( V \). Show that the following two statements are equivalent:

(i) There exists some basis \( w_1, \ldots, w_n \) for \( W \) such that \( \lambda(v_i, w_j) = \delta_{ij} \) for every choice of \( i, j \in \{1, \ldots, n\} \).

(ii) The pairing \( \lambda \) is non-singular.

(b) Suppose that \( \lambda \) is non-degenerate. Show that \( V \) and \( W \) have the same rank.

(c) Suppose that \( V \) and \( W \) are of rank \( n \) and suppose we are given \( v_1, \ldots, v_n \in V \) and \( w_1, \ldots, w_n \in W \) such that \( \det(\lambda(v_i, w_j)) = \pm 1 \). Show that \( v_1, \ldots, v_n \) is a basis for \( V \) and that \( w_1, \ldots, w_n \) is a basis for \( W \).

Exercise 90.2. Let \( V \) be a free \( \mathbb{Z} \)-module of finite rank, i.e. \( V \) is a free abelian group. Let \( \varphi : V \times V \to \mathbb{Z} \) be a form. Given a subgroup \( U \subset V \) we write

\[
U^\perp = \{ v \in V \mid \varphi(u, v) = 0 \text{ for all } u \in U \}.
\]

We suppose that the form \( \varphi \) is non-singular. Show that for any subgroup \( U \subset V \) we have \( \text{rank}(U^\perp) = \text{rank}(V) - \text{rank}(U) \).

Exercise 90.3. Let \( m, n \in \mathbb{N} \). We denote by \( p : S^m \times S^n \to S^m \) and by \( q : S^m \times S^n \to S^n \) the two obvious projection maps. Use Poincaré Duality to show that

\[
p^*([S^m]^*) \cup q^*([S^n]^*) = \pm [S^m \times S^n]^*.
\]

Put differently, you should show the equality without using the Product Theorem 84.1.

Exercise 90.4. For which \( n \in \mathbb{N} \) is the complex projective space \( \mathbb{C}P^n \) chiral, i.e. for which \( n \in \mathbb{N} \) does \( \mathbb{C}P^n \) admit an orientation-reversing self-homeomorphism?

Exercise 90.5. Does there exist a degree one map from \( \mathbb{C}P^2 \) to \( S^2 \times S^2 \)?

Exercise 90.6. Is \( S^3 \lor \mathbb{R}P^2 \) homotopy equivalent to a smooth manifold?

Exercise 90.7. Show that there exists a connected CW-complex \( X \) with base point \( x_0 \) and a homomorphism \( \varphi : \pi_1(X, x_0) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}P^2, *) \) which cannot be realized by a map \( g : X \to \mathbb{R}P^2 \), i.e. such that there is no map \( f : X \to \mathbb{R}P^2 \) with \( f(x_0) = * \) such that \( f_* = \varphi \).

Remark. This gives a negative answer to Question 79.11 (3).

\(^{1289}\)The basis \( w_1, \ldots, w_n \) is in fact unique.
Exercise 90.8.
(a) Let $n \in \mathbb{N}$ and let $M$ be a closed orientable $2n$-dimensional smooth manifold. Suppose that $M$ admits a CW-structure with precisely three cells. Show that $M$ has precisely one cell in dimensions $0$, $n$ and $2n$.
(b) Show that there is no closed orientable 6-dimensional smooth manifold that has only three cells.
(c) In (a) and (b), do we really need to assume that $M$ is orientable?

Exercise 90.9. Let $n \in \mathbb{N}_0$ and let $\varphi: \mathbb{C}P^n \to \mathbb{C}P^n$ be map.
(a) Show that there exists a $d \in \mathbb{Z}$ such that
\[
\sum_{k=0}^{2n} (-1)^k \cdot \text{tr}(\varphi_*: H_k(\mathbb{C}P^n) \to H_k(\mathbb{C}P^n)) = 1 + \sum_{i=1}^{n} d^i.
\]

Hint. Use the cohomological reformulation of the Lefschetz number given in Exercise 75.12.
(b) Suppose $n$ is odd. Use the Lefschetz Fixed Point Theorem [65.9] to show that $\varphi$ admits a fixed point.

Remark. In Exercise 65.8 we showed that for any even $n \in \mathbb{N}_0$ there exists a self-map of $\mathbb{C}P^n$ with no fixed points.

Exercise 90.10. Let $n \in \mathbb{N}_{\geq 2}$ and let $\varphi: S^2 \to S^2$ be a map of degree $n$. We consider $X := \text{Cone}(S^2 \xrightarrow{\varphi} S^2 = \mathbb{C}P^1 \subset \mathbb{C}P^2)$ and $Y := \text{Cone}(S^2 \xrightarrow{\varphi} S^2) \vee S^4$.
(a) Show that the cohomology rings of $X$ and $Y$ with $\mathbb{Z}$-coefficients are isomorphic.
(b) Show that the cohomology rings of $X$ and $Y$ with $\mathbb{Z}$-coefficients are not isomorphic.
91. The Hopf invariant

In previous chapters we have seen that the introduction and the calculation of the cup product allowed us to answer many questions on topological spaces that we could not deal with before. In this section we want to use the cup product to address the following question that we formulated a long time ago.

**Question 40.18.** Does the Hopf map \( H : S^3 \to S^2 \) represent a non-trivial element in the homotopy group \( \pi_3(S^2) \)?

In this chapter we will use the calculation of the cup product of \( \mathbb{C}P^2 \) to give an affirmative answer to this question. Furthermore we will use the quaternions and octonions to define higher dimensional analogues of the Hopf map which also represent non-trivial elements in homotopy groups of spheres.

91.1. **The Hopf map is not null-homotopic.** First we recall the definition of the Hopf map. On page 197 we gave an explicit identification \( \mathbb{C}P^1 = S^2 \). Furthermore on page 1071 we made the following definition.

**Definition.** We refer to the map

\[
H : S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\} \to S^2 = \mathbb{C}P^1 \smallskip
(z_1, z_2) \mapsto [z_1 : z_2]
\]

as the **Hopf map**.

The idea for answering Question 40.18 is to translate this question about maps to a question about topological spaces for which we can then bring our new invariants to bear. To carry out this approach we recall the following definitions from earlier on:

**Definition.**

(1) On page 692 we defined the cone of a topological space \( A \) to be the topological space \( \text{Cone}(A) := (A \times [0, 1]) / \sim \) where \((a, 0) \sim (a', 0)\) for all \(a, a' \in A\).
91. THE HOPF INVARIANT

(2) On page 701 we defined the mapping cone of a map \( f : A \to X \) between topological spaces as

\[ \text{Cone}(f : A \to X) := (\text{Cone}(A) \cup X) / \sim \]

where \((a, 1) \sim f(a)\) for all \(a \in A\).

Both definitions are illustrated in Figure 1255.

Example.

(1) It follows from Proposition 2.43 (3) and Lemma 3.22 that the map

\[ \text{Cone}(S^{n-1}) \to \overline{B}^n \]

\[ \left([P, t]\right) \mapsto t \cdot P \]

is a homeomorphism. We use this homeomorphism to identify \(\text{Cone}(S^{n-1})\) with \(\overline{B}^n\). In particular, if \(X\) is a topological space and if \(f : S^{n-1} \to X\) is a map, then we get an identification

\[ \text{Cone}(f : S^{n-1} \to X) = \overline{B}^n \cup f X. \]

It follows immediately from this observation that any finite CW-complex can be viewed as an iterated mapping cone (where we start out with a finite discrete set).

(2) In Exercise 91.1 we will see that the mapping cone of the map \(f : S^1 \to S^1\) that is given by \(f(z) = z^2\) is a topological space that we are very familiar with.

The next lemma gives us another elementary but oddly useful example.

**Lemma 91.1.** If \(f : S^k \to X\) is a constant map, then there exists a homeomorphism

\[ \text{Cone}(f : S^k \to X) \xrightarrow{\cong} S^{k+1} \vee X, \]

where we perform the wedge for suitable points in \(S^{k+1}\) and \(X\).

**Proof.** Suppose \(f : S^k \to X\) is a constant map. It follows easily from the example on page 2213 and the homeomorphism \(\overline{B}^{k+1} / S^k \cong S^{k+1}\) from page 182 that \(\text{Cone}(f : S^k \to X)\) is homeomorphic to a wedge \(S^{k+1} \vee X\). We leave it to the reader to fill in the details. ■
The following lemma gives a particularly interesting example of a mapping cone.

**Lemma 91.2.** There exist homeomorphisms

\begin{align*}
(1) \quad \text{Cone}(H : S^3 \to S^2) & \cong \mathbb{C}P^2 \\
(2) \quad \text{Cone}(H_H : S^7 \to S^4) & \cong \mathbb{H}P^2 \\
(3) \quad \text{Cone}(H_O : S^{15} \to S^8) & \cong \mathbb{O}P^2.
\end{align*}

**Proof.**

(1) In Lemma 36.1 we saw that $\mathbb{C}P^2$ is a CW-complex that is obtained from the CW-complex $\mathbb{C}P^1 \cong S^2$ by attaching a 4-cell. The attaching map $S^3 \to \mathbb{C}P^1$ of the 4-cell is precisely the Hopf map. This observation, together with the discussion on page 2213, already implies the statement. For completeness’ sake we give the argument more explicitly and in more detail. We consider the maps

$$f : \text{Cone}(S^3) \rightarrow \mathbb{C}P^2 \quad \text{and} \quad g : \mathbb{C}P^1 \rightarrow \mathbb{C}P^2,$$

where $f((z_0, z_1), r) \mapsto [r \cdot z_0 : r \cdot z_1 : 1 - r]$ and $g([z_0 : z_1]) \mapsto [z_0 : z_1 : 0]$.

It follows immediately from the definitions together with Lemma 3.22 that these two maps define a continuous map

$$\text{Cone}(H : S^3 \to S^2) \rightarrow \mathbb{C}P^2.$$

One can easily verify that this map is a bijection. Furthermore, using Proposition 2.43 and Proposition 3.40 one sees that the map is in fact a homeomorphism. (2) The proof of (2) is basically identical to the proof of (1).

(3) Implicitly we mostly proved this statement in the proof of Proposition 60.10. Alternatively we also refer to [Lackm12], p. 4 for details. ■

Now we can finally answer Question 40.18 in the affirmative. More precisely we have the following theorem. The statement regarding the “classical” Hopf map was first proved by Heinz Hopf [Hopf31] in 1931.

**Theorem 91.3.**

\begin{itemize}
  \item[(1)] The Hopf map $H : S^3 \rightarrow S^2$ represents a non-trivial element in the third homotopy group $\pi_3(S^2)$.
  \item[(2)] We have $[H_H] \neq 0 \in \pi_7(S^4)$.
  \item[(3)] We have $[H_O] \neq 0 \in \pi_{15}(S^8)$.
\end{itemize}

**Proof.** First we prove (1). Recall that for two topological spaces $X$ and $Y$ we write $X \simeq Y$ if they are homotopy equivalent. We have

$$\text{Cone}(\text{Hopf map } H) \cong \mathbb{C}P^2 \neq S^2 \vee S^4 \cong \text{Cone}(\text{constant map}).$$

\[ \Uparrow \quad \text{Lemma 91.2(1)} \quad \text{Lemma 91.4} \quad \text{Lemma 91.1} \]

\[ \text{It follows from Lemma 3.22 and Lemma 3.21(3) that these two maps are continuous.} \]
But by Lemma 24.12 this means that the Hopf map is not homotopic to the constant map. In particular the Hopf map $H: S^3 \to S^2$ represents a non-trivial element in the homotopy group $\pi_3(S^2)$.

The proof of the other two statements is quite similar. We again use Lemma 91.2 and we use the calculations of the cup products of $\mathbb{H}P^2$ and $\mathbb{O}P^2$, see Proposition 90.20, to conclude that the mapping cones of the quaternionic and octonionic Hopf maps are not homotopy equivalent to a wedge of spheres. ■

### 91.2. The Hopf invariant

It is natural to ask how far we can push the methods of Theorem 91.3 to gain more insight into homotopy groups of spheres. In this section, given $n \geq 2$ we will introduce the Hopf invariant $\text{Hopf}: \pi_{2n-1}(S^n) \to \mathbb{Z}$ which satisfies $\text{Hopf}(H) = \pm 1$, $\text{Hopf}(H_H) = \pm 1$ and $\text{Hopf}(H_O) = \pm 1$.

The idea behind the definition of the Hopf invariant is straightforward. Namely, given $n \in \mathbb{N}_{\geq 2}$ and given a map $f: S^{2n-1} \to S^n$ we consider again the corresponding mapping cone $\text{Cone}(f): S^{2n-1} \to S^n$. We will see in Lemma 91.5 that it follows from the fact that $n \geq 2$ that we have $H^n(\text{Cone}(f); \mathbb{Z}) \cong \mathbb{Z}$ and $H^2n(\text{Cone}(f); \mathbb{Z}) \cong \mathbb{Z}$. We will equip $H^n(\text{Cone}(f); \mathbb{Z})$ with a “preferred generator”. We pick a generator $\varphi \in H^n(\text{Cone}(f); \mathbb{Z})$ and we define $\text{Hopf}(f)$ to be the unique integer that satisfies

$$\varphi \cup \varphi \ = \ \text{Hopf}(f) \cdot \text{preferred generator} \ \in H^{2n}(\text{Cone}(f); \mathbb{Z}).$$

To carry out this program we need to carefully study the cohomology groups of a mapping cone. Recall that in Lemma 46.18 we saw that the homology groups of a mapping cone fit naturally into a long exact sequence of homology groups. The following lemma shows that the analogous statement also holds for the cohomology groups of a mapping cone.

**Lemma 91.4.** Let $R$ be a commutative ring.

1. Let $f: A \to X$ be a map between topological spaces.
   a. We denote by $j(f): X \to \text{Cone}(f) = (\text{Cone}(A) \sqcup X)/\sim$ the obvious inclusion map.
   b. We denote by $U$ the image of $A \times [0, \frac{3}{4})$ in $\text{Cone}(f)$ and we denote by $V$ the complement of the image of $A \times [0, \frac{1}{4}]$. (See also Figure 1257) We consider the following diagram

$$\cdots \to H^{k-1}(U \cap V; R) \overset{=}\to H^k(\text{Cone}(f); R) \to H^k(U; R) \oplus H^k(V; R) \to \cdots$$

Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 74.15 for Cohomology Groups and the vertical map comes from the obvious identifications $H^{k-1}(U \cap V; R) = H^{k-1}(A \times \frac{1}{2}; R) = H^{k-1}(A; R)$. From
the above diagram we obtain the map
\[ \delta^{k-1}(f) : H^{k-1}(A; R) \to H^k(Cone(f); R). \]

The following sequence is exact
\[ \ldots \to \tilde{H}^k(Cone(f); R) \xrightarrow{j(f)^*} H^k(X; R) \xrightarrow{f^*} H^k(A; R) \xrightarrow{\delta^k(f)} \tilde{H}^{k+1}(Cone(f); R) \to \ldots \]

(2) The connecting homomorphism in (1) is natural. In particular given any commutative diagram
\[ A \xrightarrow{f} X \]
\[ \varphi \downarrow \quad \downarrow \psi \]
\[ \tilde{A} \xrightarrow{\tilde{f}} \tilde{X} \]
of maps between topological spaces the following diagram commutes:
\[ \ldots \to \tilde{H}^k(Cone(f); R) \xrightarrow{j(\tilde{f})^*} H^k(\tilde{X}; R) \xrightarrow{\tilde{f}^*} H^k(\tilde{A}; R) \xrightarrow{\delta^k(\tilde{f})} \tilde{H}^{k+1}(Cone(\tilde{f}); R) \to \ldots \]

Here the vertical maps between the cohomology groups of the mapping cones are induced by the maps from Lemma \[24.10\] (3).

Figure 1257. Illustration of Lemma 91.4.

Proof. The proof is basically identical to the proof of Lemma 46.18. The meticulous reader who filled in the details of the proof of Lemma 46.18 will have no troubles working out the details of the present proof.

We continue with the following lemma.

Lemma 91.5. Let \( f : S^m \to S^n \) be a map. If \( m \geq n + 1 \) and \( n \geq 1 \), then the maps
\[ H^m(Cone(f); \mathbb{Z}) \xrightarrow{j(f)^*} H^n(S^n; \mathbb{Z}) \]
and
\[ H^m(S^m; \mathbb{Z}) \xrightarrow{\delta^m(f)} H^{m+1}(Cone(f); \mathbb{Z}) \]

Note that \( U \) and \( V \) are open subsets of \( Cone(f) \). Thus it follows from Proposition 74.12 that we can in fact apply the theorem.
are isomorphisms and all other reduced cohomology groups of \( \text{Cone}(f) \) are zero. An analogous statement holds for homology groups. In particular we have isomorphisms

\[
H_k(\text{Cone}(f; S^m \to S^n); Z) \cong H^k(\text{Cone}(f; S^m \to S^n); Z) \cong \left\{ \begin{array}{ll} Z, & \text{if } k = 0, n, m + 1, \\ 0, & \text{otherwise.} \end{array} \right.
\]

Proof. The lemma is an almost immediate consequence of Lemma \[91.4\] and the calculation of the cohomology groups of spheres, see page \[1844\]. For \( n = 1 \) one also needs to invoke Exercise \[73.6\].

Throughout this section we use the notation that we had already introduced in the formulation of Lemma \[91.4\]. More precisely, given a map \( f: A \to X \) between two topological spaces we denote by \( j(f): X \to \text{Cone}(f) = (\text{Cone}(A) \cup X)/\sim \) the obvious inclusion map and furthermore we denote by \( \delta^{-1}(f): H^{k-1}(A; Z) \to H^k(\text{Cone}(f); Z) \) the coboundary map in the long exact sequence in cohomology of Lemma \[91.4\].

Now we are finally in a position to turn the idea from page \[2215\] into a proper definition.

Definition. Let \( f: S^{2n-1} \to S^n \) be a map with \( n \geq 2 \). The Hopf invariant \( \text{Hopf}(f) \) is defined to be the unique integer that satisfies

\[
(j(f)^*)^{-1}([S^n]^*) \cup (j(f)^*)^{-1}([S^n]^*) = \text{Hopf}(f) \cdot \delta^{2n-1}(f)([S^{2n-1}]*)
\]

in \( H^{2n}(\text{Cone}(f); Z) \cong \mathbb{Z} \).

Remark.

1. In the definition of the Hopf invariant we could have squared any of the two generators of \( H^n(\text{Cone}(f); Z) \cong \mathbb{Z} \), since the sign ambiguity goes away with the square.

2. It follows immediately from the (anti-) commutativity of the cup product, see Proposition \[81.8\] that the Hopf invariant is zero for all odd \( n \).

Example.

1. As usual we denote by \( H: S^3 \to S^2 \) the Hopf map. In Lemma \[91.2\] we showed that the mapping cone \( \text{Cone}(H) \) is homeomorphic to \( \mathbb{C}P^2 \). By Lemma \[91.5\] we know that \( (j(H)^*)^{-1}([S^2]^*) \in H^2(\mathbb{C}P^2; Z) \) and \( \delta^3(f)([S^3]^*) \in H^4(\mathbb{C}P^2; Z) \) are generators. It follows from the calculation of the cup product on \( \mathbb{C}P^2 \), see Proposition \[90.7\] that \( \text{Hopf}(H) = -1 \) or \( \text{Hopf}(H) = 1 \).

2. Using Proposition \[90.2\] one can show, by the same argument as in (1), that the Hopf invariants of the quaternionic Hopf map \( H_{\mathbb{H}}: S^7 \to S^4 \) and the octonionic Hopf map \( H_{\mathbb{O}}: S^{15} \to S^8 \) are equal to \( \pm 1 \).

Lemma 91.6. Let \( n \geq 2 \) and let \( f_0, f_1: S^{2n-1} \to S^n \) be two maps. If \( f_0 \) and \( f_1 \) are homotopic, then \( \text{Hopf}(f_0) = \text{Hopf}(f_1) \).
Proof. Let $H : S^{2n-1} \times [0,1] \rightarrow S^n$ be a homotopy between $f_0$ and $f_1$. We denote by $i_0, i_1 : S^{2n-1} \rightarrow S^{2n-1} \times [0,1]$ the two obvious inclusion maps. We obtain the following two commutative diagrams

$$
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{f_0} & S^n \\
i_0 \downarrow & & \downarrow = \\
S^{2n-1} \times [0,1] & \xrightarrow{H} & S^n \\
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{f_1} & S^n \\
i_1 \downarrow & & \downarrow = \\
S^{2n-1} \times [0,1] & \xrightarrow{H} & S^n \\
\end{array}
$$

By Lemma 24.10 (3) the diagrams give rise to inclusion maps $\Xi_0 : \text{Cone}(f_0) \rightarrow \text{Cone}(H)$ and $\Xi_1 : \text{Cone}(f_1) \rightarrow \text{Cone}(H)$. From Lemma 91.4 we obtain the following commutative diagram of long exact sequences:

$$
\ldots \rightarrow \tilde{H}^k(\text{Cone}(f_0)) \xrightarrow{j(f_0)^*} H^k(S^n) \xrightarrow{f_0^*} H^k(S^{2n-1}) \xrightarrow{\delta} \tilde{H}^{k+1}(\text{Cone}(f_0)) \rightarrow \ldots
$$

$$
\uparrow \Xi_0 \quad \text{id} \quad \uparrow \Xi_0
$$

$$
\ldots \rightarrow \tilde{H}^k(\text{Cone}(H)) \xrightarrow{j(H)^*} H^k(S^n) \xrightarrow{H^*} H^k(S^{2n-1} \times [0,1]) \xrightarrow{\delta} \tilde{H}^{k+1}(\text{Cone}(H)) \rightarrow \ldots
$$

$$
\uparrow \Xi_1 \quad \text{id} \quad \uparrow \Xi_1
$$

Note that the vertical maps between the cohomology groups of the mapping cones are isomorphisms. This can be shown using the Five Lemma 43.12 or alternatively, in a more fancy way using Lemma 24.12.

Next we consider the generator $\Theta := (i_0^*)^{-1}([S^{2n-1}]^*) = (i_1^*)^{-1}([S^{2n-1}]^*)$ of the group $H^{2n-1}(S^{2n-1} \times [0,1]; \mathbb{Z})$. We define a number $\text{Hopf}(H)$ via the equality

$$(j(H)^* - 1([S^n]^*) \cup (j(H)^* - 1([S^n]^*) = \text{Hopf}(H) \cdot \delta^{2n-1}(H)(\Theta)$$

in $H^{2n}(\text{Cone}(H); \mathbb{Z}) \cong \mathbb{Z}$. Finally we apply the above commutative diagram and apply Lemma 81.10 to the maps $\Xi_0 : \text{Cone}(f_0) \rightarrow \text{Cone}(H)$ and $\Xi_1 : \text{Cone}(f_1) \rightarrow \text{Cone}(H)$ and we see that $\text{Hopf}(f_0) = \text{Hopf}(H) = \text{Hopf}(f_1)$.

It follows from Lemma 91.6 that the Hopf invariant descends to a well-defined map on homotopy groups:

Definition. It follows from Lemma 91.6 that for each $n \geq 2$ the map

$$
\pi_{2n-1}(S^n, *) \rightarrow \mathbb{Z}
$$

$[f] \mapsto \text{Hopf}(f)$

is well-defined. This map is called the Hopf invariant.

Our next proposition says that the Hopf invariant is a homomorphism. This is arguably somewhat surprising since at first glance the definition of the Hopf variant, given by squaring an element, does not look particularly like a linear map.

Proposition 91.7. For any $n \geq 2$ the Hopf invariant $\text{Hopf} : \pi_{2n-1}(S^n, *) \rightarrow \mathbb{Z}$ is a homomorphism.

Together with the calculation of the Hopf invariant for the Hopf maps $H$, $H_\mathbb{H}$ and $H_\mathbb{O}$ on page 2217 we obtain the following immediate corollary to Proposition 91.7.
**Corollary 91.8.** The Hopf invariants

\[
\begin{align*}
(1) \quad & \text{Hopf: } \pi_3(S^2) \to \mathbb{Z} \\
(2) \quad & \text{Hopf: } \pi_7(S^4) \to \mathbb{Z} \\
(3) \quad & \text{Hopf: } \pi_{15}(S^8) \to \mathbb{Z}
\end{align*}
\]

are epimorphisms.

The technically slightly dicey proof of Proposition 91.7 will require the remainder of this section. The reader is cordially invited to skip the argument and to jump to the much more entertaining content of the next section.

Our proof of Proposition 91.7 will require a few preparations. First of all, on several occasions we will need the following construction.

**Construction 91.9.** Suppose we are given the following commutative diagram of topological spaces:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\varphi} & & \downarrow{\psi} \\
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{Y}
\end{array}
\]

Then, as discussed in Lemma 24.10 (3), we obtain an induced map

\[
\text{Cone}(f: X \to Y) \to \text{Cone}(\tilde{f}: \tilde{X} \to \tilde{Y})
\]

\[
[P] \mapsto \begin{cases} 
[\varphi(x), t], & \text{if } P = (x, t) \text{ with } x \in X, \ t \in [0, 1], \\
[\psi(y)], & \text{if } P = y \text{ with } y \in Y
\end{cases}
\]

By Lemma 24.10 (4) the map fits into the following commutative diagram:

\[
\begin{array}{ccc}
Y & \xrightarrow{j} & \text{Cone}(f: X \to Y) \\
\downarrow{\psi} & & \downarrow{\Sigma(\varphi)} \\
\tilde{Y} & \xrightarrow{j} & \text{Cone}(\tilde{f}: \tilde{X} \to \tilde{Y})
\end{array}
\]

where the horizontal maps to the left are the inclusions maps \(i\) that we introduced in Lemma 24.9 (2) and where the horizontal maps \(p\) on the right are given by the projection and the homeomorphism from Lemma 24.9 (4).

Finally we will need the following slight reinterpretation of the Hopf invariant.

**Lemma 91.10.** Let \(f: S^{2n-1} \to S^n\) be a map. We denote by \(j: S^n \to \text{Cone}(f)\) the inclusion map and we denote by \(p: \text{Cone}(f) \to \text{Cone}(f)/S^n = \Sigma(S^{2n-1})\) the map given by the projection and homeomorphism from Lemma 24.9 (4). Then

\[
(j)^{-1}([S^n]^*) \cup (j)^{-1}([S^n]^*) = \text{Hopf}(f) \cdot p^*(\Sigma([S^{2n-1}]^*)) \in H^{2n}(\text{Cone}(f); \mathbb{Z}).
\]

**Proof of Lemma 91.10.** The statement follows basically immediately from the discussion on page 1857\(^{1295}\) and the cohomological analogue of Lemma 46.20. \(\blacksquare\)

\(^{1294}\) Our proof is based on the proof in [MTa68, p. 35]. An alternative proof is sketched in [Stro11, p. 557].

\(^{1295}\) Note that here we use the convenient fact that \((-1)^{(2n-1)+1} = +1\). In reality the sign is largely irrelevant, as long as we can be sure that the sign depends only on \(n\).
Proof of Proposition 91.7: We start out with a few preparations.

1. Given a pointed topological space \((X, x_0)\) we define \(X \vee X\) by identifying two copies of \(X\) along the base point. We refer to the map \(\varphi: X \vee X \to X\) which is given by the identity on either of the two copies as the folding map.

2. Let \(k \in \mathbb{N}_{\geq 2}\). On page 1060 we introduced a pinching map \(\pi: S^k \to S^k \vee S^k\). The precise definition is rather irrelevant to us right now. What matters is that we saw on page 1060 that given any pointed topological space \((X, x_0)\) and given any two maps \(f_1, f_2: (S^k, \ast) \to (X, x_0)\) we have

\[
[f_1 \ast f_2] = \left[ S^k \xrightarrow{\pi} S^k \vee S^k \xrightarrow{f_1 \vee f_2} X \vee X \xrightarrow{\varphi} X \right] \in \pi_k(X, x_0).
\]

Now we turn to our actual situation. Let \(n \in \mathbb{N}_{\geq 2}\). Suppose we are given two maps \(f_1, f_2: (S^{2n-1}, \ast) \to (S^n, \ast)\). For \(i = 1, 2\) we consider the following diagram

\[
\begin{array}{ccccccccc}
S^n & \xrightarrow{j} & \text{Cone}(\varphi \circ (f_1 \vee f_2) \circ \pi: S^{2n-1} \to S^n) & \xrightarrow{p} & \Sigma S^{2n-1} \\
\varphi \uparrow & & \uparrow \varphi & & \uparrow = \\
S^n \vee S^n & \xrightarrow{j} & \text{Cone}((f_1 \vee f_2) \circ \pi: S^{2n-1} \to S^n \vee S^n) & \xrightarrow{p} & \Sigma S^{2n-1} \\
\downarrow \psi & & \downarrow \psi & & \downarrow \Sigma(\pi) \\
S^n \vee S^n & \xrightarrow{j} & \text{Cone}(f_1 \vee f_2: S^{2n-1} \vee S^{2n-1} \to S^n \vee S^n) & \xrightarrow{p} & \Sigma( S^{2n-1} \vee S^{2n-1}) \\
\downarrow \varphi & & \downarrow \varphi & & \downarrow \Omega \\
S^n & \xrightarrow{j} & \text{Cone}(f_1: S^{2n-1} \to S^n) \vee \text{Cone}(f_2: S^{2n-1} \to S^n) & \xrightarrow{p \vee p} & \Sigma S^{2n-1} \vee \Sigma S^{2n-1} \\
\end{array}
\]

The top three vertical maps are illustrated in Figure 1259. We make the following clarifi-
cations:

(1) The horizontal maps to the left are the inclusions maps \( j \) introduced in Lemma 24.9 and the horizontal maps \( p \) on the right are given by the projection and the homeomorphism from Lemma 24.9 (4).

(2) The vertical maps between the first and the second and between the second and the third row are obtained from Construction 91.9 applied to the following two commutative diagrams

\[
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{(f_1 \vee f_2) \circ \pi} & S^n \vee S^n \\
\downarrow & & \downarrow \varphi \\
S^{2n-1} & \xrightarrow{\varphi \circ (f_1 \vee f_2) \circ \pi} & S^n
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{(f_1 \vee f_2) \circ \pi} & S^n \vee S^n \\
\downarrow & & \downarrow \\
S^{2n-1} \vee S^{2n-1} & \xrightarrow{f_1 \vee f_2} & S^n \vee S^n.
\end{array}
\]

In particular we see that the four upper squares commute.

(3) Next we consider the two diagrams

\[
\begin{array}{ccc}
S^{2n-1} & \xrightarrow{f_1} & S^n \\
\downarrow & & \downarrow \\
S^{2n-1} \vee S^{2n-1} & \xrightarrow{f_1 \vee f_2} & S^n \vee S^n
\end{array}
\]

which are given by the injections into the first respectively second factor. By Construction 91.9 these diagrams give rise to two sequences of maps. We “wedge” the two sequences and we obtain the vertical maps from the fourth to the third row.

(4) At the bottom, in each column the map \( q_i \) is the projections onto the \( i \)-th factor.

Next we apply the cohomology functor \( X \mapsto H^k(X) = H^k(X; \mathbb{Z}) \) with \( k = n \) and \( k = 2n \) to the above diagram (except that at the bottom we consider both maps \( q_1 \) and \( q_2 \)). We obtain the following commutative diagram 12990.

\[
\begin{array}{ccc}
H^k(S^n) & \leftarrow & H^k(\text{Cone}(\varphi \circ (f_1 \vee f_2) \circ \pi; S^{2n-1} \to S^n)) \\
\varphi^* & \cong & \downarrow \varphi^* \\
H^k(S^n \vee S^n) & \cong & H^k(\text{Cone}((f_1 \vee f_2) \circ \pi; S^{2n-1} \to S^n \vee S^n)) \\
\cong & \uparrow \psi^* & \cong \uparrow \Sigma(\pi)^* \\
H^k(S^n \vee S^n) & \cong & H^k(\text{Cone}(f_1 \vee f_2; S^{2n-1} \vee S^{2n-1} \to S^n \vee S^n)) \\
\cong & \downarrow & \Sigma^\ast \\
H^k(S^n) & \leftarrow & H^k(\text{Cone}(f_1)) \oplus H^k(\text{Cone}(f_2)) \\
\cong & \leftarrow & H^k(\Sigma(S^{2n-1} \vee S^{2n-1})) \\
q_1 \oplus q_2 & \cong & q_1 \oplus q_2 \cong q_1 \oplus q_2 \\
H^k(S^n) \oplus H^k(S^n) & \leftarrow & H^k(\text{Cone}(f_1)) \oplus H^k(\text{Cone}(f_2)) \\
\cong & \leftarrow & H^k(\Sigma(S^{2n-1})) \oplus H^k(\Sigma(S^{2n-1})).
\end{array}
\]

\[12990\] Any reader who knows of a program which can automatically turn the latex-code for a diagram of topological spaces into the latex-code for the corresponding diagram of cohomology groups should contact me urgently.
We make the following observations:

1. It follows almost immediately from Lemma 91.4 that the horizontal maps to the left are isomorphisms in degree $n$. Since these isomorphisms are only in degree $n$ they are colored in red.

2. It follows easily from Lemma 91.4 and the cohomological analogue of Lemma 46.20 that the horizontal maps to the right are isomorphisms for $k = 2n$. Since these isomorphisms are only in degree $2n$ they are colored in green.

3. Similar to the calculation in Exercise 47.1 we see that the map $\Omega^*$ is an isomorphism.

4. It follows from (1), (2) and (3) that the map $\Xi^*$ is an isomorphism.

5. The vertical maps at the very bottom are induced by the obvious projection maps.

The maps are isomorphisms by Proposition 74.17.

Next we denote by $\alpha = [S^n]^* \in H^n(S^n)$ the dual fundamental class. Furthermore we write $\beta = ([\Sigma([S^{2n-1}]^*)]) \in H^{2n}(\Sigma S^{2n-1})$.

Claim 1. We have $\varphi^*(\alpha) = q_1^*(\alpha) + q_2^*(\alpha)$ and $((\Sigma(\pi)^* \circ (\Omega)^{-1}))(q_1^*(\beta) + q_2^*(\beta)) = \beta$.

We leave it to the reader to verify this claim.

The key calculation takes place in the fourth row. More precisely, we have the following claim.

Claim 2. The following equality holds in $H^{2n}(\text{Cone}(f_1) \vee \text{Cone}(f_2))$:

$$((j \vee j)^{*-1}(q_1^*(\alpha) + q_2^*(\alpha)))^2 = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).$$

We calculate that

$$((j \vee j)^{*-1}(q_1^*(\alpha) + q_2^*(\alpha)))^2 = (q_1^*(j_1^{-1}) + q_2^*(j_2^{-1}))(q_1^*(j_1^{-1}) + q_2^*(j_2^{-1}))$$

by Lemma 82.7 the “mixed” terms are zero since the cup product is natural, see Lemma 81.10

$$= q_1^*(\text{Hopf}(f_1) \cdot p_1^*(\beta)) + q_2^*(\text{Hopf}(f_2) \cdot p_2^*(\beta)) = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).$$

by the reinterpretation of $\text{Hopf}(f_1)$ and $\text{Hopf}(f_2)$ given in Lemma 91.10

It follows from $[f_1 * f_2] = [\varphi \circ (f_1 \vee f_2) \circ \pi]$, the definition of $\alpha$ and $\beta$ and the re-interpretation of the Hopf invariant given in Lemma 91.10 that it remains to prove the following claim.

Claim 3. The following equality holds in the first row:

$$(j^{*-1})(\alpha))^2 = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot p^*(\beta).$$

The idea is of course to push the equality from Claim 2 through the above commutative diagram towards the top. The key tool hereby is the naturality of the cup product, see Lemma 81.10. First we note that it follows from Lemma 81.10 and the fact that $\varphi^*$ is an isomorphism in degree $2n$ that it remains to prove that the following equality holds in the
second row:

\[(\ast) \quad (j^*)^{-1}(\varphi^*(\alpha))^2 = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot p^*(\beta).\]

To prove this equality we note that it follows from Claims 1 and 2 together with Lemma \[81.10\] that the following equality holds in the third row:

\[(((j^*)^{-1}(\varphi^*(\alpha)))^2 = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot p^*((\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta))).\]

Again, using Lemma \[81.10\] we see that the following equality holds in the second row:

\[(((j^*)^{-1}(\varphi^*(\alpha)))^2 = (\text{Hopf}(f_1) + \text{Hopf}(f_2)) \cdot p^*(\sum(\pi)^*(\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta)))) = \beta \text{ by Claim 1}.\]

But using Claim 1 we see that this is precisely the desired equality that we formulated in \((\ast)\).

\[\square\]

91.3. **The Hopf invariant and multiplication maps.** By a multiplication map we mean any map of the form \(f: S^k \times S^k \to S^k\). In this section we will see that such multiplication maps give rise to potentially interesting maps \(\Theta_f: S^{2k+1} \to S^k\). In the key calculation of this section we show how we can determine the Hopf invariant \(\text{Hopf}(\Theta_f)\) directly in terms of homological data of the original map \(f\).

We start out with recalling the following not terribly inspired definition from Exercise \[45.20\].

**Definition.** Let \(n \in \mathbb{N}\) and let \(f: S^n \times S^n \to S^n\) be a map. We pick \(x_0, y_0 \in S^n\). We define the **bidegree** of \(f\) as \[1297\]

\[
\text{bideg}(f) := (p, q) \text{ where } p := \deg \left( S^n \to S^n \right) \quad \text{and} \quad q := \deg \left( S^n \to S^n \right).
\]

**Examples.**

1. The map \(f: S^1 \times S^1 \to S^1\) that is given by complex multiplication has bidegree \((1, 1)\). This can be seen as follows: taking \(x_0 = y_0 = 1\), we see that the two maps \(S^1 \to S^1\) given by \(z \mapsto f(z, 1)\) and \(z \mapsto f(1, z)\) are in fact the identity.
2. The same argument as in (1) shows that the quaternion multiplication \(S^3 \times S^3 \to S^3\) is a map of bidegree \((1, 1)\) and that the octonion multiplication \(S^7 \times S^7 \to S^7\) is also a map of bidegree \((1, 1)\).
3. Let \(n \in \mathbb{N}\) and let \(f: S^n \times S^n \to S^n\) be a map of bidegree \((p, q)\). Furthermore let \(\varphi, \psi: S^n \to S^n\) two maps. It follows almost immediately from the definitions that the bidegree of the map \((x, y) \mapsto f(\varphi(x), \psi(y))\) equals \((p \cdot \deg(\varphi), q \cdot \deg(\psi))\).

The previous example shows that the division algebras \(\mathbb{C}, \mathbb{H}\) and \(\mathbb{O}\) give rise to maps of bidegree \((1, 1)\). This result can be generalized to all division algebras.

**Lemma 91.11.** Let \(n \in \mathbb{N}_{\geq 2}\). If \(\mathbb{R}^n\) admits the structure of a division algebra\[1298\] then there exists a map \(S^{n-1} \times S^{n-1} \to S^{n-1}\) of bidegree \((p, q)\) where both \(p\) and \(q\) are odd.

\[\text{In Exercise } 45.20\text{ (a) we saw that the definition not depend on the choice of } x_0 \text{ and } y_0.\]
**Proof.** Let $*$ be the multiplication map of a division algebra on $\mathbb{R}^n$. As in the proof of Theorem 60.4 we consider the map

$$f : S^{n-1} \times S^{n-1} \to S^{n-1},$$

$$(x, y) \mapsto f(x, y) := \frac{x \ast y}{\|x \ast y\|}.$$ 

In the proof of Theorem 60.4 we already showed, using the hypothesis that “$\ast$” defines a division algebra, that this map is well-defined and that it is continuous. Now we pick a point $\ast \in S^{n-1}$ and we consider the maps

$$\varphi : S^{n-1} \to S^{n-1}$$

and

$$\psi : S^{n-1} \to S^{n-1},$$

$$x \mapsto f(x, \ast) \quad \text{and} \quad y \mapsto f(\ast, y).$$

It follows easily from the fact that $\ast$ is the multiplication of a real algebra that for all $z \in S^{n-1}$ we have $\varphi(-z) = -\varphi(z)$ and $\psi(-z) = -\psi(z)$. By Proposition 59.4 this implies that $\deg(\varphi)$ and $\deg(\psi)$ are odd. Conveniently enough that is exactly what he had set out to show. □

Before we continue we recall a few conventions that we had introduced along the way. Most of them are also illustrated in Figure 1260.

1. Given a topological space we consider the cone $\text{Cone}(X)$, the suspension $\Sigma(X)$ and we consider the two copies $\text{Cone}_\pm(X)$ of the cone in the suspension.

2. Let $m \in \mathbb{N}_0$. Note that by the discussion on page 692 we can make the identification $\text{Cone}(S^m) = B^{m+1}$ and by the discussion on page 695 we can make the identification $\Sigma(S^m) = S^{m+1}$.

3. Let $m, n \in \mathbb{N}_0$. By the discussion on page 203 we can make the identification

$$(S^m \times B^{n+1}) \cup_{\text{id}_{S^m} \times S^n} (B^{m+1} \times S^n) \xrightarrow{\cong} S^{m+n+1}.$$

Now we can move on to the promised construction of potentially interesting maps between spheres.

---

Recall that by the definition on page 1461 a division algebra is an algebra that has left and right inverses. We do not assume that division algebras are associative and we do not assume that they preserve the scalar product.

Here we implicitly use Lemma 24.2.
**Definition.** Let $f: S^p \times S^q \to S^r$ be a map. We consider the maps
\[
S^p \times \text{Cone}(S^q) \to \text{Cone}_+(S^r) \quad \text{and} \quad \text{Cone}(S^p) \times S^q \to \text{Cone}_-(S^r)
\]
\[
(P, [(Q,t)]) \mapsto [(f(P,Q),1-t)] \quad \text{and} \quad ([(P,t)],Q) \mapsto [(f(P,Q),t-1)].
\]
We will see in Exercise 91.2 that these two maps are continuous. Evidently the two maps agree on the overlap $S^p \times S^q$. Thus by Lemma 3.44 these two maps define a continuous map
\[
\Theta_f: (S^p \times \text{Cone}(S^q)) \cup_{S^p \times S^q} (\text{Cone}(S^p) \times S^q) = S^{p+q+1} \to \Sigma(S^r).
\]
We refer to Figure 1261 for a moderately successful attempt at illustrating the map $\Theta_f$.

**Example.**

1. Again we consider the map $f: S^1 \times S^1 \to S^1$ that is given by complex multiplication. We obtain by the above construction a map $\Theta_f: S^3 \to S^2$. The heroically inclined reader will surely rise to the challenge of showing that this map is homotopic to the Hopf map.

2. Similarly to (1) one can show that the quaternion multiplication $S^3 \times S^3 \to S^3$ gives rise to the quaternionic Hopf map $S^7 \to S^4$ and that the octonion multiplication $S^7 \times S^7 \to S^7$ gives rise to the quaternionic Hopf map $S^{15} \to S^8$.

Given a map $f: S^{n-1} \times S^{n-1} \to S^{n-1}$ the next proposition computes the Hopf invariant of $\Theta_f$ in terms of the bidegree of $f$.

**Proposition 91.12.** Let $n \in \mathbb{N}_{\geq 2}$. If $f: S^{n-1} \times S^{n-1} \to S^{n-1}$ is a map of bidegree $(r,s)$, then the induced map $\Theta_f: S^{2n-1} \to S^n$ has Hopf invariant $\pm rs$.

**Proof.** We make the following preparations:

1. Throughout the proof all cohomology groups are understood to be with $\mathbb{Z}$-coefficients.
2. To simplify the notation we write $C(\Theta_f)$ instead of $\text{Cone}(\Theta_f)$.
3. By Lemma 24.6 we know that the inclusion $S^n \to C(\Theta_f): S^{2n-1} \to S^n$ is actually an embedding, thus we can identify $S^n$ with its image in $C(\Theta_f)$.
4. We denote by $\overline{B}^n_+$ the upper hemisphere of $S^n$ and we denote by $\overline{B}^n_-$ the lower hemisphere of $S^n$.

\[\text{To be on the safe side, let us more cautiously say that the map } \Theta_f \text{ is either homotopic to the Hopf map or that it is homotopic to the composition of the Hopf map with a reflection in a hyperplane.}\]

\[\text{We leave it to the sign aficionados to determine the correct sign.}\]
(5) By the discussion on page 692 we can make the identification
\[ \overline{B}^n \times \overline{B}^n = \overline{B}^{2n} = \text{Cone} \left( (S^{n-1} \times \overline{B}^n) \cup_{S^{n-1} \times S^{n-1}} (\overline{B}^n \times S^{n-1}) \right). \]

We denote by
\[ F: \overline{B}^n \times \overline{B}^n \to C(\Theta_f: S^{2n-1} \to S^n) = \text{Cone}(S^{2n-1}) \cup_{\Theta_f} S^n \]
the obvious map which is given by the identification \( \overline{B}^n \times \overline{B}^n = \text{Cone}(S^{2n-1}) \) followed by the projection.

\[ S^{n-1} \times S^{n-1} \quad \overline{B}^n \times S^{n-1} \]
\[ S^{2n-1} \quad \overline{B}_+^n \]
\[ S^{n-1} \times \overline{B}^n \quad \Theta_f \quad S^n \]
\[ \overline{B}_-^n \]
\[ \overline{B}^n \times \overline{B}^n \]

**Figure 1262.** Illustration for the proof of Proposition 91.12

Next we pick generators for various cohomology groups:

1. We denote by \( x \in H^n(C(\Theta_f)) \) and \( z \in H^{2n}(C(\Theta_f)) \) the generators that are given in the definition of the Hopf invariant, see page 2217.

2. The long exact sequence in cohomology of the pair \((C(\Theta_f), \overline{B}_\pm^a)\) shows that the maps \( H^n(C(\Theta_f), \overline{B}_\pm^a) \to H^n(C(\Theta_f)) \) are isomorphisms. Let \( x_\pm \in H^n(C(\Theta_f), \overline{B}_\pm^a) \) be the generators that correspond to \( x \) under the given isomorphisms.

3. We denote by \([S^{n-1}]^* \in H^{n-1}(S^{n-1})\) and \([\overline{B}^n]^* \in H^n(\overline{B}^n, S^{n-1})\) the standard dual generators. For \( i = 1, 2 \) we denote by \( p_i: \overline{B}^n \times \overline{B}^n \to \overline{B}^n \) the projection onto the first respectively second coordinate. We write
\[ y_1 = p_i^*([\overline{B}^n]^*) \in H^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \quad \text{and} \]
\[ y_2 = p_2^*([\overline{B}^n]^*) \in H^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}). \]

The following claim contains the key calculation of the proof.

**Claim.** The map \( F \) induces the following maps on relative cohomology:

1. \[ H^n(C(\Theta_f), \overline{B}_+^a) \xrightarrow{F} H^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \]
\[ x_+ \quad \mapsto \quad \pm r \cdot y_1 \]

2. \[ H^n(C(\Theta_f), \overline{B}_-^a) \xrightarrow{F} H^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}) \]
\[ x_- \quad \mapsto \quad \pm s \cdot y_2. \]

Before we turn to the actual calculation we make the following two preparations:
(a) We point out that the restrictions of \( F \) to various subsets gives us the following commutative diagram
\[
\begin{array}{c}
\Bbb{B}^n \times \Bbb{B}^n & \xrightarrow{F} & C(\Theta_f) \\
\uparrow & & \uparrow \\
\Bbb{B}^n \times S^{n-1} & \xrightarrow{\Theta_f} & \Bbb{B}^n_-
\end{array}
\]
\[
\begin{array}{c}
\downarrow & & \downarrow \\
S^{n-1} \times S^{n-1} & \xrightarrow{f} & S^{n-1}.
\end{array}
\]

(b) We pick a point \( * \in S^{n-1} \).

To provide the actual proof of the claim we consider the following diagram:
\[
\begin{array}{c}
H^n(C(\Theta_f)) & \xrightarrow{\cong} & H^n(C(\Theta_f), \Bbb{B}^n_+) \\
\downarrow & & \downarrow \\
H^n(S^n) & \xleftarrow{\cong} & H^n(S^n, \Bbb{B}^n_+) \\
\cong & & \cong \\
H^n(S^n, S^{n-1}) & \xrightarrow{\cong} & H^n(S^n, S^{n-1} \times *) \\
\delta \downarrow & & \delta \downarrow \\
H^n(S^{n-1}) & \xrightarrow{f^*} & H^n(S^{n-1} \times *)
\end{array}
\]

We make the following clarifications and observations:

1. The maps that are not specified are induced by the obvious inclusions of (pairs) of topological spaces.
2. The inclusion induced maps that are decorated by \( \cong \) are isomorphisms for the following reasons:
   (a) by the long exact sequence in cohomology for the corresponding pair,
   (b) the maps are induced by a homotopy equivalence,
   (c) by the long exact sequence provided by Lemma 91.4
   (d) by an appropriate version of the Excision Theorem, see the remark on page 1840.
3. The quadrilateral to the left commutes since all maps are induced by inclusions.
4. It follows from (2) and (3) that the diagonal map is an isomorphism.
5. The triangle towards the center commutes since all maps are induced by inclusions.
6. It follows from (2), (4) and (5) that the middle vertical map is an isomorphism.
7. The squares to the right commute by the commutative diagram shown in (a) and by the naturality of the connecting homomorphisms.
8. The connecting homomorphisms \( \delta \) are easily seen to be isomorphisms since the other groups in the corresponding long exact sequence are zero.
9. Basically by the definition of the bidegree of the map \( f \) the bottom horizontal map is given by \( [S^{n-1}]^* \mapsto r \cdot [S^{n-1} \times *]^* \).

The above arguments show that the vertical maps of the blue part of the diagram are isomorphisms. Since the bottom map is given by multiplication by \( r \) we see that the top map, with whatever choice of generators is also given by multiplication by \( \pm r \). This concludes the proof of part (i) of the claim. The proof of part (ii) is evidently basically the same.
Finally we consider the following diagram

\[
\begin{array}{cccc}
\bigtimes_{x_\leftarrow x_-} & \bigtimes_{x_\leftarrow x_+} & \bigtimes_{x_\rightarrow \pm r \cdot y_1} & \bigtimes_{x_\rightarrow \pm s \cdot y_2} \\
H^n(C(\Theta_f)) & \cong & H^n(C(\Theta_f), \overline{B_-^n}) & \cong \\
H^n(C(\Theta_f)) & \cong & H^n(C(\Theta_f), \overline{B_+^n}) & \cong \\
H^n(\overline{B_-^n}) & \cong & H^n(\overline{B_+^n}) & \cong \\
\cup (x,x)\mapsto x^2 = \text{Hopf}(\Theta_f) \cdot z & \cup & \cup (y_1,y_2)\mapsto y_1 \cup y_2 = [\overline{B^n \times B^n}]^* & \\
H^2n(C(\Theta_f)) & \cong & H^2n(C(\Theta_f), S^n) & \cong \\
\pm z \mapsto [\overline{B^n \times B^n}]^* & \cong & \pm z \mapsto [\overline{B^n \times B^n}]^* & \cong \\
\end{array}
\]

We make the following comments:

1. It follows almost immediately from Proposition 74.12 (5) that \((C(\Theta_f), \overline{B_-^n}, \overline{B_+^n})\) and \((\overline{B_-^n} \times \overline{B_+^n}, S^{n-1} \times \overline{B_+^n}, \overline{B_+^n} \times S^{n-1})\) are excisive triads. Thus we see that the relative cup product in the center and to the right are actually defined.

2. It follows from the naturality of the cup product, see Proposition 5.1.3 that the two squares commute.

3. By Proposition 84.2 (1) we have \(y_1 \cup y_2 = p^*_1([\overline{B^n^1}]) \cup p^*_2([\overline{B^n^2}]) = [\overline{B^n \times B^n}]^*\).

4. By the above claim we know that the top right horizontal map is in fact given by \(x_- \mapsto \pm r \cdot y_1\) and \(x_+ \mapsto \pm s \mapsto s \cdot y_2\).

5. Since the bottom horizontal maps are isomorphisms we see that going right to left the generator \([\overline{B^n \times B^n}]^*\) gets sent to \(\pm z\).

It follows immediately from the above comments that \(\text{Hopf}(\Theta_f) = \pm r \cdot s\).

Since the Hopf invariant gives us a homomorphism \(\pi_{2n-1}(S^n) \to \mathbb{Z}\) we are now interested in finding interesting maps \(S^{n-1} \times S^{n-1} \to S^{n-1}\). Perhaps somewhat surprisingly it is not that hard to find interesting maps.

**Proposition 91.13.** Given any even \(n \in \mathbb{N}\) the map

\[
f: S^{n-1} \times S^{n-1} \to S^{n-1} \\
(x, y) \mapsto y - 2 \cdot (x, y) \cdot x = \text{reflection of } y \text{ in the } \text{hyperplane } x^\perp
\]

has bidegree \((2, -1)\).

**Proof.** We need to show that the given map \(f: S^{n-1} \times S^{n-1} \to S^{n-1}\) has bidegree \((2, -1)\). The proof of this statement naturally breaks up into two parts.

1. We take \(y_0 = (1, 0, \ldots, 0)\). We consider the map \(\varphi: S^{n-1} \to S^{n-1}\) that is given by \(x \mapsto (x, y_0)\). Note that \(\varphi^{-1}((1, 0, \ldots, 0)) = (\pm 1, 0, \ldots, 0)\). Using this observation...
together with Proposition 45.23 and Proposition 45.22 one can easily show that the degree of the map $x \mapsto (x, y_0)$ equals $1 + (-1)^{n-2}$. Since $n$ is by hypothesis even we see that the degree equals two.

(2) We take $x_0 = (1, 0, \ldots, 0)$. The corresponding $S^{n-1} \to S^{n-1}$, $y \mapsto (x_0, y)$ is the reflection in a hyperplane, hence it follows from Lemma 45.11 that the map has degree $-1$. 

The combination of Propositions 91.7 and 91.13 gives us the following interesting corollary.

**Corollary 91.14.** Given any even $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$.

As always in mathematics, every result opens up lots of new questions. Here are a few:

**Question 91.15.**

1. We have now seen that there exists an epimorphism $\pi_3(S^2) \to \mathbb{Z}$. Is this map an isomorphism?
2. We have now seen that there exists an epimorphism $\pi_7(S^4) \to \mathbb{Z}$. Is this map an isomorphism?

We will provide the answer to Question 91.15 (1) in Theorem 113.10 and we will see the answer to Question 91.15 (2) in Theorem 117.19 (1).

Question 91.13 points to a problem: we have now developed some tools for showing that certain homotopy groups of spheres are non-trivial, but we have no tools yet for computing any interesting homotopy groups. We will partially rectify this problem in Chapter 117.

Here is another question. We delay the answer to Theorem 118.1.

**Question 91.16.** Given any $n \in \mathbb{N}$ we know by Lemma 53.2 and Corollary 91.14 that $\pi_n(S^n)$ and $\pi_{4n-1}(S^{2n})$ admit an epimorphism onto $\mathbb{Z}$. Are there any other homotopy groups of spheres that admit an epimorphism onto $\mathbb{Z}$?

In light of Lemma 91.11 and Proposition 91.13 the following question becomes interesting:

**Question 91.17.** For which $n \in \mathbb{N}_{\geq 2}$ does there exist a map $f: S^{2n-1} \to S^n$ such that $\text{Hopf}(f) = 1$?\footnote{Note that Propositions 91.7 and 91.13 tell us that this question is equivalent to the question, for which $n \in \mathbb{N}$ does there exist a map $f: S^{2n-1} \to S^n$ such that $\text{Hopf}(f)$ is odd?}

We will see the complete answer to Question 91.17 in Theorems 110.10 and 110.11.

Initially one might not appreciate Question 91.17. But rather mysteriously it is not that hard to come up with maps of Hopf degree 2, but it is strikingly difficult to come up with maps of Hopf degree 1. To underline our point we conclude this chapter with another construction of a map of Hopf degree 2.

**Example.** Let $n \in \mathbb{N}$. We start out with the following two reminders:

1. We can view $S^n$ as a CW-complex with one 0-cell and one $n$-cell. In particular, if we denote by $S^n_a$ and $S^n_b$ two copies of $S^n$ then we view $S^n_a$ as a CW-complex with one 0-cell $P$ and one $n$-cell that we denote by $S^n_a$. Similarly we view $S^n_b$ as a CW-complex with one 0-cell $Q$ and one $n$-cell $S^n_b$. 

Note that Propositions 91.7 and 91.13 tell us that this question is equivalent to the question, for which $n \in \mathbb{N}$ does there exist a map $f: S^{2n-1} \to S^n$ such that $\text{Hopf}(f)$ is odd?
Given two finite CW-complexes $X$ and $Y$ we introduced on page 960 the product CW-structure on $X \times Y$. Recall that the $n$-cells of $X \times Y$ correspond precisely to products $e_x \times f_y$ where $e_x$ is a $p$-cell of $X$ and $f_y$ is an $(n-p)$-cell of $Y$.

It follows from (1) and (2) that we can view $S^n_a \times S^n_b$ as a CW-complex with one 0-cell $(P,Q)$, two $n$-cells $S^n_a \times \{Q\}$ and $\{P\} \times S^n_b$ and one $2n$-cell $S^n_a \times S^n_b$. We consider the maps

$$S^{2n-1} \xrightarrow{\varphi} S^n_a \times \{Q\} \cup \{P\} \times S^n_b \xrightarrow{p} S^n.$$  

attaching map of the $2n$-cell to the (2n-1)-skeleton of $S^n_a \times S^n_b$ which is precisely $S^n_a \times \{Q\} \cup \{P\} \times S^n_b$

The composition of the maps $\varphi$ and $p$ defines a map $f: S^{2n-1} \to S^n$. It is clear from Figure 1264 that this map is not very interesting for $n = 1$. But using fairly elementary arguments one can show that for all even $n$ we have $\text{Hopf}(f) = \pm 2$. We refer to \cite{Hat02}, p. 428 or \cite{Vic94}, p. 138 for details. Alternatively we leave it as a brain teaser for the reader to perform this calculation.

Exercises for Chapter 91

Exercise 91.1. What is the homeomorphism type of the mapping cone of the map $S^1 \to S^1$ given by $z \mapsto z^2$?

*Hint.* It is a topological space that we are quite familiar with.

Exercise 91.2. Let $f: S^p \times S^q \to S^r$ be a map. (As always, $f$ is understood to be continuous.) Show that the map

$$(P, [(Q,t)]) \mapsto [(f(P,Q),t)]$$

is continuous.

*Hint.* Use Theorem 5.16 and Lemma 5.17 (2).

Exercise 91.3. Let $f: S^k \times S^k \to S^k$ be the projection onto the first factor. Show that the corresponding map $\Theta_f: S^{2k+1} \to S^{k+1}$, that is defined on page 2225, is homotopic to a constant map.

*Hint.* The exercise is very easy.
Exercise 91.4. Let \( n \in \mathbb{N} \) be even and let \( a, b \in \mathbb{Z} \). Show that if at least one of \( a \) or \( b \) is even, then there exists a map \( S^{n-1} \times S^{n-1} \to S^{n-1} \) of bidegree \( (a, b) \).
92. Alexander Duality

In this chapter we will study the Alexander Duality Theorem which, given a “reasonable” subset $X$ of $S^n$ relates the homology groups of $S^n \setminus X$ to the cohomology groups of $X$.

92.1. The basic Alexander Duality Theorem. We start out with the basic Alexander Duality Theorem which will be surprisingly easy to prove and which is already very helpful.

**Theorem 92.1. (Alexander Duality Theorem)** Let $K$ be a compact non-empty subset of $S^n$ that admits a regular neighborhood. For any $i \in \mathbb{N}_0$ there exist isomorphisms

(a) \[ \tilde{H}_i(S^n \setminus K; \mathbb{Z}) \cong \tilde{H}^{n-i-1}(K; \mathbb{Z}) \]

and

(b) \[ \tilde{H}^i(S^n \setminus K; \mathbb{Z}) \cong \tilde{H}_{n-i-1}(K; \mathbb{Z}). \]

By the Regular Neighborhood Theorem 10.3 this conclusion holds for any closed non-empty submanifold of $S^n$. In this particular case the isomorphisms are natural.

**Proof.** Let $K$ be a compact non-empty subset of $S^n$ that admits a regular neighborhood $N$. We first consider statement (a) and the case that $i > 0$. In this case we have the following isomorphisms:

\[
\begin{align*}
\tilde{H}_i(S^n \setminus K; \mathbb{Z}) & \xrightarrow{\cong} \tilde{H}_i(S^n \setminus \hat{N}; \mathbb{Z}) & \xrightarrow{\cong} H^{n-i}(S^n \setminus \hat{N}, \partial N; \mathbb{Z}) & \xrightarrow{\cong} H^{n-i}(S^n, N; \mathbb{Z}) \\
& \xrightarrow{\cong} \tilde{H}^{n-i-1}(N; \mathbb{Z}) & \xrightarrow{\cong} \tilde{H}^{n-i-1}(K; \mathbb{Z}).
\end{align*}
\]

where we use that $i > 0$.

The case $i = 0$ is proved almost the same way. Thus we leave it to the reader to verify this case. This concludes the proof of (a). The proof of the existence of the isomorphism (b) is basically identical.

Finally suppose that $K$ is a closed non-empty submanifold of $S^n$. It follows from the General Tubular Neighborhood Theorem 10.5 and Proposition 10.11 that we can take a tubular neighborhood as a regular neighborhood. By Proposition 10.7 tubular neighborhoods are unique in an appropriate sense which then allows us to get a natural isomorphism.

**Remark.**

(1) The argument in the proof of the Alexander Duality Theorem 92.1 implies in particular that given any compact, non-empty $n$-dimensional submanifold $W$ of $S^n$ there exists an isomorphism

\[ \tilde{H}_i(S^n \setminus \hat{W}; \mathbb{Z}) \cong \tilde{H}^{n-i-1}(W; \mathbb{Z}). \]
(2) In Alexander Duality Theorem [92.1] we explicitly do not write “natural” isomorphism. The isomorphism that we construct in the proof depends on the choice of a regular neighborhood. It is not clear to me whether two regular neighborhoods are necessarily in any way “equivalent”.

In practice we often like to consider objects that lie in \( \mathbb{R}^n \) instead of \( S^n \). The following variation on the Alexander Duality Theorem [92.1] deals with this situation.

**Corollary 92.2.** Let \( K \) be a compact non-empty subset of \( \mathbb{R}^n \). If \( K \) admits a regular neighborhood, then for any \( i \in \mathbb{N}_0 \) we have an isomorphism

\[
\tilde{H}_i(\mathbb{R}^n \setminus K) \cong H^{n-i-1}(K).
\]

By the Regular Neighborhood Theorem [10.3] this conclusion holds for any compact submanifold of \( \mathbb{R}^n \).

**Proof.** Let \( K \) be a compact non-empty subset of \( \mathbb{R}^n \) that admits a regular neighborhood \( N \) in \( \mathbb{R}^n \). Recall that \( N \) is by definition compact. It follows easily that \( N \) is also a regular neighborhood for \( K \) in \( S^n \). Now let \( i \in \mathbb{N}_0 \). Then

\[
\tilde{H}^{n-i-1}(K) \cong \tilde{H}_i(S^n \setminus K) \cong \begin{cases} \tilde{H}_i(\mathbb{R}^n \setminus K), & \text{if } i \neq n - 1, \\ \tilde{H}_{n-1}(\mathbb{R}^n \setminus K) \oplus \mathbb{Z}, & \text{if } i = n - 1. \end{cases}
\]

Alexander Duality Theorem [92.1] which we can apply since \( K \) admits a regular neighborhood in \( S^n \).

The corollary now follows from Lemmas [73.16] and [19.8] (1).

In the remainder of this section we discuss a few applications of the Alexander Duality Theorem [92.1]. The following definition generalizes the notion of a knot.

**Definition.** An \( m \)-component link is a 1-dimensional submanifold of \( S^3 \) that is diffeomorphic to the disjoint union of \( m \) circles.

![Illustration for the proof of the Alexander Duality Theorem 92.1](image)

**Figure 1265.** Illustration for the proof of the Alexander Duality Theorem 92.1

![Examples of 2-component links](image)

**Figure 1266.** Examples of 2-component links.

---

Sometimes, to distinguish this notion from the higher-dimensional analogue that we define on page ?? we refer to such a link in \( S^3 \) as a classical link.
The following lemma computes the homology groups of a link complement. It can be viewed as a generalization of Lemma 68.16 (4).

**Lemma 92.3.** For any \( m \)-component link \( L \) in \( S^3 \) we have

\[
H_i(S^3 \setminus L; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}^{m-1}, & \text{if } i = 2, \\
\mathbb{Z}^m, & \text{if } i = 1, \\
\mathbb{Z}, & \text{if } i = 0, \\
0, & \text{otherwise.}
\end{cases}
\]

**Proof.** Let \( L \) be an \( m \)-component link. We calculate that

\[
\tilde{H}_i(S^3 \setminus L; \mathbb{Z}) \cong \tilde{H}^{2-i}(L; \mathbb{Z}) \cong \tilde{H}^{2-i}(S^1 \sqcup \cdots \sqcup S^1; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}^{m-1}, & \text{if } i = 2, \\
\mathbb{Z}^m, & \text{if } i = 1, \\
\mathbb{Z}, & \text{if } i = 0, \\
0, & \text{otherwise.}
\end{cases}
\]

\[\uparrow\text{ Alexander Duality Theorem 92.1}\]

The lemma follows from this calculation together with Lemma 73.16 (3). \(\blacksquare\)

For any 2-component link \( L = K_1 \cup K_2 \), for example for any of the links shown in Figure 1266, we see that

\[
H_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^2 \quad \text{and} \quad H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}.
\]

The problem with this calculation is that we do not obtain any understanding of what the homology classes “look like”. It seems reasonable to guess, along the lines of Lemma 68.16 that the first homology group is generated by the two meridians. But (a), we do not know how to prove it, and (b), we have no idea what a generator of the second homology group looks like. So the following question arises:

**Question 92.4.** Given a link \( L \), what are explicit bases for the homology groups of \( S^3 \setminus L \)?

We will return to this question in Lemma 99.18. We continue with another example.

**Examples.**

1. We consider the connected topological graph \( G \) with two vertices and three edges that is illustrated in Figure 1267 on the left. On the right of Figure 1267 we show a spatial graph \( G' \) in \( S^3 = \mathbb{R}^3 \cup \{\infty\} \) that is homeomorphic to \( G \). We have the following isomorphisms:

\[
\tilde{H}_i(S^3 \setminus G'; \mathbb{Z}) \cong \tilde{H}^{2-i}(G'; \mathbb{Z}) \cong \tilde{H}^{2-i}(S^1 \sqcup \cdots \sqcup S^1; \mathbb{Z}) \cong \begin{cases} 
\mathbb{Z}^{m-1}, & \text{if } i = 2, \\
\mathbb{Z}^m, & \text{if } i = 1, \\
\mathbb{Z}, & \text{if } i = 0, \\
0, & \text{otherwise.}
\end{cases}
\]

In this case it is also rather unclear what a basis of \( H_1(S^3 \setminus G; \mathbb{Z}) \) should look like. Later, on page 2405 we will find an explicit basis for \( H_1(S^3 \setminus G; \mathbb{Z}) \).

2. Let \( G \) be the spatial graph that we consider in Exercise 10.6. The same argument as in (1) shows that \( H_1(S^3 \setminus G; \mathbb{Z}) \cong \mathbb{Z}^2 \). Together with the Hurewicz Theorem 52.5 and Exercise 46.12 we obtain that the answer to Exercise 10.6 (b) is \( \mathbb{Z}^2 \).
We conclude this section with the following variation on the above Alexander Duality Theorem 92.1. It will come in handy at times. But arguably it is best to study it only when it is actually needed.

**Theorem 92.5. (Alexander Duality Theorem)** (*) Let \( n \in \mathbb{N}_0 \) and let \( j \in \{0, \ldots, n\} \). Given any compact oriented \( n \)-dimensional smooth manifold \( X \) which has the property that \( H_j(X; \mathbb{Z}) = H_{j+1}(X; \mathbb{Z}) = 0 \) and given any compact proper submanifold \( G \) of \( X \) there exist natural isomorphisms

\[
\alpha_G : H_j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} H^{n-j-1}(G, \partial G; \mathbb{Z}) \quad \text{and} \quad \alpha_G : H^j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} H_{n-j-1}(G, \partial G; \mathbb{Z})
\]

such that the following conditions are satisfied:

1. If \( X = S^n \), then the isomorphisms are precisely the isomorphisms from the Alexander Duality Theorem 92.1.
2. The isomorphisms decompose in the obvious way if \( X \) is disconnected.
3. If \( W \) is a compact oriented \( n \)-dimensional smooth manifold with

\[
H_j(W; \mathbb{Z}) = H_{j+1}(W; \mathbb{Z}) = H_j(\partial W; \mathbb{Z}) = H_{j+1}(\partial W; \mathbb{Z}) = 0,
\]

and if \( F \) is a compact proper submanifold of \( W \), then we have commutative diagrams

\[
\begin{array}{ccc}
H_j(W \setminus F; \mathbb{Z}) & \xrightarrow{\cong} & H^{n-j-1}(F, \partial F; \mathbb{Z}) \\
i_* & & i_* \\
\downarrow \delta & & \downarrow \delta \\
H_j(\partial W \setminus \partial F; \mathbb{Z}) & \xrightarrow{\cong} & H^{n-j-2}(\partial F; \mathbb{Z})
\end{array}
\]

and

\[
\begin{array}{ccc}
H^j(W \setminus F; \mathbb{Z}) & \xrightarrow{\cong} & H_{n-j-1}(F, \partial F; \mathbb{Z}) \\
i_* & & i_* \\
\downarrow \delta & & \downarrow \delta \\
H^j(\partial W \setminus \partial F; \mathbb{Z}) & \xrightarrow{\cong} & H_{n-j-2}(\partial F; \mathbb{Z})
\end{array}
\]

where we denote by \( i : \partial W \setminus \partial F \to W \setminus F \) the inclusion map and where the right-hand vertical maps are the connecting homomorphisms of the long exact sequences in (co-)homology of the pair \((F, \partial F)\).

**Example.** The above Alexander Duality Theorem 92.5 will be applied later on to the smooth manifolds \( W = [0, 1] \times S^n \) and to \( W = \overline{B^4} \). For example, suppose that \( F \) is a connected properly embedded surface in \( \overline{B^4} \) such that \( \partial F = K \) is a knot. We can apply the Alexander Duality Theorem 92.5 for \( j = 1 \). Together with Proposition 88.26 we obtain the following commutative diagram:

\[
\begin{array}{ccc}
H_1(\overline{B^4} \setminus F; \mathbb{Z}) & \xrightarrow{\alpha_F} & H^2(F, K; \mathbb{Z}) \\
i_* & & \xrightarrow{\cong} \delta \\
H_1(S^3 \setminus K; \mathbb{Z}) & \xrightarrow{\alpha_K} & H^1(K; \mathbb{Z})
\end{array}
\]

and

\[
\begin{array}{ccc}
H^2(F, K; \mathbb{Z}) & \xrightarrow{\cong} & H_0(F; \mathbb{Z}) \\
\cong[\overline{F}] & & \\
H^1(K; \mathbb{Z}) & \xrightarrow{\cong} & H_0(K; \mathbb{Z})
\end{array}
\]
The right hand vertical map is of course an isomorphism and both groups are isomorphic to \( \mathbb{Z} \). Now we see that both groups on the left are isomorphic to \( \mathbb{Z} \) and that the inclusion induced map is an isomorphism.

**Sketch of proof.** Let \( n \in \mathbb{N}_0 \) and let \( j \in \{0, \ldots, n\} \). Let \( X \) be a compact orientable \( n \)-dimensional smooth manifold with \( H_j(X; \mathbb{Z}) = H_{j+1}(X; \mathbb{Z}) = 0 \) and let \( G \) be a compact proper submanifold of \( X \). We pick a tubular neighborhood \( N \) for \( G \) as provided by the General Tubular Neighborhood Theorem \[10.5\]. Recall that \( N \) is a submanifold with corner. We define \( \hat{N} \) as in Lemma \[89.1\]. We write \( M := N \cap \partial X \). Note that \( M \) is a tubular neighborhood for \( \partial F \subset \partial X \). We refer to Figure 1268 for an illustration. We consider the following diagram

\[
\begin{array}{ccc}
H_j(X \setminus \hat{N}) & \xleftarrow{\cong} & H^{n-j}(X \setminus \hat{N}, \partial(X \setminus \hat{N})) \\
\cong & & \cong \\
H_j(X \setminus G) & \xrightarrow{\alpha_G} & H^{n-j}(G, \partial G)
\end{array}
\]

We make the following comments:

(a) All maps where no map is specified are induced by inclusions. It follows from Proposition \[10.11\] together with Corollary \[42.8\] and Lemma \[73.13\](4) that the vertical inclusion maps to the left and bottom right are isomorphisms.

(b) The two maps that are decorated with “exc” are inclusion induced maps that are isomorphisms by “excision”. We leave it to the reader to verify that these inclusion maps are indeed isomorphisms. As an example, if \( \partial X = \emptyset \), then it follows from the Excision Theorem \[43.20\] that the top “exc”-map is an isomorphism.

(c) The map on the top right indicated by “\( \delta \)” is the connecting homomorphism of the long exact sequence in cohomology of the triple \((X, N \cup \partial X, \partial X)\). By our hypothesis we have \( H_j(X; \mathbb{Z}) = H_{j+1}(X; \mathbb{Z}) = 0 \). By the Poincaré Duality Theorem \[88.1\] this implies that \( H^{n-j}(X, \partial X; \mathbb{Z}) \) is an isomorphism.

We have now seen that all maps in the diagram are isomorphisms. Thus we can define \( \alpha_G \) to be the map on the bottom. A priori the definition of \( \alpha_G \) depends on the choice of the tubular neighborhood \( N \). But by Proposition \[10.7\] tubular neighborhoods are unique in
an appropriate sense. This implies that isomorphisms do not depend on the choice of the tubular neighborhood.

First note that Statement (1) is basically clear once one compares the definitions. Next note that Statement (2) follows from all the usual results for the behavior of invariants under the disjoint union. Finally we turn to the proof of Statement (3). Let $W$ be a compact oriented $n$-dimensional smooth manifold with

\[(\ast) \quad H_j(W;\mathbb{Z}) = H_{j+1}(W;\mathbb{Z}) = H_j(\partial W;\mathbb{Z}) = H_{j+1}(\partial W;\mathbb{Z}) = 0.\]

Furthermore let $F$ be a compact proper submanifold of $W$. We pick a tubular neighborhood $N$ for $F$. We define $\tilde{N}$ as above. We write $M := N \cap \partial W$. Note that $M$ is a tubular neighborhood for $\partial F$. We consider the following diagram

\[
\begin{array}{c}
H_j(W \setminus \tilde{N}) \xrightarrow{\cong_{\text{PD}}} H^{n-j}(W \setminus \tilde{N}, \partial(W \setminus \tilde{N})) & \xrightarrow{\cong_{\text{exc}} H^{n-j}(W, N \cup \partial W)} \xrightarrow{\cong_{\delta}} H^{n-j-1}(N \cup \partial W, \partial W) \\
\cong & \downarrow \cong & \downarrow \cong \\
H_j(W \setminus F) & \xrightarrow{\alpha_F} & H^{n-j-1}(F, \partial F) \\
\downarrow \alpha_{\partial F} & & \downarrow \delta \\
H_j(\partial W \setminus \partial F) & \xrightarrow{\cong_{\text{PD}}} H^{n-j-2}(\partial F) \\
\cong & \downarrow \cong \\
H_j(\partial W \setminus M) & \xleftarrow{\cong_{\text{PD}}} H^{n-j}(\partial W \setminus M, \partial M) & \xrightarrow{\cong_{\text{exc}}} H^{n-j-1}(\partial W, M) & \xleftarrow{\cong_{\delta}} H^{n-j-2}(M).
\end{array}
\]

We make the following observations:

1. By our hypothesis $(\ast)$ and the discussion above the horizontal maps $\alpha_G$ and $\alpha_{\partial G}$ are defined.
2. One can easily see that the bottom “$\cup$” of the diagram is indeed the map $\alpha_{\partial F}$.
3. If one ignores the blue arrows, then the brave reader can verify that the diagram does indeed commute.

This concludes the proof of Statement (3) for the diagram to the left. Basically the same argument also takes care of the proof of the diagram to the right.

92.2. Immersions and smooth embeddings of smooth manifolds into $\mathbb{R}^n$. In Question 3.46 we had asked whether the projective space $\mathbb{R}P^2$ or the Klein bottle can be viewed as subsets of $\mathbb{R}^3$. We can reinterpret this question in three different ways:

**Question 92.6.**

1. Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit an immersion into $\mathbb{R}^3$?
2. Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit a smooth embedding into $\mathbb{R}^3$?
3. Does $\mathbb{R}P^2$ (respectively the Klein bottle) admit an embedding into $\mathbb{R}^3$?
We start out with Question \[92.6\) (1).

(a) We saw in Figure \[87\) that there exists an immersion of the Klein bottle \(K\) into \(\mathbb{R}^3\). In Figure \[1269\) we show the images of two other immersions of the Klein bottle into \(\mathbb{R}^3\). This gives a positive answer to Question \[92.6\) (1) for the Klein bottle.

Figure 1269

(b) The case of the real projective plane is much more interesting. In 1901 David Hilbert, arguably the greatest German mathematician of his generation, gave his PhD student Werner Boy [Boy1903] the task to prove that there is no immersion of \(\mathbb{R}P^2\) into \(\mathbb{R}^3\). To everyone’s surprise Boy did the opposite, he showed that it was possible to immerse \(\mathbb{R}P^2\) into \(\mathbb{R}^3\). In Figure \[1270\) we give several illustrations of the image of the immersion. A detailed description of the immersion is given in [Kir07, Ap87]. But perhaps it is more helpful to just watch the following video:

https://www.youtube.com/watch?v=uiq-EcQz_uU

A fun description of Boy’s surface, and of many other concepts from topology, can also be found here:

http://www.savoir-sans-frontieres.com/JPP/telechargeables/English/Topo_the_world_eng.pdf

Figure 1270

Boy’s surface at Oberwolfach

Lemma \[6.48\] says that the projective plane \(\mathbb{R}P^2\) and the Klein bottle are non-orientable. Therefore the following proposition gives in particular a negative answer to Question \[92.6\) (2).

**Proposition 92.7.** Let \(N\) be a closed \(n\)-dimensional connected smooth manifold. If \(N\) is non-orientable, then there is no smooth embedding of \(N\) into \(\mathbb{R}^{n+1}\).

**Proof.** Let \(N\) be a closed \(n\)-dimensional connected non-orientable smooth manifold. Suppose that \(N\) can be embedded into \(\mathbb{R}^{n+1}\). We can thus view \(N\) as a submanifold of \(\mathbb{R}^{n+1}\).

---

1304 Werner Boy (1879-1914) was a German mathematician who died in the first weeks of World War I.
We obtain that
\[ \mathbb{Z}_2 \cong H^n(N; \mathbb{Z}) \cong \tilde{H}_0(\mathbb{R}^{n+1} \setminus N; \mathbb{Z}) \cong \mathbb{Z} \] number of path-components of \( \mathbb{R}^{n+1} \setminus N \) minus 1.

**Proposition 92.7** [Alexander Duality]

\[ \Box \]

But this is absurd. We have thus obtained the desired contradiction.

We recall the following related question.

**Question 11.9.** Given \( n \in \mathbb{N} \), what is the minimal \( k \in \mathbb{N} \) such that \( \mathbb{R}P^n \) admits a (topological) smooth embedding into \( \mathbb{R}^k \)?

Recall that it follows from Theorem 87.1 and the calculation of the homology groups of \( \mathbb{R}P^n \) in Proposition 48.10 that \( \mathbb{R}P^n \) is orientable if and only if \( n \) is odd. In particular it follows from Proposition 92.7 that for \( n \) even it is not possible to embed \( \mathbb{R}P^n \) into \( S^{n+1} \). But this raises the question, whether for \( n \) odd one can embed \( \mathbb{R}P^n \) into \( S^{n+1} \). It turns out that this is also not the case:

**Proposition 92.8.** If \( n \in \mathbb{N}_{\geq 2} \), then there is no smooth embedding from \( \mathbb{R}P^n \) into \( S^{n+1} \).

In the proof of Proposition 92.8 we will need the following lemma which is interesting in its own right.

**Lemma 92.9.** If \( K \) is a closed orientable connected \( (n-1) \)-dimensional submanifold of the smooth manifold \( S^n \), then there exist two compact \( n \)-dimensional submanifolds \( A \) and \( B \) of \( S^n \) such that \( A \cap B = \partial A = \partial B = K \).

**Proof (†).** First we note that by Proposition 10.9 the submanifold \( K \) admits a tubular neighborhood \([-1, 1] \times K \). Our hypothesis that \( K \) is connected implies that \([-1, 0] \times K \) and \([0, 1] \times K \) are also connected.

We first calculate that
\[ H_0(S^n \setminus K; \mathbb{Z}) \cong \tilde{H}_0(S^n \setminus K; \mathbb{Z}) \oplus \mathbb{Z} \cong H^{n-1}(K; \mathbb{Z}) \oplus \mathbb{Z} \cong \mathbb{Z} \oplus \mathbb{Z}. \]

**Lemma 43.1 (4a)** [Theorem 92.1] [Theorem 87.1]

It follows from Proposition 41.5 that \( S^n \setminus K \) has precisely two path-components \( A' \) and \( B' \). Since \([-1, 0] \times K \) is connected and since it is contained in \( S^n \setminus K = A' \cup B' \) it follows that \([-1, 0] \times K \) is either contained in \( A' \) or it is contained in \( B' \). Without loss of generality we can assume that \([-1, 0] \times K \) is contained in \( A' \).

**Claim.** The subset \([0, 1] \times K \) is contained in \( B' \).

We consider the set \( A'' := A' \cup [-1, 1] \times K \). Note that \( S^n = A'' \cup B' \). Since both \( A'' \) and \( B' \) are open and since \( S^n \) is connected it follows that \( A'' \cap B' \neq \emptyset \). But this implies that
[0, 1] × K ∩ B' ≠ ∅. But since [0, 1] × K is connected we see that [0, 1] × K is contained in B'.

We set A := A' ∪ K = A' ∪ [−1, 0] × K and B := B' ∪ K = B' ∪ [0, 1] × K. It is easy to show that A and B are compact submanifolds of S^n such that A ∩ B = ∂A = ∂B = K. ■

Now we can provide the proof of Proposition 92.8.

Proof of Proposition 92.8. As we had discussed just before the proposition, it remains to deal with the case that n is odd. So suppose that n ≥ 3 is odd and that there exists a smooth embedding of \(\mathbb{R}P^n\) into \(S^{n+1}\). We identify \(\mathbb{R}P^n\) with its image under the smooth embedding, i.e. we view \(\mathbb{R}P^n\) as a submanifold of \(S^{n+1}\). Note it follows from \(n ≥ 3\) and the discussion on page 1841 that \(H^1(S^n; \mathbb{F}_2) = H^2(S^n; \mathbb{F}_2) = 0\).

Since n is odd we know that \(\mathbb{R}P^n\) is orientable. Thus we can apply Lemma 92.9 which tells us that there exist two compact \((n + 1)\)-dimensional submanifolds A and B of \(S^{n+1}\) with \(A ∩ B = ∂A = ∂B = K\). We denote by \(i: \mathbb{R}P^n → A\) and by \(j: \mathbb{R}P^n → B\) the inclusion maps. As usual we denote by \(x ∈ H^1(\mathbb{R}P^n; \mathbb{F}_2) ≃ \mathbb{F}_2\) the unique generator.

By Proposition 74.12 (5) we can apply the Mayer–Vietoris Theorem 74.15 for Cohomology Groups to \(S^{n+1} = A ∪ B\) and we obtain the long exact sequence

\[
\cdots → H^1(S^{n+1}; \mathbb{F}_2) → H^1(A; \mathbb{F}_2) ⊕ H^1(B; \mathbb{F}_2) \xrightarrow{i^*+j^*} H^1(\mathbb{R}P^n; \mathbb{F}_2) → H^2(S^{n+1}; \mathbb{F}_2) → \cdots
\]

Thus we see that the map \(i^*+j^*: H^1(A; \mathbb{F}_2) ⊕ H^1(B; \mathbb{F}_2) → H^1(\mathbb{R}P^n; \mathbb{F}_2) ≃ \mathbb{F}_2 ∗ x\) is an isomorphism. Without loss of generality we can assume that \(i^*\) is non-trivial which means that there exists an \(a ∈ H^1(A; \mathbb{F}_2)\) with \(i^*(a) = x\). We have

\[
i^*(a^n) = (i^*(a))^n = x^n ≠ 0 ∈ H^n(\mathbb{R}P^n; \mathbb{F}_2).
\]

In particular the map \(i^*: H^n(A; \mathbb{F}_2) → H^n(\mathbb{R}P^n; \mathbb{F}_2)\) is non-zero. Now we consider the other end of the above Mayer–Vietoris sequence and we obtain the exact sequence

\[
\cdots H^n(A; \mathbb{F}_2) ⊕ H^n(B; |\mathbb{F}_2|) \xrightarrow{i^*+j^*} H^n(\mathbb{R}P^n; \mathbb{F}_2) \xrightarrow{∂F_2} H^{n+1}(S^{n+1}; \mathbb{F}_2) → H^{n+1}(A; \mathbb{F}_2) ⊕ H^{n+1}(B; \mathbb{F}_2).
\]

Both are zero by Proposition 75.12 since A and B are compact, connected \((n + 1)\)-dimensional smooth manifolds with non-empty boundary.

Thus we see that the map on the left is an epimorphism and that the group on the right is trivial. But then the fact that \(H^{n+1}(S^{n+1}; \mathbb{F}_2) ≠ 0\) shows that the sequence cannot possibly be exact. We have thus obtained the desired contradiction. ■

Remark. The above proposition does not give a complete answer to Question 11.9 we have only shown that \(\mathbb{R}P^n\) cannot embed into \(S^{n+1}\). More lower bounds on the minimal dimension of some \(\mathbb{R}^k\) into which we can embed \(\mathbb{R}P^n\) have been obtained by Michael Atiyah [At61].
92.3. The generalized Alexander Duality Theorem. In a bout of optimism one might hope that the statement of Alexander Duality Theorem 92.1 holds for any (compact) subset of $S^n$. But this is not the case. More precisely, once again we consider the topologist’s sine curve

$$X = \{(0, y) \mid y \in [-1, 1]\} \cup \{(x, \sin(\frac{1}{x})) \mid x \in (0, \pi]\} \subset \mathbb{R}^2$$

that we had initially introduced on page 131. It is fairly straightforward to see that $X$ is a closed subset of $\mathbb{R}^2$. Evidently $X$ is bounded. Thus the Heine-Borel Theorem 2.20 implies that $X$ is in fact a compact subset of $\mathbb{R}^2$ and thus of $S^2 = \mathbb{R}^2 \cup \{\infty\}$. Back on page 131 we saw that $X$ is not path-connected, which by Proposition 73.11 and Lemma 73.14 implies that $\tilde{H}^0(X; \mathbb{Z}) \neq 0$. On the other hand, with some effort one can show that there exists a deformation retraction from $S^2 \setminus X = (\mathbb{R}^2 \setminus X) \cup \{\infty\}$ to $\infty$, which implies that $H_1(S^2 \setminus X; \mathbb{Z}) = 0$. But this shows that $\tilde{H}_1(S^2 \setminus X; \mathbb{Z}) \neq \tilde{H}^0(X; \mathbb{Z})$.

Perhaps rather surprisingly one only needs a fairly modest hypothesis to ensure that Alexander Duality holds after all. More precisely, we have the following theorem which, by Lemma 85.2, is a significant generalization of the earlier Alexander Duality Theorem 92.1 (a).

**Theorem 92.10. (Generalized Alexander Duality Theorem)** Let $n \geq 2$ and let $X \subseteq S^n$ be a weakly locally contractible, non-empty compact subset of $S^n$. Given any $j \in \mathbb{N}_0$ we have a natural\footnote{What does “natural” mean in this context? What are the categories? What are the functors?} isomorphism

$$\tilde{H}_j(S^n \setminus X; \mathbb{Z}) \xrightarrow{\cong} \tilde{H}^{n-j-1}(X; \mathbb{Z}).$$

**Example.** In Figure 1274 we show a subset $X$ of $\mathbb{R}^3$ that is homeomorphic to the compact interval $[0, 1]$. (We had already encountered this subset in Figure 805.) We leave it as a somewhat challenging exercise to convince oneself that $X$ does not admit a regular
neighborhood. In particular this is a situation where the Generalized Alexander Duality Theorem 92.10 applies, even though our initial Alexander Duality Theorem 92.1 fails.

weakly locally contractible compact subset of $\mathbb{R}^3$

**Remark.** We leave it to the reader to determine whether the obvious generalization of Alexander Duality Theorem 92.1 (b) holds.

For most applications of Alexander Duality we will actually need the following straightforward consequence of the above theorem.

**Theorem 92.11. (Alexander Duality Theorem for Topological Submanifolds)** Let $n \geq 2$ and let $k < n$. Furthermore let $X$ be a compact, non-empty $k$-dimensional topological manifold. If $f: X \to S^n$ is an injective map, then for any $j \in \mathbb{N}_0$ we have a natural isomorphism

$$\tilde{H}_j(S^n \setminus f(X); \mathbb{Z}) \xrightarrow{\simeq} \tilde{H}^{n-j-1}(X; \mathbb{Z}).$$

**Proof of the Alexander Duality Theorem 92.11** Let $f: X \to S^n$ be an injective map from a compact, non-empty $k$-dimensional topological manifold to $S^n$ where $k < n$. It is a consequence of Proposition 2.43 (3) that $f: X \to f(X)$ is a homeomorphism. From $k < n$ and Proposition 44.4 it follows that $f(X) \neq S^n$. We have the following isomorphisms:

$$\tilde{H}_j(S^n \setminus f(X); \mathbb{Z}) \xrightarrow{\simeq} \tilde{H}^{n-j-1}(f(X); \mathbb{Z}) \xrightarrow{\simeq} \tilde{H}^{n-j-1}(X; \mathbb{Z}).$$

we can apply the Generalized Alexander Duality Theorem 92.10 since $f(X)$ is weakly locally contractible and since $f(X) \neq S^n$. □

**Example.** Let $n \geq 2$ and let $k < n$. Furthermore let $f: S^k \to S^n$ be an injective map. We obtain that

$$\tilde{H}_j(S^n \setminus f(S^k); \mathbb{Z}) \cong \tilde{H}^{n-j-1}(S^k; \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } j = n - k - 1, \\ 0, & \text{otherwise.} \end{cases}$$

This calculation gives a new proof for Proposition 50.1 (2). Basically the same approach also gives a new proof of Proposition 50.1 (1). Finally note that this calculation gives an answer to Exercise 85.3 (b).

**Remark.** The Generalized Alexander Duality Theorem 92.10 can be generalized even further. More precisely, an analogous statement also holds for any compact subset $K$ of $S^n$, e.g. the topologist’s sine curve. But hereby one needs to replace the usual singular cohomology on the right-hand side by the Čech cohomology of $K$. We refer to [Hat02, p. 256] or [Pra07, p. 271] for more details.
Proof of the Generalized Alexander Duality Theorem 92.10. Let \( n \geq 2 \). Furthermore let \( X \neq S^n \) be a weakly locally contractible, non-empty compact subset of the sphere \( S^n = \mathbb{R}^n \cup \{\infty\} \). Without loss of generality we can assume that \( X \subset \mathbb{R}^n \subset S^n \).\(^{1306}\)

We recall the following definition:

1. Given a topological space \( Y \) we denote by \( \mathcal{K}(Y) \) the set of all compact subsets of \( Y \). Given \( K, L \in \mathcal{K}(Y) \) we write \( K \leq L \) if \( K \subset L \). The set \( \mathcal{K}(X) \) together with the relation “\( \leq \)” is a directed set since the union of two compact subsets is again compact.

We also introduce a new definition and notation:

2. We denote by \( \mathcal{N}(X) \) the set of all open neighborhoods of \( X \). Given \( U, V \in \mathcal{N}(X) \) we write \( U \leq V \) if \( V \subset U \). (Note the reversal of \( V \) and \( U \).) The set \( \mathcal{N}(X) \) together with the relation “\( \leq \)” is a directed set since the intersection of two open neighborhoods of \( X \) is again an open neighborhood of \( X \).\(^{1307}\)

3. Given any subsets \( A \subset B \) of \( S^n \) we denote by \( i_{A:B} : A \to B \) the inclusion map.

4. It follows from our definition of “\( \leq \)” on \( \mathcal{N}(X) \) that for any \( m \in \mathbb{N}_0 \) the cohomology groups \( \{\widetilde{H}^m(U)\}_{U \in \mathcal{N}(X)} \) together with the inclusion induced maps form a direct system of abelian groups.

By our hypothesis we know that \( X \) is compact and weakly locally contractible. Thus it follows from Borsuk’s Theorem \(^{85.3}\) that there exists an open neighborhood \( W \subset \mathbb{R}^n \) of \( X \subset \mathbb{R}^n \) for which there exists a retraction \( r : W \to X \). (We refer to Figure 1276 for an

\[^{1306}\] Indeed, by our hypothesis that \( X \neq S^n \) there exists a point \( P \in S^n \) that does not lie in \( X \). By Lemma \(^{8.32}\) (3) we know that the group \( O(n + 1) \) acts transitively on \( S^n \). In particular there exists a homeomorphism \( h \) of \( S^n \) with \( h(P) = \infty \). Thus we can replace \( X \) by \( h(X) \) which evidently lies in \( \mathbb{R}^n \).

\[^{1307}\] Here the idea is that the neighborhoods “approximate” \( X \), in particular \( U \leq V \) means that \( V \) is a “better approximation of \( X \), which just means that \( V \subset U \).
We consider the following commutative diagram

\[
\begin{array}{ccc}
\tilde{H}^m(W) & \xleftarrow{r^*} & \lim_{U \in \mathcal{N}(X)} \tilde{H}^m(U) \\
\nearrow_{i_{X,u}} & & \downarrow_{\Phi} \\
\tilde{H}^m(X) & \xrightarrow{i_{V,u}} & \tilde{H}^m(V).
\end{array}
\]

From \((i_{X,u}^* \circ r^*) = (r \circ i_{X,u})^* = \text{id}_X^*\) we deduce that the map \(i_{X,u}^*\) is an epimorphism. It follows that the horizontal map \(\Phi\) is also an epimorphism. It remains to show that \(\Phi\) is a monomorphism.

By Lemma \[76.2\], it remains to show that for any \(U \in \mathcal{N}(X)\) there exists a \(V \in \mathcal{N}(X)\) with \(U \leq V\), i.e. with \(V \subset U\), such that

\[
\ker(i_{X,u}^* \circ \tilde{H}^m(U) \to \tilde{H}^m(X)) \subset \ker(i_{V,u}^* \circ \tilde{H}^m(U) \to \tilde{H}^m(V)).
\]

So let \(U \in \mathcal{N}(X)\). After possibly replacing \(U\) by \(U \cap W\) we can without loss of generality assume that \(U \subset W\). We continue with the following subclaim.

**Subclaim.** There exists an open neighborhood \(V\) with \(X \subset V \subset U\) such that the inclusion \(i_{V,u} : V \to U\) and the retraction \(r : V \to X \subset U\) are homotopic maps from \(V\) to \(U\).

We consider the homotopy

\[
F : U \times [0,1] \to \mathbb{R}^n
\]

\[
(x,t) \mapsto (1-t) \cdot x + t \cdot r(x)
\]

from the identity \(\text{id}_U\) to the retraction \(r : U \to X\). Note that \(F(X \times [0,1]) = X\). Since \(X\) is compact and since \(F\) is continuous there exists an open neighborhood \(V\) of \(X\), contained in \(U\), such that \(F(V \times [0,1]) \subset U\).

But then the restriction of \(F\) to \(F : V \times [0,1] \to U\) defines a homotopy from the inclusion \(V \to U\) to the retraction \(r : V \to X \subset U\). (We refer to Figure \[1276\] for an illustration.) This concludes the proof of the subclaim.

We consider the following diagram

\[
\begin{array}{ccc}
\tilde{H}^m(U) & \xrightarrow{i_{X,u}} & \tilde{H}^m(X) \\
\downarrow_{i_{V,u}} & & \downarrow_{i_{V,u}} \\
\tilde{H}^m(V) & \xrightarrow{r^*} & \tilde{H}^m(V).
\end{array}
\]

The above subclaim says that the two maps \(i_{V,u} : V \to U\) and \(r : V \to X \subset U\) are homotopic. It follows from Lemma \[73.13\] that the two maps \(i_{V,u}^*\) and \(r^*\) from \(\tilde{H}^m(U)\) to \(\tilde{H}^m(V)\) agree. Since \(r\) is the identity on \(X\) we see that \(r : U \to X \subset V\) equals the map

\[1308\] This can be seen as follows. The set \(W := F^{-1}(U) \subset X \times [0,1]\) is open and it evidently contains \(X \times [0,1]\). Since \(X\) and \([0,1]\) are compact and since \(W\) is open one sees easily that there exists an \(r > 0\) such that for any \(z \in X\) we have \(B_r(z) \times [0,1] \subset W\). But then \(V := \bigcup_{x \in X} B_r(x)\) has the property that \(V \times [0,1] \subset W\).
\(i_{X,U} \circ r: U \to X\). This shows that the diagram commutes. It follows immediately from these observations that \(V\) has the desired property.

\[\begin{array}{c}
\text{Figure 1276}
\end{array}\]

We turn to the actual proof of the theorem. First let \(j \neq 0\). The desired isomorphism will be given by a sequence of natural isomorphisms as follows:

\[
\begin{align*}
H_j(S^n \setminus X) &\overset{\cong}{\twoheadrightarrow} H_n(S^n \setminus X) \overset{\cong}{\twoheadrightarrow} \lim_{\kappa \in \mathcal{K}(S^n \setminus X)} H_{n-j}(S^n \setminus X, (S^n \setminus X) \setminus K) \overset{\cong}{\twoheadrightarrow} \lim_{U \in \mathcal{N}(X)} H_{n-j}(S^n \setminus X, U \setminus X) \\
&\overset{\cong}{\twoheadrightarrow} \lim_{U \in \mathcal{N}(X)} H_{n-j}(S^n, U) \overset{\cong}{\twoheadrightarrow} \tilde{H}_{n-j-1}(U) \overset{\cong}{\twoheadrightarrow} \tilde{H}_{n-j-1}(X).
\end{align*}
\]

We explain the natural isomorphisms in more detail:

(1) Since \(X\) is compact we know from Lemma 2.17(2) that \(S^n \setminus X\) is an open subset of \(S^n \setminus X\). In particular it is also an \(n\)-dimensional smooth manifold and via Lemma 86.17 it inherits an orientation from \(S^n\). Also note that it follows from Proposition 44.2 that \(S^n \setminus X\) has no boundary. After this preamble the first isomorphism is the Poincaré Duality isomorphism from Theorem 88.19 corresponding to the oriented smooth manifold \(S^n \setminus X\). By Lemma 88.25 this isomorphism is natural.

(2) The second isomorphism is provided by Proposition 77.4.

(3) The third isomorphisms comes from the straightforward observation that the map \(\mathcal{N}(X) \to \mathcal{K}(S^n \setminus X)\) given by \(U \mapsto S^n \setminus U\) is an isomorphism of directed sets which gives us an isomorphism of direct systems.

(4) For any open neighborhoods \(U\) and \(V\) of \(X\) with \(U \leq V\), i.e. with \(V \subset U\), we have a commutative diagram

\[
\begin{array}{ccc}
H^{n-j}(S^n \setminus X, V \setminus X) &\overset{}{\longleftrightarrow}& H^{n-j}(S^n, V) \\
\uparrow & & \uparrow \\
H^{n-j}(S^n \setminus X, U \setminus X) &\overset{}{\longleftrightarrow}& H^{n-j}(S^n, U)
\end{array}
\]

where all the maps are induced by the obvious inclusions of pairs of topological spaces. It follows from the Excision Theorem 74.1 for Cohomology Groups that the horizontal maps are isomorphisms. The desired isomorphism of direct limits is now an immediate consequence of Lemma 76.4.
For any open neighborhoods $U$ and $V$ of $X$ with $U \subseteq V$, i.e. with $V \subseteq U$, we have a commutative diagram

$$
\begin{array}{ccl}
H^{n-j}(S^n, V) & \xleftarrow{\delta} & \tilde{H}^{n-j-1}(V) \\
\uparrow & & \uparrow \\
H^{n-j}(S^n, U) & \xleftarrow{\delta} & \tilde{H}^{n-j-1}(U)
\end{array}
$$

where the vertical maps are induced by the obvious inclusions and where the horizontal maps are the connecting homomorphisms of the long exact sequences in reduced cohomology provided by Lemma 73.17. Since $j \geq 1$ we obtain from these long exact sequences and the calculation of the cohomology groups of $S^n$ that the horizontal maps are in fact isomorphisms. As in (4) we appeal to Lemma 76.4 to obtain the desired isomorphism of direct limits.

The last map is the isomorphism of the above claim.

It still remains to deal with the case $j = 0$. In this case all of the above maps are still isomorphisms, except for map (5). To address this issue we consider the following diagram:

$$
\begin{array}{ccl}
H_0(S^n \setminus X) & \xrightarrow{(1)} & H_c(S^n \setminus X) \\
\downarrow & & \downarrow \\
H_0(S^n) & \xrightarrow{(1)} & H_c(S^n)
\end{array}
\quad
\begin{array}{ccl}
\lim_{U \in \mathcal{N}(X)} H^n(S^n \setminus X, U \setminus X) & \xrightarrow{(4)} & \lim_{U \in \mathcal{N}(X)} H^n(S^n, U) \\
\downarrow & & \downarrow \\
\lim_{U \in \mathcal{N}(X)} H^n(S^n, U) & \xrightarrow{(4)} & \lim_{U \in \mathcal{N}(X)} H^n(S^n).
\end{array}
$$

Here the second vertical map is the inclusion induced map defined by Lemma 77.5. The first and the fourth vertical maps are the obvious inclusion induced maps. Furthermore the third vertical map is the inverse of the isomorphism which is induced by the isomorphisms $H^n(S^n, U) \to H^n(S^n \setminus X, U \setminus X)$ that are given by the Excision Theorem 74.1 for Cohomology Groups. The top horizontal maps are precisely the above maps (1), (2), (3) and (4). The bottom horizontal maps are defined completely analogously with $X = \emptyset$. Since the maps defined in (1), (2), (3) and (4) are natural we see that the diagram commutes. It follows that

follows easily from $H_0(S^n) \cong \mathbb{Z}$

by the above commutative diagram

$$
\begin{array}{ccl}
\tilde{H}_0(S^n \setminus X) & \cong & \ker(H_0(S^n \setminus X) \to H_0(S^n)) \\
\downarrow & & \downarrow \\
\tilde{H}_0(S^n) & \cong & \ker(H^n(S^n, U) \to H^n(S^n))\cong \ker(H^n(S^n \setminus X, U \setminus X) \to H^n(S^n))
\end{array}
$$

by the long exact sequence by the claim

of Lemma 73.17 and since $n \geq 2$

The following proposition finally gives a negative answer to Question 92.6 (3).

**Proposition 92.12.** Let $M$ be a closed connected $n$-dimensional topological manifold. If $M$ is non-orientable, then there is no topological embedding of $M$ into $\mathbb{R}^{n+1}$. 

Proof. The proof of Proposition 92.12 is verbatim the same as the proof of Proposition 92.1 we only need to replace the original Alexander Duality Theorem 92.11 by the Alexander Duality Theorem 92.11 for Topological Submanifolds.

We also give an alternative argument that does not require the slightly obscure Generalized Alexander Duality Theorem 92.10. Thus let \( M \) be a closed connected \( n \)-dimensional topological manifold which admits an embedding \( f: M \to \mathbb{R}^{n+1} \). We have to show that \( M \) is orientable. As usual we view \( \mathbb{R}^{n+1} \) as a subset of \( S^{n+1} \). We make the following observations:

(1) It follows from Borsuk’s Theorem 85.5 together with Proposition 85.7 (1) that there exists a compact \( (n+1) \)-dimensional smooth submanifold \( X \) of \( \mathbb{R}^{n+1} \) that contains \( f(M) \) and such that there exists a retraction \( r: X \to f(M) \). In the following we denote by \( i: f(M) \to X \) the inclusion map.

(2) Since \( r \circ i = \text{id}_{f(M)} \) we see that the map \( r^*: H^n(f(M); \mathbb{Z}) \to H^n(X; \mathbb{Z}) \), induced by the retraction, is a monomorphism.

(3) By the remark on page 2232 there is an isomorphism \( H^n(X; \mathbb{Z}) \cong H_0(S^{n+1} \setminus X; \mathbb{Z}) \). It follows in particular from Proposition 41.5 that \( H^n(X; \mathbb{Z}) \) is a free abelian group.

(4) It follows from (2) and (3) that \( H^n(f(M); \mathbb{Z}) \) is a torsion-free abelian group.

(5) Since \( f: M \to f(M) \) is a homeomorphism we obtain from (4) that \( H^n(M; \mathbb{Z}) \) is a torsion-free abelian group.

(6) We deduce from (5) and Proposition 75.15 that the closed connected \( n \)-dimensional topological manifold \( M \) is orientable.

\[ \begin{array}{c}
\text{Figure 1277. Illustration of the proof of Proposition 92.12} \\
\end{array} \]

The following proposition is a strengthening of Proposition 92.8.

Proposition 92.13. If \( n \in \mathbb{N}_{\geq 2} \), then there is no embedding of \( \mathbb{RP}^n \) into \( S^{n+1} \).

Proof. First let \( n \) be even. In this case \( \mathbb{RP}^n \) is non-orientable and the result is an immediate consequence of Proposition 92.12.

Now let \( n \) be odd. This case is significantly harder and it was first proved by René Thom [Tho52, p. 180] in 1952. We cannot provide the argument. But it seems like the argument of Thom is somewhat reminiscent of the argument in the proof of Proposition 92.8. So suppose there exists an embedding \( f: \mathbb{RP}^n \to S^{n+1} \). It follows from Proposition 41.5 the Generalized Alexander Duality Theorem 92.10 and the fact that \( H^n(\mathbb{RP}^n; \mathbb{Z}) \cong \mathbb{Z} \) (here we use that \( n \) is odd), that \( S^{n+1} \setminus f(\mathbb{RP}^n) \) consists of two path components. We denote the closures of the path components by \( A \) and \( B \). The problem is that the triad \((S^{n+1}, A, B)\) is in general not excisive so we cannot apply the Mayer–Vietoris Theorem 74.15 for Cohomology Groups. The idea in the proof is to replace usual singular cohomology by Alexander-Spanier cohomology for which the above triad is excisive. We refer to [Mas78a, Chapter 8] or [Mas78b] for an introduction to Alexander-Spanier cohomology and we
We conclude this chapter with the following convenient variation on the Generalized Alexander Duality Theorem \[\text{92.10}\].

**Theorem 92.14. (Alexander Duality Theorem for Balls)** Let \( n \geq 2 \) and let \( X \neq \mathbb{B}^n \) be a weakly locally contractible, non-empty compact subset of \( \mathbb{B}^n \). We write \( \partial X := X \cap S^{n-1} \). Given any \( j \in \mathbb{N}_0 \) we have a natural isomorphism

\[
\tilde{H}\_j(\mathbb{B}^n \setminus X; \mathbb{Z}) \cong \tilde{H}^{n-j-1}(X, \partial X; \mathbb{Z}).
\]

such that the following diagram commutes

\[
\begin{array}{ccc}
\tilde{H}\_j(\mathbb{B}^n \setminus X; \mathbb{Z}) & \xrightarrow{\cong} & \tilde{H}^{n-j-1}(X, \partial X; \mathbb{Z}) \\
\downarrow^\partial & & \downarrow^{j\ast} \\
\tilde{H}\_{j-1}(S^{n-1} \setminus \partial X; \mathbb{Z}) & \xrightarrow{\cong} & \tilde{H}^{n-j-1}(\partial X; \mathbb{Z}),
\end{array}
\]

up to a sign that depends only on \( j \) and \( n \).\[1309\] Here the bottom map is the isomorphism given in the proof of the Generalized Alexander Duality Theorem \[\text{92.10}\].

![Illustration of the Alexander Duality Theorem 92.14 for Balls.](image)

**Figure 1278.** Illustration of the Alexander Duality Theorem \[\text{92.14}\] for Balls.

**Sketch of proof.** One could try to imitate the proof of the Generalized Alexander Duality Theorem \[\text{92.10}\] but instead we will do a little trick to reduce most of the statement to the Generalized Alexander Duality Theorem \[\text{92.10}\].

Let \( X \subseteq \mathbb{B}^n \) be a weakly locally contractible compact non-empty subset. We consider

\[
K := (X \times \{0\}) \cup (\partial X \times [0,1]) \cup (\mathbb{B}^n \times \{1\}) \subset (\mathbb{B}^n \times \{0\}) \cup (\partial K \times [0,1]) \cup (\mathbb{B}^n \times \{1\}).
\]

Now we consider the following maps

\[
\begin{array}{ccc}
\tilde{H}\_j(\mathbb{B}^n \setminus X) & \xrightarrow{(a)} & \tilde{H}\_j((\mathbb{B}^n \times 0) \setminus (X \times \{0\})) \\
\cong & & \cong \\
\tilde{H}\_{j-1}(\partial (\mathbb{B}^n \times [0,1]) \setminus K) & \xrightarrow{(b)} & \tilde{H}^{n-j-1}(X, \partial X; \mathbb{Z}) \\
\cong & & \cong \\
\tilde{H}^{n-j-1}(K, Y) & \xleftarrow{(c)} & \tilde{H}^{n-j-1}(K).
\end{array}
\]

We make the following observations regarding the various maps:

(a) This map is induced by the obvious homeomorphism.

---

\[1309\] I will not embarrass myself by trying to guess the sign.
(b) This map is an isomorphism since \((\overline{B}^n \times 0) \setminus (X \times \{0\})\) is a deformation retract of \(\partial(\overline{B}^n \times [0, 1]) \setminus K\).

(c) Note that \(\partial(\overline{B}^n \times [0, 1])\) is homeomorphic to \(S^n\). Also note that one can easily verify that \(K\) is again weakly locally contractible.\footnote{The only points one needs to worry about for a second are the points \((x, 0)\), with \(x \in \partial X\). But given any neighborhood \(R\) of \(x \in X\) there exists a neighborhood \(S\) of \((x, 0) \in K\) which admits a deformation retraction to \(R\). Using this observation it is now straightforward to see that \(K\) is indeed weakly locally contractible.} Thus we can appeal to the Generalized Alexander Duality Theorem \([92.10]\) to obtain a natural isomorphism.

(d) This map is an isomorphism since \(Y\) is contractible.

(e) This map is an isomorphism by a suitable variation on the Excision Theorem \([74.1]\).

The combination of the above gives us a natural vertical isomorphism to the left. Unfortunately this neat argument does not elucidate why the diagram in the statement of the theorem commutes. We leave the verification of this statement as a slightly challenging exercise to the reader. 

\[
\begin{array}{c}
\includegraphics[width=0.5\textwidth]{figure1279.png}
\end{array}
\]

**Figure 1279.** Illustration for the proof of Theorem \([92.14]\).

**Remark.** More information on Alexander dualities in manifolds can be found in [Mas81b].

---

**Exercises for Chapter 92**

**Exercise 92.1.** Let \(X \subset S^3\) be a closed orientable connected 2-dimensional submanifold. We view \(S^3\) as a subset of \(S^4\) in the usual way.

(a) Determine the homology groups of \(S^4 \setminus X\).

(b) Now let \(X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}\) be the surface shown in Figure 1280. Give an example of a closed curve in \(S^4 \setminus X\) that is not null-homotopic.

\[
\begin{array}{c}
\includegraphics[width=0.5\textwidth]{figure1280.png}
\end{array}
\]

**Figure 1280**

**Exercise 92.2.** This exercise is a continuation of Exercise 92.1.

(a) Let \(X \subset S^n\) be a closed submanifold. We view \(S^n\) as a subset of \(S^{n+1}\) in the usual way. Show that \(S^{n+1} \setminus X\) is homotopy equivalent to \(\Sigma(S^n \setminus X)\). (Here \(\Sigma(S^n \setminus X)\)
denotes the suspension of $S^n \setminus X$.)

Remark. You will need to use at some point that $X$ is a “reasonable subset”, e.g. that $X$ is a closed submanifold. The statement does not hold for all subsets of $S^n$.

(b) Again let $X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be the surface shown in Figure 1280. As above we view it as a submanifold of $S^4$. Determine $\pi_1(S^4 \setminus X)$.

Exercise 92.3.

(a) Let $F$ be an orientable connected 2-dimensional smooth manifold with non-empty boundary and let $i : F \to \mathbb{R}^3$ be an injective map. Is the complement $\mathbb{R}^3 \setminus F$ necessarily path-connected?

(b) Let $F$ be an orientable connected surface non-compact 2-dimensional smooth manifold with empty boundary and let $i : F \to S^3$ be an injective map. Is the complement $S^3 \setminus F$ necessarily path-connected?
93. Applications of cohomology groups

In this chapter we give two applications of cohomology groups, namely we prove the table theorem and we address two special cases of the square peg problem. Neither of these applications can count as a “real life” application, but at least in both cases cohomology, Poincaré duality and Alexander duality get used to prove statements which initially have absolutely no connection to cohomology theory at all.

93.1. The Table Theorem ★. As a warm-up we start out with the fairly elementary but charming Wobbly Table Theorem. In the vernacular it says that given a wobbly table we can rotate it around its center, by an angle of at most $\frac{\pi}{2}$, such that eventually all four legs touch the ground. Slightly more precisely, it can be formulated as follows:

**Theorem 93.1. (Wobbly Table Theorem)** Let $f: \mathbb{C} = \mathbb{R}^2 \to \mathbb{R}$ be a function, let $x \in \mathbb{C}$ and let $z \in \mathbb{C} \setminus \{0\}$. There exists a $\theta \in [0, \frac{\pi}{2}]$ such that

$$f(x + e^{i\theta}z) = f(x + e^{i(\theta + \frac{\pi}{2})}z) = f(x + e^{i(\theta + \pi)}z) = f(x + e^{i(\theta + \frac{3\pi}{2})}z).$$

**Proof.** The theorem is a fairly elementary consequence of the Intermediate Value Theorem from real analysis. Filling in the details is your task in Exercise [93.1](#). Alternatively the reader can look at [Loy17](#) p. 289 for a proof.

Our goal in this section is to prove a much more fancy theorem. More precisely we will prove the following “Table Theorem” which was first formulated and proved by Roger Fenn [Fen70](#) in 1970.

**Theorem 93.2. (Table Theorem)** Let $D \subseteq \mathbb{R}^2$ be a compact convex non-empty subset and let $f: \mathbb{R}^2 \to \mathbb{R}$ be a map such that $f(x) \geq 0$ for all $x \in D$ and such that $f(x) = 0$ for all $x \notin D$. Given any $d \in \mathbb{R}_{>0}$ there exist four points $a_1, a_2, a_3, a_4 \in \mathbb{R}^2$ with the following properties:

1. the points form a square of side length $d$,
2. the center of the square lies in $D$,
3. we have $f(a_1) = f(a_2) = f(a_3) = f(a_4)$.

In other words, the Table Theorem [93.2](#) says that any given square table can be placed on the ground defined by the graph of $f$, such that all four legs lie on the ground, such that the table is horizontal and such that the center of the table is located in $D$.

![Diagram of Table Theorem](#)

**Figure 1281.** Illustration of the Table Theorem [93.2](#)

**Remark.** In [Meye81](#) it is shown that in the formulation of the Table Theorem [93.2](#) one cannot drop the hypothesis that $D$ is convex.
The proof of the Table Theorem 93.2 will require the remainder of this section. Throughout the section we fix a compact convex non-empty subset $D \subset \mathbb{R}^2$ and we fix a function $f: \mathbb{R}^2 \to \mathbb{R}$ such that $f(x) \geq 0$ for all $x \in D$ and such that $f(x) = 0$ for all $x \not\in D$. Let $d \in \mathbb{R}_{>0}$. We make the following elementary observations and preparations:

(i) Since we can rescale $D$ we can and will without loss of generality assume that $d = 1$.

(ii) If the interior of $D$ is the empty set, then the function $f$ is necessarily the zero function. Thus the conclusion of the Table Theorem 93.2 holds trivially.

(iii) If follows from (ii) that henceforth we can assume that the interior of $D$ is non-empty. Note that Proposition 2.52 implies that there exists a homeomorphism of pairs $(D, \partial D) \cong (B^2, S^1)$.

(iv) After a translation we can and will assume that the origin $(0, 0)$ is contained in the interior of $D$.

(v) As always we will make the identification $\mathbb{R}^2 = \mathbb{C}$, in particular we will work a lot with the multiplication “$\cdot i$”, i.e. with “rotation by $\pi/2$.”

(vi) If there exists a square in $\mathbb{R}^2$ of side length $d = 1$ with center in $D$, such that the $f$-value at all of the four vertices is zero, then we have evidently found the desired table. Thus we can henceforth assume that for any square of side length $d = 1$ with center in $D$ the $f$-value of at least one vertex is non-zero.

In the following discussion we will at times take a few liberties with mathematical language, but these liberties will not infringe on the rigor of the argument.

We start out with introducing the following notation, which gives us a convenient way for parameterizing the set of all squares with side length $d = 1$ and whose center lies in $D$.

**Notation.**

1. We consider the map $a: D \times S^1 \to \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R}^2 \times \mathbb{R}^2$ given by

\[(x, \gamma) \mapsto a_1, a_2, a_3, a_4\]

the four vertices $a_1, a_2, a_3, a_4$ of the unique square with center $x$ such that $a_2 - a_1 = \gamma$ and such that $a_1, a_2, a_3, a_4$ are ordered in the counterclockwise direction.

This definition is illustrated in Figure 1282 on the left.

2. We also consider the closely related map

\[Q: D \times S^1 \to \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}^3\]

\[(x, \gamma) \mapsto Q_1, Q_2, Q_3, Q_4\] on the graph corresponding to $a(x, \gamma)$.

When $(x, \gamma) \in D \times S^1$ is understood from the context, then we drop it at times from the notation. In other words, often we write $a_i$ instead of $a_i(x, \gamma)$ and we write $Q_i$ instead of $Q_i(x, \gamma)$.

\[\text{Why is that?}\]

\[\text{We leave the task of writing down an explicit formula to the reader. Once the formula is written down it is clear that $a$ is actually continuous.}\]
One of the key ideas behind the proof of the Table Theorem \[93.2\] is to split Condition (3) of the Table Theorem \[93.2\] into two separate statements. Namely we note that the condition

\[ f(a_1) = f(a_2) = f(a_3) = f(a_4), \]

is satisfied precisely if the following two conditions are satisfied:

1. The points \( \{a_1, f(a_1)\}, \ldots, \{a_4, f(a_4)\} \) lie on a plane,

2. The plane from (3a) is horizontal.

The trick now is to encode these two statements in a clever way. We will do so by introducing two maps.

**Definition.**

1. Given \((x, \gamma) \in D^2 \times S^1\) we denote by \(\pi(x, \gamma)\) the plane through the three points \(Q_1(x, \gamma), Q_2(x, \gamma)\) and \(Q_3(x, \gamma)\).

2. We consider the map \(\phi : D \times S^1 \to \mathbb{R}\)

\[
(x, \gamma) \mapsto \frac{x_3\text{-value of the plane } \pi(x, \gamma) \text{ at } a_4(x, \gamma) \text{ minus } f(a_4(x, \gamma))}{= f(a_1)+f(a_2)-f(a_2)-f(a_4)}
\]

The definition of this map is illustrated in Figure 1283. Note that \(\phi(x, \gamma) = 0\) if and only if the corresponding points \(Q_1, Q_2, Q_3, Q_4\) lie on a plane.

3. We set \(A := \{(x, \gamma) \in D \times S^1 | \phi(x, \gamma) = 0\}\).

4. Given \((x, \gamma) \in D^2 \times S^1\) we denote by \(n(x, \gamma) \in \mathbb{R}^3\) the unique vector that is normal to \(\pi(x, \gamma)\), that has unit length and that has positive \(x_3\)-coordinate. This definition is illustrated in Figure 1284 on the left.

5. We consider the map

\[
\psi : D \times S^1 \to \mathbb{R}^2
\]

\[
(x, \gamma) \mapsto \text{projection of } n(x, \gamma) \text{ onto the } x_1x_2\text{-plane}.
\]

The definition of this map is illustrated on the right hand side of Figure 1286. Note that \(\psi(x, \gamma) = 0\) if and only if the plane \(\pi(x, \gamma)\) is horizontal.

6. We set \(B := \{(x, \gamma) \in D \times S^1 | \psi(x, \gamma) = 0\}\).

Note that the equality

\[
a_4 = a_2 + (a_3 - a_2) + (a_4 - a_3) = a_2 + (a_1 - a_2) + (a_4 - a_2) = a_1 + a_3 - a_2,
\]
Remark. The Wobbly Table Theorem 93.1 implies that given any \( x \in D \) there exist at least four \( \gamma \in S^1 \) with \( (x, \gamma) \in A \). In particular the set \( A \) is more complicated than in our subsequent illustrations.

We make the following elementary observation.

**Observation 93.3.** To prove the Table Theorem 93.2 it suffices to show that \( A \cap B \neq \emptyset \).

In the following two lemmas we collect some properties of the two maps \( \phi \) and \( \psi \).

**Lemma 93.4.** The map \( \phi: D \times S^1 \to \mathbb{R} \) has the following properties:

1. The map \( \phi: D \times S^1 \to \mathbb{R} \) is continuous.
2. For any \( (x, \gamma) \in D \times S^1 \) we have \( \phi(x, i \cdot \gamma) = -\phi(x, \gamma) \).
3. Given \( (x, \gamma) \in D \times S^1 \) the following statements are equivalent:
   - (a) \( \phi(x, \gamma) = 0 \),
   - (b) \( \phi(x, i \cdot \gamma) = 0 \),
   - (c) \( (x, \gamma) \) lies in \( A \),
   - (d) the corresponding points \( Q_1, Q_2, Q_3, Q_4 \) lie on a plane.

**Proof.**

1. As we pointed out above, we have

\[
\phi(x, \gamma) = f(a_1(x, \gamma)) + f(a_3(x, \gamma)) - f(a_2(x, \gamma)) - f(a_4(x, \gamma)).
\]

It follows from the continuity of \( f \) and the continuity of \( (x, \gamma) \mapsto a_i(x, \gamma) \) that \( \phi \) is indeed continuous.

Together with the fact that the \( x_3 \)-coordinate of the plane \( \pi(x, \gamma) \) is an affine function on \( \mathbb{R}^2 \), implies that \( x_3 \)-coordinate of the plane \( \pi(x, \gamma) \) at \( a_4 = f(a_1) + f(a_3) - f(a_2) \).
(2) Note that for any \((x, y) \in D \times S^1\) and any \(j \in \{1, 2, 3, 4\}\) we have the equality
\[a_j(x, i \cdot \gamma) = a_{j+1}(x, \gamma)\]. In particular the odd/even vertices corresponding to \((x, i \cdot \gamma)\) are precisely the even/odd vertices corresponding to \((x, \gamma)\). It follows immediately from this observation and the explicit formula for \(\phi\) given in (1) that the equality \(\phi(x, i \cdot \gamma) = -\phi(x, \gamma)\) holds. We refer to Figure 1285 for an illustration.

(3) This statement follows immediately from (2) and the definition of \(A\).

\[\text{Figure 1285}\]

Next we turn to the study of the map \(\psi: D \times S^1 \to \mathbb{R}^2\). In the formulation of the next lemma we need the following definition.

**Definition.** We say that \(v, w \in \mathbb{R}^2\) are parallel if one of \(v, w\) is zero or if there exists an \(\lambda \in \mathbb{R}_{>0}\) such that \(v = \lambda w\).

**Lemma 93.5.** The map \(\psi: D \times S^1 \to \mathbb{R}^2\) has the following properties:

1. The map \(\psi: D \times S^1 \to \mathbb{R}\) is continuous.
2. If \((x, \gamma) \in A\), then \(\psi(x, \gamma) = \psi(x, i^k \cdot \gamma)\) for any \(k \in \mathbb{Z}\).
3. Let \(x \in \partial D\) and let \(\gamma \in S^1\). If \((x, \gamma) \in A\), then the vector \(\psi(x, \gamma)\) is not parallel to \(-x\).

**Sketch of proof.**

1. Let \((x, \gamma) \in D \times S^1\). Basic linear algebra shows that

the vector in \(\mathbb{R}^3\) that is obtained as follows:

\[\psi(x, \gamma) = \begin{cases} (1) \text{ perform the cross product } (Q_3(x, \gamma) - Q_2(x, \gamma)) \times (Q_1(x, \gamma) - Q_2(x, \gamma)) \\ (2) \text{ normalize the vector from (1) to length one} \end{cases}\]

(3) project the vector from (2) onto the \(xy\)-plane.

It follows immediately from this observation that \(\psi\) is continuous.

2. Let \((x, \gamma) \in A\). As mentioned in Lemma 93.4 (3), this means that the four points \(Q_1(x, \gamma), Q_2(x, \gamma), Q_3(x, \gamma)\) and \(Q_4(x, \gamma)\) lie on a plane. But this immediately implies that for any \(k \in \mathbb{Z}\) we have \(\pi(x, \gamma) = \pi(x, i^k \cdot \gamma)\) which then gives us the equality \(\psi(x, \gamma) = \psi(x, i^k \cdot \gamma)\).

3. The final statement is a little more interesting. So let \(x \in \partial D\) and let \(\gamma \in S^1\). We assume that \((x, \gamma) \in A\). We write \(a_i = a_i(x, \gamma), i = 1, 2, 3, 4\).

**Claim.** There exist two adjacent vertices which lie outside of \(\tilde{D}\) and there are two adjacent vertices which have non-zero \(f\)-value.

\[\text{Since } a_3(x, \gamma) - a_2(x, \gamma) \text{ and } a_1(x, \gamma) - a_2(x, \gamma) \text{ are linearly independent we see that the two vectors in the cross product are linearly independent, in particular the cross product is indeed non-zero. Thus it makes sense to normalize the vector to length one.}\]
We make the following observations:
(a) Since \((x, \gamma) \in A\) we have \(f(a_1) + f(a_3) - f(a_2) - f(a_4) = 0\).
(b) By choice of \(f\) we know that all \(f\)-values are non-negative.
(c) By the preliminary remark (vi) on page 2252 we know that not all of the \(f\)-values are zero.
(d) Since \(x\) lies on \(\partial D\) and since \(D\) is convex we see that at most two \(f\)-values can be non-zero.\(^{1315}\)

The claim follows easily from the above considerations and the elementary observation that every odd vertex is adjacent to every even vertex. \(\Box\)

To simplify the notation let us now assume that the adjacent vertices \(a_1\) and \(a_3\) do not lie in the interior of \(D\). Consequently \(f(a_3) > 0\) and \(f(a_4) > 0\). A straightforward calculation shows that
\[
\psi(x, \gamma) = \text{projection of} \quad \left( \frac{a_3 - a_2}{f(a_3)} \right) \times \left( \frac{a_1 - a_2}{0} \right) \text{ into the } xy\text{-plane} = \lambda(a_2 - a_3)
\]
for some \(\lambda > 0\).

Now suppose that \(\psi(x, \gamma)\) is parallel to \(-x\). This means, by the above calculation, that \(a_3 - a_2 = -\mu \cdot x\) for some \(\mu > 0\). It is now straightforward to verify that \(x\) lies in the interior of the convex hull of \(0, a_3\) and \(a_4\). Since \(0, a_3\) and \(a_4\) lie in the interior of \(D\) we see that \(x\) also lies in the interior of \(\hat{D}\). But that is a contradiction to our hypothesis that \(x \in \partial D\). \(\blacksquare\)

\[\text{Figure 1286. Illustration for the proof of Lemma 93.5(2).}\]

**Lemma 93.6.** We set
\[
T := (D \times S^1)/\sim \quad \text{where} \; (x, \gamma) \sim (x, i \cdot \gamma)
\]
and we consider the following diagram

\[
\begin{array}{ccc}
D \times S^1 & \xrightarrow{\psi} & \mathbb{R}^2 \\
\downarrow_{=} & & \downarrow_{=} \\
T & \xrightarrow{=} & \mathbb{R}^2. \\
\end{array}
\]

The following statements hold:

1. The map \( p: D \times S^1 \to T \) is a 4-fold covering and the topological space \( T \) is homeomorphic to the solid torus \( D^2 \times S^1 \).
2. The map \( \psi' \) is continuous.
3. The restriction of the diagram to \( A \subseteq D \times S^1 \) is commutative.
4. If we set \( A' := p(A) \) and \( B' := \{[(x, \gamma)] \in T | \psi'([x, \gamma]) = 0\} \), then we have \( p(A \cap B) = A' \cap B' \).

**Proof.**

1. For the experienced reader it should be clear that \( p: D \times S^1 \to T = (D \times S^1)/\sim \) is a 4-fold covering and that \( T \cong D \times (S^1/\sim) \cong D \times S^1 \). On page 2252 we remarked that \( D \) is homeomorphic to \( B^2 \), thus we see that \( T \) is indeed homeomorphic to the solid torus \( B^2 \times S^1 \).

2. The map \( D^2 \times S^1 \to \mathbb{R}^2 \) given by \( (x, \gamma) \to \frac{1}{4} \sum_{k=0}^3 \psi(x, i^k \gamma) \) is continuous. It descends to our map \( \psi': T = (D \times S^1)/\sim \to \mathbb{R}^2 \). Thus it follows from Lemma 3.22 that \( \psi' \) is continuous.

3. It follows immediately from Lemma 93.5 (2) that for any \((x, \gamma) \in A\) we have the equality \( \psi'([x, \gamma]) = \psi(x, \gamma) \).

4. The equality \( p(A \cap B) = A' \cap B' \) follows easily from (3). □

From Lemma 93.6 (3) and Observation 93.3 we obtain the following observation.

**Observation 93.7.** To prove the Table Theorem 93.2 it suffices to show that \( A' \cap B' \neq \emptyset \).

After spending so much time on preparations we can now finally apply the machinery from algebraic topology to tackle the problem. We introduce the following convention.

**Convention.** By Lemma 93.6 (1) we know that \( T \) is a solid torus. Given any \( x_0 \in T \) we make an identification \( \pi_1(T, x_0) = \mathbb{Z} \).

The following lemma turns our data into algebraic-topological information.

**Lemma 93.8.** We continue with the above notation. Let \( x_0 \in T \setminus A' \). The image of \( \pi_1(T \setminus A', x_0) \) in \( \pi_1(T, x_0) = \mathbb{Z} \) is contained in the subgroup \( 2 \cdot \mathbb{Z} \).

---

\[1316\] In the following we do not care about the precise isomorphism, in particular we do not care about any sign ambiguity.
Proof. Let $x_0 = [(x, \gamma)] \in T \setminus A'$. Note that by definition of $A'$ we have $\phi(x, \gamma) \neq 0$.

(*) Without loss of generality we can assume that $\phi(x, \gamma) > 0$. 

Now let $[f] \in \pi_1(X \setminus A', x_0)$. In other words, $f : [0, 1] \to T \setminus A'$ is a loop in $x_0 = [(x, \gamma)]$. We need to show that $[f] \in 2 \cdot \mathbb{Z}$. By Proposition 16.11 we know that there exists a unique lift $\tilde{f} : [0, 1] \to (D \times S^1) \setminus A$ with $\tilde{f}(0) = (x, \gamma)$. We consider the following diagram:

$$
\begin{align*}
\phi & : \mathbb{R} \setminus \{0\} \to D \times S^1 \\
\phi & : \mathbb{R} \setminus \{0\} \to D \times S^1 \\
\tilde{f} & : [0, 1] \to (D \times S^1) \setminus A \\
f & : [0, 1] \to T \setminus A' \\
\end{align*}
$$

We make the following observations:

1. By definition of a lift we know that $\tilde{f}(1)$ lies in the subset $p^{-1}(f(1)) = p^{-1}(f(0)) = \{x, \gamma), (x, i \cdot \gamma), (x, -\gamma), (x, -i \cdot \gamma)\}$.

2. By Lemma 93.4 (2) and (*) we know that $\phi(x, \gamma) = \phi(x, -\gamma) > 0$ and we know that $\phi(x, i \cdot \gamma) = \phi(x, -i \cdot \gamma) < 0$.

3. Recall that by definition $A' = p(A)$. Therefore it follows from Lemma 93.4 (3) that $A = p^{-1}(A')$. In particular we have $(D \times S^1) \setminus A = p^{-1}(T \setminus A')$.

4. It follows from (3) and the above diagram that the image of $\phi \circ \tilde{f} : [0, 1] \to \mathbb{R}$ is contained in $\mathbb{R} \setminus \{0\}$.

5. Since $[0, 1]$ is connected and since $\phi(\tilde{f}(0)) = \phi(x, \gamma) > 0$ we obtain from (4) that $\phi(\tilde{f}(1)) > 0$.

6. It follows from (1), (2) and (5) that $\tilde{f}(1) = (x, \gamma)$ or $\tilde{f}(1) = (x, -\gamma)$.

7. It follows easily from (6) that the loop $f \ast f$ lifts to a loop in $(D \times S^1, (x, \gamma))$. 

8. It follows from (7) and Lemma 16.15 (1) that $2 \cdot [f] = [f] \cdot [f] = [f \ast f]$ actually lies in the subgroup $p_\ast (\pi_1(D \times S^1, (x, \gamma)))$.

9. Since $p : D \times S^1 \to T$ is a 4-fold connected covering we obtain from Lemma 16.15 (3) that $p_\ast (\pi_1(D \times S^1, (x, \gamma))) = 4 \cdot \mathbb{Z}$.

10. The combination of (8) and (9) shows that $[f]$ lies in $2 \cdot \mathbb{Z}$.

The next convention is basically self-explanatory.

Convention. Any map denoted by $i$ is given by an inclusion of the corresponding (pairs) of topological spaces.

The following lemma consists mostly of repackaging the result of Lemma 93.8.

Lemma 93.9. We continue with the above notation. Suppose that we are given a compact submanifold with corner $L \subset T$ such that $A' \subset \hat{L} := L \setminus \partial_0 L$. \[1318\] The map

$$
i_\ast : H_2(L, L \cap \partial T; \mathbb{Z}_2) \to H_2(T, \partial T; \mathbb{Z}_2)
$$

is an epimorphism.

\[1317\] How does this work?
We make the following clarifications and observations:

**Claim.** For any homomorphism \( \varphi: H_1(T; \mathbb{Z}) \to \mathbb{Z}_2 \) the composition

\[
H_1(T \setminus \hat{L}; \mathbb{Z}) \xrightarrow{i} H_1(T; \mathbb{Z}) \xrightarrow{\varphi} \mathbb{Z}_2
\]

is the zero map.

To prove the claim it suffices to show the analogous statement for any path-component \( Y \) of \( T \setminus \hat{L} \). So let \( Y \) be a path-component of \( T \setminus \hat{L} \). We pick a point \( x_0 \in Y \). We consider the following commutative diagram

\[
\begin{array}{ccccccccc}
\pi_1(Y, x_0) & \to & \pi_1(T \setminus \hat{L}, x_0) & \to & \pi_1(T \setminus A', x_0) & \xrightarrow{\eta} & \mathbb{Z}_2 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
H_1(Y; \mathbb{Z}) & \to & H_1(T \setminus \hat{L}; \mathbb{Z}) & \to & H_1(T \setminus A'; \mathbb{Z}) & \to & H_1(T; \mathbb{Z}).
\end{array}
\]

We make the following clarifications and observations:

1. The map \( \eta: \pi_1(T, x_0) \to \mathbb{Z}_2 \) is the unique epimorphism.
2. All the vertical maps are given by the corresponding Hurewicz homomorphism. The diagram commutes by the naturality of the Hurewicz homomorphisms.
3. The Hurewicz homomorphism to the left is an epimorphism by the Hurewicz Theorem \( \text{52.3} \) since \( Y \) is path-connected. The Hurewicz homomorphism to the right is

\[ \text{since } Y \text{ is path-connected.} \]

\[ \text{The Hurewicz homomorphism to the right is} \]

\[ \text{is the unique epimorphism.} \]

\[ \text{All the vertical maps are given by the corresponding Hurewicz homomorphism. The diagram commutes by the naturality of the Hurewicz homomorphisms.} \]

\[ \text{The Hurewicz homomorphism to the left is an epimorphism by the Hurewicz Theorem \( \text{52.3} \) since \( Y \) is path-connected. The Hurewicz homomorphism to the right is} \]

\[ \text{since } Y \text{ is path-connected.} \]

\[ \text{The Hurewicz homomorphism to the right is} \]

\[ \text{is the unique epimorphism.} \]

\[ \text{All the vertical maps are given by the corresponding Hurewicz homomorphism. The diagram commutes by the naturality of the Hurewicz homomorphisms.} \]

\[ \text{The Hurewicz homomorphism to the left is an epimorphism by the Hurewicz Theorem \( \text{52.3} \) since \( Y \) is path-connected. The Hurewicz homomorphism to the right is} \]

\[ \text{since } Y \text{ is path-connected.} \]

\[ \text{The Hurewicz homomorphism to the right is} \]
an isomorphism by the Hurewicz Theorem \cite{hurewicz-theorem} since \( T \) is path-connected and since \( \pi_1(T, x_0) \cong \mathbb{Z} \) is abelian.

(4) It follows from Lemma \cite{lemma} that the map \( \pi_1(T \setminus A', x_0) \to \pi_1(T, x_0) \xrightarrow{\eta} \mathbb{Z}_2 \) is the trivial map.

(5) The claim follows immediately from combining (1) to (4).

Now we turn to the actual proof of the desired statement. We write \( W := T \setminus \hat{L} \). We consider the following diagram

\[
\begin{array}{ccc}
\text{Hom}(H_1(W; \mathbb{Z}), \mathbb{Z}_2) & \xleftarrow{ev} & H^1(W; \mathbb{Z}_2) \\
& i^* \uparrow & \cong \otimes [W] \xrightarrow{\cong} H_2(W, \partial W; \mathbb{Z}_2) \xrightarrow{i_*} H_2(T, \partial T \cup L; \mathbb{Z}_2) \\
\text{Hom}(H_1(T; \mathbb{Z}), \mathbb{Z}_2) & \xleftarrow{ev} & H^1(T; \mathbb{Z}_2) \\
& i^* \uparrow & \cong \otimes [T] \xrightarrow{\cong} H_2(T, \partial T; \mathbb{Z}_2) \xrightarrow{i_*} H_2(L, L \cap \partial T; \mathbb{Z}_2) \\
& \downarrow & \cong \otimes [L] \xrightarrow{\cong} H_2(T, \partial L \cup \partial T; \mathbb{Z}_2) \\
H_2(L, L \cap \partial T; \mathbb{Z}_2) & \xrightarrow{i_*} & H_2(\partial L \cup \partial T; \mathbb{Z}_2).
\end{array}
\]

We make the following comments and clarifications:

(1) The vertical maps are induced by the various inclusions.

(2) The square to the left commutes by the naturality of the evaluation homomorphism.

Furthermore, the horizontal maps to the left are isomorphisms by Proposition \cite{proposition}.

(3) By Lemma \cite{lemma} we know that \( W \) is a compact 3-dimensional smooth manifold. We equip it with the orientation coming from \( T \).

(4) The horizontal maps “\( \otimes [W] \)” and “\( \otimes [T] \)” in the center are given by capping with the fundamental classes \([W]\) and \([T]\). These maps are isomorphisms by the Poincaré Duality Theorem \cite{poincare-duality}.

(5) The horizontal map to the top right is an isomorphism by the Excision Theorem \cite{excision}.

(6) The vertical maps to the right are a piece of the long exact sequence of the triple \((T, \partial T \cup L, \partial T)\), see Proposition \cite{long-exact-sequence}.

(7) The rectangle to the right commutes by Lemma \cite{rectangle} see in particular the example (a) on page \cite{example}.

(8) By the above claim we know that the vertical map to the left is zero. Since all horizontal maps are isomorphisms and since the upper part of the diagram commutes we see that the vertical map to the top right is also the zero map.

(9) It follows from (6) and (8) that the vertical map to the bottom right is an epimorphism.

(10) The bottom triangle commutes since all maps are inclusion induced maps.

(11) The horizontal map at the very bottom is an isomorphism by the Excision Theorem \cite{excision}.

(12) Finally we note that it follows immediately from (9), (10) and (11) that the diagonal \( i_* : H_2(L, L \cap \partial T; \mathbb{Z}_2) \to H_2(T, \partial T; \mathbb{Z}_2) \) is an epimorphism. Fortunately that is precisely what we wanted to show. \[\blacksquare\]
Lemma 93.10. Let \( X \) be a topological space and let \( f, g : X \to S^1 \) be maps. If for every \( x \in X \) we have \( f(x) \neq -g(x) \in S^1 \), then \( f \) and \( g \) are homotopic.

Sketch of proof. We consider the map
\[
X \xrightarrow{f \times g} S^1 \times S^1 \to S^1, \quad (z, w) \mapsto z \cdot w.
\]
It follows from our hypothesis that this map takes values in \( S^1 \setminus \{-1\} \cong (-\pi, \pi) \). Since \( (-\pi, \pi) \) admits a deformation retraction to 0 one can now easily show that \( f \) and \( g \) are homotopic. We are fully confident that the reader did not fail to fill in all details when solving Exercise 18.1.

Lemma 93.11. Let \( f, g : X \to Y \) be two maps between topological spaces. Suppose that there exists a compact subset \( K \subset X \) such that \( f(x) \neq g(x) \) for all \( x \in K \). If \( Y \) is Hausdorff and normal (by Lemma 2.46 these conditions are satisfied if \( Y \) is Hausdorff and compact), then there exists an open neighborhood \( U \) of \( K \) such that \( f(x) \neq g(x) \) for all \( x \in U \).

Proof (\(*\)). We consider the map
\[
f \times g : X \to Y \times Y, \quad x \mapsto (f(x), g(x)).
\]
By Lemma 3.6 (1) we know that \( f \times g \) is continuous. Since \( K \) is compact we obtain from Lemma 2.40 (1) that \( (f \times g)(K) \) is a compact subset of \( Y \times Y \). Let \( D := \{(y, y) \mid y \in Y\} \) be the "diagonal" in \( Y \times Y \). Since \( Y \) is Hausdorff we obtain from Exercise 3.21 that \( D \) is a closed subset of \( Y \times Y \). Now, using our hypothesis that \( Y \) is normal, we obtain from Lemma 2.46 an open neighborhood \( V \) of \( (f \times g)(K) \) with \( V \cap D = \emptyset \). We set \( U := (f \times g)^{-1}(V) \). Since \( f \times g \) is continuous we see that \( U \) is an open neighborhood of \( K \). Evidently for any \( x \in U \) we have \( (f \times g)(x) \notin D \), i.e., we have \( f(x) \neq g(x) \).

![Figure 1289. Illustration for the proof of Lemma 93.11](image)

Now we head towards the denouement.

Proof of the Table Theorem 93.2. First recall that by Observation 93.7 it suffices to show that \( A' \cap B' \neq \emptyset \). We do a proof by contradiction. So we make the following assumption:

\( \ast \) We assume that \( A' \cap B' = \emptyset \).

In other words, we assume that \( \psi' \) never vanishes on \( A' \). Throughout the proof the following two maps will play a major role:
\[
\hat{\psi} : \{ z \in T \mid \psi'(z) \neq 0 \} \to S^1, \quad z \mapsto \frac{1}{\|\psi'(z)\|} \cdot \psi'(z)
\]
and
\[
\theta : \partial T = \partial D \times (S^1 / \sim) \to \partial D \to S^1, \quad z \mapsto \frac{1}{\|z\|} \cdot z.
\]
Note that $A'$ has the following two properties:

(α) $\psi'$ is non-zero on $A'$ (in particular $\hat{\psi}$ is defined on $A'$), and
(β) By Lemma [93.5] (3) we know that for any $z \in A' \cap \partial T$ we have $\hat{\psi}(z) \neq -\theta(z)$.

The following claim says that we can enlarge $A'$ to a submanifold with corner which still has properties (α) and (β). More precisely, we have the following claim.

Claim. The smooth manifold $T$ admits a compact submanifold with corner $L$ with the following properties:

(i) $A' \subseteq \overset{\sim}{L}$,
(ii) $\psi'$ is non-zero on $L$ (in particular $\hat{\psi}$ is defined on $L$), and
(iii) for any $z \in L \cap \partial T$ we have $\hat{\psi}(z) \neq -\theta(z)$.

![Image](image.png)

**Figure** 1290. Illustration for the proof of the Table Theorem 93.2.

Recall that $T$ is a solid torus, in particular $T$ is compact. Since $A$ is a closed subset of $D \times S^1$ we obtain from Lemma [2.17] (1) and Lemma [2.40] that $A' = p(A)$ is compact.

(1) It follows from (α), the fact that $A'$ is compact and Lemma [93.11] that there exists an open neighborhood $U$ of $A'$ such that $\psi'$ vanishes nowhere on $U$.
(2) It follows from (β), Exercise [2.28] and Lemma [93.11] that there exists an open neighborhood $V$ of $A' \cap \partial T$ such that $\hat{\psi}(z) \neq -\theta(z)$ for all $z \in V$.

It follows from Lemma [11.5] (2) that there exists a submanifold $L$ with corner of $T$ such that $A' \subseteq \overset{\sim}{L} \subseteq L \subseteq U$ and such that $L \cap \partial T \subseteq V$. In particular we see that $\psi'$ is non-zero on $L$ and that for any $z \in L \cap \partial T$ we have $\hat{\psi}(z) \neq -\theta(z)$. $\blacksquare$
We consider the following diagram:

We make the following comments, clarifications and observations:

1. The horizontal maps at the top respectively the bottom are extracts of the long exact sequence in homology of the pair \((T, \partial T)\) respectively of the pair \((L, L \cap \partial T)\).

2. The maps \(i, j, k, l\) indicate the obvious inclusion maps.

3. We denote by \(m: S^1 / \sim \xrightarrow{\cong} \{0\} \times S^1 / \sim \rightarrow D \times (S^1 / \sim) = T\) the obvious map. Since \(D\) is convex we see that \(m\) is a homotopy equivalence, hence we obtain from Corollary 42.8 that \(m_*\) is an isomorphism.

4. The map \(\pi: \partial T = \partial D \times (S^1 / \sim) \rightarrow S^1 / \sim\) is the obvious projection. It is elementary to show that the maps \(m \circ \pi\) and \(j\) from \(\partial T\) to \(T\) are homotopic. Thus we obtain from Proposition 42.5 that they induce the same map on homology. In other words, the triangle to the top right commutes.

5. It follows from the naturality of the connecting homomorphism, see Proposition 43.15 that the rectangle to the left commutes. All the remaining triangles to the right commute basically by definition or by the functoriality of homology groups.

6. By the discussion on page 126 the map \(\theta: \partial D \rightarrow S^1\) is a homeomorphism. It follows easily from this observation, together with the fact that \(\partial T = \partial D \times (S^1 / \sim)\), that the map \(\theta_* \oplus \pi_*: H_1(\partial T; \mathbb{Z}_2) \rightarrow H_1(S^1; \mathbb{Z}_2) \oplus H_1(S^1 / \sim; \mathbb{Z}_2)\) is an isomorphism.

7. It follows from (ii) and Lemma 93.10 that the restrictions of \(\hat{\psi}\) and \(\theta\) to \(L \cap \partial T\) are homotopic. We deduce from Proposition 42.5 that the induced maps on homology are the same. Put differently, the two maps indicated at the upward-pointing diagonal arrow are actually the same.

8. By Lemma 93.9 the left vertical map is an epimorphism. Since \(H_2(T, \partial T; \mathbb{Z}_2) \neq 0\) there exists a \(\xi \in H_1(L, L \cap \partial T; \mathbb{Z}_2)\) with \(i_*(\xi) \neq 0\).

9. It follows from the long exact sequence on top that \(\partial i_*(\xi) \neq 0\) and that \(j_* \partial i_*(\xi) = 0\).

10. It follows from (3), (4) and (9) that \(\pi_* \partial i_*(\xi) = 0\).
93.2. Trivial and non-trivial solutions to the table theorem. In this short section we want to discuss the (non-) existence of trivial solutions to the table theorem. More precisely, we have the following definition.

Definition. Let $D \subset \mathbb{R}^2$ be a compact convex non-empty subset of $\mathbb{R}^2$.

1. Let $s \in \mathbb{R}_{>0}$.
2. Let $s \in \mathbb{R}_{>0}$.

We say $D$ is s-trivial if there exists a square in $\mathbb{R}^2$ such that the vertices lie outside of $\hat{D}$ and such that the center of the square lies in $D$. Otherwise we say that $D$ is s-non-trivial.

We say $D$ is trivial if $D$ is s-trivial for every $s \in \mathbb{R}_{>0}$.

It is basically clear that any compact convex subset with empty interior is trivial. One might initially hope that every compact convex subset with non-empty interior is non-trivial. But that is not the case.

Example. We consider the convex subset $D$ that is the convex hull of the points $(0, 0)$, $(2, 1)$ and $(2, -1)$. We claim that it is trivial. Indeed, let $s \in \mathbb{R}_{>0}$. We write $t = \frac{s}{2}$. The square with vertices $a_1 = (-t + \frac{t}{4}, t), a_2 = (-t + \frac{t}{4}, -t), a_3 = (t + \frac{t}{4}, -t)$ and $a_4 = (t + \frac{t}{4}, t)$, whose center equals $\left(\frac{t}{4}, 0\right)$, shows that $D$ is s-trivial.

This example leads us to the following definition.

Definition. We say that a subset $D$ of $\mathbb{R}^2 = \mathbb{C}$ is obtuse if given any $x \in \partial D$ there exists a $v \in \mathbb{R}^2 \setminus \{(0, 0)\} = \mathbb{C} \setminus \{0\}$ and a $\theta > \frac{\pi}{4}$ such that
\[ \{x + r \cdot v \cdot e^{i\varphi} \mid \varphi \in [-\theta, \theta] \text{ and } r \in [0, 1]\} \subset D. \]

The definition is illustrated in Figure 1292.

We conclude this short section with the following lemma.
Lemma 93.12. Let $D$ be a compact convex non-empty subset of $\mathbb{R}^2$. If $D$ is obtuse, then there exists an $t > 0$ such that $D$ is $s$-non trivial for every $s \in (0, t)$.

Proof. We leave the elementary proof of this lemma to the reader. ■

93.3. The square-peg problem 🗾. In this section we will give another amusing, but unfortunately even less practical application of cohomology theory. To introduce the topic we need the following definition.

Definition.

1. The image of an injective map $S^1 \to \mathbb{R}^2$ is called a Jordan curve.

2. Given a Jordan curve $C$ we say that a rectangle $R$ is inscribed in $C$ if all vertices of $R$ lie on $C$.

The following question was asked by Otto Toeplitz [Toep1911] in 1911.

Question 93.13. Does every Jordan curve admit an inscribed square?

This question is known as the “inscribed square problem” or the “square-peg problem”. Lev Schnirelmann [Schni44] gave a positive answer if the curve is smooth, in fact he gave a proof if the curve is $C^2$, i.e. if the map $S^1 \to \mathbb{R}^2$ is twice continuously differentiable. But the general case is still open. A detailed discussion of the question and its history is given in [Matsc14].

In this section we will provide two partial answers to Question 93.13.

1. We will use the Table Theorem 93.2 to deal with the case that the Jordan curve is the boundary of a compact convex obtuse subset of $\mathbb{R}^2$.

Figure 1293

Figure 1294. The more common square peg problem.

---

1319 Note that this definition is slightly different from the definition we gave on page 452 where we defined a Jordan curve to be an injective map $S^1 \to \mathbb{T} = S^2$.

1320 Otto Toeplitz (1881-1940) was a Jewish German mathematician who was forced to emigrate in 1939. He is mainly known for his contributions to analysis.

1321 We had already encountered Lev Schnirelmann in Theorem 59.5.

1322 Recently the Fields medalist Terence Tao [Tao17] wrote a long paper in which he outlined an approach to the square-peg problem. See also the following video:

https://www.youtube.com/watch?v=RGxnWgy5180
(2) We will show that we can inscribe a rectangle into every Jordan curve.

Let us start with the first result.

**Proposition 93.14.** Let $J$ be a Jordan curve which is the boundary of a compact convex subset $D$. If $D$ is obtuse, then $J$ admits an inscribed square.

**Remark.** This proposition also admits proofs that do not rely on topology, see for example [Zi21, Chr50].

**Proof.** Let $D \subset \mathbb{R}^2$ be a compact convex obtuse subset. We need to show that there exist four points $a_1, a_2, a_3, a_4 \in \partial D$ which form a square. After a translation we can assume that the origin $0$ is contained in the interior of $D$. Given $x \in D \setminus \{0\}$ we set

$$\rho(x) := \sup \{ \|rx\| \mid r \in \mathbb{R}_{>0} \text{ and } r \cdot x \in D \} \in \mathbb{R}_{>0}.$$ 

It follows almost immediately from Lemma 2.54 that the map

$$f: \mathbb{R}^2 \to [0,1]$$

$$x \mapsto \begin{cases} 
1 - \|x\| \cdot \frac{1}{\rho(x)}, & \text{if } x \in D \setminus \{0\}, \\
1, & \text{if } x = 0, \\
0, & \text{if } x \not\in D 
\end{cases}$$

is continuous. Since $D$ is obtuse we obtain from Lemma 93.12 that there exists a $d > 0$ such that $D$ is $d$-non trivial. By the Table Theorem 93.2 there exist four points $b_1, b_2, b_3, b_4 \in \mathbb{R}^2$ with the following properties:

1. the points form a square of side length $d$,
2. the center of the square lies in $D$,
3. we have $f(b_1) = f(b_2) = f(b_3) = f(b_4)$.

Since $D$ is $d$-non trivial we see that at least one vertex lies inside of $\hat{D}$. But since $f$ is non-zero on $\hat{D}$ we see that the common $f$-value, let’s call it $y$, lies in the open interval $(0,1)$. It follows immediately from the definition of $f$ that the four points $b_1, b_2, b_3, b_4$ lie on the subset $(1 - y) \cdot \partial D$. In other words, if we multiply these four points by $\frac{1}{1-y}$, then we obtain the desired four points $a_1, a_2, a_3, a_4$ on $\partial D$.

We conclude this chapter with the second contribution to the square-peg problem.

![Figure 1295. Illustration for the proof of Proposition 93.14](image)
**Proposition 93.15.** Every Jordan curve admits an inscribed rectangle.

In [Meye82] the subsequent ingenious proof of Proposition 93.15 is attributed to Herbert Vaughan. In preparation for the proof we need the following elementary lemma.

**Lemma 93.16.** Let $T = S^1 \times S^1$ be the torus. Let $\sim$ be the equivalence relation on $T$ generated by $(z,w) \sim (w,z)$. The quotient space $T/\sim$ is homeomorphic to the Möbius band and 

$$\partial(T/\sim) = \{(z,z) \mid z \in S^1\}.$$

**Proof.** The homeomorphism is illustrated in Figure 1296.

Proof of Proposition 93.15. Let $\gamma : S^1 \to \mathbb{R}^2$ be an injective map. We have to show that $\gamma(S^1)$ admits an inscribed rectangle. We consider the map

$$\Phi : T := S^1 \times S^1 \to \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$$

$$(z,w) \mapsto \left(\frac{\gamma(z)+\gamma(w)}{2}, |\gamma(z) - \gamma(w)|\right).$$

Since for all $z, w \in S^1$ we have $\Phi(z,w) = \Phi(w,z)$ we see that $\Phi$ descends to a map

$$\Psi : T/\sim \to \mathbb{R}^3$$

where $\sim$ denotes of course the equivalence relation generated by $(z,w) \sim (w,z)$.

**Claim.** The map $\Psi : T/\sim \to \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is not injective.

We first show that the claim implies the proposition. So now that we know that $\Psi$ is not injective we know that there exist distinct pairs of points $\{z,w\}$ and $\{u,v\}$ with $\Phi(z,w) = \Phi(u,v)$. We consider the quadrilateral given by the points $z, u, v, w$. It follows from $\Phi(z,w) = \Phi(u,v)$ that the diagonals bisect each other and that the diagonals have the same length. But such a quadrilateral is necessarily a rectangle. [3324] We refer to Figure 1297 for an illustration.

It remains to prove the claim. Let us assume that $\Psi : T/\sim \to H := \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is injective. By Lemma 93.16 the quotient $M := T/\sim$ is homeomorphic to the Möbius band and the boundary $\partial M$ is given by $\{(z,z) \mid z \in S^1\}$. We see immediately from the definition of $\Psi$ that for a point $[(z,w)] \in M = T/\sim$ we have $\Psi([(z,w)]) \in \partial H = \mathbb{R} \times \mathbb{R} \times \{0\}$ if and only if $[(z,w)] \in \partial M$. We denote by $M_1$ and $M_2$ two copies of $M$ and we denote by $D M = M_1 \cup_{\partial M_1=\partial M_2} M_2$ the double of $M$. It follows from the proof of Lemma 8.33.

1324 Hmm, why is that?
(1) that $DM$ is in fact homeomorphic to the Klein bottle, in particular $DM$ is a closed, non-orientable 2-dimensional smooth manifold.

We denote by $\rho: \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the $xy$-plane, i.e. $\rho$ is the map that is given by $\rho(x, y, z) = (x, y, -z)$. We consider the map

$$DM = M_1 \cup_{\partial M_1 = \partial M_2} M_2 \to \mathbb{R}^3$$

that is given by

$$P \mapsto \Psi(P), \quad \text{if } P \in M_1,$$

$$P \mapsto \rho(\Psi(P)), \quad \text{if } P \in M_2.$$ 

It follows immediately from the above discussion that this map is well-defined and injective. Furthermore it follows from Lemma 3.22 that the map is in fact continuous. But now we have constructed an injective map from the Klein bottle to $\mathbb{R}^3$. On page 133 we pointed out that such a map is in fact an embedding. But we had just proved in Proposition 92.12 that such an embedding cannot exist. \hfill \blacksquare

**Remark.**

(1) The above proof of Proposition 93.15 is also explained in the following video:

[https://www.youtube.com/watch?v=AmgkJdHK4K8](https://www.youtube.com/watch?v=AmgkJdHK4K8)

(2) There are many variations on Question 93.13. For example, given $r \neq 1$ one can ask whether every Jordan curve admits an inscribed rectangle with aspect ratio $r$. Even for smooth curves this had been an open problem for a long time. The first real progress since the work by Schnirelmann [Schn44] happened in 2018 when Cole Hugelmeyer [Hug18] showed that a deep result in knot theory, due to Josh Batson [Bats14], implies that every smooth Jordan curve admits an inscribed rectangle of aspect ratio $\sqrt{3}$. The key idea of [Hug18] is rather similar to the proof of Proposition 93.15. Even more impressively, an affirmative answer for smooth curves and any aspect ratio was given in 2020 by Josh Greene and Andrew Lobb [GrL20].
Exercises for Chapter 93

**Exercise 93.1.** Let \( f: \mathbb{C} = \mathbb{R}^2 \to \mathbb{R} \) be a function, let \( x \in \mathbb{C} \) and let \( z \in \mathbb{C} \setminus \{0\} \). Show that there exists a \( \theta \in [0, \frac{\pi}{2}] \) such that
\[
f(x + e^{i \theta} z) = f(x + e^{i(\theta + \frac{\pi}{2})} z) = f(x + e^{i(\theta + \pi)} z) = f(x + e^{i(\theta + \frac{3\pi}{2})} z).
\]

**Exercise 93.2.** Let \( X \) be a non-empty compact subset of \( \mathbb{R}^2 \) of diameter \( d \). Does there exist a \( P \in \mathbb{R}^2 \) such that \( X \subset B_2^2(P) \)?

**Exercise 93.3.** We consider the solid torus \( T = \overline{B}^2 \times S^1 \). Let \( f: T \to \mathbb{R} \) be a map such that for any \((x, \gamma) \in T\) we have \( f(x, -\gamma) = -f(x, \gamma) \). We write \( A := \{(x, \gamma) \in T \mid f(x, \gamma) = 0\} \).

(a) Show that the inclusion induced map \( H_1(T \setminus A; \mathbb{Z}_2) \to H_1(T; \mathbb{Z}_2) \) is the zero map.

(b) Give an example of a map \( f: T \to \mathbb{R} \) as above such that the inclusion induced map \( H_1(T \setminus A; \mathbb{Z}) \to H_1(T; \mathbb{Z}) \) is *not* the zero map.
The cup product and algebraic intersection numbers

In this chapter we will introduce the algebraic intersection number of two oriented submanifolds of complementary dimensions of a given smooth manifold $M$. In Theorem 94.5 we relate this algebraic intersection number to the cup product of suitable cohomology classes of $M$. This result can be used to compute cup products in a geometric and often entertaining way. Conversely this result can also be used to prove deep statements about intersections of submanifolds.

94.1. Algebraic intersection numbers of submanifolds. Before we introduce the algebraic intersection number of submanifolds we want to recall a definition from page 350 and we want to give a motivating question.

**Definition.** Let $M$ be a smooth manifold.

1. We say that two oriented proper submanifolds $Z_0$ and $Z_1$ of $M$ are *properly smoothly isotopic* if there exists a proper smooth isotopy between $Z_0$ and $Z_1$, i.e. if there exists a proper smooth isotopy $F: Z_0 \times [0,1] \to M$ with $F_0 = \text{id}_{Z_0}$ and such that $F_1: Z_0 \to Z_1$ is an orientation-preserving diffeomorphism.
2. Let $X$ and $Y$ be two oriented proper submanifolds of $M$. We say that $X$ and $Y$ can be made disjoint if there exist oriented proper disjoint submanifolds $\tilde{X}$ and $\tilde{Y}$ of $M$ such that $X$ and $\tilde{X}$ and also $Y$ and $\tilde{Y}$ are properly smoothly isotopic.

**Example.** We consider the three submanifolds $X$, $Y$, and $Z$ of the torus that are illustrated in Figure 1299 on the left. As is shown in the same figure on the right, one can make $X$ and $Y$ disjoint.

![Figure 1299](image)

It does not look like we can make the submanifolds $X$ and $Z$ disjoint. But how can we prove it? We will record this question for later.

**Question 94.1.** Can we make the submanifolds $X$ and $Z$, that are illustrated in Figure 1299 disjoint?

Our approach to addressing Question 94.1 is to introduce the “algebraic intersection number”. Before we can introduce this notion we need to recall the following definition from page 306.

**Definition.** Let $M$ be an $m$-dimensional smooth manifold. Let $X$ and $Y$ be proper submanifolds of $M$.

1. Let $P \in X \cap Y$. We say $P$ is a *transverse intersection point* if $P \notin \partial M$ and if $X$ and $Y$ intersect transversally in $P$, i.e. if the equality $T_P X + T_P Y = T_P M$ holds.
(2) We say that \( X \) and \( Y \) intersect transversally if each intersection point is a transverse intersection point.

**Lemma 94.2.** Let \( M \) be an \( m \)-dimensional smooth manifold, let \( X \subset M \) be a proper submanifold of dimension \( k \) and let \( Y \subset M \) be a proper submanifold of the complementary dimension \( m - k \). If \( X \) and \( Y \) intersect transversally and if \( X \) and \( Y \) are both compact, then the intersection \( X \cap Y \) consists of finitely many points.

**Proof (\( \ast \)).** By Lemma 6.52 we know that \( X \cap Y \) is a 0-dimensional submanifold of \( M \). It follows easily from the definition of a 0-dimensional submanifold that \( X \cap Y \) is a discrete subset of \( M \). Since \( X \) and \( Y \) are compact we know by Lemma 2.16 (2) that \( X \cap Y \) is also compact. It now follows from Lemma 2.18 that \( X \cap Y \) is finite. \( \blacksquare \)

**Definition.** Let \( m \in \mathbb{N} \) and let \( k \in \{1, \ldots, m - 1\} \). Furthermore let \( M \) be an \( m \)-dimensional oriented smooth manifold, let \( X \subset M \) be a compact oriented proper submanifold of dimension \( k \) and let \( Y \subset M \) be a compact oriented proper submanifold of the complementary dimension \( m - k \). Suppose that \( X \) and \( Y \) intersect transversally.

1. Let \( P \) be an intersection point of \( X \) and \( Y \). We set \( \text{sign}(P) = 1 \), if 
   
   \[
   \text{positive basis of } T_P X, \text{positive basis of } T_P Y = \text{positive basis of } T_P M.
   \]

   Otherwise we set \( \text{sign}(P) = -1 \).

2. We define \( ^{1325} \)

   geometric intersection number of \( X \) and \( Y \) := \( \#(X \cap Y) \)

   and

   algebraic intersection number of \( X \) and \( Y \) := \( X \cdot Y := \sum_{P \in X \cap Y} \text{sign}(P) \in \mathbb{Z} \).

   If \( X \) and \( Y \) do not intersect, then the algebraic intersection number of \( X \) and \( Y \) is of course zero.

**Examples.**

1. In Figure 1300 we show pieces of oriented submanifolds of the oriented smooth manifold \( \mathbb{R}^2 \). On the left the sign of the intersection point is positive, on the right it is negative.

   ![Figure 1300](image)

   **Figure 1300**

\(^{1325}\) It is a straightforward exercise in linear algebra to show that the definition of \( \text{sign}(P) \) does not depend on the choice of the positive bases of \( T_P X \) and \( T_P Y \).

\(^{1326}\) It follows from Lemma 94.2 that the geometric intersection number is finite and that the algebraic intersection number is given by a finite sum.
(2) We consider the surface of genus 2 with the orientation where the normal vector “sticks outward”. Furthermore we consider the oriented submanifolds $A, B, C, D$ and $E$ that are illustrated in Figure 1301. For the submanifolds $A$ and $B$ we have

- geometric intersection number of $A$ and $B = 1$,
- the sign of the intersection point is negative, hence
- algebraic intersection number of $A$ and $B = -1$.

For the submanifolds $A$ and $C$ we have

- geometric intersection number of $A$ and $C = 2$,
- the intersection points have opposite signs, therefore
- algebraic intersection number of $A$ and $C = 0$.

Finally for the submanifolds $D$ and $E$ we have

- geometric intersection number of $D$ and $E = 2$,
- here both intersection points have negative sign, thus
- algebraic intersection number of $D$ and $E = -2$.

It is particularly instructive to consider the submanifolds $A$ and $C$. They intersect geometrically in two points, but the signs are opposite. Note that these two intersection points also “vanish” if we “pull $A$ and $C$ apart” by a smooth isotopy.

(3) Now suppose that $M$ and $N$ are oriented smooth manifolds of dimensions $m$ respectively $n$. We saw in Propositions 6.51 (1) and 80.9 that $M \times N$ is naturally an $(m + n)$-dimensional smooth manifold. It is straightforward to show that for each $P \in M \setminus \partial M$ and $Q \in N \setminus \partial N$ the natural map

$$T_P M \oplus T_Q N \to T_{(P,Q)} (M \times N)$$

is an isomorphism. If $\{v_1, \ldots, v_m\}$ is a positive basis for $T_P M$ and $\{w_1, \ldots, w_n\}$ is a positive basis for $T_Q N$, then we endow $T_{(P,Q)} (M \times N)$ with the orientation that makes the above isomorphism orientation-preserving.

Given $P \in M$ and $Q \in N$ it follows easily from the definitions that

- algebraic intersection number of $M \times \{Q\}$ and $\{P\} \times N = 1$.

\[\text{Figure 1301}\]

\[\text{orientation of } \Sigma\]
In Figure 1302 we illustrate the statement that in the torus $S^1 \times S^1$ we have algebraic intersection number of $S^1 \times \{1\}$ and $\{1\} \times S^1$ = 1.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1302.png}
\caption{Figure 1302}
\end{figure}

(4) In Section 94.4 we will study the algebraic intersection number of complex submanifolds of a given complex manifold.

(5) The above example (2) suggests that if two submanifolds have non-zero algebraic intersection number, then they cannot be made disjoint. As we will see in Proposition 94.6 this hunch is basically correct. But if we deal with submanifolds with boundary one needs to think carefully about the correct setting. For example in Figure 1303 on the left we show a smooth manifold $M$ and we show two proper submanifolds $X$ and $Y$ such that the boundaries $\partial X$ and $\partial Y$ lie on the same component of $\partial M$. The algebraic intersection number is +1, but as we see in Figure 1303 on the right, these two submanifolds can be made disjoint. Therefore in the following discussion we will always assume that the boundary components of $X$ and $Y$ lie in different boundary components of $M$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1303.png}
\caption{Figure 1303}
\end{figure}

the algebraic intersection number of $X$ and $Y$ equals +1

Before we continue, and in light of the last example, we introduce the following definition.

\textbf{Definition.} Let $M$ be a compact oriented smooth manifold.

1. A boundary decomposition for $M$ is a decomposition $\partial M = A \cup B$ where $A$ and $B$ are unions of components of $\partial M$ and $A \cap B = \emptyset$.
2. Let $X$ and $Y$ be two submanifolds of $M$. We say $X$ and $Y$ are complementary if the following five conditions are satisfied:
   1. $X$ and $Y$ are proper non-empty submanifolds,
   2. there exists a boundary decomposition $\partial M = A \cup B$ with $\partial X \subset A$ and $\partial Y \subset B$,
   3. both $X$ and $Y$ are oriented,
   4. we have $\dim(X) + \dim(Y) = \dim(M)$ and we have $\dim(X), \dim(Y) \geq 1$,
   5. the submanifolds $X$ and $Y$ intersect transversally.
We would be able to answer Question 94.1 if we could prove the following statement.

**Statement 94.3.** Let $M$ be a compact oriented smooth manifold and let $\{X,Y\}$ and $\{X',Y'\}$ be two pairs of complementary submanifolds of $M$. Then the following holds:

$$X, X' \text{ are properly smoothly isotopic and } \quad Y, Y' \text{ are properly smoothly isotopic } \quad \Rightarrow \quad X \cdot Y = X' \cdot Y'.$$

But how can we prove such a statement? In Figure 1305 we sketch an idea: We break the smooth isotopies from $X$ to $X'$ and from $Y$ to $Y'$ into “smaller isotopies” such that each smaller isotopy either does not change the type of intersection points, or two intersection points of opposite sign get created or erased. Even though the idea is fairly convincing, it is very hard to turn this idea into a proper proof. So for the time being we will not attempt to provide a proof for Statement 94.3.

intersection points of opposite signs “cancel” under the smooth isotopy $F$

We conclude this introduction to algebraic intersection numbers with the following elementary lemma.

**Lemma 94.4.** Let $M$ be a compact oriented smooth manifold. If $X$ and $Y$ are complementary submanifolds of $M$, then

$$Y \cdot X = (-1)^{\dim(X) \cdot \dim(Y)} \cdot X \cdot Y.$$

**Sketch of proof.** The statement follows easily from the definitions and the observation that the matrix that represents the linear homeomorphism that swaps the first $k$ vectors with the last $(m-k)$ vectors of a basis of an $m$-dimensional vector space is represented by the matrix $\begin{pmatrix} 0 & \text{id}_k \\ \text{id}_{m-k} & 0 \end{pmatrix}$. One easily verifies that the determinant of this matrix equals $(-1)^{(m-k)}$.

---

You will see it is already hard to prove the statement in dimension 2, let alone in higher dimensions. In fact I am not aware of a direct geometric proof of Statement 94.3.

Even though we will not follow this approach, it was certainly this type of picture mathematicians had in mind when they developed the concept of algebraic intersection numbers in the early 20th century.
94.2. The cup product and algebraic intersection numbers. We recall the following notation.

Notation.

(1) Given a compact oriented $n$-dimensional smooth manifold $W$ we denote as usual by $[W] \in H_n(W, \partial W)$ the fundamental class that we introduced on page 1712 or alternatively on page 2120. If $W$ is a proper submanifold of some topological manifold $M$, then sometimes we denote by $[W] \in H_n(M, \partial M)$ the image of $[W]$ under the inclusion induced map $H_n(W, \partial W) \to H_n(M, \partial M)$.

(2) Let $M$ be a compact oriented $n$-dimensional smooth manifold and suppose that we are given a boundary decomposition $\partial M = A \cup B$. By the Poincaré Duality Theorem 88.1 we know that for each $k \in \mathbb{N}_0$ the map

$$H^k(M, A) \xrightarrow{\cup [M]} H_{n-k}(M, B)$$

is an isomorphism. We denote by

$$\text{PD}_M : H_{n-k}(M, B) \to H^k(M, A)$$

its inverse. If $M$ is understood from the context then often we just write $\text{PD}$ instead of $\text{PD}_M$.

The following theorem relates the cup product on a smooth manifold to algebraic intersection numbers. Or conversely, it expresses the algebraic intersection number of submanifolds as a cup product.

Theorem 94.5. Let $M$ be a compact oriented $m$-dimensional smooth manifold together with a boundary decomposition $\partial M = A \cup B$. Let $X$ and $Y$ be a complementary pair of submanifolds of $M$ with $\partial X \subset A$ and $\partial Y \subset B$. We write $k = \dim(X)$ and we denote by $i: X \to M$ and $j: Y \to M$ the obvious inclusion maps. Furthermore we denote by $[X] \in H_k(X, \partial X)$ and $[Y] \in H_{m-k}(Y, \partial Y)$ the fundamental classes of $X$ and $Y$. Then

$$X \cdot Y = \left\langle \text{PD}_M(i_*([X])) \cup \text{PD}_M(j_*([Y])), [M] \right\rangle \in \mathbb{Z}.$$  

In particular with the abbreviation $[X] = i_*([X])$ and $[Y] := j_*([Y])$ we have the slightly more readable equality

$$X \cdot Y = \langle \text{PD}_M([X]) \cup \text{PD}_M([Y]), [M] \rangle.$$  

Remark.

(1) As a reality check, note that a short moment's thought shows that the (anti-) commutativity of the algebraic intersection number of Lemma 94.4 does indeed correspond precisely to the (anti-) commutativity of the cup product from Proposition 82.3.
The following citation from [Kir89, p. 21] encapsulates the roles of algebraic intersection numbers and cup products:

“Think with [algebraic] intersection [numbers], prove with cup products.”

More precisely, algebraic intersection numbers are very intuitive and often they can be used to guess a statement. But when it comes to proving statements, e.g. why does the intersection number only depend on the smooth isotopy type of a submanifold?, it is usually much easier to work with cup products.

Alternative proofs of Theorem 94.5 are given in [GH81, Proposition 31.7], [Bre93, Theorem VI.11.9] and [DaK01, Theorem 10.32]. Furthermore a quick outline of a proof is given in [GoS99, Proposition 1.2.5].

One could use the right-hand side of Theorem 94.5 as the definition of the algebraic intersection number. We will discuss this idea in Exercise 94.3.

If we drop the condition that $M$, $X$ and $Y$ are orientable, then we can still define an algebraic intersection number $X \cdot F_2 Y$ and we can formulate Poincaré Duality with $\mathbb{Z}$ coefficients. This allows us to formulate a variation on Theorem 94.5. To save the trees we will not spell out the details at this point, instead we refer to the more general Theorem 95.15 for details.

Before we move on to the somewhat lengthy proof of Theorem 94.5 we want to convince ourselves that proving the theorem is worth the effort.

One application of Theorem 94.5 is that now we can provide a proof of a strengthened version of Statement 94.3. More precisely, we have the following proposition.

**Proposition 94.6.** Let $M$ be a compact oriented smooth manifold.

1. Let $\{X, Y\}$ and $\{X', Y'\}$ be pairs of complementary submanifolds of $M$. If $X, X'$ are properly smoothly isotopic and if $Y, Y'$ are also properly smoothly isotopic, then $X \cdot Y = X' \cdot Y'$.
2. If $X$ and $Y$ are two complementary submanifolds of $M$ that can be made disjoint, then $X \cdot Y = 0$.

**Example.** Now we can answer Question 94.1. It follows from Proposition 94.6 that the submanifolds $X$ and $Z$, that are illustrated in Figure 1299 cannot be made disjoint since their algebraic intersection number is non-zero.

**Proof.** Let $M$ be a compact oriented smooth manifold. We start out with the following claim.

**Claim.** Let $Z$ and $Z'$ be oriented proper $s$-dimensional submanifolds of $M$. If $Z$ and $Z'$ are properly smoothly isotopic, then $[Z] = [Z'] \in H_s(M, \partial M)$.

We denote by $i : Z \to M$ and $i' : Z' \to M$ the inclusion maps. Since $Z$ and $Z'$ are properly smoothly isotopic there exists in particular an orientation-preserving diffeomorphism $f: Z \to Z'$ such that the maps $i, i' \circ f : (Z, \partial Z) \to (M, \partial M)$ are homotopic. We obtain that

$$[Z] = i_*([Z]) \quad \uparrow \quad (i' \circ f)_*([Z]) = i'_*(f_*(i([Z]))) \quad \uparrow \quad i'_*([Z']) \quad = \quad [Z']$$

by Proposition 72.2 since $f$ is an orientation-preserving homeomorphism.
Now let \{X, Y\} and \{X', Y'\} be two pairs of complementary submanifolds of \(M\). We assume that the submanifolds \(X, X'\) are properly smoothly isotopic and that the smooth manifolds \(Y, Y'\) are smoothly isotopic. We obtain that

\[
X \cdot Y = \langle \PD_M([X]), \PD_M([Y]), [M] \rangle = \langle \PD_M([X']), \PD_M([Y']), [M] \rangle = X' \cdot Y'.
\]

This concludes the proof of the first statement. The second statement is an immediate consequence of the first statement. \(\blacksquare\)

Now we will use Theorem 94.5 “the other way”, i.e. we will apply the theorem to use the algebraic intersection number to draw conclusions on (co-) homology classes and to determine cup products using our geometric understanding of submanifolds.

**Corollary 94.7.** Let \(M\) be a compact oriented connected \(m\)-dimensional smooth manifold together with a boundary decomposition \(\partial M = A \cup B\). Let \(X\) be a \(k\)-dimensional proper submanifold of \(M\) with \(\partial X \subset A\). If there exists a proper submanifold \(Y\) with \(\partial Y \subset B\) such that \(X\) and \(Y\) form a complementary pair and if \(X \cdot Y = \pm 1\), then we can write \(\H_k(M, A) = \mathbb{Z} \cdot [X] \oplus K\) for some abelian group \(K\). In particular we see that \([X]\) is a primitive element of \(\H_k(M, A)\).

**Proof.** We consider the homomorphism

\[
\Theta: \H_k(M, A) \to \mathbb{Z} \\
\varphi \mapsto \langle \PD_M(\varphi) \cup \PD_M([Y]), [M] \rangle.
\]

It follows from our hypothesis and Theorem 94.5 that \(\Theta([X]) = \pm 1\). The corollary now follows from the elementary discussion on page 1208. \(\blacksquare\)

**Examples.**

1. Let \(M\) be the complement in \(S^3\) of the two open 3-dimensional tori shown in Figure 1306 on the left. On the right of that figure we show an annulus \(X\) that is properly embedded in \(M\). On the right we also see a closed 1-dimensional submanifold \(Y\) of \(M\). The two submanifolds \(X\) and \(Y\) are clearly transverse and they intersect in one point. So with whatever orientation, we have \(X \cdot Y = \pm 1\). By Corollary 94.7 this implies in particular that \([X] \in \H_2(M, \partial M)\) is a primitive element.

\(M\) is the complement in \(S^3\) of

\[
\begin{array}{c}
\text{two open solid tori} \\
\text{properly embedded surface } X \text{ in } M
\end{array}
\]

\[
\begin{array}{c}
\text{closed curve } Y \text{ in } M
\end{array}
\]

**Figure 1306**
(2) This time let $M$ be the complement in $S^3$ of the two open 3-dimensional tori shown in Figure 1307 on the left. Almost the same argument as in (1) shows that the surface $X$ defines a primitive element in $H_2(M)$.

$M$ is the complement in $S^3$ of two open solid tori

closed embedded surface $X$ in $M$

properly embedded curve $Y$ in $M$

**Figure 1307**

In the next example we will show how to use Theorem 94.3 to compute cup products.

**Example.** We consider the torus $T = S^1 \times S^1$ together with the submanifolds $X = S^1 \times \{1\}$ and $Y = \{1\} \times S^1$ which we endow with the usual orientations. By now we have many ways for showing that $\text{PD}(X)$ and $\text{PD}(Y)$ form a basis for $H^1(T)$. Thus if we want to understand the cup product on the torus, it suffices to understand the cup products involving these two cohomology classes. We calculate that

$$-\langle \text{PD}(Y) \cup \text{PD}([X]), [S^1 \times S^1] \rangle = \langle \text{PD}([X]) \cup \text{PD}([Y]), [S^1 \times S^1] \rangle = X \cdot Y = +1.$$ 

Proposition 81.8

Theorem 94.3

Figure 1308

Next we want to calculate the “square” $\text{PD}(X) \cup \text{PD}(X)$. This requires a little trick since evidently $X$ is not transverse to itself. To deal with this issue we consider a “parallel copy” of $X$, namely we consider $X' = S^1 \times \{z\}$ with $z \neq 1$. We calculate that

$$\langle \text{PD}(X) \cup \text{PD}(X), [S^1 \times S^1] \rangle = \langle \text{PD}(X') \cup \text{PD}(X'), [S^1 \times S^1] \rangle = X \cdot X' = 0.$$ 

by the claim in the proof of Proposition 94.6

by Theorem 94.3 since $X$ and $X'$ are disjoint, in particular transverse

and with the same argument we show that $\langle \text{PD}(Y) \cup \text{PD}(Y), [S^1 \times S^1] \rangle = 0$. We will now convince ourselves that these calculations match our previous calculations. To do so we denote by $p_1$ respectively $p_2$ the projection $S^1 \times S^1 \to S^1$ onto the first respectively the second factor and we denote by $\theta := \theta_z \in C^1; \mathbb{Z})$ the singular 1-cocycle that we introduced on page 1825. Now we see that

$$\begin{pmatrix}
\text{PD}(X) \cup \text{PD}(X) & \text{PD}(X) \cup \text{PD}(Y) \\
\text{PD}(Y) \cup \text{PD}(X) & \text{PD}(Y) \cup \text{PD}(Y)
\end{pmatrix}
= \begin{pmatrix}
[p_2^*\theta] \cup [p_2^*\theta] & -[p_2^*\theta] \cup [p_1^*\theta] \\
-[p_1^*\theta] \cup [p_2^*\theta] & [p_1^*\theta] \cup [p_1^*\theta]
\end{pmatrix}
= \begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix}.$$

on page 2022 we already showed that see page 2022

$[p_1^*\theta] \cap [T] = [1 \times S^1] = [Y]$ and $[p_2^*\theta] \cap [T] = [-S^1 \times 1] = -[X]$.

Since this was so much fun, let us consider one more example.

---

1333 So, how many ways do you know?
**Example.** Let \( \Sigma \) be the surface of genus two. We consider the following bilinear pairing:

\[
Q : H_1(\Sigma) \times H_1(\Sigma) \rightarrow \mathbb{Z},
\]

\[(\sigma, \tau) \mapsto \langle PD_\Sigma(\sigma) \cup PD_\Sigma(\tau), [\Sigma] \rangle.
\]

Recall that by Proposition 48.9 we know that \( H_1(\Sigma) \cong \mathbb{Z}^4 \). Next we consider the closed oriented curves \( a_1, b_1, a_2, b_2 \) that are shown in Figure 1309. It follows easily from Theorem 94.5 that

\[
\begin{pmatrix}
Q([a_1], [a_1]) & Q([a_1], [b_1]) & Q([a_1], [a_2]) & Q([a_1], [b_2]) \\
Q([b_1], [a_1]) & Q([b_1], [b_1]) & Q([b_1], [a_2]) & Q([b_1], [b_2]) \\
Q([a_2], [a_1]) & Q([a_2], [b_1]) & Q([a_2], [a_2]) & Q([a_2], [b_2]) \\
Q([b_2], [a_1]) & Q([b_2], [b_1]) & Q([b_2], [a_2]) & Q([b_2], [b_2])
\end{pmatrix}
= \begin{pmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & -1 & 0
\end{pmatrix}.
\]

Note that the determinant of the matrix to the right is one. Since \( Q \) is bilinear we obtain from Lemma 74.8 a new proof that \([a_1], [b_1], [a_2], [b_2]\) is a basis for \( H_1(\Sigma) \). By the Poincaré Duality Theorem 88.1 together with Theorem 94.5 we have now also computed the cup product \( H^1(\Sigma; \mathbb{Z}) \times H^1(\Sigma; \mathbb{Z}) \rightarrow H^2(\Sigma; \mathbb{Z}) \).

---

1334 Later on, on page 2413 we will refer to this map as the *intersection form of \( \Sigma \)* and we will introduce the intersection form of any closed oriented even-dimensional topological manifold.

1335 For the diagonal terms we use the “little trick” from the previous example, namely we use a “parallel copy” of the curves \( a_1, b_1, a_2, b_2 \).

1336 We gave a different argument on page 1270.
We denote by \( i: X \to M \) and \( j: Y \to M \) the inclusion maps. Then we refer to
\[
\langle \text{PD}_M( i_*([X])) \cup \text{PD}_M( j_*([Y])), [M] \rangle \in \mathbb{Z}
\]
as the algebraic intersection number of \( X \) and \( Y \). By Theorem 94.5 this definition is consistent with the earlier definition on page 2271.

94.3. Proof of Theorem 94.5. In this section we will prove Theorem 94.5. Our proof of Theorem 94.5 relies heavily on Lemmas 89.5 and 89.6 that relate Poincaré duality in an oriented topological manifold \( M \) to Poincaré duality in a compact codimension 0 submanifold \( W \). For the reader’s convenience we recall Lemma 89.5. This lemma says that given a homology class in \( W \) we can apply Poincaré duality in \( M \) or \( W \) and essentially we end up with the same result:

**Lemma 89.5.** Let \( M \) be a compact oriented \( m \)-dimensional topological manifold and let \( W \) be a compact \( m \)-dimensional submanifold with \( \partial M \cap \partial W = \emptyset \). We write \( \hat{W} = W \setminus \partial W \).

We fix the following notation:

1. We denote by \( w \) the inclusion map \( W \to M \) and also the inclusion map of the pairs \( (W, \partial W) \to (M, M \setminus \hat{W}) \).
2. We denote by \( p: (M, \partial M) \to (M, M \setminus \hat{W}) \) the inclusion map of pairs.

For every \( k \in \mathbb{N}_0 \) the following diagram commutes:
\[
\begin{array}{ccc}
H_k(W; \mathbb{Z}) & \xrightarrow{\text{PD}_W} & H^{m-k}(W, \partial W; \mathbb{Z}) \\
\downarrow \text{w}_* & & \downarrow \text{(w*)}^{-1} \\
H_k(M; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & H^{m-k}(M, \partial M; \mathbb{Z})
\end{array}
\]

**Figure 1310. Illustration of Lemma 89.5**

We take a short rest from more technicalities and enjoy the fact that we can already prove Theorem 94.5 in the special case that \( M \) is closed and that the submanifolds do not intersect.

**Proof of Theorem 94.5 for disjoint submanifolds.** Let \( M \) be a closed oriented \( m \)-dimensional smooth manifold and let \( X \) and \( Y \) be a complementary pair of disjoint
submanifolds of \( M \). Since the submanifolds are disjoint it suffices to show that the cup product of the Poincaré duals of \([X]\) and \([Y]\) is also zero.

We write \( k = \dim(X) \). We apply the General Tubular Neighborhood Theorem \[10.5\] to the submanifold \( X \cup Y \) of \( M \). We obtain disjoint tubular neighborhoods \( A \) for \( X \) and \( B \) for \( Y \). We denote by \( p: (M, \emptyset) \to (M, M \setminus \hat{A}) \) and \( p: (M, \emptyset) \to (M, M \setminus \hat{B}) \) the obvious inclusion maps of pairs of topological spaces.

We apply Lemma \[89.5\] to the codimension-zero submanifold \( A \) and the homology class \([X]\) \( \in \text{H}_k(A; \mathbb{Z}) \). We obtain an \( \alpha \in \text{H}^{m-k}(M, M \setminus \hat{A}; \mathbb{Z}) \) with \( p^*(\alpha) = \text{PD}_M([X]) \). Similarly we see that there exists a \( \beta \in \text{H}^k(M, M \setminus \hat{B}; \mathbb{Z}) \) with \( p^*(\beta) = \text{PD}_M([Y]) \).

We consider the following diagram

\[
\begin{array}{c}
\text{H}^{m-k}(M; \mathbb{Z}) \times \text{H}^k(M; \mathbb{Z}) \xrightarrow{\cup} \text{H}^m(M; \mathbb{Z}) \\
p^* \times p^* \downarrow \quad \quad \downarrow (\text{PD}_M([X]), \text{PD}_M([Y])) \\
\text{H}^{m-k}(M, M \setminus \hat{A}; \mathbb{Z}) \times \text{H}^k(M, M \setminus \hat{B}; \mathbb{Z}) \xrightarrow{\cup} \text{H}^m(M, (M \setminus \hat{A}) \cup (M \setminus \hat{B}); \mathbb{Z}).
\end{array}
\]

The diagram commutes by Proposition \[82.4\] (1). It follows from the fact that the lower right group is zero that the cup product of \( \text{PD}_M([X]) \) and \( \text{PD}_M([Y]) \) is zero.

**Figure 1311.** Illustration for the proof of Theorem \[94.5\]

After this refreshing proof of the special case we continue with trying to prove the general case of Theorem \[94.5\]. We will need Lemma \[89.6\]. Since the statement is rather technical, we recall the statement of the special case that is discussed in example (a) on page 2188.

**Lemma 89.6.** Let \( M \) be a compact oriented \( m \)-dimensional smooth manifold and let \( W \) be a compact \( m \)-dimensional submanifold with corner. We fix the following notation:

1. We write \( \partial_1 W = W \cap \partial M \) and \( \partial_0 W = \partial W \setminus \partial_1 W \).
2. We write \( \hat{W} = W \setminus \partial_0 W \).
3. The inclusion maps \((W, \partial_0 W) \to (M, M \setminus \hat{W})\) and \((W, \partial_1 W) \to (M, \partial M)\) are denoted by \( w \).
4. Finally we denote by \( p: (M, \emptyset) \to (M, M \setminus \hat{W}) \) the obvious map.

For every \( k \in \mathbb{N}_0 \) the following diagram commutes:

\[
\begin{array}{cccc}
\text{H}_k(M; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & \text{H}^{m-k}(M, \partial M; \mathbb{Z}) \\
p^* \downarrow & & \downarrow w^* \\
\text{H}_k(M, M \setminus \hat{W}; \mathbb{Z}) & \xrightarrow{(w_*)^{-1}} & \text{H}_k(W, \partial W; \mathbb{Z}) & \xrightarrow{\text{PD}_W} & \text{H}^{m-k}(W, \partial_1 W; \mathbb{Z}).
\end{array}
\]
In the proof of Theorem 94.5, we will also need the following proposition.

**Proposition 94.8.** Let $M$ be a compact oriented smooth manifold and let $X$ and $Y$ be two complementary proper submanifolds of dimensions $k$ and $l$. We denote by $P_1, \ldots, P_s$ the intersection points of $X$ and $Y$. Then there exist

1. compact submanifolds with corner $A$ and $B$ such that $A$ is a neighborhood for $X$ and $B$ is a neighborhood for $Y$, and
2. injective maps $\Psi_i : \overline{B}^k \times \overline{B}^l \to M$, $i = 1, \ldots, s$

such that the following statements hold:

(a) For each $i \in \{1, \ldots, s\}$ we have $\Psi_i((0,0)) = P_i$.
(b) The images $Q_i := \Psi_i(\overline{B}^k \times \overline{B}^l)$, $i = 1, \ldots, s$ are disjoint.
(c) We have $Q_1 \cup \cdots \cup Q_s = A \cap B$.
(d) For each $i \in \{1, \ldots, s\}$ the following statements hold:
   (d1) the restriction of $\Psi_i$ to $B^k \times B^l$ is a diffeomorphism onto its image,
   (d2) we have $Q_i \cap X = \Psi_i(B^k \times \{0\})$ and the map $\Psi_i : B^k \times \{0\} \to X$ is an orientation-preserving smooth embedding,
   (d3) we have $Q_i \cap Y = \Psi_i(\{0\} \times B^l)$ and the map $\Psi_i : \{0\} \times B^l \to Y$ is an orientation-preserving smooth embedding.

**Sketch of a proof.** Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $X$ and $Y$ be two complementary proper submanifolds of dimensions $k$ and $l$. We denote by $P_1, \ldots, P_s$ the intersection points of $X$ and $Y$. For $i = 1, \ldots, s$ we can and will pick smooth embeddings $\Psi_i : \overline{B}^n \to M \setminus \partial M$ such that the following conditions are satisfied:

1. the images are disjoint,
(2) for each \( i \in \{1, \ldots, s\} \) the map \( \Psi_i \) restricts to orientation-preserving diffeomorphisms \( B^k \times \{0\} \to \Psi_i(B^n) \cap X \) and \( \{0\} \times B^l \to \Psi_i(B^n) \cap Y \).

We consider \( W := M \setminus \bigcup_{i=1}^s \Psi_i(B^n) \). Note that \( X' := W \cap X \) and \( Y' := W \cap Y \) are proper submanifolds of the compact smooth manifold \( W \). Thus we can apply the General Tubular Neighborhood Theorem \(^{10.5}\) to obtain tubular neighborhoods for \( X' \) and \( Y' \). Using Proposition \(^{8.35}\) we can arrange the intersections of the tubular neighborhoods with \( \Psi_i(S^{n-1}) \) to be ‘standard \( (n-1) \)-dimensional balls’.

At this stage it is fairly straightforward to extend the tubular neighborhoods to the interiors of the \( \Psi_i(B^n) \) and to obtain all the desired objects. We have faith in the unwavering enthusiasm of our readers for filling in the details.

\[\begin{array}{c}
\text{Figure 1314. Illustration of the proof of Proposition 94.8.}
\end{array}\]

**Remark.** An alternative approach to Proposition 94.8 would be to use tubular neighborhoods provided by Lemma 10.12.

Given the situation of Proposition 94.8 we can make one more statement.

**Lemma 94.9.** We use the notation of Proposition 94.8. Let \( i \in \{1, \ldots, s\} \). We equip the topological manifold \( Q_i \), which is a codimension-zero submanifold of \( M \), with the induced orientation coming from Lemma 86.17. Furthermore we equip the topological manifold \( B^k \times B^l \) with the orientation coming from the standard orientation of \( \mathbb{R}^k \times \mathbb{R}^l = \mathbb{R}^{k+l} \).

With these choices the following statement holds:

(f) If we denote by \( \sigma_i \) the sign of the intersection point \( P_i \), then

\[ \Psi_i([B^k \times B^l]) = \sigma_i \cdot [Q_i]. \]

**Proof.** Let \( i \in \{1, \ldots, s\} \). If follows from (d2) and (d3) that at the point \((0,0)\) the diffeomorphism \( \Psi_i: B^k \times B^l \to \tilde{Q} \) is orientation-preserving if and only if \( \sigma_i = 1 \). Now the statement follows easily from the definition of \( \sigma_i \), Proposition 72.2 and Lemma 86.12.

The last preparation we need before we can provide the actual proof of Theorem 94.5 is Proposition 88.2 which for the reader’s convenience we recall using our present notation.

**Proposition 88.2.** Let \( X \) be a compact oriented connected \( m \)-dimensional topological manifold and let \( Y \) be a compact oriented connected \( n \)-dimensional topological manifold. We denote by \( p: X \times Y \to X \) and \( q: X \times Y \to Y \) the obvious projection maps. We equip...
Given any points \( P \in X \) and \( Q \in Y \) we have the following equality in \( H^{m+n}(X \times Y, \partial(X \times Y); \mathbb{Z}) \):

\[
\text{PD}_{X \times Y}([X \times \{Q\}] \cup \text{PD}_{X \times Y}([\{P\} \times Y]) = [X \times Y]^*.
\]

We turn to the actual proof of Theorem 94.5.

**Proof of Theorem 94.5.** Let \( M \) be a compact oriented connected \( m \)-dimensional smooth manifold. To simplify the notation we assume that \( M \) is closed. The case that \( M \) has boundary is proved in a rather similar fashion.\(^{1337}\)

Let \( X \) and \( Y \) be a complementary pair of submanifolds of \( M \). We introduce the following notation:

1. We write \( k = \dim(X) \) and \( l = \dim(Y) \). Note that \( l = m - k \).
2. As usual we denote by \( [X] \in H_k(X) \) and \( [Y] \in H_l(Y) \) the fundamental classes of \( X \) and \( Y \). By a slight abuse of notation we denote by \( [X] \) respectively \( [Y] \) also the images of these homology classes in any subset of \( M \) that contains \( X \) respectively \( Y \).
3. We denote the intersection points of \( X \) and \( Y \) by \( P_1, \ldots, P_s \) and we denote the corresponding signs by \( \sigma_1, \ldots, \sigma_s \).
4. As usual, given a topological space \( X \) we denote by \( \epsilon_X = \epsilon : H_0(X) \to \mathbb{Z} \) the augmentation map.

With the notation that we just introduced, and keeping in mind Lemma 83.4 (1), the statement of Theorem 94.5 can be reformulated as the following statement.

**Statement.**

\[
\epsilon_M([\text{PD}_M([X]) \cup \text{PD}_M([Y])] \cap [M]) = \sum_{i=1}^{s} \sigma_i.
\]

We introduce many more objects, notations and conventions:

5. We apply Proposition 94.8 to the submanifolds \( X \) and \( Y \). In the remainder of the proof we use the notation that we introduced in that proposition. As a reminder, most of the relevant objects are illustrated in Figure 1313.
6. We write \( \hat{A} = A \setminus \partial A \) and \( \hat{B} = B \setminus \partial B \).
7. We denote all of the inclusion maps \( (M, \emptyset) \to (M, M \setminus \hat{A}), (M, \emptyset) \to (M, M \setminus \hat{B}) \) and \( (M, \emptyset) \to (M, M \setminus (\hat{A} \cap \hat{B})) \) by \( \rho \).
8. We write \( C = A \cap B = Q_1 \cup \cdots \cup Q_s \). Furthermore we write \( \partial_A C = \partial A \cap B \) and \( \partial_B C = A \cap \partial B \). Note that \( \partial C = \partial_A C \cup \partial_B C \) and also that \( (M \setminus \hat{A}) \cup (M \setminus \hat{B}) = M \setminus \hat{C} \).
9. We denote by \( c : C \to M \) the inclusion map and we denote by \( c \) all the corresponding inclusion maps of pairs where the first terms are \( C \) and \( M \).
10. Given \( i \in \{1, \ldots, s\} \) we write \( \partial_A Q_i = \partial_A C \cap Q_i \) and \( \partial_B Q_i = \partial_B C \cap Q_i \). Note that \( \partial Q_i = \partial_A Q_i \cup \partial_B Q_i \).
11. Given \( i \in \{1, \ldots, s\} \) we denote by \( q_i : Q_i \to C \) the inclusion map and we denote by \( q_i \) also all the corresponding inclusion maps of pairs where the first terms are \( Q_i \) and \( C \).
12. Note that \( C \) and each \( Q_i \) are codimension-zero submanifolds of \( M \). We equip these submanifolds with the corresponding orientation introduced in Lemma 86.17.

\(^{1337}\) Admittedly, the case that \( M \) has boundary also requires the generalization of Lemma 89.5 to the case that \( W \) is a codimension-zero submanifold with corner. But that is not really a problem.
We illustrate some of the definitions in Figure 1315.

Now we consider the following diagram:

\[
\begin{array}{c}
H^i(M) \times H^k(M) \xrightarrow{\cdot} H^m(M) \xrightarrow{\cap [M]} H_0(M) \xrightarrow{\epsilon_M} \mathbb{Z} \\
\uparrow p^* \times p^* \qquad \uparrow p^* \qquad \downarrow \\
H^i(M, M \setminus \hat{A}) \times H^k(M, M \setminus \hat{B}) \xrightarrow{\cdot} H^m(M, M \setminus \hat{C}) \xrightarrow{\cap p_*(|M|)} H_0(M) \xrightarrow{\epsilon_M} \mathbb{Z} \\
\downarrow c_* \times c_* \qquad \downarrow c_* \qquad \uparrow c_* \\
H^i(C, \partial A C) \times H^k(C, \partial B C) \xrightarrow{\cdot} H^m(C, \partial C) \xrightarrow{\cap [C]} H_0(C) \xrightarrow{\epsilon_C} \mathbb{Z} \\
\bigoplus_{i=1}^s H^i(Q_i, \partial A Q_i) \times H^k(Q_i, \partial B Q_i) \xrightarrow{\bigoplus \cup} \bigoplus_{i=1}^s H^m(Q_i, \partial Q_i) \xrightarrow{\bigoplus \epsilon_i} \bigoplus_{i=1}^s H_0(Q_i) \xrightarrow{\sum q_*} \mathbb{Z}.
\end{array}
\]

Claim 1. The above diagram commutes.

In the following we deal with all of the nine squares of the diagram.

(a) The left squares in the first and second row commute by Proposition 82.4 (1).

(b) The left square in the third row commutes by Lemma 83.9 (1) together with the aforementioned Proposition 82.4 (1).

(c) The middle square in the first row commutes by Lemma 83.8 (1).

(d) It follows from our orientation conventions and Lemma 87.24 that \(c_*([C]) = p_*(|M|)\).

It follows from Lemma 83.8 (1) that the middle square in the second row commutes.

(e) It follows from the remark on page 2121 that \(\sum_{i=1}^n q_*(|Q_i|) = [C]\). Now we obtain from Lemma 83.8 (1) and Lemma 83.9 (2) that the middle square in the third row commutes.

(f) The squares that involve the augmentation maps commute by the discussion on page 1088.

We introduce a few last pieces of notation:

(1) We denote by \(a: (A, \partial A) \to (M, M \setminus \hat{A})\) and \(b: (B, \partial B) \to (M, M \setminus \hat{B})\) the inclusion maps, note that \(a\) and \(b\) induce isomorphisms on cohomology by excision, see page 1840 for details.

\[1338\] Many of the vertical maps in the diagram are isomorphisms by excision, see page 1840 for details. But this is in fact irrelevant for our purpose.
We provide the proofs for the three statements of the claim.

(14) We write
\[ \alpha = (a^*)^{-1}(\text{PD}_A([X])) \in H^i(M, M \setminus \hat{A}) \] and \[ \beta = (b^*)^{-1}(\text{PD}_B([Y])) \in H^k(M, M \setminus \hat{B}). \]

(15) Given \( i \in \{1, \ldots, s\} \) we write \( X_i = X \cap Q_i \) and \( Y_i = Y \cap Q_i \). It follows from Proposition 94.8 (e) and (f) that \( X_i \) and \( Y_i \) are codimension 0 submanifolds of \( X \) and \( Y \). Since \( X \) and \( Y \) are oriented we can view \( X_i \) and \( Y_i \) also as oriented topological manifolds. As usual we denote by \([X_i] \in H_k(X_i, \partial X_i)\) and \([Y_i] \in H_k(Y_i, \partial Y_i)\) the corresponding fundamental classes. With the same convention as before we denote by \([X_i]\) also the image under the inclusion induced map \( H_k(X_i, \partial X_i) \to H_k(Q_i, \partial B Q_i) \) and similarly we denote by \([Y_i]\) also the image under the inclusion induced map \( H_k(Y_i, \partial Y_i) \to H_k(Q_i, \partial A Q_i) \).

Claim 2. We have
(a) We have \( p^*(\alpha) = \text{PD}_M([X]) \in H^i(M) \) and \( p^*(\beta) = \text{PD}_M([Y]) \in H^k(M) \).
(b) For any \( i \in \{1, \ldots, s\} \) we have
\[ (q_i^* \circ c)^*(\alpha) = \text{PD}_{Q_i}([X_i]) \in H^i(Q_i, \partial A Q_i) \] and \( (q_i^* \circ c)^*(\beta) = \text{PD}_{Q_i}([Y_i]) \in H^k(Q_i, \partial B Q_i) \).
(c) For any \( i \in \{1, \ldots, s\} \) we have
\[ \epsilon_{Q_i}((\text{PD}_{Q_i}([X_i]) \cup \text{PD}_{Q_i}([Y_i])) \cap [Q_i]) = \sigma_i. \]

We provide the proofs for the three statements of the claim.

(a) By Lemma 89.5 the following diagram commutes:

\[
\begin{array}{c}
H_k(A) \\
\text{PD}_A \downarrow \ \\
H_k(M) \\
\end{array} \xymatrix{ & H^i(A, \partial A) \ar[r]^\cong & H^i(M, M \setminus \hat{A})}
\]

We apply this commutative diagram to \([X] \in H_k(A)\) and we obtain immediately that \( p^*(\alpha) = \text{PD}_M([X]) \). The same way one shows that \( p^*(\beta) = \text{PD}_M([Y]) \).

(b) Let \( i \in \{1, \ldots, s\} \). We denote by \( r_i: Q_i \to A \) the inclusion map. We consider the following diagram:

\[
\begin{array}{c}
H_k(A) \\
\text{PD}_A \downarrow \ \\
H_k(A, A \setminus \hat{Q_i}) \\
\end{array} \xymatrix{ & H^i(A, \partial A) \ar[r]^\cong & H^i(M, M \setminus \hat{A})}
\]

We make the following observations:
(a) The triangle on the right commutes since \( a \circ r_i = c \circ q_i: Q_i \to M \) are both the inclusion map.
(β) It follows from Lemma 89.6 applied to the codimension-zero submanifold $Q_i$ of $A$, that the rectangle commutes.\footnote{One can easily convince oneself that $\partial A Q_i = \partial_i Q_i$ and $\partial B Q_i = \partial_j Q_i$ for $Q_i$ viewed as a submanifold with corner of $A$.}

(γ) By Lemma 87.24 we have $r_{is}(\{X_i\}) = [X] \in H_k(\partial A \setminus \partial_i Q_i)$.

(δ) By the Excision Theorem 89.2 the map $r_{is}: H_k(Q_i, \partial_i Q_i) \to H_k(\partial A \setminus \partial_i Q_i)$ is an isomorphism.

The desired equality $(q_i^* \circ e^*)(\alpha) = PD_{Q_i}(\{X_i\})$ follows from the above commutative diagram applied to $[X] \in C_k$. Exactly the same way we can also show that $(q_i^* \circ e^*)(\beta) = PD_{Q_i}([Y_i])$.

(c) Let $i \in \{1, \ldots, s\}$. We set $Z = B_k \times B'$. We consider the following diagram:

$$
\begin{array}{ccc}
H^t(Q_i, \partial A Q_i) \times H^k(Q_i, \partial B Q_i) & \to & H^m(Q_i, \partial B Q_i) \\
\psi^* \times \psi^* & & \psi^* \\
H^t(Z, B_k \times \partial B) \times H^k(Z, \partial B^k \times B') & \to & H^m(Z, \partial B) \times \psi^* [Z] \quad \psi^* = \\
\end{array}
$$

As in the previous diagram, the squares to the left and right commute. The middle square is slightly more interesting. Lemma 94.9 says that $\Psi_{is}(\{Q_i\}) = \sigma_i \cdot [Z]$. Using this observation we obtain once again from Lemma 83.8 (1) that the middle square commutes. We calculate that

by the above commutative diagram

$$
\epsilon_Q(\{PD_{Q_i}(\{X_i\}) \cup PD_{Q_i}(\{Y_i\})\} \cap \{Q_i\}) = \sigma_i \cdot \epsilon_Z(\{\Psi^*_i(PD_{Q_i}(\{X_i\})) \cup \Psi^*_i(PD_{Q_i}(\{Y_i\}))\} \cap [Z])
$$

$$
= \sigma_i \cdot \epsilon_Z(\{PD_Z([B_k \times 0]) \cup PD_Z([0 \times B'])\} \cap [Z])
$$

by Proposition 94.8 (d)

$$
= \sigma_i \cdot \epsilon_{B_k \times B'}([B_k \times B']^* \cap [B_k \times B']) = \sigma_i.
$$

Proposition 88.2 definition of the dual fundamental class \tag*{\Box}

After all these preparations we can prove the desired equality:

by the first row of the commutative diagram from Claim 1 and by Claim 2 (a)

$$
\epsilon_M((PD_M([X]) \cup PD([Y])) \cap [M]) = \sigma_M((\alpha \cap \beta) \cap p_*(\{M\}))
$$

$$
= \sum_{i=1}^{s} \epsilon_Q((PD_{Q_i}(\{X_i\}) \cup PD_{Q_i}(\{Y_i\})) \cap \{Q_i\}) = \sum_{i=1}^{s} \sigma_i.
$$

by the second and third row of commutative diagram from Claim 1 and by Claim 2 (b) by Claim 2 (c)

This concludes the proof of the theorem. \tag*{\blacksquare}

Remark. Towards the end of the proof of the theorem we marked in red color that we used Proposition 88.2. Most of the other statements that we used in the proof were fairly straightforward lemmas regarding cup and cap products. But arguably the key ingredient
in the proof is Proposition 88.2 which was a variation on Proposition 84.2 and which in turn was a fairly straightforward consequence of the Product Theorem 84.1.

94.4. **Algebraic intersection numbers of complex submanifolds.** In the following section we will apply Theorem 94.5 to the study of the complex projective spaces \( \mathbb{CP}^n \). Before we do so it is convenient to study the algebraic intersection numbers of complex submanifolds of any complex manifold.

First let us recall the following definition that goes all the way back to pages 447 and 450.

**Definition.**

(1) An *n*-dimensional complex manifold is a \( 2n \)-dimensional smooth manifold \( M \) without boundary together with a smooth atlas \( \{ \phi_j: U_j \to V_j \}_{j \in J} \) such that all transition maps are biholomorphisms.

(2) We define the maximal holomorphic atlas of a complex manifold the same way as we defined the maximal smooth atlas of a smooth manifold, see page 279.

(3) We say \( W \subset M \) is a *k*-dimensional complex submanifold if for every point \( P \in W \) there exists a chart \( \phi_j: U_j \to V_j \) from the maximal holomorphic atlas with \( P \in U_j \) and which satisfies that \( \phi_j(U_j \cap W) \subset \mathbb{C}^k \times \{0\} \).

(4) Let \( V \) be an \( n \)-dimensional complex vector space. We say that a set of vectors \( \{v_1, \ldots, v_n\} \) in \( V \) is **totally real** if the vectors \( v_1, iv_1, \ldots, v_n, iv_n \) form a basis of \( V \), viewed as a \( 2n \)-dimensional real vector space.

**Remark.**

(1) Let \( M \) be a complex manifold. It follows easily from the definitions that every complex submanifold of \( M \) is a complex manifold in its own right.

(2) Let \( V \) be an \( n \)-dimensional complex vector space. In Lemma 12.6 we showed that \( V \) admits a set of totally real vectors and that the ordered basis \( v_1, iv_1, \ldots, v_n, iv_n \) give a well-defined basis of the \( 2n \)-dimensional real vector space \( V \), called the canonical basis.

(3) Let \( M \) be an \( n \)-dimensional complex manifold. In Proposition 12.7 we showed that \( T_PM \) is canonically a complex vector space and we showed that the corresponding canonical orientations define a canonical orientation of \( M \), viewed as a \( 2n \)-dimensional smooth manifold.

Now we can formulate this elementary but rather useful lemma.

**Lemma 94.10.** Let \( M \) be a closed complex manifold and let \( X \) and \( Y \) be two closed complex submanifolds of \( M \) with \( \dim(X) + \dim(Y) = \dim(M) \). Then the following hold:

1. The sign at every transverse intersection point of \( X \) and \( Y \) is equal to +1.
2. If \( X \) and \( Y \) intersect transversally, then the algebraic intersection number equals the geometric intersection number.

**Proof.**

(1) We write \( k = \dim(X) \) and \( l = \dim(Y) \). Suppose that \( P \) is a transverse intersection point of \( X \) and \( Y \). We pick a totally real basis \( v_1, \ldots, v_k \) for the complex vector space \( T_PX \) and we pick a totally real basis \( w_1, \ldots, w_l \) for the complex vector space...
\( T_P Y \). Then \( v_1, \ldots, v_k, w_1, \ldots, w_l \) is evidently a totally real basis for the complex vector space \( T_P X \oplus T_P Y = T_P M \). We have

\[
\begin{align*}
  v_1, iv_1, \ldots, v_k, iv_k, w_1, iw_1, \ldots, w_l, iw_l &= v_1, iv_1, \ldots, v_k, iv_k, w_1, iw_1, \ldots, w_l, iw_l.
\end{align*}
\]

This shows that \( \text{sign}(P) = +1 \). We have concluded the proof of the first statement. \( \square \)

**Example.** We consider the complex projective space \( \mathbb{C}P^n \). In Lemma 12.5 we saw that \( \mathbb{C}P^n \) is a complex manifold of complex dimension \( n \). It follows easily from the definitions that for any \( k \leq n \) the subset

\[
X_k := \{ [z_0 : \ldots : z_k : 0 : \ldots : 0] \mid (z_0, \ldots, z_k) \in \mathbb{C}^{k+1} \setminus \{0\} \}
\]

is a \( k \)-dimensional complex submanifold. Similarly we see that for any \( l \leq n \) the subset

\[
Y_l := \{ [0 : \ldots : 0 : z_{n-l} : \ldots : z_n] \mid (z_{n-l}, \ldots, z_n) \in \mathbb{C}^{l+1} \setminus \{0\} \}
\]

is an \( l \)-dimensional complex submanifold. Evidently \( X_k \) and \( Y_l \) are biholomorphic to \( \mathbb{C}P^k \) respectively \( \mathbb{C}P^l \). Furthermore given any \( k \leq n \) we have

\[
X_k \cap Y_{n-k} = \begin{bmatrix} 0 : \ldots : 0 : 1 : 0 : \ldots : 0 \end{bmatrix}
\]

consists of a single point \( P \). We leave it as an illuminating exercise to verify that \( X_k \) and \( Y_{n-k} \) intersect transversally at \( P \). It follows from Lemma 94.10 that \( X_k \cdot Y_{n-k} = 1 \). The same way we also see that \( Y_k \cdot X_{n-k} = 1 \).

### 94.5. Applications of Theorem 94.5 to complex projective spaces.

In this section we will give two more applications of Theorem 94.5.

**Notation.** Let \( n \in \mathbb{N} \) and let \( m \in \{0, \ldots, n\} \).

1. We consider the inclusion map

\[
i_{m,n} : \mathbb{C}P^m \rightarrow \mathbb{C}P^n \quad \quad [z_0 : \ldots : z_m] \mapsto [z_0 : \ldots : z_m : 0 : \ldots : 0].
\]

When \( m \) and \( n \) are understood we write \( i \) instead of \( i_{m,n} \). Recall that in Lemma 90.6 we showed that for any \( k \leq 2m \) the induced maps \( i_* : H_k(\mathbb{C}P^m; \mathbb{Z}) \rightarrow H_k(\mathbb{C}P^n; \mathbb{Z}) \) and \( i^* : H^k(\mathbb{C}P^m; \mathbb{Z}) \rightarrow H^k(\mathbb{C}P^n; \mathbb{Z}) \) are isomorphisms.

2. By a slight abuse of notation we abbreviate \( (i_{m,n})_*([\mathbb{C}P^m]) \) to \( [\mathbb{C}P^m] \in H_{2m}(\mathbb{C}P^n; \mathbb{Z}) \). Furthermore, again by a slight abuse of notation, we write \( [\mathbb{C}P^m]^* \in H^{2m}(\mathbb{C}P^n; \mathbb{Z}) \) for the unique element with \( \langle [\mathbb{C}P^m]^*, [\mathbb{C}P^m] \rangle = 1 \). Finally we write \( x = [\mathbb{C}P^1]^* \).

Now we can formulate the main result of this section.

**Proposition 94.11.** Let \( n \in \mathbb{N} \). For every \( k \in \{0, \ldots, n\} \) we have

\[
([\mathbb{C}P^1]^*)^k = [\mathbb{C}P^k]^* \in H^{2k}(\mathbb{C}P^n; \mathbb{Z}).
\]
Remark. In Proposition 90.7 we had used the Poincaré Duality Theorem 88.1 to show that for given \( n \in \mathbb{N} \) and \( k \in \{0, \ldots, n\} \) the \( k \)-th power \( x^k \in H^{2k}(\mathbb{C}P^n; \mathbb{Z}) \cong \mathbb{Z} \) is a generator. In other words, we had proved that \( x^k = \pm [\mathbb{C}P^n]^* \). Proposition 94.11 is a much better result since it allows us to nail down the cohomology class \( x^k \). In particular we see that Proposition 94.11 gives an affirmative answer to Question 90.8.

The key to the proof of Proposition 94.11 is the following lemma.

**Lemma 94.12.** Let \( n \in \mathbb{N} \). For any \( k \in \{0, \ldots, n\} \) we have

\[
\text{PD}_{\mathbb{C}P^n}([\mathbb{C}P^k]) \cup \text{PD}_{\mathbb{C}P^n}([\mathbb{C}P^{n-k}]) = [\mathbb{C}P^n]^* \in H^{2n}(\mathbb{C}P^n; \mathbb{Z}).
\]

**Proof.** Let \( n \in \mathbb{N} \). For \( k \in \{0, \ldots, n\} \) we consider the inclusion map

\[
t_k,n : \mathbb{C}P^k \to \mathbb{C}P^n
\]

\[
[z_0 : \ldots : z_k] \mapsto [0 : \ldots : 0 : z_0 : \ldots : z_k].
\]

We also consider the map

\[
\Phi : \mathbb{C}P^k \times [0, 1] \to \mathbb{C}P^n
\]

\[
([z], t) \mapsto \left[ \left( z \cdot \cos \left( t \cdot \frac{\pi}{2} \right), 0 \right) + \left( 0, z \cdot \sin^2 \left( t \cdot \frac{\pi}{2} \right) \right) \right].
\]

Then

\[
\text{PD}([\mathbb{C}P^k]) \cup \text{PD}([\mathbb{C}P^{n-k}]), [\mathbb{C}P^n]) = \text{PD}(i_{k,n*}([\mathbb{C}P^k])) \cup \text{PD}(i_{n-k,n*}([\mathbb{C}P^{n-k}]), [\mathbb{C}P^n])
\]

\[
= \text{PD}(t_{k,n*}([\mathbb{C}P^k])) \cup \text{PD}(i_{n-k,n*}([\mathbb{C}P^{n-k}]), [\mathbb{C}P^n])
\]

\[
\uparrow
\]

by Proposition 9.5 since \( \Phi \) is a homotopy from \( i_{k,n} \) to \( t_{k,n} \)

\[
= \text{PD}([t_{k,n}(\mathbb{C}P^k)]) \cup \text{PD}([i_{n-k,n}(\mathbb{C}P^{n-k})], [\mathbb{C}P^n])
\]

\[
= t_{k,n}(\mathbb{C}P^k) \cdot i_{n-k,n}(\mathbb{C}P^{n-k}) = 1.
\]

\[
\uparrow
\]

by Theorem 94.5 since the submanifolds \( t_{k,n}(\mathbb{C}P^k) \) and \( i_{n-k,n}(\mathbb{C}P^{n-k}) \) are transverse

By definition of the dual fundamental class this implies the desired result. \( \blacksquare \)

We record the following fairly immediate corollary.

**Corollary 94.13.** Let \( n \in \mathbb{N} \). For any \( k \in \{0, \ldots, n\} \) we have

\[
\text{PD}_{\mathbb{C}P^n}([\mathbb{C}P^k]) = [\mathbb{C}P^{n-k}]^* \in H^{2n-2k}(\mathbb{C}P^n; \mathbb{Z}).
\]

\[1340\text{It is quite straightforward to verify that this map is well-defined, i.e. it does not depend on the choice of the representative } z \in \mathbb{C}P^{k+1} \setminus \{0\} \text{ and it does indeed take values in } \mathbb{CP}^n \text{ since for any } t \in [0, 1] \text{ we have } (z \cdot \cos^2 (t \cdot \frac{\pi}{2}), 0) + (0, z \cdot \sin^2 (t \cdot \frac{\pi}{2})) \neq 0. \text{ Also note that it follows fairly easily from Proposition 18.20 that the map is continuous.} \]
Proof. Let \( n \in \mathbb{N} \) and let \( k \in \{0, \ldots, n\} \). Then

\[
\langle \text{PD}_{\mathbb{P}^n}([\mathbb{C}P^k]), [\mathbb{C}P^{n-k}] \rangle = \langle \text{PD}_{\mathbb{P}^n}([\mathbb{C}P^k]), \text{PD}_{\mathbb{P}^n}([\mathbb{C}P^{n-k}]) \cap [\mathbb{C}P^n] \rangle = \langle \text{PD}_{\mathbb{P}^n}([\mathbb{C}P^k]) \cup \text{PD}_{\mathbb{P}^n}([\mathbb{C}P^{n-k}]), [\mathbb{C}P^n] \rangle = 1.
\]

By definition of the dual fundamental class this implies the desired result. \[\square\]

Now we can provide the proof of Proposition 94.11.

Proof of Proposition 94.11. Recall that we need to show that for every \( n \in \mathbb{N} \) and every \( k \in \{0, \ldots, n\} \) we have \( ([\mathbb{C}P^1]^*)^k = [\mathbb{C}P^k]^* \in H^{2k}(\mathbb{C}P^n; \mathbb{Z}) \). We start out with the following observation that follows immediately from the discussion on page 2289 and Lemma 81.10.

Observation. Let \( m \in \mathbb{N} \) and let \( k \in \{1, \ldots, m\} \). If \( ([\mathbb{C}P^1]^*)^k = [\mathbb{C}P^k]^* \in H^{2k}(\mathbb{C}P^m; \mathbb{Z}) \), then for any \( n \geq m \) we also have \( ([\mathbb{C}P^1]^*)^k = [\mathbb{C}P^k]^* \in H^{2k}(\mathbb{C}P^n; \mathbb{Z}) \).

By the observation it suffices to prove the following claim.

Claim. For any \( n \in \mathbb{N} \) we have \( ([\mathbb{C}P^1]^*)^n = [\mathbb{C}P^n]^* \in H^{2n}(\mathbb{C}P^n; \mathbb{Z}) \).

We prove the claim by induction on \( n \). For \( n = 1 \) the statement holds by definition. So suppose that the statement holds for some \( n - 1 \) with \( n \geq 2 \). Then the following equality holds in \( H^{2n}(\mathbb{C}P^n; \mathbb{Z}) \):

\[
([\mathbb{C}P^1]^*)^n = ([\mathbb{C}P^1]^*)^{n-1} \cup [\mathbb{C}P^1]^* = [\mathbb{C}P^{n-1}]^* \cup [\mathbb{C}P^1]^* = \text{PD}([\mathbb{C}P^1]) \cup \text{PD}([\mathbb{C}P^{n-1}]) = [\mathbb{C}P^n]^*.
\]

This concludes the proof of the claim and thus of the proposition. \[\square\]

Now we can answer Question 10.10.

Proposition 94.14. Every tubular neighborhood of \( \mathbb{C}P^1 = i_{1,2}(\mathbb{C}P^1) \) in \( \mathbb{C}P^2 \) is non-trivial.

In Figure 147 we had implicitly seen that the tubular neighborhood of \( \mathbb{R}P^1 \) in \( \mathbb{R}P^2 \) is a Möbius band, and thus non-trivial. The above proposition is thus an analogue of this simpler, and more visual, observation.

Proof. Suppose that \( \mathbb{C}P^1 \) admits a trivial tubular neighborhood in \( \mathbb{C}P^2 \). By definition this would mean that there exists a smooth embedding \( \Phi: \mathbb{C}P^1 \times \overline{B}^2 \to \mathbb{C}P^2 \) with \( \Phi(P,0) = P \) for all \( P \in \mathbb{C}P^1 \). We denote by \( i = i_{1,2} : \mathbb{C}P^1 \to \mathbb{C}P^2 \) the usual inclusion map and we denote

\[\text{We refer to page 421 for the definition of a trivial tubular neighborhood.}\]
by \( f : \mathbb{CP}^1 \to \mathbb{CP}^2 \) the smooth embedding that is given by \( P \mapsto \Phi(P, 1) \). Then

\[
\pm 1 = \langle \text{PD}(i_*(\langle \mathbb{CP}^1 \rangle)) \cup \text{PD}(i_*(\langle \mathbb{CP}^1 \rangle)), [\mathbb{CP}^2] \rangle = \langle \text{PD}(i_*(\langle \mathbb{CP}^1 \rangle)) \cup \text{PD}(f_*(\langle \mathbb{CP}^1 \rangle)), [\mathbb{CP}^2] \rangle
\]

Proposition 94.11 or alternatively by Proposition 42.5 since \( i, f : \mathbb{CP}^1 \to \mathbb{CP}^2 \) are homotopic via the homotopy \( (P, t) \mapsto \Phi(P, t) \).

\[
i((\mathbb{CP}^1)) \cdot f((\mathbb{CP}^1)) = 0.
\]

by Theorem 94.5 since \( i(\mathbb{CP}^1) \) and \( f(\mathbb{CP}^1) \) are disjoint.

We have thus obtained a contradiction.

94.6. Is the algebraic intersection number a complete invariant? It is natural to ask whether the converse to Proposition 94.6 (2) holds. Playing around with curves on a surface shows that this looks dubious:

**Example.** We consider the oriented curves \( X \) and \( Y \) on the surface of genus 2 that are illustrated in Figure 1316. Their algebraic intersection number is zero. There are several ways to see that the curves cannot be made disjoint:

1. In Exercise 94.12, we will use covering spaces to see that the curves cannot be made disjoint.

2. The so-called bigon criterion says that if \( M \) is a closed 2-dimensional smooth manifold and if \( C \) and \( D \) are closed oriented curves on \( M \) that intersect transversally, then \( C \) and \( D \) have the minimal number of geometric intersection points within their smooth isotopy classes if and only if \( C \) and \( D \) do not form a bigon, see Figure 1317. We refer to [FaM11] Proposition 1.7] for details and a proof.

If one thinks for a while about the previous example, then one realizes that the issue in the example is that the smooth manifold \( M \) is not simply connected. So it is more reasonable to demand some condition on the fundamental groups.

**Question 94.15.** Let \( M \) be an oriented \( m \)-dimensional smooth manifold and let \( X \) and \( Y \) be complementary connected submanifolds of \( M \). Suppose that \( X \cdot Y = 0 \) and that \( M \) is simply connected, does it follow that \( X \) and \( Y \) can be made disjoint?

It turns out that the answer depends on the dimension of \( M \).
Theorem 94.16. (Whitney) Let $M$ be an oriented simply connected smooth manifold and let $X$ and $Y$ be complementary connected submanifolds of $M$.

1. The answer to Question 94.15 is yes if $\dim(X) \geq 3$ and $\dim(Y) \geq 3$.
2. The answer to Question 94.15 is yes if $\dim(X) = 2$, $\dim(Y) \geq 3$ and $\pi_1(M \setminus Y) = 0$.

Remark. The fact that we have a positive answer to Question 94.15 in dimensions $\geq 6$ turns out to be extremely useful, since, together with Theorem 94.5, it makes it possible to translate algebraic topological data, namely cup products, directly into geometric statements. This fact was a key ingredient in Hassler Whitney’s proof that every $n$-dimensional smooth manifold without boundary can be embedded into $\mathbb{R}^{2n}$, see Theorem 11.14. Furthermore, as explained in [Miln65b], this fact played a crucial role in Steven Smale’s proof of the Poincaré Conjecture in dimensions $\geq 5$, see Theorem ??.

For dimensions $\geq 5$ the theorem was proved by Hassler Whitney [Why44a, Theorem 4] in 1944. An exposition of the proof is also given in [Kir13, Scor05, Chapter 1.5], [Miln65b, Theorem 6.6], [GoS99, Theorem 9.2.7] or [RS72, Theorem 5.12]. We only give a quick outline of the proof. Our main goal is to show where the restrictions on the dimensions enter.

Sketch of a proof of Theorem 94.16 (1). Let $M$ be an oriented simply connected $m$-dimensional smooth manifold and let $X$ and $Y$ be complementary connected submanifolds of $M$ with $X \cdot Y = 0$ and with $\dim(X) \geq 3$ and $\dim(Y) \geq 3$. We do induction on the geometric intersection number $\#(X \cap Y)$. If $X \cap Y = \emptyset$, then there is nothing to prove. Now suppose that $X \cap Y \neq \emptyset$. There exist two intersection points $P$ and $Q$ of opposite signs. Since $X$ is connected we obtain from Corollary 8.38 an embedded curve $\alpha$ on $X$ from $P$ to $Q$ and since $Y$ is connected we can similarly find an embedded curve $\beta$ on $Y$ from $Q$ to $P$. Note that $\varphi := \alpha \ast \beta$ is in fact a loop. Since $M$ is simply connected the curve $\varphi = \alpha \ast \beta$: $S^1 \to M$ is null-homotopic.

By Lemma 14.1 there exists a map $\Phi: \overline{B}^2 \to M$ with $\Phi|_{S^1} = \varphi$. Theorem 9.15 suggests that we can find a homotopy from $\Phi$ to a map $\Psi: \overline{B}^2 \to M$ with $\Psi(S^1) = \Phi(S^1)$ and such that $\Psi: \overline{B}^2 \to M$ is a smooth embedding. It follows from $\dim(X) \geq 3$ and $\dim(Y) \geq 3$ that $\dim(\Phi(\overline{B}^2)) + \dim(X) < \dim(M)$ and $\dim(\Phi(\overline{B}^2)) + \dim(Y) < \dim(M)$. Thus the Transversality Theorem 9.10 suggests that we can find a further smooth isotopy so that we end up with an embedded disk $D$ with $\partial D = |\varphi| = |\alpha| \cup |\beta|$ and such that the interior of the disk intersects neither $X$ nor $Y$. One can now use this disk to find a smooth isotopy of $X$ that removes the two intersection points $P$ and $Q$ without creating new intersection points. The precise construction of the smooth isotopy is rather delicate. In fact, as the perspicacious reader might have noticed, so far we have not yet used that $P$ and $Q$ have opposite signs. We need it in finding this last smooth isotopy. We refer to the aforementioned references for the details.

\[\text{Here the exposition starts becoming rather vague.}\]
\[\text{Here there are some issues since the map } \alpha \ast \beta: S^1 \to M \text{ is not smooth at two points. In particular it is not quite clear what “smooth embedding” is supposed to mean.}\]
Remark. The approach taken in the proof of making submanifolds disjoint using embedded disks is often referred to as the “Whitney trick”.

It turns out that we also have an affirmative answer to Question 94.15 in very low dimensions.

**Theorem 94.17.** The answer to Question 94.15 is also yes if the dimension of the smooth manifold is \( \leq 3 \).

**Proof.** The theorem is trivial for 1-dimensional smooth manifolds. For 2-dimensional smooth manifolds the proof is an amusing exercise using the fact, proved in the Surface Classification Theorem 23.4, that every simply connected 2-dimensional smooth manifold is diffeomorphic to \( S^2 \) or to \( \overline{B^2} \).

For 3-dimensional smooth manifolds the proof is similar to the proof in dimensions \( \geq 5 \) except that one also needs to make use of the Loop Theorem (see [Pap57a] and [Hem76]) to find the embedded disk needed for the “Whitney trick”. We leave it as a slightly challenging exercise to fill in the details in the 3-dimensional setting.

So we are still missing 4-dimensional smooth manifolds. Here the situation becomes tricky. It was known by 1961, see [KeM61], that the approach of the proof of Theorem 94.16, i.e. the Whitney trick, does not work for 4-dimensional smooth manifolds. Later, see [Lacke96], it was also shown that the Whitney trick does not work for 4-dimensional topological manifolds either.

In the 4-dimensional setting it is not only the case that the Whitney trick does not work. But more fundamentally, Question 94.15 has in fact a negative answer. For example it is known that there exist closed simply connected 4-dimensional smooth manifolds and embedded spheres \( X, Y \) with zero intersection number that cannot be made disjoint by a smooth isotopy, in fact they cannot even be made disjoint by an isotopy that is not
necessarily smooth, see e.g. [As98] Theorem 1.2 for details. As is pointed out in [As98], Proposition 3.9, it is a consequence of the Freedman disk smooth embedding theorem [FQ90], Theorem 5.1.A that under even stronger hypotheses the algebraic intersection number is in fact a complete invariant in the setting of 4-dimensional topological manifolds.

Later, in Chapter ?? we will see that 4-dimensional smooth manifolds exhibit many peculiar properties. Arguably the main reason why 4-dimensional smooth manifolds differ dramatically from higher-dimensional smooth manifolds is the failure of the Whitney trick.

94.7. Higher dimensional analogue of Theorem 94.5. Let $M$ be a compact oriented $m$-dimensional smooth manifold, let $X \subset M$ be a closed oriented submanifold of dimension $k$ and let $Y$ be a compact oriented proper submanifold of the complementary dimension $m - k$. We suppose that $X$ and $Y$ are transverse. By assigning to each intersection point in $X \cap Y$ the sign introduced on page 2271 we can view $X \cap Y$ as a 0-dimensional oriented submanifold of $M$.

With this convention we can reformulate the conclusion of Theorem 94.5 as follows:

**Theorem 94.18.** With the above notation we have

$$\text{PD}_M([X]) \cup \text{PD}_M([Y]) = \text{PD}_M([X \cap Y]) \in H^m(M, \partial M; \mathbb{Z}).$$

**Proof.** Using Lemma 83.9 one can easily verify that it suffices to prove the theorem for each connected component of $M$ separately. Put differently, without loss of generality we can assume that $M$ is connected. We denote by $P_1, \ldots, P_n$ the points in $X \cap Y$ and we denote by $\sigma_1, \ldots, \sigma_n \in \{\pm 1\}$ the corresponding signs. Now we calculate that

$$\text{PD}_M([X]) \cup \text{PD}_M([Y]) = (X \cdot Y) \cdot [M]^* = \sum_{i=1}^n \sigma_i [M]^* = \sum_{i=1}^n \text{PD}_M(\sigma_i \cdot \{P_i\}) = \text{PD}_M([X \cap Y]).$$

by Theorem 94.5 and since $M$ is connected see page 2154.

The formulation of Theorem 94.18 has the nice feature that with some effort one can also generalize it to submanifolds that are not of complementary dimensions. Before we can formulate this generalization we need to formulate the following lemma.

**Lemma 94.19.** Let $M$ be an oriented $m$-dimensional smooth manifold, let $X \subset M$ be an oriented proper submanifold and let $Y$ be an oriented proper submanifold. Suppose that $X$ and $Y$ intersect transversally. By Lemma 6.52 we know that $X \cap Y$ is a submanifold. Given $P \in X \cap Y$ we have a natural short exact sequence induced by the various inclusion maps:

$$0 \to T_P(X \cap Y) \to T_P X \oplus T_P Y \xrightarrow{\rho} T_P M \to 0.$$

We pick a set of vectors $C$ in $T_P X \oplus T_P Y$ such that $\rho(C)$ is a positive basis for $T_P M$. We say that a basis $B$ for $T_P(X \cap Y)$ is positive if the basis $\{B, C\}$ is a positive basis for $T_P X \oplus T_P Y$. This definition is independent of the choices and it turns $X \cap Y$ into an oriented submanifold of $M$.

More examples for the failure of the Whitney trick in dimension 4, i.e. for fact that the conclusion of Theorem 94.16 does not hold in dimension 4, are given in [Strl04, Section 15.1] and [Gil81].

Recall that on page 1718 we defined the orientation of a 0-dimensional manifold $M$ as a map $M \to \{\pm 1\}$.
**Proof.** We leave the elementary proof to the reader. ■

**Example.** Let \(n \in \mathbb{N}\) and let \(0 \leq k \leq l \leq n\). We consider \(\mathbb{C}P^n\) with the complex submanifolds

\[
A = \{[z_0 : \cdots : z_l : 0 : \cdots : 0] | (z_0, \ldots, z_l) \in \mathbb{C}^{l+1} \setminus \{0\}\}
\]

\[
B = \{[0 : \cdots : 0 : z_k : \cdots : z_l : 0 : \cdots : 0] | (z_k, \ldots, z_l) \in \mathbb{C}^{n+1-k} \setminus \{0\}\}
\]

and

\[
C = \{[0 : \cdots : 0 : z_k : \cdots : z_l : 0 : \cdots : 0] | (z_k, \ldots, z_l) \in \mathbb{C}^{l+1-k} \setminus \{0\}\}.
\]

As usual we equip \(\mathbb{C}P^n\) and \(A, B, C\) with the natural orientations coming from Proposition \(12.7\). Then \(A \cap B = C\) and one can easily show that the orientation of \(A \cap B\) equals the orientation of \(C\).

The following theorem is a generalization of Theorem \(94.18\) and thus also of Theorem \(94.5\).

**Theorem 94.20.** Let \(M\) be a compact oriented \(m\)-dimensional smooth manifold. Furthermore let \(X \subset M\) be a closed oriented submanifold of codimension \(k\) and let \(Y\) be a compact oriented proper submanifold of codimension \(l\). Then

\[
\text{PD}_M([X]) \cup \text{PD}_M([Y]) = \text{PD}_M([X \cap Y]) \in H^{k+l}(M, \partial M; \mathbb{Z}).
\]

**Proof.** A proof is given in [Bre93, Theorem VI.11.9]. ■

**Remark.**

(1) Theorem \(94.20\) can be summarized as saying that cup products correspond to taking intersections of submanifolds. With this point of view, the symbol “\(\cup\)” for the cup product does not seem to be a great choice.

(2) It is conceivable that the conclusion of Theorem \(94.20\) also holds if we have a decomposition \(\partial M = A \cup B\) of the boundary and have proper submanifold \(X\) and \(Y\) with \(\partial X \subset A\) and \(\partial Y \subset B\). We leave the task of verifying such a generalization to other authors.

**Examples.**

(1) Let \(M\) be the smooth manifold that is the complement in \(S^3\) of the three open solid tori and the open ball that are shown in Figure \(1320\). Furthermore let \(X\) and \(Y\) be the surfaces shown in that figure. Basically the same argument as on page \(2278\) shows that \([X]\) and \([Y]\) are non-trivial in \(H_2(M; \mathbb{Z})\). On the other hand the class \([X \cap Y]\) is clearly trivial. Therefore we deduce from Theorem \(94.20\) that \(\text{PD}_M([X]) \cup \text{PD}_M([Y]) = 0\).

(2) Using Theorem \(94.20\) and using the example preceding that theorem one can fairly easily give a completely geometric calculation of the cup product of \(\mathbb{C}P^n\).

**Remark.** Using Theorem \(94.20\) one can easily modify the proof of Proposition \(94.14\) to show that given any \(n \geq 2\) every tubular neighborhood of \(\mathbb{C}P^{n-1}\) in \(\mathbb{C}P^n\) is non-trivial.
Exercise 94.1. Let $M$ be a smooth manifold that admits two compact codimension-zero submanifolds $A$ and $B$ such that $A \cap B$ is a union of boundary components of $A$ and a union of boundary components of $B$. By the Mayer–Vietoris Theorem for Manifolds we obtain a long exact sequence

$$
\cdots \rightarrow H_n(A \cap B) \xrightarrow{i_A \cap B - i_A \cap B} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(M) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \rightarrow \cdots
$$

Let $X$ be a closed oriented $n$-dimensional submanifold of $M$ that intersects $A \cap B$ transversally.

(a) Show that $X \cap (A \cap B)$ is a closed $(n-1)$-dimensional submanifold of $A \cap B$.

We equip $X \cap (A \cap B)$ with the orientation coming from $X \cap (A \cap B) = \partial(X \cap A)$. We view the fundamental class $[X]$ as an element in $H_n(M)$ and we view the fundamental class $[X \cap (A \cap B)]$ as an element in $H_{n-1}(A \cap B)$.

(b) Show that $\partial_n([X]) = \pm [X \cap (A \cap B)] \in H_{n-1}(A \cap B)$.

(c) Determine the correct sign in (b).

Exercise 94.2. Let $A, B$ be two 1-dimensional oriented submanifolds of $S^2$ with $A \cdot B = 0$. Sketch a proof for the claim that $A$ and $B$ can be made disjoint via isotopies of $A$ and $B$.

Exercise 94.3. Let $M$ be a compact oriented $m$-dimensional smooth manifold. Furthermore let $k \in \{1, \ldots, m-1\}$, let $X$ be a proper oriented $k$-dimensional submanifold of $M$ and let $Y$ be a proper oriented $(m-k)$-dimensional submanifold of $M$. We denote by $i: X \rightarrow M$ and $j: Y \rightarrow M$ the inclusion maps. We could define the algebraic intersection number of $X$ and $Y$ via the formula in Theorem 94.5, i.e. we could define

$$
X \cdot Y := \langle \text{PD}_M(i_*([X])) \cup \text{PD}_M(j_*([Y])), [M] \rangle.
$$
Exercise 94.4. Let $M$ be a closed oriented connected $m$-dimensional smooth manifold. Furthermore let $p: \tilde{M} \to M$ be a finite covering.

(a) Let $X, Y$ be a complementary pair of submanifolds of $M$. We write $\tilde{X} := p^{-1}(X)$ and $\tilde{Y} := p^{-1}(Y)$. What is the relationship between $X \cdot Y$ and $\tilde{X} \cdot \tilde{Y}$? It suffices to give a short justification.

(b) Let $X$ be a closed oriented submanifold of $M$. What is the relationship between $PD_{\tilde{M}}([\tilde{X}])$ and $p^*(PD_M([X]))$?

(c) Reprove (a) using (b) and Theorem 94.5.

Exercise 94.5. Let $M$ be an oriented $m$-dimensional smooth manifold, let $X$ be a $k$-dimensional oriented proper submanifold and let $Y$ be an $(m-k)$-dimensional oriented proper submanifold of $M$. We suppose that $X \cap Y \cap \partial M = \emptyset$. What is the relationship between the algebraic intersection number $X \cdot Y$ in $M$ and $DX \cdot DY$ in $D M$?

Here, as always, given a smooth manifold $N$ we denote by $D M = N \cup_{\partial N = \partial N'} N'$ the double of $N$. We view $D M$ as an oriented smooth manifold where the orientation is chosen such that the orientation of $D M$ agrees with the orientation on $N$.

Exercise 94.6. Let $n \in \mathbb{Z}$. In Exercise 12.3 we showed that

$$W_n := \{ [x : y : z] \in \mathbb{CP}^2 \mid x^n + y^n + z^n = 0 \}$$

is a closed 1-dimensional complex submanifold of the complex projective space $\mathbb{CP}^2$. Show that $[W_n] = n \cdot [\mathbb{CP}^1] \in H_2(\mathbb{CP}^2; \mathbb{Z})$.

Hint. Use Lemma 94.10.

Exercise 94.7. Let $\Sigma \subset S^2 \times (-1, 1)$ be a closed surface. Suppose that there exists a $P \in S^2$ such that $\Sigma$ intersects $\{P\} \times [-1, 1]$ in a single point. Show that if this intersection point is a transversal intersection point, then $\Sigma$ intersects every path $\gamma: [0, 1] \to S^2 \times [-1, 1]$ from a point in $S^2 \times \{-1\}$ to a point in $S^2 \times \{1\}$.

Exercise 94.8. We consider the 2-dimensional smooth manifold $M$ that is shown together with the two proper submanifolds $X$ and $Y$ that are shown in Figure 1322. Show that $X$ and $Y$ cannot be made disjoint by a smooth isotopy that keeps the boundaries of $X$ and $Y$ fixed.

Figure 1322. Illustration of Exercise 94.8
Exercise 94.9. By accident you ended up buying a clock where both hands have the same length, so you can not distinguish the hand which shows the hour from the hand that indicates the minute. Fortunately, very often you can still tell the precise time. For example, in the configuration in Figure [1323] it does not make sense for the hand that is indicating the hour to be just before 9 whereas the hand showing the minute is at 15. We refer to Figure [1323] for an illustration.

Of course there will be some configurations when it is indeed impossible to tell which hand is which. How many such confusions moments will there be in a 12 hour period? 

*Hint.* Consider a suitable map $\gamma: S^1 \to S^1 \times S^1$.

\begin{figure}[h]
  \centering
  \includegraphics[width=0.6\textwidth]{clocks.png}
  \caption{Illustration for Exercise 94.11.}
\end{figure}

Exercise 94.10. Let $C$ and $D$ be closed curves in $\mathbb{R}^2$ that intersect transversally. Give a rigorous proof that the number of intersection points between $C$ and $D$ is an even number.

Exercise 94.11. Let $\alpha: S^1 \to S^1 \times S^2$ be a smooth embedding. We assume that there exists a $z \in S^1$ such that $\gamma(S^1)$ intersects the submanifold $\{z\} \times S^2$ in a single point $P$ and we assume that the intersection point is transversal intersection point of sign $+1$. Show that $\alpha: S^1 \to S^1 \times S^2$ is smoothly isotopic to the embedding $\beta: S^1 \to S^1 \times S^2$ that is given by $t \mapsto (t, P)$.

*Remark.* This statement is sometimes referred to as the *light bulb trick*.

\begin{figure}[h]
  \centering
  \includegraphics[width=0.5\textwidth]{light_bulb.png}
  \caption{Illustration for Exercise 94.11.}
\end{figure}

Exercise 94.12.

(a) Let $p: \widetilde{M} \to M$ be a finite covering and let $X$ and $Y$ be two submanifolds of $M$. Show that if $X$ and $Y$ can be made disjoint, then any component of $p^{-1}(X)$ can be made disjoint from any component of $p^{-1}(Y)$.

(b) We consider the surface $M$ of genus two together with the two submanifolds $X$ and $Y$ that are shown in Figure [1325]. Show that $X$ and $Y$ cannot be made disjoint.

*Remark.*
Exercise 94.13. Let $M$ be a compact oriented 2-dimensional smooth manifold. We consider the following construction:

$$H_1(M, \partial M) \times H_1(M, \partial M) \to \mathbb{Z}$$

$$(\sigma, \tau) \mapsto \text{algebraic intersection number } S \cdot T \text{ of proper transverse submanifolds } S \text{ and } T \text{ of } M \text{ with } [S] = \sigma \text{ and } [T] = \tau.$$ 

Does this give a well-defined map? We refer to Figure 1326 for an illustration.

Exercise 94.14. We consider the surface $\Sigma$ of genus 2 together with the four oriented curves $a_1, b_1, a_2, b_2$ that are shown in Figure 1327.

(a) Let $X$ be a closed oriented 1-dimensional submanifold of $\Sigma$ that intersects $a_1, b_1, a_2, b_2$ transversally. Show that

$$[X] = (X \cdot b_1) \cdot [a_1] - (X \cdot a_1) \cdot [b_1] + (Y \cdot b_2) \cdot [a_2] - (X \cdot a_2) \cdot [b_2] \in H_1(\Sigma).$$

These are the algebraic intersection numbers of oriented curves.

(b) Let $X$ and $Y$ be two closed oriented 1-dimensional submanifolds of $\Sigma$ that are both transverse to $a_1, a_2, b_1, b_2$. Show that if $X$ and $Y$ have the same algebraic intersection numbers with $a_1, a_2, b_1, b_2$, then $[X] = [Y] \in H_1(\Sigma)$.

Remark. The above gives a practical way, for $\Sigma$ and similarly for many other smooth manifolds, to determine precisely the homology class represented by a submanifold. In particular it can be used to deal with the type of problems as in Exercise 48.16.
95. INTERSECTIONS OF CYCLES AND THE CUP PRODUCT

In this chapter we generalize some of the results from Chapter 94. In particular we will define the "algebraic intersection number" of two maps of topological manifolds into a given topological manifold, as long as the maps intersect "nicely". This notion generalizes the algebraic intersection number of two transverse submanifolds of a given smooth manifold that we introduced on page 2271.

Furthermore we introduce the algebraic intersection number of two singular cycles that intersect "nicely". Afterwards we will see in Theorems 95.7 and 95.9 how these algebraic intersection numbers relate to the cup product. These theorems can be viewed as a generalization of Theorem 94.5.

For many applications the results from Chapter 94 are good enough and for many readers it might make sense to move on to the next chapter. The main application of the results of this chapter will be the Lefschetz-Hopf Theorem 96.9 and the Poincaré-Hopf Theorem 97.5.

Since much of this chapter is quite technical we start out with the following motivating question.

**Question 95.1.** As shown in Figure 1328 we consider the disk $\overline{B}^2$ together with the four points $P_\pm = (\pm 1, 0)$ and $Q_\pm = (0, \pm 1)$. Do there exist disjoint paths $\alpha$ and $\beta$ such that $\alpha$ connects $P_-$ to $P_+$ and $\beta$ connects $Q_-$ to $Q_+$?

![Figure 1328](image)

It is pretty clear that the answer should be no. In fact once we have developed all the tools we will find it quite easy to answer Question 95.1 in the negative. We refer to Lemma 95.8 for the details.

95.1. **The algebraic intersection number of maps of topological manifolds.** In this section we introduce the algebraic intersection number of two maps of topological manifolds into a given topological manifold. The precise setup and the definitions require some preparations. First we recall the following definition from page 414.

**Definition.** Let $W$ be a compact topological manifold and let $A \subset W \setminus \partial W$ be a subset. A regular neighborhood of $A$ is a compact codimension-zero submanifold $N$ of $W$ with the following properties:

1. $N$ is contained in $W \setminus \partial W$ and $A$ is contained in the interior of $N$.
2. $A$ is a deformation retract of $N$.
3. $\partial N$ is a deformation retract of $N \setminus A$. 
The following proposition can be viewed as a variation on the Poincaré Duality Theorem \[88.1\].

**Proposition 95.2.** Let \(Z\) be a compact oriented \(m\)-dimensional topological manifold and let \(A\) be a closed submanifold of \(\partial Z\).

1. Let \(N \subset \partial Z\) be a regular neighborhood of \(A\). We denote by \(j: A \to N\) the inclusion map. Given any \(l \in \mathbb{N}_0\) the following two maps are isomorphisms\[1347\]:
   \[
   H^l(Z, \partial Z \setminus A) \xrightarrow{\cap[Z]} H_{m-l}(Z, N) \xleftarrow{j_*} H_{m-l}(Z, A).
   \]

2. We make the following technical hypothesis:
   
   (*) Given any neighborhood \(U\) of \(A \subset \partial Z\) there exists a regular neighborhood \(N\) of \(A \subset \partial Z\) with \(N \subset U\).

Under this hypothesis the isomorphism

\[
\text{PD}_Z: H^l(Z, \partial Z \setminus A) \xrightarrow{\sim} H_{m-l}(Z, A)
\]

given in (1) does not depend on the choice of the regular neighborhood \(N\). We denote the inverse of this map by \(\text{PD}_Z\) as well.

**Proof (\(*\)).**

1. Let \(N \subset \partial Z\) be a regular neighborhood of \(A\). We denote by \(i: \partial Z \setminus \hat{N} \to \partial Z \setminus A\) and \(j: A \to N\) the inclusion maps. We consider the following diagram:

\[
\begin{array}{ccc}
H^l(Z, \partial Z \setminus A) & \xrightarrow{\cap[Z]} & H_{m-l}(Z, N) \\
 \downarrow{i_*} & & \downarrow{j_*} \\
H^l(Z, \partial Z \setminus \hat{N}) & \xleftarrow{\cap[Z]} & H_{m-l}(Z, A).
\end{array}
\]

\[1347\] It follows from Proposition \[74.12\] (3) that the cap product \(\cap[Z] : H^l(Z, \partial Z \setminus A) \to H_{m-l}(Z, N)\) is actually defined. It is also worth pointing out that it is not possible to go directly from \(H^l(Z, \partial Z \setminus A)\) to \(H_{m-l}(Z, A)\) via capping with \([Z]\), since \((\partial Z, \partial Z \setminus A, A)\) is not an excisive triad.

**Figure 1329**

**Figure 1330. Illustration for Proposition 95.2**
We make the following observations:
(a) The diagonal cap product exists by Proposition 44.3 (4) together with Proposition 74.12 (4).
(b) It follows from Lemma 83.8 (1) that the triangle commutes.
(c) It follows from the hypothesis that $N$ is a regular neighborhood, together with Lemma 16.1 (1), that the maps $i$ and $j$ are both homotopy equivalences. Thus we obtain from Corollary 43.18 and Lemma 73.13 that the induced maps $i^*$ and $j^*$ are isomorphisms.
(d) It follows from the Poincaré Duality Theorem 88.1, which we can apply by Proposition 44.3 (4), that the right diagonal map is an isomorphism.

The above argument shows that the two horizontal maps are both isomorphisms.

(2) We need to show that the map in (1) does not depend on the choice of the regular neighborhood $N$. Thus let $M$ and $N$ be regular neighborhoods of $A \subset \partial Z$. It follows immediately from our hypothesis ($\ast$) that it suffices to consider the case that $M \subset N$. We consider the following diagram:

\[
\begin{array}{ccc}
H^i(Z, \partial Z \setminus A) & \xrightarrow{\cap[Z]} & H_{m-i}(Z, M) \\
& \cong & \\
& \cong & H_{m-i}(Z, N) & \xleftarrow{\triangleq} & H_{m-i}(Z, A).
\end{array}
\]

Here all unmarked maps are induced by inclusions. The triangle to the left commutes by Lemma 83.8 and the triangle to the right commutes by the functoriality of cohomology groups. But this shows that the upper and the lower path from the left to the right give exactly the same map.

\[\square\]

**Definition.** Let $Z$ be a topological manifold. We say a proper submanifold $X$ of $Z$ is **well-behaved** if given any open neighborhood $U$ of $\partial X \subset \partial Z$ the submanifold $\partial X$ of $\partial Z$ admits a regular neighborhood $N$ with $N \subset U$.

**Remark.** Almost any proper submanifold $X$ of some topological manifold $Z$ that appears in nature is well-behaved. For example it follows from Proposition 64.12 and Theorem 10.3 that $X$ is well-behaved if $\partial X$ is a PL-submanifold of $\partial Z$ or if $\partial X$ is a smooth submanifold of $\partial Z$.

In the following we will study maps between topological manifolds. To simplify the discussion we use the following convention.
**Convention.** Let $M$ be a topological manifold and let $X$ be a submanifold of $M$. In our notation and our language often we do not distinguish between $X$ as a submanifold and between the embedding $X \to M$.

Next we fix a convenient notation.

**Notation.** Given a map $f: Y \to X$ between topological spaces we write $|f| = f(Y)$.

Now we can give the first key definition of this chapter.

**Definition.** Let $M$ be an $m$-dimensional topological manifold, let $X$ be a $k$-dimensional topological manifold and let $Y$ be an $(m-k)$-dimensional topological manifold. Furthermore let $f: X \to M$ and $g: Y \to M$ be maps.

1. We say a point $P \in |f| \cap |g|$ is a **nice intersection point** of $f$ and $g$ if given any neighborhood $U$ of $P$ there exists a nice neighborhood $Z$, this means a submanifold $Z \subset M \setminus \partial M$ such that the following holds:
   a. $Z$ is homeomorphic to $B^m$.
   b. $P$ is contained in $Z \setminus \partial Z$ and $Z$ is contained in $U$.
   c. $|f| \cap |g| \cap Z = \{P\}$.
   Before we continue we set $\tilde{X} := f^{-1}(|f| \cap Z)$ and we set $\tilde{Y} := g^{-1}(|g| \cap Z)$. With this notation we also demand the following:
   d. $\tilde{X}$ is a compact codimension-zero submanifold of $X$ and $\tilde{Y}$ is a compact codimension-zero submanifold of $Y$.
   e. The maps $f: \tilde{X} \to Z$ and $g: \tilde{Y} \to Z$ are both proper embeddings.
   f. $f(\tilde{X})$ and $g(\tilde{Y})$ are both well-behaved submanifolds of $Z$.
   g. $f(\tilde{X})$ is homeomorphic to $B^k$ and $g(\tilde{Y})$ is homeomorphic to $B^{m-k}$.
   In Figure 1332 we illustrate the definition for two different nice intersection points.

2. We say that $f$ and $g$ **intersect nicely**, if all points in $|f| \cap |g|$ are nice intersection points.

---

**Remark.** By the above convention we now also defined the notion of a nice intersection point of two submanifolds and we defined the notion that two submanifolds intersect nicely.

**Convention.** Let $W$ be an oriented topological manifold. We equip any codimension-zero submanifold of $W$ with the orientation coming from Lemma 86.17.

---

Note that by (a) we know that $Z$ is a codimension-zero submanifold of $M$. Since $Z \subset M \setminus \partial M$ we know by Proposition 44.3 that the boundary of $Z$ as a topological manifold agrees with the boundary of $Z$ as a subset of $M$.  

---

**Figure 1332**
Now we are ready to give the second key definition of this chapter.

**Definition.** Let $M$ be an oriented $m$-dimensional topological manifold, let $X$ be an oriented $k$-dimensional topological manifold and let $Y$ be an oriented $(m-k)$-dimensional topological manifold. Furthermore let $f: X \to M$ and $g: Y \to M$ be maps and let $P$ be a nice intersection point of $f$ and $g$. We pick a nice neighborhood $Z$ of $P$. We define the index of $f$ and $g$ at $P$ as follows:

$$\text{index}(f, g, P) = \left\langle \begin{array}{c} \text{PD}_Z(f_*(\lvert \tilde{X} \rvert)) \cup \text{PD}_Z(g_*(\lvert \tilde{Y} \rvert)) \quad \in H^m(Z, \partial Z) \\ \in \text{H}_k(Z, \partial \tilde{X}(\tilde{X})) \\ \in \text{H}_{m-k}(Z, \partial \tilde{Z} \setminus \partial \tilde{f}(\tilde{X})) \\ \in \text{H}^k(Z, \partial \tilde{Z} \setminus \partial g(\tilde{Y})) \end{array} \right\rangle \in \mathbb{Z}.$$ 

**Example.** In Figure 1333 we show, in three cases, the indices of nice intersection points. The first two indices can be determined with some effort using Proposition 88.2 together with Proposition 80.11. Alternatively see Proposition 95.5 below. Finally we outsource the calculation of the third index to Exercise 95.2.

![Figure 1333](image)

Next we need to show that the index of a nice intersection point is well-defined.

**Lemma 95.3.** Let $M$, $f: X \to M$ and $g: Y \to M$ as in the previous definition and let $P$ be a nice intersection point of $f$ and $g$. The corresponding index $\text{index}(f, g, P)$ is well-defined, i.e. it is independent of the choice of the nice neighborhood $Z$ of $P$.

**Sketch of a proof (⋆).** By the “given any neighborhood $U$ of $P$” aspect of the definition of a nice intersection point it suffices to deal with nice neighborhoods $Z_1$ and $Z_2$ with

---

1349 Here are a few clarifications:

1. By hypothesis we know that $Z$, $\tilde{X}$ and $\tilde{Y}$ are compact codimension-zero submanifolds of $M$, $X$ and $Y$. As we just remarked, by Lemma 86.17 they inherit an orientation from the given orientations on $M$, $X$ and $Y$. As always we denote by $\lvert Z \rvert$, $\lvert \tilde{X} \rvert$ and $\lvert \tilde{Y} \rvert$ the corresponding fundamental classes.

2. By hypothesis $f(\tilde{X})$ and $g(\tilde{Y})$ are well-behaved submanifolds of $Z$. Thus we obtain from Proposition 95.2 the corresponding maps $\text{PD}_Z$.

3. By hypothesis $f(\tilde{X})$ and $g(\tilde{Y})$ are compact. It follows from Proposition 44.2 (4b) that $\partial f(\tilde{X})$ and $\partial g(\tilde{Y})$ are compact. By Lemma 2.17 (2) this implies that $\partial Z \setminus \partial f(\tilde{X})$ and $\partial Z \setminus \partial g(\tilde{Y})$ are open subsets of $\partial Z$. Since $P$ is the only intersection point of $f$ and $g$ in $Z$ we see that these two open subsets cover all of $\partial Z$. It now follows from Proposition 74.12 (4) that the cup product is actually defined.
Z_1 \subset \tilde{Z}_2. We define \( \tilde{X}_1, \tilde{X}_2, \tilde{Y}_1 \) and \( \tilde{Y}_2 \) in the obvious way. We pick regular neighborhoods \( A_1 \) of \( \partial X_1 \subset \partial Z_1 \) and \( B_1 \) of \( \partial Y_1 \subset \partial Z_1 \). Similarly we pick \( A_2 \) and \( B_2 \) with the obvious meaning.

Let \( i \in \{1, 2\} \). We write \( C_i := \partial Z_i \setminus \tilde{A}_i \) and \( D_i := \partial Z_i \setminus \tilde{B}_i \). Similar to the proof of the Excision Theorem for Topological Manifolds [44.10] we use the Topological Collar Neighborhood Theorem [44.5] to find open subsets \( \tilde{A}_i, B_i, \tilde{C}_i \) and \( \tilde{D}_i \) of \( \partial Z_i \) that admit deformation retractions to \( A_i, B_i, C_i \) respectively \( D_i \). Now we consider the following maps of triads of topological spaces:

\[
\begin{array}{cccc}
Z_1 & Z_1 & Z_2 & Z_2 \\
\partial Z_1 \setminus A_1 & \tilde{A}_1 & \tilde{A}_1 \cup ((\tilde{Z}_2 \setminus Z_1) \cup \tilde{A}_2) & \tilde{A}_2 \\
\partial Z_1 \setminus A_1 & \tilde{A}_1 & (\partial Z_1 \setminus A_1) \cup (\tilde{Z}_2 \setminus Z_1) \cup (\partial Z_2 \setminus A_2) & \partial Z_2 \setminus A_2.
\end{array}
\]

It follows from Proposition [74.12 (4)] that all these triads are excisive. Evidently the analogous statement also holds if we replace the \( A \)'s by \( B \)'s. Now the lemma can be deduced from Proposition [82.4] and Lemma [83.8] together with Lemma [87.24]. We leave it to the reader to fill in the details.

![Figure 1334. Illustration for the proof of Lemma 95.3.](image)

The following lemma is a generalization of Lemma [94.2]

**Lemma 95.4.** Let \( M \) be an \( m \)-dimensional topological manifold, let \( X \) be a compact \( k \)-dimensional topological manifold and let \( Y \) be a compact \((m - k)\)-dimensional topological manifold. Furthermore let \( f : X \to M \) and \( g : Y \to M \) be maps. If \( f \) and \( g \) intersect nicely, then \( |f| \cap |g| \) is finite.

**Proof (⋆).** Let \( P \) be a nice intersection point of \( f \) and \( g \). We pick a nice neighborhood \( Z \) for \( P \). Note that this means in particular that \( Z \) is a codimension-zero submanifold of \( M \) with \( Z \subset M \setminus \partial M, P \in Z \setminus \partial Z \) and with \( |f| \cap |g| \cap Z = \{P\} \). By Proposition [44.3 (3)] we know that \( Z \setminus \partial Z \) is an open subset of \( M \). We have thus shown that \( P \) is an isolated point, in the sense of the definition on page [174] of the subspace \( |f| \cap |g| \). Since by hypothesis every intersection point is nice we see that \( |f| \cap |g| \) is a discrete subset of \( M \). Since \( X \) and \( Y \) are compact we know by Lemma [2.40] together with Lemma [2.16 (2)] that \( |f| \cap |g| \) is also compact. Thus we see that \( |f| \cap |g| \) is a discrete compact topological space. By Lemma [2.18 (1)] this implies that \( |f| \cap |g| \) is a finite set.

By Lemma [95.4] it now makes sense to introduce the following definition which can be viewed as an analogue of the definition on page [227].
Definition. Let $M$ be an oriented $m$-dimensional topological manifold. Let $X$ be a compact oriented $k$-dimensional topological manifold and let $Y$ be a compact oriented $(m-k)$-dimensional topological manifold. Furthermore let $f: X \to M$ and $g: Y \to M$ be maps. If $f$ and $g$ intersect nicely, then we define the algebraic intersection number of $f$ and $g$ to be

$$ f \cdot g := \sum_{P \in |f|^g} \text{index}(f, g, P). $$

Remark. Recall that by our convention on page 2304 we do not distinguish between a submanifold $X$ of $M$ and the actual embedding $X \to M$. In particular in the above definition we also introduced the algebraic intersection number $X \cdot Y$ of two suitable submanifolds of $M$.

95.2. Transverse intersection points of maps. In this section we will see that the notion of a nice intersection points incorporates the notion of a transverse intersection point that we introduced on pages 2270. We will also see that the concept of the algebraic intersection number that we defined in the previous section is a generalization of the algebraic intersection number that we introduced on page 2271.

The following definition can be viewed as a generalization of the concepts we introduced on pages 306 and 2270.

Definition. Let $M$ be an $m$-dimensional smooth manifold and let $k \in \{1, \ldots, m-1\}$. Furthermore let $X$ be a $k$-dimensional smooth manifold and let $Y$ be a $(m-k)$-dimensional smooth manifold. Furthermore let $f: X \to M$ and $g: Y \to M$ be smooth maps.

1. We say a point $P \in |f| \cap |g|$ is a transverse intersection point of $f$ and $g$ if $P \in M \setminus \partial M$, if $f^{-1}(|P|)$ contains a single point $x_0$, if $g^{-1}(|P|)$ contains a single point $y_0$, if $x_0 \in X \setminus \partial X$ and $y_0 \in Y \setminus \partial Y$, and if $f_*(T_{x_0}X) + g_*(T_{y_0}Y) = T_P M$.

2. Now we assume that $M$, $X$ and $Y$ are oriented. Let $P$ be a transverse intersection point of $f$ and $g$. We set $\text{sign}(f, g, P) := 1$ if

$$(f_*(\text{positive basis of } T_{x_0}X), g_*(\text{positive basis of } T_{y_0}Y)) = \text{positive basis of } T_P M,$$

and otherwise we set $\text{sign}(f, g, P) := -1$.

Remark. If $X$ and $Y$ are compact proper submanifolds of $M$ and if $f$ and $g$ are just the inclusion maps, then the above definitions are precisely the definitions provided on pages 306 and 2270.
Proposition 95.5. Let $M$ be an $m$-dimensional smooth manifold and let $k \in \{1, \ldots, m-1\}$. Furthermore let $X$ be a $k$-dimensional smooth manifold and let $Y$ be a $(m-k)$-dimensional smooth manifold. Finally let $f : X \to M$ and $g : Y \to M$ be smooth maps.

(1) Let $P \in [f] \cap [g]$. If $P$ is a transverse intersection point of $f$ and $g$, then $P$ is a nice intersection point of $f$ and $g$.

(2) If $M$, $X$ and $Y$ are oriented, then for any transverse intersection point $P$ of $f$ and $g$ we have $\text{index}(f, g, P) = \text{sign}(f, g, P)$.

Proof. The alert reader will doubtlessly notice that the proof of the proposition mostly recycles ideas from the proof of Proposition 94.8 and Lemma 94.9.

Let $U$ be an open neighborhood of $P$. It follows from Exercise 8.1, which can be solved using the Inverse Function Theorem 6.18, that there exists an open neighborhood $A$ of $x_0$ such that the restriction of $f$ to $f : A \to M$ is a smooth embedding and such that $f(A) \subset U$. Furthermore, using the hypothesis that $f^{-1}(\{P\}) = \{x_0\}$ and using Exercise 6.25 we see that, after possibly shrinking $A$, we can assume that $f^{-1}(f(A)) = A$.

The same way we can evidently find an open neighborhood $B$ of $y_0$ such that $g : B \to M$ is a smooth embedding, such that $g(B) \subset U$ and such that $g^{-1}(g(B)) = B$.

By Proposition 8.1 we know that $f(A)$ and $g(B)$ are smooth submanifolds of $M$. By our hypothesis we know that $P$ is a transverse intersection point of $f(A)$ and $g(B)$. It follows from Lemma 6.52 that there exists a chart $\Phi : V \to W$ for $M$ around $P$ with

$$\Phi(V \cap f(X)) = W \cap (\mathbb{R}^k \times \{0\}) \quad \text{and} \quad \Phi(V \cap g(Y)) = W \cap (\{0\} \times \mathbb{R}^{m-k}).$$

Next note that after possibly rescaling $W$ we can assume that $\overline{B}^k \times \overline{B}^{m-k} \subset W$. We set $Z := \Phi^{-1}(\overline{B}^k \times \overline{B}^{m-k})$ and $\widetilde{X} := f^{-1}(Z)$ and $\widetilde{Y} := g^{-1}(Z)$. Note that by construction the maps $\Phi \circ f : \widetilde{X} \to \overline{B}^k \times \{0\}$ and $\Phi \circ g : \widetilde{Y} \to \{0\} \times \overline{B}^{m-k}$ are diffeomorphisms. It follows easily from the construction that $Z$ has all the properties stated in the definition of a nice intersection point. This concludes the proof of Statement (1).

Now assume that $M$, $X$ and $Y$ are oriented. We set $\sigma := \text{sign}(f, g, P)$. We make the following preparations:

(1) We equip each $B^n$ with the usual orientation coming from $\mathbb{R}^n$. 
(2) After possibly composing \( \Phi: Z \to \overline{B}^k \times \overline{B}^{m-k} \) with reflections in some \( (x_i = 0) \)-hyperplanes we can assume that the diffeomorphisms \( \Phi \circ f: f^{-1}(Z) = \tilde{X} \to \overline{B}^k \times \{0\} \) and \( \Phi \circ g: g^{-1}(Z) = \tilde{Y} \to \{0\} \times \overline{B}^{m-k} \) are both orientation-preserving.

(3) We equip the topological manifold \( \overline{B}^k \times \overline{B}^{m-k} \) with the product orientation as defined on page 204. It follows from Proposition 80.11 that with this orientation the inclusion map \( \overline{B}^k \times \overline{B}^{m-k} \to \mathbb{R}^m \) is orientation-preserving.

(4) Elementary linear algebra shows that (2) implies that \( \Phi: Z \to \overline{B}^k \times \overline{B}^{m-k} \) is orientation-preserving if and only if \( \sigma = +1 \).

(5) It follows from Proposition 72.2 and Lemma 86.12 that \( \Phi_*([Z]) = \sigma \cdot [\overline{B}^k \times \overline{B}^{m-k}] \).

Now we perform the following calculation:

\[
\begin{align*}
\langle \text{PD}(f_*[\tilde{X}]) \cup \text{PD}(g_*[\tilde{Y}]), [Z] \rangle &= \langle \Phi^*(\text{PD}(f_*[\tilde{X}])) \cup \Phi^*(\text{PD}(g_*[\tilde{Y}])), \Phi_*([Z]) \rangle \\
&= \langle \sigma \cdot \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([\overline{B}^k \times \{0\}]) \cup \sigma \cdot \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([0 \times \overline{B}^{m-k}]), \sigma \cdot [\overline{B}^k \times \overline{B}^{m-k}] \rangle \\
&= \text{by Proposition 88.2} \\
&= \text{by Lemma 74.6 (3) and Lemma 81.10} \\
&= \text{by (4) and the pretty elementary Exercise 88.16} \\
&= \sigma^2 \cdot \langle \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([\overline{B}^k \times \{0\}]) \cup \text{PD}_{\overline{B}^k \times \overline{B}^{m-k}}([0 \times \overline{B}^{m-k}]), [\overline{B}^k \times \overline{B}^{m-k}] \rangle \\
&= \text{sign}(f, g, P) \quad \text{by Proposition 88.2}
\end{align*}
\]

\[= 1 \quad \text{by Proposition 88.2}\]

\[= \sigma \]

\[\blacksquare\]

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure1337.png}
\caption{Illustration for the proof of Proposition 95.5.}
\end{figure}

The following is an immediate corollary to Proposition 95.5.

**Corollary 95.6.** Let \( M \) be an oriented \( m \)-dimensional smooth manifold, let \( X \) be an oriented \( k \)-dimensional submanifold and let \( Y \) be an oriented \( (m-k) \)-dimensional submanifold of \( M \). We denote by \( i: X \to M \) and \( j: Y \to M \) the inclusion maps. If the submanifolds are transverse in the sense of the definition on page 206 then the maps \( i: X \to M \) and \( j: Y \to M \) are intersect nicely and the two definitions of the algebraic intersection given on pages 2271 and 2307 agree.

By Corollary 95.6 the following theorem is a generalization of Theorem 94.5.

**Theorem 95.7.** Let \( M \) be a compact oriented connected \( m \)-dimensional topological manifold. Furthermore let \( A \) and \( B \) be two compact \( (m-1) \)-dimensional submanifolds of \( \partial M \) with \( \partial A = \partial B = A \cap B \) and with \( \partial M = A \cup B \). Let \( X \) be a compact oriented \( k \)-dimensional
topological manifold and let $Y$ be a compact oriented $(m-k)$-dimensional topological manifold. Finally let $f : X \to M$ and $g : Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If $f$ and $g$ intersect nicely, then

$$f \cdot g = \langle \text{PD}_M(f_*(\{X\})) \cup \text{PD}_M(g_*(\{Y\})), [M] \rangle \in \mathbb{Z}.$$  

Figure 1338. Illustration of Theorem 95.7

**Remark.** It follows immediately from Proposition 95.5 that Theorem 95.7 contains our earlier Theorem 94.5 as a special case.

In Theorem 95.14 below we will give a result which takes more time to formulate and which implies the above Theorem 95.7. To keep at least the flow of the definitions and statements coherent we decided to formulate Theorem 95.14 in this section. But rather awkwardly this means that we now provide a proof of Theorem 95.7 that relies on the future Theorem 95.14.

**Proof of Theorem 95.7 using Theorem 95.14.** It follows easily from Lemma 95.12 that there exists a $k$-cycle $\sigma \in C_k(M, A)$ and an $(m-k)$-cycle $\tau \in C_{m-k}(M, B)$ with the following properties:

1. we have $[\sigma] = f_*(\{X\})$ and $[\tau] = g_*(\{Y\})$,
2. the cycles $\sigma$ and $\tau$ are transverse,
3. the equality $f \cdot g = \sigma \cdot \tau$ holds.

It follows that

$$f \cdot g = \sigma \cdot \tau = \langle \text{PD}_M([\sigma]) \cup \text{PD}_M([\tau]), [M] \rangle = \langle \text{PD}_M(f_*(\{X\})) \cup \text{PD}_M(g_*(\{Y\})), [M] \rangle.$$  

As promised, we now find it quite easy to answer Question 95.1 in the negative.

**Lemma 95.8.** We consider the disk $\overline{B}^2$ together with the four points $P_{\pm} = (\pm 1, 0)$ and $Q_{\pm}(0, \pm 1)$. If $\alpha : [-1, 1] \to \overline{B}^2$ is a proper map with $\alpha(\pm 1) = P_{\pm}$ and if $\beta : [-1, 1] \to \overline{B}^2$ is a proper map with $\beta(\pm 1) = Q_{\pm}$, then $\alpha$ and $\beta$ intersect in at least one point.
Proof. We write $I = [-1, 1]$. Suppose that there exist proper maps $\alpha : I \to \overline{B}^2$ and $\beta : I \to \overline{B}^2$ with $\alpha(\pm 1) = P_\pm$ and with $\beta(\pm 1) = Q_\pm$ such that $|\alpha| \cap |\beta| = \emptyset$. We introduce the following notation:

(1) We consider the “straight paths” $\alpha' : I \to \overline{B}^2$ given by $\alpha'(t) = (t, 0)$ and $\beta' : I \to \overline{B}^2$ given by $\beta'(t) = (0, t)$.

(2) We write $A = \{e^{it} | t \in [-\frac{\pi}{4}, \frac{\pi}{4}] \cup [\frac{3\pi}{4}, \frac{5\pi}{4}]\}$ and $B = \{e^{it} | t \in [-\frac{3\pi}{4}, -\frac{\pi}{4}] \cup [\frac{5\pi}{4}, \frac{7\pi}{4}]\}$.

(3) We denote by $\text{PD}_{\overline{B}^2}$ the isomorphisms from the Poincaré Duality Theorem \ref{pd} corresponding to the decomposition $\partial \overline{B}^2 = A \cup B$.

We refer to Figure \ref{fig:1339} for an illustration. We have

$$0 = \alpha \cdot \beta = \langle \text{PD}_{\overline{B}^2}(\alpha_\ast([I])) \cup \text{PD}_{\overline{B}^2}(\beta_\ast([I])), \overline{B}^2 \rangle$$

$$= \langle \text{PD}_{\overline{B}^2}(\alpha_\ast([I])) \cup \text{PD}_{\overline{B}^2}(\beta_\ast([I])), \overline{B}^2 \rangle = \alpha' \cdot \beta' = \pm 1.$$ 

by considering the long exact sequences in homology of the pairs $(\overline{B}^2, A)$ and $(\overline{B}^2, B)$ we see that $\alpha_\ast([I]) = \alpha'_\ast([I])$ and $\beta_\ast([I]) = \beta'_\ast([I])$.

We have thus obtained a contradiction.

\[ \text{Figure 1339} \]

95.3. Intersections of cycles. Now we turn to the study of singular chains in a topological manifold. To be on the safe side in our subsequent definitions we introduce the following convention.

Convention.

(1) Let $X$ be a topological space. When we write “let $\sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r$ be a singular $m$-chain in $X$” it is is understood that the $\sigma_i$ are pairwise different and that all the $a_i$ are non-zero. We write $|\sigma| = |\sigma_1| \cup \cdots \cup |\sigma_r|$.

(2) Let $M$ be an oriented $m$-dimensional topological manifold $M$ and let $\sigma : \Delta^k \to M$ and $\tau : \Delta^{m-k} \to M$ be singular simplices. Since each $\Delta^n$ is in particular a topological manifold it makes sense to say that the singular simplices intersect nicely. Furthermore, throughout this chapter we equip the topological manifold $\Delta^n$ with the orientation given by the discussion on page \ref{orient} together with Proposition \ref{orient}. In particular, if $\sigma : \Delta^k \to M$ and $\tau : \Delta^{m-k} \to M$ intersect nicely, then we obtain an algebraic intersection number $\sigma \cdot \tau$. 
**Definition.** Let $M$ be an $m$-dimensional topological manifold and let $\sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r$ be a singular $k$-chain and let $\tau = b_1 \cdot \tau_1 + \cdots + b_s \cdot \tau_s$ be a singular $(m-k)$-chain in $M$. We say that $\sigma$ and $\tau$ *intersect nicely* if the following two conditions are satisfied:

1. For all $i \in \{1, \ldots, r\}$ and $j \in \{1, \ldots, s\}$ the maps $\sigma_i: \Delta^k \to M$ and $\tau_j: \Delta^{m-k} \to M$ intersect nicely.
2. For all $(i, j) \neq (i', j') \in \{1, \ldots, r\} \times \{1, \ldots, s\}$ we have
   $$((|\sigma_i| \cap |\tau_j|) \cap (|\sigma_{i'}| \cap |\tau_{j'}|)) = \emptyset.$$ Put differently, any intersection point is the intersection point of a unique pair of singular simplices.

If this is the case and if $M$ is oriented, then we define the *algebraic intersection number of $\sigma$ and $\tau$* to be

$$\sigma \cdot \tau := \sum_{i,j} (a_i \cdot b_j) \cdot (\sigma_i \cdot \tau_j).$$

**Figure 1340**

Before we can state the main theorem of this chapter we recall the formulation of the Poincaré Duality theorem for (not necessarily compact) topological manifolds without boundary. Thus let $W$ be an oriented $m$-dimensional topological manifold without boundary and let $K \subset W$ be a compact subset. By Theorem [87.10](#) there exists a unique lift of the orientation classes of $W$ to a class in $H_m(W, W \setminus K)$. Given any $k \in \mathbb{N}_0$ we denote by

$$- \cap W: H^k(W, W \setminus K) \to H_{m-k}(W)$$

the map that is given by capping with this unique lift. Lemma [88.18](#) says that these maps define a well-defined map

$$- \cap W: H^k_c(W) \to H_{m-k}(W).$$

Furthermore the Poincaré Duality Theorem [88.19](#) says that this map is an isomorphism. We denote by

$$\text{PD}_W: H_{m-k}(W) \to H^k_c(W)$$

the inverse map. Finally we remind the reader that given a topological space $X$ we denote by $\epsilon_X = \epsilon: H_0(X) \to \mathbb{Z}$ the augmentation map.

Now we can formulate the main theorem of this chapter.
95. INTERSECTIONS OF CYCLES AND THE CUP PRODUCT

Theorem 95.9. Let \( M \) be an oriented \( m \)-dimensional topological manifold without boundary. Let \( \sigma \in C_k(M) \) and \( \tau \in C_{m-k}(M) \) be two cycles. If \( \sigma \) and \( \tau \) intersect nicely, then

\[
\sigma \cdot \tau = \epsilon_M \left( \left[ \frac{\text{PD}_M([\sigma]) \cup \text{PD}_M([\tau])}{\in \mathcal{H}_k(M)} \right] \cap M \right).
\]

95.4. Proof of Theorem 95.9. Before we can provide the proof of Theorem 95.9 we need to recall some definitions and we need to prove several lemmas. First let us recall the following definition from page 120.

Definition. Let \( X \) be a topological space.

1. Let \( A \) and \( B \) be disjoint subsets of \( X \). We say \( U \) and \( V \) are separating open neighborhoods for \( A \) and \( B \) if \( U \) and \( V \) are disjoint, if \( U \) is an open neighborhood of \( A \) and if \( V \) is an open neighborhood of \( B \).
2. A topological space \( X \) is called normal if any two disjoint closed subsets \( A \) and \( B \) admit separating open neighborhoods.

Proposition 95.10.

1. Every topological manifold is normal.
2. Let \( M \) be a topological manifold and let \( A \) and \( B \) be two closed disjoint subsets of \( M \). If \( U' \subset \partial M \) and \( V' \subset \partial M \) are separating open neighborhoods for \( A \cap \partial M \) and \( B \cap \partial M \), then there exist separating open neighborhoods \( U \) and \( V \) of \( A \) and \( B \) such that \( U \cap \partial M = U' \) and \( V \cap \partial M = V' \).

Remark. For many situations it suffices to find separating open neighborhoods for \textit{compact} subsets \( A \) and \( B \) of a Hausdorff space \( X \). In this situation the existence of such open neighborhoods is proved in Lemma 2.46.

Sketch of proof (*).

1. First note that by Corollary 9.2 the topological space \( M \) is metrizable, i.e. \( M \) admits a metric such that the topology from the metric agrees with the given topology. It now follows from Proposition 2.47 that \( M \) is normal.
2. Let \( M \) be a topological manifold and let \( A \) and \( B \) be two closed disjoint subsets of \( M \). We pick a collar neighborhood \( \partial M \times [0,1] \) as given by the Topological Collar Neighborhood Theorem 44.5. Suppose that we are given separating neighborhoods \( U' \subset \partial M \) and \( V' \subset \partial M \) for \( A \cap \partial M \) and \( B \cap \partial M \). By Proposition 44.2 the complement \( M \setminus \partial M \) is again a smooth manifold.

\textsuperscript{1350}We refer to page 2008 for the definition of the cup product on cohomology with compact support.
manifold. By (1) it is normal. Thus there exist separating open neighborhoods $\tilde{U}$ and $\tilde{V}$ for the closed subsets $A \cap (M \setminus \partial M)$ and $B \cap (M \setminus \partial M)$. It follows from Lemma 6.7 (1) that $\tilde{U}$ and $\tilde{V}$ are open subsets of $M$. It is now straightforward to verify that $U := \tilde{U} \cup ([0,1) \times U')$ and $V := \tilde{V} \cup ([0,1) \times V')$ have all the desired properties.

Lemma 95.11. Let $M$ be an oriented $m$-dimensional topological manifold with $\partial M = \emptyset$ and let $U \subset M$ be an open subset. Let $i: U \to M$ be the inclusion map. For any compact subset $K \subset U$ and any $k \in \mathbb{N}_0$ the map

$$i^*: H^{m-k}(M, M \setminus K) \to H^{m-k}(U, U \setminus K)$$

is an isomorphism and the following diagram commutes:

![Diagram for Lemma 95.11](image)

**Figure 1342.** Illustration for Lemma 95.11

**Proof.** We make the following comments and observations:

(i) By excision, see page 1840 the map $i^*: H^{m-k}(M, M \setminus K) \to H^{m-k}(U, U \setminus K)$ is an isomorphism.

(iii) The triangles on the top and the bottom commute by definition of $PD_U$ and $PD_M$, see Lemma 88.18.

(iv) The square to the left commutes by definition of the map $i_*: H^c_{m-k}(U) \to H^c_{m-k}(M)$, see page 1908.

(v) It follows from Lemma 83.8 and Corollary 87.12 (2) that the square to the right commutes.

(vi) The rectangle in the back commutes by Lemma 88.25.

As in the case of Theorem 94.5 it is perhaps instructive to first prove Theorem 95.9 in the special case that the cycles do not intersect.

**Proof of Theorem 95.9 for Disjoint Cycles.** Let $M$ be an oriented $m$-dimensional topological manifold with $\partial M = \emptyset$. Let $\sigma \in C_k(M)$ and $\tau \in C_{m-k}(M)$ be two cycles such that $|\sigma| \cap |\tau| = \emptyset$. We have to show that $PD_M([\sigma]) \cup PD_M([\tau]) = 0$. 
By Proposition 95.10 we can find separating open neighborhoods \( U \) and \( V \) for \(|\sigma|\) and \(|\tau|\). Given a compact subset \( J \) of \( M \) and given \( i \in \mathbb{N}_0 \) we denote by \( \varphi_J : \text{H}^i(M, M \setminus J) \to \text{H}^i_c(M) \) the natural map.

Claim.

1. There exists a compact subset \( K \subset U \) and a cohomology class \( \alpha \in \text{H}^{m-k}(M, M \setminus K) \) such that \( \varphi_K(\alpha) = \text{PD}_M([\sigma]) \).

2. There exists a compact subset \( L \subset V \) and a cohomology class \( \beta \in \text{H}^k(M, M \setminus L) \) such that \( \varphi_L(\beta) = \text{PD}_M([\tau]) \).

We consider \( \text{PD}_U([\sigma]) \in \text{H}^{m-k}_c(U) \). By definition of cohomology with compact support there exists a compact subset \( K \) of \( U \) such that \( \text{PD}_U([\sigma]) \) lies in the image of the natural map \( \text{H}^{m-k}(U, U \setminus K) \to \text{H}^{m-k}_c(U) \). The first statement of the claim now follows from Lemma 95.11. The proof of the second statement is evidently basically the same. \( \square \)

We consider the following diagram

\[
\begin{array}{ccc}
\text{H}^{m-k}_c(M) \times \text{H}^k_c(M) & \longrightarrow & \text{H}^m_c(M) \\
\varphi_K \times \varphi_L \downarrow & & \varphi_M \\
\text{H}^{m-k}(M, M \setminus K) \times \text{H}^k(M, M \setminus L) & \longrightarrow & \text{H}^m(M, (M \setminus K) \cup (M \setminus L)).
\end{array}
\]

The diagram commutes by the definition of the cup product on cohomology with compact support, see page 2008. It follows from the observation that the lower right group is zero that the cup product of \( \text{PD}_M([\sigma]) \) and \( \text{PD}_M([\tau]) \) is zero. \( \square \)

**Figure 1343.** Illustration for the proof of Theorem 95.9 for disjoint cycles.

**Lemma 95.12.** Let \( X \) be a compact oriented, \( n \)-dimensional topological manifold. Furthermore let \( \varphi_i : \Delta^n \to X \setminus \partial X, i = 1, \ldots, r \), be orientation-preserving embeddings such that the images are disjoint. We write \( W = X \setminus (\varphi_1(\Delta^n) \cup \cdots \cup \varphi_r(\Delta^n)) \). Given any representative \( \mu \in C_{n-1}(\partial X) \) of the fundamental class of \( \partial X \) there exists a singular \( n \)-chain \( \sigma \in C_n(W) \) such that

\[
\partial(\sigma + \varphi_1 + \cdots + \varphi_r) = \mu \quad \text{and with} \quad [\sigma + \varphi_1 + \cdots + \varphi_r] = [X].
\]

**Example.** In the proof below of Theorem 95.9 we will apply Lemma 95.12 to the case that \( X = \Delta^n \) itself is the standard \( n \)-simplex. This particular situation is illustrated in Figure 1344.
Proof. By Proposition 44.3 we know that $W$ is a compact $n$-dimensional topological manifold with $\partial W = \varphi_1(\partial \Delta^n) \cup \cdots \cup \varphi_r(\partial \Delta^n) \cup \partial X$. Since the $\varphi_i$ are orientation-preserving we obtain from Proposition 87.27 that $-\partial \varphi_1 - \cdots - \partial \varphi_r + \mu \in C_{n-1}(\partial W)$ represents the fundamental class of $\partial W$. Again by Proposition 87.27 we know that there exists a singular $n$-chain $\sigma \in C_n(W)$ with $\partial \sigma = -\partial \varphi_1 - \cdots - \partial \varphi_r + \mu$. It follows from Proposition 68.4 that $\sigma + \varphi_1 + \cdots + \varphi_r$ represents the fundamental class of $X$.

The formulation of the following, rather technical lemma, might initially be somewhat intimidating. We hope that Figure 1345 helps somewhat with keeping track of the various objects. Also note that the lemma can be viewed as a cousin of first degree to Lemma 89.5

**Lemma 95.13.** Let $M$ be an oriented $m$-dimensional topological manifold and let $Z$ be a compact codimension-zero submanifold of $M$. Furthermore let $C$ and $D$ be two compact codimension-zero submanifolds of $\partial Z$ with $C \cup D = \partial Z$ and with $\partial C = \partial D = C \cap D$. Let $U \subset M$ be an open subset with $U \cap \partial Z \subset C$ and let $K \subset U$ be a compact subset. We consider the three inclusion maps $p: (U, \emptyset) \to (U, U \setminus \hat{Z})$, $g: (Z \cap U, C \cap U) \to (Z, C)$ and $z: (Z \cap U, C \cap U) \to (U, U \setminus \hat{Z})$. We note that the induced map

$$z_*: H_k(Z \cap U, C \cap U) \to H_k(U, U \setminus \hat{Z})$$

is an isomorphism by the Excision Theorem 44.10 for topological manifolds. With this preparation we can now formulate the conclusion of the lemma. Namely, the following diagram commutes:

$$\begin{array}{ccc}
H_k(M) & \xrightarrow{\cap^M} & H^{m-k}(M, M \setminus K) \\
\downarrow p_* & & \downarrow \\
H_k(U) & \xrightarrow{\cap^U} & H^{m-k}(U, U \setminus K) \\
\downarrow (z^*) & & \downarrow \\
H_k(U, U \setminus \hat{Z}) & \xrightarrow{(z_*)^{-1}} & H_k(Z \cap U, C \cap U) & \xrightarrow{g_*} & H_k(Z, C) & \xrightarrow{\cap[Z]} & H^{m-k}(Z, D).
\end{array}$$

Here all the unmarked maps are induced by the obvious inclusion maps of pairs of topological spaces. Also note that the bottom cap product $\cap[Z]: H^{m-k}(Z, D) \to H_k(Z, C)$ is defined since our hypothesis on $C$ and $D$ together with Proposition 74.12 (5) imply that $(Z, C, D)$ is an excisive triad.

\[1351] In fact in the proof we only need that we have a decomposition $\partial Z = C \cup D$ such that $(Z, C, D)$ is an excisive triad.
Proof. We make the following preparations:

(a) We pick a representative $\nu_M \in H_m(M, M \setminus K)$ for the lift of the orientation of $M$ and similarly we pick $\nu_U \in H_m(U, U \setminus K)$.

(b) We consider the two obvious inclusion maps $f: (Z, \partial Z) \to (Z, Z \setminus (\hat{Z} \cap K))$ and $g: (Z \cap U, (Z \cap U) \setminus (\hat{Z} \cap K)) \to (Z, Z \setminus (\hat{Z} \cap K))$. It follows from the Excision Theorem 43.20 that the map $g_*: H_m(Z \cap U, (Z \cap U) \setminus (\hat{Z} \cap K)) \to H_m(Z, Z \setminus (\hat{Z} \cap K))$ is an isomorphism. We write $\nu_Z := g_*^{-1}(\nu([Z]))$.

Next we consider the following expanded version of the diagram shown in the lemma:

$$
\begin{array}{c}
\xymatrix{
H_k(M) & \cap^{\nu_M} & H^{m-k}(M, M \setminus K) \\
H_k(U) & \cap^{\nu_U} & H^{m-k}(U, U \setminus K) \\
H_k(U, U \setminus \hat{Z}) & \cap^{Z} & H_k(Z \cap U, C \cap U) \\
H_k(U, U \setminus \hat{Z}) & \cap^{Z} & H_k(Z \cap U, (Z \cap U) \setminus K). \\
H_k(Z, C) & \cap^{Z} & H^{m-k}(Z, Z \setminus K) \\
H_k(Z, C) & \cap^{Z} & H^{m-k}(Z, D). \\
\end{array}
$$

It suffices to show that all the five regions of the diagram commute:

1. The parallelogram on the top of the diagram commutes by Lemma 83.8 applied to the map $h: (U, U \setminus K, \varnothing) \to (M, M \setminus K, \varnothing)$, together with the observation that Lemma 87.24 implies that $h_*(\nu_U) = \nu_M$.

2. The 4-gon on the right commutes since all maps are induced by inclusions.

3. For the lower parallelogram we obtain commutativity from applying Lemma 83.8 to the inclusion map $g: (Z \cap U, Z \cap U \setminus K, C \cap U) \to (Z, Z \setminus K, C)$.

4. To show commutativity of the lower rectangle we apply Lemma 83.8 to the inclusion map $f: (Z, D, C) \to (Z, Z \setminus K, C)$.

\[^{1352}\text{Here we use the symbol for this map of triples of topological spaces. We feel that recycling the name $g$ is justified since this map of triples "contains" our original map $g: (Z \cap U, C \cap U) \to (Z, C)$ of pairs of topological spaces.}\]
Finally we turn to the upper rectangle. We need to show that the following rectangle commutes:

\[
\begin{array}{ccc}
\text{H}_k(U) & \xleftarrow{\cap p_U} & \text{H}^{m-k}(U, U \setminus K) \\
\downarrow p_* & & \downarrow z^* \\
\text{H}_k(U, U \setminus \hat{Z}) & \xleftarrow{z^*} & \text{H}_k(Z \cap U, C \cap U) & \xleftarrow{\cap p_Z} & \text{H}^{m-k}(Z \cap U, (Z \cap U) \setminus K) .
\end{array}
\]

Now let \( \beta \in \text{H}^{m-k}(U, U \setminus K) \). We have the following equalities in \( \text{H}_k(U, U \setminus \hat{Z}) \):

\[
\text{it follows from Lemma 87.31 that } \quad \text{we have } p_*(\nu_U) = z_*(\nu_Z) \text{ in } H_m(U, U \setminus K \cup U \setminus \hat{Z})
\]

\[
p_*(\beta \cap \nu_U) = \beta \cap p_*(\nu_U) = \beta \cap z_*(\nu_Z) = z_*(z^*(\beta) \cap \nu_Z). \quad \uparrow
\]

\[\text{Lemma 83.8 applied to the map} \quad p: (U, U \setminus K, \emptyset) \to (U, U \setminus K, U \setminus \hat{Z}) \quad \text{Lemma 83.8 applied to the map} \quad z: (Z \cap U, Z \cap U \setminus K, C \cap U) \to (U, U \setminus K, U \setminus \hat{Z})\]

We have thus shown that the diagram commutes. \[\blacksquare\]

After all these preparations we can finally attack Theorem 95.9

**Proof of Theorem 95.9** Let \( M \) be an oriented \( m \)-dimensional topological manifold with \( \partial M = \emptyset \). Also let \( \sigma = a_1 \cdot \sigma_1 + \cdots + a_r \cdot \sigma_r \in C_k(M) \) and \( \tau = b_1 \cdot \tau_1 + \cdots + b_s \cdot \tau_s \in C_{m-k}(M) \) be two singular cycles that intersect nicely.

**Claim 1.** We can assume that we are in the following setting: There exists an \( n \in \mathbb{N}_0 \), there exist distinct points \( P_1, \ldots, P_n \in M \) and there exist disjoint \( m \)-dimensional submanifolds \( Z_1, \ldots, Z_n \) of \( M \) such that the following hold:

1. For \( i \neq j \) we have \( |\sigma_i| \cap |\tau_j| = \emptyset \).
2. For each \( i \in \{1, \ldots, n\} \) we have \( |\sigma_i| \cap |\tau_i| = \{P_i\} \).
3. For \( i = n + 1, \ldots, \min\{r, s\} \) we have \( |\sigma_i| \cap |\tau_i| = \emptyset \).
4. For \( i \in \{1, \ldots, n\} \) the following hold: \((1353)\)
   a. \( P_i \) is contained in \( Z_i \setminus \partial Z_i \).
   b. \( Z_i \) is homeomorphic to \( 
   \]
   c. The map \( \sigma_i: \Delta^k \to M \) is actually a proper embedding \( \sigma_i: \Delta^k \to Z_i \) such that \( X_i := \sigma_i(\Delta^k) \) is a well-behaved submanifold of \( Z_i \). By the definition, see page 2303 this means that the submanifold \( \partial X_i = \sigma_i(\partial \Delta^k) \) of \( \partial Z_i \) admits a regular neighborhood \( A_i \).
   d. Similarly to (c) the map \( \tau_i: \Delta^{m-k} \to M \) is a proper embedding \( \tau_i: \Delta^{m-k} \to Z_i \) such that \( Y_i := \tau_i(\Delta^{m-k}) \) is a well-behaved submanifold of \( Z_i \). This means that the submanifold \( \partial Y_i = \tau_i(\partial \Delta^k) \) of \( \partial Z_i \) admits a regular neighborhood \( B_i \).
   e. We have \( A_i \cap B_i = \emptyset \).
   f. For \( j \neq i \) we have \( |\sigma_j| \cap Z_i = \emptyset \) and \( |\tau_j| \cap Z_i = \emptyset \).

\[\text{These statements imply in particular that } P_i \text{ is a nice intersection point of } \sigma_i \text{ and } \tau_i.\]
The proof of the claim is built out of the following ingredients:

(i) The fact, established in Exercise 6.25 that given any map \( f : \Delta^l \to M \) and given any \( P \in M \setminus f(\Delta^l) \) there exists an open neighborhood \( U \) of \( P \) with \( f(\Delta^l) \cap U = \emptyset \).

(ii) The “given any neighborhood \( U^m \)” feature of the definition of a nice intersection point.

(iii) By Lemma 41.1 we know that any \( \Delta^l \) is homeomorphic to \( B^l \).

(iv) We use that it follows from (iii) and the definition of a nice intersection point that any \( f(\tilde{X}) \) is homeomorphic to \( \Delta^k \) and any \( g(\tilde{Y}) \) is homeomorphic to \( \Delta^{m-k} \). (Here we use the notation from the definition of a nice intersection point, i.e. \( \tilde{X} \) and \( \tilde{Y} \) are defined on page 2304.) We combine this piece of information with Lemma 95.12.

We leave it to the reader to work out the elementary albeit slightly messy details. \( \square \)

Next we introduce the following notation:

(5) We write \( Z = Z_1 \cup \cdots \cup Z_n \).

(6) We write \( \tilde{\sigma} = a_{n+1} \cdot \sigma_{n+1} + \cdots + a_r \cdot \sigma_r \) and we denote by \( |\tilde{\sigma}| \) the union of the images of \( \sigma_{n+1}, \ldots, \sigma_r \). Similarly we define \( \tilde{\tau} \) and \( |\tilde{\tau}| \).

We refer to Figure 1346 on the left for an illustration.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1346.png}
\caption{Figure 1346}
\end{figure}

\textit{Claim 1.} There exist compact subsets \( K \) and \( L \) of \( M \) with the following properties:

(a) There exists a cohomology class \( \varphi \in H^{m-k}(M, M \setminus K) \) such that the image of \( \varphi \) in \( H^c_{m-k}(M) \) equals \( PD_M(|\tilde{\sigma}|) \).

(b) There exists a cohomology class \( \psi \in H^k(M, M \setminus L) \) such that the image of \( \psi \) in \( H^k_c(M) \) equals \( PD_M(|\tilde{\tau}|) \).

(c) We have \( K \cap L \cap (M \setminus Z) = \emptyset \).

(d) For each \( i \in \{1, \ldots, n\} \) we have \( K \cap \partial Z_i \subset A_i \) and \( L \cap \partial Z_i \subset B_i \).

We refer to Figure 1346 on the right for an illustration.

By Proposition 44.3 we know that \( W := M \setminus \tilde{Z} \) is an \( m \)-dimensional topological manifold.

It follows from Proposition 95.10 (2) that there exist disjoint open neighborhoods \( \tilde{U} \subset W \) of \( |\tilde{\sigma}| \) and \( \tilde{V} \subset W \) of \( |\tilde{\tau}| \) such that for each \( i \in \{1, \ldots, n\} \) we have \( \tilde{U} \cap \partial Z_i = \tilde{A}_i \) and \( \tilde{V} \cap \partial Z_i = \tilde{B}_i \). Next we write \( U = \bigcup_{i=1}^n \tilde{U}_i \) and \( V = \bigcup_{i=1}^n \tilde{V}_i \). Note that it follows from the elementary Lemma 2.6 (2) that \( U \) and \( V \) are open subsets of \( M \). We refer to Figure 1347 for an illustration.
We denote by \( i: U \to M \) the inclusion map. Evidently we have \( \sigma \in C_k(U) \). Since \( U \) is an open subset of \( M \) we can thus consider \( \text{PD}_U([\sigma]) \in H_c^{m-k}(U) \). By Lemma \( \text{[77.2]} \) there exists a compact subset \( K \) of \( U \) and a cohomology class \( \tilde{\varphi} \in H^{m-k}(U, U \setminus K) \) such that \( \text{PD}_U([\sigma]) \) equals the image of \( \tilde{\varphi} \) under the natural map \( H^{m-k}(U, U \setminus K) \to H_c^{m-k}(U) \). By excision, see page \( \text{[1840]} \) the map \( i^*: H^{m-k}(M, M \setminus K) \to H_c^{m-k}(U, U \setminus K) \) is an isomorphism. We set \( \varphi := (i^*)^{-1}(\tilde{\varphi}) \). By Lemma \( \text{[95.11]} \) we know that the image of \( \varphi \) in \( H_c^{m-k}(M) \) equals \( \text{PD}_M([\sigma]) \).

By precisely the same argument we can also find a compact subset \( L \) of \( V \) and some cohomology class \( \psi \in H^k(M, M \setminus L) \) such that the image of \( \psi \) in \( H_c^k(M) \) equals \( \text{PD}_M([\tau]) \).

Finally note that by construction \( K \) and \( L \), and also \( \varphi \) and \( \psi \) satisfy all the desired conditions set out in (a), (b), (c) and (d).

We continue with some more observations and notation.

(7) For \( i = 1, \ldots, n \) we write \( K_i = K \cap Z_i \) and \( L_i = L \cap Z_i \). Note that by construction we have \( K_i \cap L_i \subset \tilde{Z}_i = Z_i \setminus \partial Z_i \).

(8) Given any compact subset \( T \) of \( M \) we denote by \( o: (M, \emptyset) \to (M, M \setminus T) \) the obvious map. Also we denote by \( o^*: H^*(M, M \setminus T) \to H^*_c(M) \) the obvious map.

(9) We denote by \( z: Z \to M \) the inclusion map and we denote by \( z \) also all the inclusion maps of pairs of topological spaces where the total spaces are \( Z \) and \( M \).

(10) Given \( i \in \{1, \ldots, n\} \) we denote by \( z_i: Z_i \to Z \) the inclusion map. We adopt the same convention as in (9) for pairs of topological spaces.

(11) We view \( Z \) as an \( m \)-dimensional submanifold of \( M \) and we equip \( Z \) with the orientation coming from Lemma \( \text{[86.17]} \). Given any subset \( W \subset Z \) with \( \partial Z \subset W \) we denote by \([Z]\) also the image of the fundamental class of \( Z \) under the map \( H_m(Z, \partial Z) \to H_m(Z, W) \). We adopt the same convention for the \([Z_i]\).

(12) Recall that for each \( i \in \{1, \ldots, n\} \) we have \( K \cap \partial Z_i \subset A_i \) and \( L \cap \partial Z_i \subset B_i \).

This implies that we obtain the maps of pairs \( (Z_i, \partial Z_i \setminus A_i) \to (Z_i, Z_i \setminus K_i) \) and \( (Z_i, \partial Z_i \setminus B_i) \to (Z_i, Z_i \setminus L_i) \). We refer to each of these maps as the canonical map \( c \).

(13) For each \( i \in \{1, \ldots, n\} \) we have maps of pairs \( d: (Z_i, \partial Z_i \setminus A_i) \to (Z_i, \partial Z_i \setminus \partial X_i) \) and \( d: (Z_i, \partial Z_i \setminus B_i) \to (Z_i, \partial Z_i \setminus \partial Y_i) \). Since \( A_i \) is a regular neighborhood of \( \partial X_i \) and \( B_i \) is a regular neighborhood of \( \partial Y_i \) we obtain from Lemma \( \text{[73.13]} \) (4) that these maps induce isomorphisms of relative cohomology groups.

(14) By Theorem \( \text{[87.10]} \) there exists a unique lift \( \mu \in H_m(M, M \setminus (K \cap L)) \) of the orientation classes of \( M \).
With the above definitions and observations it now makes sense to consider the following diagram:

\[
\begin{array}{ccccccc}
H^{m-k}_c(M) \times H^k_c(M) & \rightarrow & H^c_c(M) & \cap M & H_0(M) & \epsilon_M & \rightarrow \mathbb{Z} \\
\downarrow o^* \times o^* & & \downarrow o^* & & \downarrow \text{id} & & \downarrow \text{id} \\
H^{m-k}(M, M \setminus K) \times H^k(M, M \setminus L) & \rightarrow & H^m(M, M \setminus (K \cap L)) & \cap M & H_0(M) & \epsilon_M & \rightarrow \mathbb{Z} \\
\downarrow z^* \times z^* & & \downarrow z^* & & \downarrow \text{id} & & \downarrow \text{id} \\
\bigoplus_{i=1}^n H^{m-k}(Z_i, Z_i \setminus K_i) \times H^k(Z_i, Z_i \setminus L_i) & \rightarrow & \bigoplus_{i=1}^n H^m(Z_i, Z_i \setminus K_i \cap L_i) & \cap [Z] & H_0(Z_i) \epsilon_Z & \rightarrow \mathbb{Z} \\
\downarrow \bigoplus_{i=1}^n c^* \times c^* & & \downarrow \bigoplus_{i=1}^n c^* & & \downarrow \text{id} & & \downarrow \text{id} \\
\bigoplus_{i=1}^n H^{m-k}(Z_i, \partial Z_i \setminus \partial A_i) \times H^k(Z_i, \partial Z_i \setminus \partial B_i) & \rightarrow & \bigoplus_{i=1}^n H^m(Z_i, \partial Z_i) & \cap [Z] & H_0(Z_i) \epsilon_Z & \rightarrow \mathbb{Z} \\
\downarrow \bigoplus_{i=1}^n d^* \times d^* & & \downarrow \text{id} & & \text{id} & & \text{id} \\
\bigoplus_{i=1}^n H^{m-k}(Z_i, \partial Z_i \setminus \partial X_i) \times H^k(Z_i, \partial Z_i \setminus \partial Y_i) & \rightarrow & \bigoplus_{i=1}^n H^m(Z_i, \partial Z_i) & \cap [Z] & H_0(Z_i) \epsilon_Z & \rightarrow \mathbb{Z}.
\end{array}
\]

Claim 2. The above diagram commutes.

In the following we deal with all of the fifteen squares of the diagram.

(a) The square on the top left commutes by definition of the cup product on cohomology with compact support, see page 2088.
(b) The left squares in the second row and also in the fourth row commute by Proposition 82.4 (1).
(c) The left square in the third row commutes by Lemma 83.9 (1) together with the aforementioned Proposition 82.4 (1).
(d) The middle square in the first row commutes by definition of the map \(\cap M\).
(e) It follows from Corollary 87.12 that \(z_*([Z]) = \mu \in H_m(M, M \setminus (K \cap L))\). Therefore we obtain from Lemma 83.8 (1) that the middle square in the second row commutes.
(f) It follows from the remark on page 2121 that \(\sum_{i=1}^n z_{i*}([Z_i]) = [Z]\). Now we obtain from Lemma 83.8 (1) and Lemma 83.9 (2) that the middle square in the third row commutes.
(g) The squares that involve the augmentation maps commute by the discussion on page 1088.
(h) It follows from Lemma 83.8 (1) and our conventions regarding the meaning of \([Z_i]\) that the middle square in the fourth row commutes.
(i) It follows from Proposition 82.4 that the bottom left square commutes.
(j) The remaining squares, that we did not discuss, commute for the trivial reason that the opposite maps in the square are actually on the nose the same map.

\(\square\)
We introduce one last piece of notation:

(15) For each $i \in \{1, \ldots, n\}$ we denote by $\text{PD}_{Z_i} : H_k(Z_i, \partial X_i) \to H^{m-k}(Z_i, \partial Z_i \setminus \partial X_i)$ the isomorphism from Proposition 95.2.

Claim 3. Let $i \in \{1, \ldots, n\}$.

(i) For the above $\varphi \in H^{m-k}(M, M \setminus K)$ we have $(c^* \circ z_i^* \circ z^*)(\varphi) = a_i \cdot d^*(\text{PD}_{Z_i}([X_i]))$.

(ii) For the above $\psi \in H^k(M, M \setminus L)$ we have $(c^* \circ z_i^* \circ z^*)(\psi) \neq b_i \cdot d^*(\text{PD}_{Z_i}([Y_i]))$.

(iii) We have

$$\epsilon_{Z_i}(\{(d^*(\text{PD}_{Z_i}([X_i]))) \cup d^*(\text{PD}_{Z_i}([Y_i]))\} \cap [Z_i]) = \text{index}(\sigma_i, \tau_i, P_i).$$

We provide the proof of the three statements:

(i) We introduce the following notation:

(a) We set $U := (M \setminus Z) \cup \bigcup_{i=1}^n \tilde{Z}_i \cup \bigcup_{i=1}^n \tilde{A}_i = M \setminus \bigcup_{i=1}^n (\partial Z_i \setminus \hat{A}_i)$. It is elementary to see that $U$ is in fact an open subset of $M$.

(b) We write $C := A_i$ and $D := \partial Z_i \setminus \hat{A}_i$. Note that it follows from Proposition 44.3 that $C$ and $D$ are compact codimension-zero submanifolds of $\partial Z_i$ with $C \cup D = \partial Z_i$ and with $C \cap D = \partial C = \partial D$.

(c) We denote by $p : (U, \emptyset) \to (U, U \setminus \tilde{Z}_i)$, $\tilde{z} : (Z_i \cap U, C \cap U) \to (U, U \setminus \tilde{Z}_i)$ and $g : (Z_i \cap U, C \cap U) \to (Z_i, C)$ the obvious inclusion maps.

We perform the following calculation in $H_k(Z_i, A_i)$:

$$(e^* \circ z_i^* \circ z^*)(\varphi) \cap [Z_i] = g_*(\tilde{z}_i^{-1}(p_*(\sigma_i))) \uparrow \downarrow g_*(\tilde{z}_i^{-1}(p_*(a_i \cdot [X_i]))) = a_i \cdot [X_i].$$

this follows from Lemma 95.13 applied to the above choices of $C$ and $D$, by Lemma 87.24 and the observation that $\varphi \cap M = [\sigma]$ with $[\sigma] \subset U$.

Now recall that in the proof of Proposition 95.2 we saw that the isomorphism $\text{PD}_{Z_i}$ is given as follows:

$$H^{m-k}(Z_i, \partial Z_i \setminus \partial X_i) \xrightarrow{d^*} H^{m-k}(Z_i, \partial Z_i \setminus \hat{A}_i) \xrightarrow{\cap[Z_i]} H_k(Z_i, A_i) \xrightarrow{j_*} H_k(Z_i, \partial X_i).$$

Since the inclusion induced map $j_* : H_k(Z_i, \partial X_i) \to H_k(Z_i, A_i)$ is an isomorphism we now see that $(c^* \circ z_i^* \circ z^*)(\varphi) = a_i \cdot d^*(\text{PD}_{Z_i}([X_i]))$.

(ii) The proof of this statement is evidently the same as the proof of (2).

(iii) This statement follows immediately from the definitions together with the fact, obtained in Claim 2, that the bottom squares in the above diagram commute. □
After all these preparations we can prove the desired equality:

by construction of $\varphi$ and $\psi$ in Claim 1 and the first row of the commutative diagram from Claim 2

\[
\epsilon_M((\text{PD}_M([\sigma]) \cup \text{PD}_M([\tau])) \cap M) \Downarrow \epsilon_M((\varphi \cup \psi) \cap \mu)
\]

\[
= \sum_{i=1}^n \epsilon_{Z_i}((c^* \circ z_i^* \circ z^*)(\varphi) \cup (c^* \circ z_i^* \circ z^*)(\psi) \cap [Z_i])
\]

by the second, third and fourth row of the commutative diagram from Claim 2

\[
= \sum_{i=1}^n a_i \cdot b_i \cdot \text{index}(\sigma_i, \tau_i, P_i) = \sigma \cdot \tau.
\]

by Claim 3 by the setting from page 2318

This concludes the proof of the theorem.

We conclude this section with the following variation on Theorem [95.9].

**Theorem 95.14.** Let $M$ be a compact orientable connected $m$-dimensional topological manifold. Furthermore let $A$ and $B$ be compact $(m-1)$-dimensional submanifolds of $\partial M$ with $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Finally let $\sigma \in C_k(M, A)$ and $\tau \in C_{m-k}(M, B)$ be two cycles. If $\sigma$ and $\tau$ intersect nicely, then

\[
\sigma \cdot \tau = \langle \text{PD}_M([\sigma]) \cup \text{PD}_M([\tau]), [M] \rangle.
\]

**Sketch of proof.** The proof of the theorem follows along the lines of the proof of Theorem [95.9]. The key difference is that we need to use Poincaré Duality for non-compact topological manifolds with boundary. More precisely, let $U$ be an oriented $m$-dimensional topological manifold with boundary. By Theorem [87.30] given any compact set $K$ of $U$ the orientation defines a natural homology class $\mu_K$ in $H_m(U, (U \setminus K) \cup \partial U)$. The same construction as in Lemma [88.18] this time using Lemma [87.31] instead of Corollary [87.12] shows that capping with these homology classes defines a well-defined map

\[
\text{PD}_U: H^k_c(U) \rightarrow H_{m-k}(U, \partial U).
\]

A moderately heroic effort shows that the proof of the Poincaré Duality Theorem [88.1] as provided in Section [88.4] can be modified to show that the above map $\text{PD}_U$ is an isomorphism. Once this is out of the way it is fairly straightforward to modify the proof of Theorem [95.9] to obtain a proof of Theorem 95.14.
95.5. **The algebraic $\mathbb{F}_2$-intersection number** (*). In this section we quickly discuss the "$\mathbb{F}_2$-analogue" of the results of the previous sections.

**Definition.** Let $M$ be an $m$-dimensional topological manifold, let $X$ be a $k$-dimensional topological manifold and let $Y$ be an $(m - k)$-dimensional topological manifold. Furthermore let $f: X \to M$ and $g: Y \to M$ be maps. If $f$ and $g$ intersect nicely, then we define

the algebraic $\mathbb{F}_2$-intersection number of $f$ and $g := f \cdot_{\mathbb{F}_2} g := \#(|f| \cap |g|)$ mod 2.

If $X$ and $Y$ are in fact submanifolds and $f$ and $g$ are the inclusion map, then we write $X \cdot_{\mathbb{F}_2} Y := f \cdot_{\mathbb{F}_2} g$.

We recall the following notation.

**Notation.**

1. In Corollary \[87.3\] we saw that any compact $n$-dimensional topological manifold $W$ comes with its $\mathbb{F}_2$-fundamental class $[W]_{\mathbb{F}_2} \in H_n(W, \partial W; \mathbb{F}_2)$. If $W$ is in fact a proper submanifold of some other topological manifold $M$, then frequently we denote by $[W]_{\mathbb{F}_2} \in H_n(M, \partial M; \mathbb{F}_2)$ the image of $[W]_{\mathbb{F}_2}$ under the inclusion induced map $H_n(W, \partial W; \mathbb{F}_2) \to H_n(M, \partial M; \mathbb{F}_2)$.

2. In this section, given a compact topological manifold we denote by $\text{PD}_M$ the Poincaré Duality isomorphisms with $\mathbb{F}_2$-coefficients provided by the Poincaré Duality Theorem \[88.1\].

Now we can formulate the following theorem, which is a variation on Theorem \[95.7\].

**Theorem 95.15.** Let $M$ be a compact connected $m$-dimensional topological manifold. Furthermore let $A$ and $B$ be compact $(m - 1)$-dimensional submanifolds of $\partial M$ such that $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let $X$ be a compact $k$-dimensional topological manifold and let $Y$ be a compact $(m - k)$-dimensional topological manifold. Finally let $f: X \to M$ and $g: Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If $f$ and $g$ intersect nicely, then

$$
 f \cdot_{\mathbb{F}_2} g = \langle \text{PD}_M([X]_{\mathbb{F}_2}) \cup \text{PD}_M([Y]_{\mathbb{F}_2}), [M]_{\mathbb{F}_2} \rangle \in \mathbb{F}_2.
$$

In particular, if $X$ and $Y$ are already submanifolds of $M$, then

$$
 X \cdot_{\mathbb{F}_2} Y = \langle \text{PD}_M([X]_{\mathbb{F}_2}) \cup \text{PD}_M([Y]_{\mathbb{F}_2}), [M]_{\mathbb{F}_2} \rangle.
$$

**Proof.** By Proposition \[86.13\] every topological manifold is $\mathbb{F}_2$-orientable. With this observation the proof of the theorem is a variation, and basically a simplification, of the proof of Theorem \[94.5\]. We leave it to the skeptical reader to fill in the details. \[\square\]

**Example.** Similar to the discussion on page \[2277\] we can use Theorem 95.15 to show that some homology classes are in fact non-zero. For example in Figure \[1349\] we show the Klein bottle $K$ together with two closed 1-dimensional submanifolds. These intersect in precisely
one point, so their algebraic $F_2$-intersection number is necessarily non-zero. Theorem $95.15$ implies that $[X]_{F_2}$ and $[Y]_{F_2}$ are non-zero in $H_1(K; F_2)$.

\[ \text{Klein bottle } K \quad \text{submanifold } X \quad \text{submanifold } Y \]

**Figure 1349**

**Remark.** A discussion of intersection numbers in topological manifolds is also given in [Do180] Chapter VIII.13.

---

**Exercises for Chapter 95**

**Exercise 95.1.** Is every topological space that is Hausdorff also normal?

**Exercise 95.2.** We consider the manifold $M = Z = [0, 1]^2$ and the two embeddings $f, g : [0, 1] \rightarrow Z$ that are shown in Figure 1333. Note that $P = (0, 0)$ is the unique intersection point of $|f|$ and $|g|$. Show that $\text{index}(f, g, P) = 0$.

**Exercise 95.3.** Can one use the Generalized Alexander Duality Theorem $92.10$ to answer Question $95.1$? Or some other of the earlier theorems? If yes, how would you do it? You could also try to restrict yourselves to the case that the map $\alpha$ is injective.

**Exercise 95.4.** Let $M$ be a compact oriented connected $n$-dimensional topological manifold and let $N \subset M$ be a compact oriented proper submanifold of codimension one. Finally let $\gamma : S^1 \rightarrow M$ be a map that intersects $N$ nicely. Show that

\[ \langle \text{PD}_M([N]), \gamma_*([S^1]) \rangle = \gamma \cdot N. \]

**Exercise 95.5.** In Figure 1333 we saw that $-1, 0, 1$ can be indices of nice intersection points of oriented submanifolds. Can any other numbers occur as indices of nice intersection points?

**Exercise 95.6.** Let $n \in \mathbb{N}$. By the discussion on page 1845 we know that for any $k \in \mathbb{N}_0$ we have

\[ H^k(\mathbb{R}P^n; F_2) \cong \begin{cases} F_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise}. \end{cases} \]

Use Theorem $95.15$ to show that the obvious map

\[ F_2[x]/(x^{n+1}) \rightarrow (H^*(\mathbb{R}P^n; F_2), \cup) \]
is a ring isomorphism.

Remark. In Proposition 90.16 we used a rather different approach to calculating the cup product on $H^*(\mathbb{R}P^n; \mathbb{F}_2)$. 
First we recall the following definition from page 1623.

**Definition.** Let $M$ be a compact topological manifold and let $f: M \to M$ be a map. We define the Lefschetz number of $f$ to be

$$\Lambda(f) := \sum_{n \in \mathbb{N}_0} (-1)^n \cdot \text{tr}(f^*_n: H_n(M; \mathbb{Z}) \to H_n(M; \mathbb{Z})).$$

The following is one of our main results on the Lefschetz number.

**Theorems 65.10 and 85.11 (Lefschetz Fixed Point Theorem)** Let $M$ be a compact smooth or topological manifold and let $f: M \to M$ be a map. If the Lefschetz number $\Lambda(f)$ is non-zero, then $f$ has a fixed point.

In this chapter we will prove the Lefschetz-Hopf Theorems 96.5 and 96.9. These allow us to compute the Lefschetz number $\Lambda(f)$ as the sum of “indices” of the fixed points of a given map $f: M \to M$. In particular, if there are no fixed points, then this sum is zero. Thus the Lefschetz-Hopf Theorems are generalizations of the above version of the Lefschetz Fixed Point Theorem.

Recall that in Theorem 65.17 we used the Lefschetz Fixed Point Theorem 65.10 to show that if a closed smooth manifold has non-zero Euler characteristic, then every vector field on $M$ has at least one zero. In the following chapter we will use the Lefschetz-Hopf Theorems 96.5 and 96.9 to prove the Poincaré-Hopf Theorem 97.5 which is a significant generalization of Theorem 65.17.

### 96.1. The Lefschetz number as an intersection number

We start out with recalling and introducing some notation. We will make use of this notation throughout this chapter.

**Notation.** Let $M$ be an $n$-dimensional topological respectively smooth manifold.

1. It follows from Propositions 6.5 and 80.9 that we can view $M \times M$ as an $2n$-dimensional topological respectively smooth manifold.
2. We denote by $p_1, p_2: M \times M \to M$ the projection onto the first respectively second factor.
3. We write $\Delta_M := \{(x, x) \in M \times M \mid x \in M\}$.
4. Let $f: M \to M$ be a map. We denote by $\text{id} \times f: M \to M \times M$ the map that is given by $x \mapsto (x, f(x))$. We write $\text{Gr}(f) = (\text{id} \times f)(M)$. Note that $\text{Gr}(\text{id}) = \Delta_M$.
5. The map $\text{id} \times f: M \to M$ is easily seen to be a (smooth) proper embedding. Thus we can view $\text{Gr}(f)$ as a proper $n$-dimensional submanifold of $M \times M$.
6. Now assume that $M$ is oriented.
   a. We equip $M \times M$ with the product orientation that we defined on pages 304 and 1623.
   b. We equip $\text{Gr}(f)$ with the unique orientation that turns $\text{id} \times f$ into an orientation-preserving map.
Examples. The statement of Proposition 96.1 gets shortened to the potentially ambiguous statement

Remark. Sometimes in the literature, in line with the notation introduced on page 2307, we will discuss the intersection form in great detail in Chapter 100.

\[ \text{Figure 1351} \]

To formulate the main result of this section we will also need the following definition.

**Definition.**

1. Given a finitely generated abelian group we write \( FH := H / \text{Tor}(H) \), where \( \text{Tor}(H) \) denotes the torsion subgroup of \( H \).
2. Let \( W \) be a closed oriented \( 2n \)-dimensional topological manifold. We refer to the map

\[
Q_W : FH_n(W; \mathbb{Z}) \times FH_n(W; \mathbb{Z}) \to \mathbb{Z}
\]

\[
(a, b) \mapsto (\text{PD}_W(a) \cup \text{PD}_W(b), [W])
\]

as the intersection form of \( W \).

Remark. We will discuss the intersection form in great detail in Chapter 100.

Now we can formulate the following, potentially quite counterintuitive proposition.

**Proposition 96.1.** Let \( M \) be a closed oriented connected non-empty \( n \)-dimensional topological manifold.

1. We have \( Q_{M \times M}([\Delta_M], [\Delta_M]) = \chi(M) \).
2. Given any map \( f : M \to M \) we have \( Q_{M \times M}([\text{Gr}(f)], [\Delta_M]) = \Lambda(f) \).

Remark. Sometimes in the literature, in line with the notation introduced on page 2307, the statement of Proposition 96.1(1) gets shortened to the potentially ambiguous statement “\( M \cdot M = \chi(M) \)”.

Examples.

1. Suppose that in Proposition 96.1 we actually have a smooth manifold \( M \) and a smooth map \( f : M \to M \). In this case we can view \( \Delta_M \) and \( \text{Gr}(f) \) as oriented \( n \)-dimensional submanifolds of \( M \times M \). If these two submanifolds are transverse, then it follows from Theorem 94.5 that we can calculate \( Q_{M \times M} \) geometrically, more precisely, we have the following equality:

\[
Q_{M \times M}([\text{Gr}(f)], [\Delta_M]) = \text{algebraic intersection number} \text{\ of \ the \ oriented} \ \text{submanifolds} \ \Delta_M \ \text{and} \ \text{Gr}(f), \ \text{as \ defined \ on \ page} 2271
\]
For example, let us consider the map $f : S^1 \to S^1$ that is illustrated in Figure 1352.

We see that
\[
\text{Gr}(f) \cdot \Delta_M = -1 + 1 - 1 = -1 = (-1)^0 \cdot 1 + (-1)^1 \cdot 2 = \Lambda(f).
\]

There are three intersection points with signs $-1, +1$ and $-1$ since $\text{tr}(f \cap H_0(S^1; \mathbb{Z})) = 1$ and $\text{tr}(f \cap H_1(S^1; \mathbb{Z})) = 2$.

Fortunately this is consistent with Proposition 96.1 (2).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{s1x_s1}
\caption{Graph $\text{Gr}(f)$ of $f$}
\end{figure}

(2) Let $n \in \mathbb{N}$. We have
\[
Q_{S^n \times S^n}([\Delta_{S^n}],[\Delta_{S^n}]) = \uparrow (1 \ 1) \begin{pmatrix} 0 & 1 \\ (-1)^n & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = 1 + (-1)^n = \chi(S^n).
\]

Again this is consistent with Proposition 96.1 (1).

The proof of Proposition 96.1 requires some preparations. In particular we will need the following lemma.

**Lemma 96.2.** Let $M$ be a closed oriented connected non-empty $n$-dimensional topological manifold, let $i \in \{0, \ldots, n\}$ and let $v_1, \ldots, v_m$ be a basis of $\text{FH}^i(M; \mathbb{Z})$. There exists a basis $\tilde{v}_1, \ldots, \tilde{v}_m$ of $\text{FH}^{n-i}(M; \mathbb{Z})$ such that for any $k, l \in \{1, \ldots, m\}$ we have $\langle v_k \cup \tilde{v}_l, [M] \rangle = \delta_{kl}$.

**Proof of Lemma 96.2** The statement of the lemma is precisely the content of Exercise 88.12. For the reader’s convenience we nonetheless provide the proof. For $j = 1, \ldots, m$ we set $\sigma_j := v_j \cap [M] \in \text{FH}_{n-i}(M; \mathbb{Z})$. By the Poincaré Duality Theorem 88.1 we know that $\sigma_1, \ldots, \sigma_m$ is a basis for $\text{FH}_{n-i}(M; \mathbb{Z})$. Next note that it follows from the Universal Coefficient Theorem 75.13 for Cohomology Groups together with Lemma 75.5 (5) and Proposition 85.13 (4) that the map
\[
\text{FH}^{n-i}(M; \mathbb{Z}) \to \text{Hom}(\text{FH}_{n-i}(M; \mathbb{Z}), \mathbb{Z})
\]
\[
\varphi \mapsto (\sigma \mapsto \langle \varphi, \sigma \rangle)
\]
is an isomorphism. We denote by $\tilde{v}_1, \ldots, \tilde{v}_m$ the cohomology classes with $\langle \tilde{v}_k, \sigma_l \rangle = \delta_{kl}$. By the above $\tilde{v}_1, \ldots, \tilde{v}_m$ are a basis for $\text{FH}^{n-i}(M; \mathbb{Z})$. Now we see that for any $k, l \in \{1, \ldots, m\}$ we have
\[
\langle v_k \cup \tilde{v}_l, [M] \rangle \downarrow (v_k \cup \tilde{v}_l) \cap [M] = \tilde{v}_l \cap (v_k \cap [M]) = \tilde{v}_l \cap \sigma_k \downarrow \langle \tilde{v}_l, \sigma_k \rangle = \delta_{kl}.
\]

by Lemma 83.4 (1), under the usual identification $H_0(M; \mathbb{Z}) = \mathbb{Z}$

Lemma 83.7
Lemma 96.2 allows us to formulate our next lemma, which will be a key ingredient in the proof of Proposition 96.1.

**Lemma 96.3.** Let $M$ be a closed oriented connected $n$-dimensional topological manifold. For $i = 0, \ldots, n$ we pick a basis $v_1^i, \ldots, v_{m_i}^i$ of $\text{FH}^i(M; \mathbb{Z})$. By Lemma 96.2 there exists a basis $\tilde{v}_1^{n-i}, \ldots, \tilde{v}_{m_i}^{n-i}$ of $\text{FH}^{n-i}(M; \mathbb{Z})$ such that for any $k, l \in \{1, \ldots, m_i\}$ we have $\langle v_k^i \cup \tilde{v}_l^{n-i}, [M] \rangle = \delta_{kl}$.

1. We have the following equality in $\text{H}^n(M \times M; \mathbb{Z})$:
   \[
   \text{PD}_{M \times M}(\Delta_M) = \sum_{i=0}^{n} (-1)^{i(n-i-1)} \cdot \sum_{r=1}^{m_i} p_1^*(\tilde{v}_r^{n-i}) \cup p_2^*(v_i^r).
   \]

2. Given any map $f : M \rightarrow M$ we have the following equality in $\text{H}^n(M \times M; \mathbb{Z})$:
   \[
   \text{PD}_{M \times M}([\text{Gr}(f)]) = \sum_{i=0}^{n} (-1)^{i(n-i-1)} \cdot \sum_{k=1}^{m_i} \sum_{l=1}^{m_l} \langle v_k^i \cup f^*(\tilde{v}_l^{n-i}), [M] \rangle \cdot p_1^*(\tilde{v}_k^{n-i}) \cup p_2^*(v_l^i).
   \]

**Proof of Lemma 96.3.** First we show that Statement (1) follows almost immediately from Statement (2). Indeed, we have

\[
\text{PD}_{M \times M}([\text{Gr}(\text{id}_M)]) = \sum_{i=0}^{n} (-1)^{i(n-i-1)} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_j} \langle v_k^i \cup \tilde{v}_s^{n-i}, [M] \rangle \cdot p_1^*(\tilde{v}_r^{n-i}) \cup p_2^*(v_l^i).
\]

Statement (2) applied to $f = \text{id}_M$ Thus it remains to prove Statement (2) of Lemma 96.3. We start out the proof of Statement (2) with the following claim.

**Claim.** For $j \in \{0, \ldots, n\}$ and $r, s \in \{1, \ldots, m_j\}$ there exist a unique $a_{j,r,s} \in \mathbb{Z}$ such that

\[
\text{PD}_{M \times M}([\text{Gr}(f)]) = \sum_{j=0}^{n} \sum_{r=1}^{m_j} \sum_{s=1}^{m_j} a_{j,r,s} \cdot p_1^*(\tilde{v}_r^{n-j}) \cup p_2^*(v_l^s) \in \text{H}^n(M \times M; \mathbb{Z}).
\]

Recall that by Proposition 85.13 (4) we know that the homology groups of $M$ are all finitely generated. Thus it follows from the Künneth Theorem 84.16 for Cohomology Groups that there exists a short exact sequence of the following form:

\[
0 \rightarrow \bigoplus_{j=0}^{n} \text{H}^{n-j}(M; \mathbb{Z}) \otimes \text{H}^j(M; \mathbb{Z}) \rightarrow \text{H}^n(M \times M; \mathbb{Z}) \rightarrow \bigoplus_{j=0}^{n+1} \text{Tor}(\text{H}^{n+1-j}(M; \mathbb{Z}), \text{H}^j(M; \mathbb{Z})) \rightarrow 0.
\]

The Künneth Theorem 84.16 also says that the short exact sequence splits. Since the group on the right is torsion it follows easily, using some of the elementary properties of tensor product that we listed in Lemma 57.3, that the map

\[
\bigoplus_{j=0}^{n} \text{FH}^{n-j}(M; \mathbb{Z}) \otimes \text{FH}^j(M; \mathbb{Z}) \xrightarrow{\varphi \otimes \psi \mapsto p_1^*(\varphi) \cup p_2^*(\psi)} \text{FH}^n(M \times M; \mathbb{Z})
\]

is an isomorphism. The claim follows immediately from this fact.  

First we remind the reader of a few facts on the cup, cap and cross product. To shorten the discussion we leave it to the reader to figure out what the various symbols stand for.

(a) Given \( \varphi \in H^i(M; \mathbb{Z}) \) and \( \sigma \in H_j(M; \mathbb{Z}) \) we have \( \varphi \cap \sigma = \langle \varphi, \sigma \rangle \in H_0(M; \mathbb{Z}) = \mathbb{Z} \).

(b) By Lemma 81.8 we have \( \psi \cap \varphi = \langle \psi, \varphi \rangle \cap \sigma = \varphi \cap (\psi \cap \sigma) \).

(c) By Proposition 81.8 we have \( \varphi \cup \psi = (-1)^{\deg(\varphi) \cdot \deg(\psi)} \cdot \psi \cup \varphi \).

(d) Given \( g : X \to Y \) we know by Lemma 4.6 (3) we have \( \langle g^*(\varphi), \sigma \rangle = \langle \varphi, g_*(\sigma) \rangle \).

(e) Given \( g : X \to Y \) we know by Lemma 81.10 that \( g^*(\varphi) \cup g^*(\psi) = g^*(\varphi \cup \psi) \).

(f) By Proposition 80.10 we have \([M \times M] = [M] \times [M] \). Furthermore, by Proposition 84.2 we have \( p_1^*([M]^1) + p_2^*([M]^1) = [M] \times [M]^* \).

(g) By the Product Theorem 84.1 we have

\[
(p_1^*(\alpha) \cup p_2^*(\beta)) \cap (\mu \times \nu) = (-1)^{\deg(\alpha) \cdot \deg(\beta) \cdot \deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu).
\]

(h) By Exercise 80.2 the cross product on \( H_0 \) corresponds to multiplication under the augmentation maps.

(i) Given any \( k \in \mathbb{Z} \) we have \((-1)^k = (-1)^{k^2}\).

Given \( i \in \{0, \ldots, n\} \) and \( k, l \in \{1, \ldots, m_i\} \) we calculate that

\[
\langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}) \cup \text{PD}_{M \times M}([\text{Gr}(f)]), [M \times M]\rangle
\]

\[
= (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}), \text{PD}_{M \times M}([\text{Gr}(f)]) \cap [M \times M] \rangle
\]

\[
= (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}), [\text{Gr}(f)] \rangle
\]

\[
= (-1)^n \cdot \langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}), (\text{id} \times f)_*(\text{[M]}) \rangle
\]

\[
= (-1)^n \cdot \langle p_1 \circ (\text{id} \times f)^*(v_k^i) \cup (p_2 \circ (\text{id} \times f))^*(\tilde{v}_l^{-n-i}), \text{[M]} \rangle
\]

\[
= (-1)^n \cdot \langle v_k^i \cup f^*(\tilde{v}_l^{-n-i}), \text{[M]} \rangle
\]

Since \( p_1 \circ (\text{id} \times f) = \text{id} \)

and \( p_2 \circ (\text{id} \times f) = f \).

Next we perform an alternative calculation:

\[
\langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}) \cup \text{PD}_{M \times M}([\text{Gr}(f)]), [M \times M]\rangle
\]

\[
= \left( \langle p_1^*(v_k^i) \cup p_2^*(\tilde{v}_l^{-n-i}) \rangle \cup \sum_{j=0}^{n-i} \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} a_{j,r,s} \langle p_1^*(v_j^i \cup \tilde{v}_r^{-n-1}) \cup p_2^*(\tilde{v}_l^{-n-i} \cup v_s^j), [M \times M] \rangle \right)
\]

by the claim

\[
= (-1)^{n-n-j} \cdot \sum_{j=0}^{n-i} \sum_{r=1}^{m_i} \sum_{s=1}^{m_i} a_{j,r,s} \langle p_1^*(v_j^i \cup \tilde{v}_r^{-n-1} \cup v_s^j), [M \times M] \rangle
\]

by (c) and (e)

\[
= (-1)^{n-i} \cdot \sum_{j=r+1}^{m_i} a_{i,r,s} \cdot \langle v_j^i \cup \tilde{v}_r^{-n-1} \cup v_s^j, [M \times M] \rangle
\]

by (f) and (i)

\[
= (-1)^{n-i} \cdot \sum_{r=1}^{m_i} a_{i,r,s} \cdot \langle v_j^i \cup \tilde{v}_r^{-n-1} \cup v_s^j, [M] \rangle \cdot \langle \tilde{v}_l^{-n-i}, [M] \rangle
\]

by (a), (g) and (h)

\[
= (-1)^{n-i} \cdot \sum_{r=1}^{m_i} a_{i,r,s} \cdot (-1)^{i-(n-i)} \cdot \delta_{kr} \cdot \delta_{ls} = (-1)^{n-i-i-(n-i)} \cdot a_{i,k,l}.
\]
Comparing these two calculations of $\langle p_1^i(v_k^i) \cup p_2^*(\bar{v}_{i}^{n-i}) \cup \text{PD}_{M \times M}([\text{Gr}(f)]), [M \times M] \rangle$ we see that $(-1)^{(n-i-1)\cdot i} \cdot \langle v_k^i \cup f^*(\bar{v}_{i}^{n-i}), [M] \rangle = a_{i,k,l}$. But that is exactly what we needed to show.

Now we are finally ready to provide the proof of Proposition 96.1 (1). Note, that as we pointed out in Lemma 65.6 we have $\Lambda(\text{id}) = \chi(M)$. Thus we see that Proposition 96.1 (1) is just a special case of Proposition 96.1 (2). Nonetheless, to reduce the notational mess we first prove Proposition 96.1 (1) separately.

**Proof of Proposition 96.1 (1).** We start out with the following claim which gives us a description of PD$_{M \times M}([\Delta_M])$ that differs slightly from the one provided by Lemma 96.3 (1).

**Claim.** We have

$$\text{PD}_{M \times M}([\Delta_M]) = \sum_{j=0}^{n} (-1)^j \cdot \sum_{s=1}^{m_j} p_1^s(v_j^s) \cup p_2^s(\bar{v}_{s}^{n-j}).$$

Let $j \in \{0, \ldots, n\}$. Recall that we have $v_j^n \cup \bar{v}_j^n = \delta_{rs}$. From Proposition 81.8 we obtain that $\bar{v}_j^j \cup v_j^{n-j} = (-1)^j(n-j) \cdot \delta_{rs}$. In other words, we have $\bar{v}_j^j \cup (-1)^j(n-j) \cdot v_j^{n-j} = \delta_{rs}$. Now we see that

$$\text{PD}_{M \times M}([\Delta_M]) = \sum_{j=0}^{n} (-1)^j(n-j-1) \cdot \sum_{s=1}^{m_j} p_1^s(v_j^s) \cup p_2^s(\bar{v}_{s}^{n-j}).$$

by Lemma 96.3 (1), applied to the bases $\{\bar{v}_j^j\}_{r=1,\ldots,m_j}$, and the corresponding dual bases $\{(1)^{j(n-j)} \cdot v_j^{n-j}\}_{s=1,\ldots,m_j}$.

Now we calculate that

$$\text{PD}_{M \times M}([\Delta_M]) \cup \text{PD}_{M \times M}([\Delta_M]) =$$

$$= \left( \sum_{i=0}^{n} (-1)^{i(n-i-1)} \cdot \sum_{r=1}^{m_i} p_1^i(\bar{v}_r^{n-i}) \cup p_2^i(v_r^i) \right) \cup \left( \sum_{j=0}^{n} (-1)^j \cdot \sum_{s=1}^{m_j} p_1^s(v_j^s) \cup p_2^s(\bar{v}_{s}^{n-j}) \right)$$

by Lemma 96.3 (1) and the claim

$$= \sum_{i=0}^{n} \sum_{j=0}^{n} (-1)^{i(n-i-1)+j} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_j} p_1^i(\bar{v}_r^{n-i}) \cup p_2^i(v_r^i) \cup p_1^s(v_j^s) \cup p_2^s(\bar{v}_{s}^{n-j})$$

by Proposition 81.8 and Lemma 81.10

$$= \sum_{i=0}^{n} \sum_{j=0}^{n} (-1)^{i(n-i-1)+j} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{m_j} (-1)^{i+j(n-i)} \cdot p_1^i(v_r^i \cup \bar{v}_{r}^{n-i}) \cup p_2^i(v_r^i \cup \bar{v}_{r}^{n-i})$$

since $i + i^2$ is even and

$$= \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} p_1^i([M]^*) \cup p_2^i([M]^*) = \chi(M) \cdot [M \times M]^*.$$  

The desired statement now follows from the observation that by definition of $[M \times M]^*$ we have $\langle [M \times M]^*, [M \times M] \rangle = 1$. 

$\blacksquare$
Proof of Proposition 96.1 (2). The proof of Proposition 96.1 (2) is a generalization of the proof of Proposition 96.1 (1). It turns out that this argument is even less readable. In the following we quickly run through the argument and we only explain the steps that differ from the proof of Proposition 96.1 (2). We calculate that

\[ \text{PD}_{M \times M}([\text{Gr}(f)]) \cup \text{PD}_{M \times M}([\Delta_M]) = \]

\[ = \sum_{i=0}^{n} (-1)^{i(n-i)} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{n_i} (v_i \cup f^*(\widetilde{v}_s^n), [M]) \cdot p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_i) \cup (\sum_{j=0}^{n} (-1)^j \cdot \sum_{t=1}^{m_j} p_1^*(v_t) \cup p_2^*(\widetilde{v}_r^{n-j})) \]

by Lemma 96.3 (2) and the rewriting procedure as in the claim in the proof of Proposition 96.1 (1)

\[ = \sum_{i=0}^{n} \sum_{j=0}^{i} (-1)^{i(n-i)+j} \cdot \sum_{r=1}^{m_i} \sum_{s=1}^{n_i} (v_i \cup f^*(\widetilde{v}_s^n), [M]) \cdot p_1^*(\widetilde{v}_r^{n-i}) \cup p_2^*(v_i) \cup p_1^*(v_j) \cup p_2^*(\widetilde{v}_r^{n-j}) \]

\[ = \sum_{i=0}^{n} \sum_{j=0}^{i} (-1)^{i(n-i)+j} \cdot (v_i \cup f^*(\widetilde{v}_s^n), [M]) \cdot p_1^*(v_j) \cup p_2^*(v_i) \cup p_2^*(\widetilde{v}_r^{n-j}) \]

\[ = \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} (v_i \cup f^*(\widetilde{v}_r^n), [M]) \cdot \sum_{r=1}^{m_i} a_{rs}^t \cdot \widetilde{v}_s^n \cdot [M] \cdot [M \times M]^* \uparrow_{\Delta_M} \]

we define \( a_{rs}^t \) in the obvious way such that this equality holds

\[ = \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} a_{rs}^t \cdot (v_i \cup f^*(\widetilde{v}_r^n), [M]) \cdot [M \times M]^* = \sum_{i=0}^{n} (-1)^i \cdot \sum_{r=1}^{m_i} a_{rs}^t \cdot [M \times M]^* = \lambda(f) \cdot [M \times M]^* \uparrow_{\Delta_M} \]

As in the proof of Proposition 96.1 (1) we are now done.

96.2. The Lefschetz–Hopf Theorem I. In Proposition 96.1 we saw that we can express the Lefschetz number of a self-map of a manifold as an intersection number. Furthermore in Theorem 94.5 and in the more fancy Theorem 95.9 we learned how to determine intersection numbers using signs and indices of intersection points. The combination of the results, together with some fairly standard arguments, allows to prove two versions of the Lefschetz–Hopf Theorem. In this section we will use the more elementary Theorem 94.5 to prove the more basic version of the Lefschetz–Hopf Theorem.

Definition.

(1) Let \( M \) be a smooth manifold and let \( f : M \to M \) be a smooth map.

(a) Let \( x \in M \) be a fixed point of \( f \). Note that the differential \( Df_x \) is an endomorphism \( Df_x : T_xM \to T_xM \). We say that the fixed point \( x \) is non-degenerate if the endomorphism \( \text{id}_{T_xM} - Df_x \) of \( T_xM \) is invertible. Otherwise we say that the fixed point is degenerate.

(b) Given a non-degenerate fixed point \( x \in M \) we define

\[ \text{index}(f, x) := \text{sign}(\det(\text{id} - Df_x)) = \frac{\det(\text{id} - Df_x)}{\|\det(\text{id} - Df_x)\|}. \]
(2) Let $X$ be a topological space and let $f: X \to X$ be a map. We say a fixed point $x$ of $f$ is isolated if there exists a neighborhood $U$ of $x$ which does not contain another fixed point.

**Example.** Let $n \in \mathbb{Z}$. We consider the map $f: S^1 \to S^1$ that is given by $f(z) = z^n$. An elementary calculation shows that for each fixed point $x \in S^1$ the differential $Df_x$ is given by multiplication by $n$.

(1) If $n = 1$, then every point on $S^1$ is a fixed point of $f$, and each fixed point is degenerate.

(2) If $n \neq 1$, then the fixed points of $f$ are $x_j = e^{2\pi ij/(n-1)}$, $j = 1, \ldots, |n-1|$. If $n \geq 1$, then the index of every fixed point is $\text{sign}(1-n) = -1$, and if $n \leq 0$, then the index of every fixed point is $\text{sign}(1-n) = +1$.

![Graph of the map](image)

**Figure 1353**

**Lemma 96.4.**

(1) Let $M$ be a smooth manifold and let $f: M \to M$ be a smooth map. Every non-degenerate fixed point is also an isolated fixed point.

(2) Let $X$ be a topological space and let $f: X \to X$ be a map. We assume that $X$ is compact and Hausdorff. In this setting every fixed point of $f$ is isolated if and only if $f$ has only finitely many fixed points.

**Proof ($\ast$).**

(1) Using charts we see that we only need to consider the case that $M$ is an open subset of some $\mathbb{R}^n$ and we can assume that the fixed point is $x = 0$. We consider the map $g: M \to \mathbb{R}^n$ that is given by $x \mapsto x - f(x)$. By our hypothesis we know that $Dg_0 = \text{id}_{\mathbb{R}^n} - Df_0$ is invertible. It follows from the Inverse Function Theorem 6.18 that the map $x \mapsto g(x) = x - f(x)$ is a local diffeomorphism. In particular there exists an open neighborhood $U$ of $0$ such that the map $x \mapsto g(x) = x - f(x)$ is injective. But since $g(0) = 0$ this implies that $U$ does not contain any other fixed point of $f$.

(2) This statement is the content of Exercise 3.17. For the reader’s peace of mind we provide the proof. Thus let $X$ be a topological space that is compact and Hausdorff. Furthermore let $f: X \to X$ be map. We denote by $F \subset X$ be the fixed point set of $f$.

If $F$ is finite, then it follows easily from the hypothesis that $X$ is Hausdorff that $F$ is a discrete subset of $X$. Conversely, suppose that $F$ is a discrete subset of $X$. Note that it follows from Lemmas 2.40 and 2.17 together with Proposition 3.12 that...
\( \Delta_X \) and \( \text{Gr}(f) \) are closed subsets of \( X \times X \). Thus \( \Delta_X \cap \text{Gr}(f) \) itself is a closed subset of \( X \times X \), in particular it is a closed subset of \( \Delta_X \). We denote by \( p: \Delta_X \to X \) the projection onto the first factor. Evidently this map is a homeomorphism and \( F = p(\Delta_X \cap \text{Gr}(f)) \). Thus we have shown that \( F \) is a closed subset of \( X \) and by hypothesis we know that \( F \) is discrete. Since \( X \) is compact we obtain from Lemma 2.18 (1) that \( F \) is indeed finite. \[ \square \]

Now we can formulate the first version of the Lefschetz-Hopf Theorem.

**Theorem 96.5. (Lefschetz-Hopf Theorem I)** Let \( M \) be a compact orientable smooth manifold and let \( f: M \to M \) be a smooth map. If every fixed point of \( f \) is non-degenerate and if there is no fixed point on \( \partial M \), then
\[ \sum_{x \text{ a fixed point of } f} \text{index}(f, x) = \Lambda(f). \]

**Remark.** If a smooth map has no fixed points, then the left hand side of the Lefschetz-Hopf Theorem 96.5 is evidently zero. Thus we see that the Lefschetz-Hopf Theorem 96.5 is a generalization of the Lefschetz Fixed Point Theorem 65.10, applied to the field \( \mathbb{F} = \mathbb{Q} \).

Our first example hopefully puts any lingering worries about signs to rest.

**Example.** Let \( n \in \mathbb{Z} \setminus \{1\} \). As on page 2334 we consider the map \( f: S^1 \to S^1 \) that is given by \( f(z) = z^n \). We perform the following calculation:
\[ \sum_{x \text{ a fixed point of } f} \text{index}(f, x) = \sum_{j=1}^{n-1} \text{index}(f, e^{2\pi i j/(n-1)}) = \sum_{j=1}^{n-1} -\text{sign}(n-1) = -(n-1). \]

Fortunately this is consistent with the Lefschetz-Hopf Theorem 96.5 and the following calculation:
\[ \Lambda(f) = \text{tr}(f_*: H_0(S^1; \mathbb{Z}) \to H_0(S^1; \mathbb{Z})) - \text{tr}(f_*: H_1(S^1; \mathbb{Z}) \to H_1(S^1; \mathbb{Z})) = 1 - n. \]

Just for fun let us consider a second example.

**Example.** Let \( n \in \mathbb{N} \). We consider \( M = \mathbb{R}^n \cup \{\infty\} \). We denote by 0 the origin of \( \mathbb{R}^n \). In Exercise 6.13 we showed that \( M \) is an \( n \)-dimensional smooth manifold with the atlas given by the obvious chart for \( \mathbb{R}^n \) together with the chart
\[ M \setminus \{0\} \to \mathbb{R}^n, \quad x \mapsto \begin{cases} \frac{1}{\|x\|^2} \cdot x, & \text{if } x \neq \infty, \\ 0, & \text{if } x = \infty. \end{cases} \]

Furthermore \( f: M \to M \) is smooth, that it has two fixed points, namely the origin 0 and \( \infty \), and that \( Df_0 = 3 \cdot \text{id} \) and \( Df_\infty = \frac{1}{3} \cdot \text{id} \). Thus we see
\[ \sum_{x \text{ a fixed point of } f} \text{index}(f, x) = \text{index}(f, 0) + \text{index}(f, \infty) = \text{sign}((1-3)^n) + \text{sign}((1-\frac{1}{3})^n) = (-1)^n + 1. \]

\[ \]Note that by Lemma 96.4 we know that the left-hand side is a finite sum.
Conveniently enough this is consistent with the Lefschetz-Hopf Theorem \[96.5\] and the following calculation:

\[
\Lambda(f) = \Lambda(id) = \chi(S^n) = 1 + (-1)^n.
\]

\[\uparrow\]

follows from Lemma \[65.7\] since \(f\) is easily seen to be homotopic to \(id\).

In Lemma \[2.44\] we gave an explicit diffeomorphism between \(\Phi: S^n \to M = \mathbb{R}^n \cup \{\infty\}\) that sends the South Pole to the origin and that sends the North Pole to \(\infty\). For \(n = 1\) and \(n = 2\) we illustrate the map \(\Phi^{-1} \circ f \circ \Phi: S^n \to S^n\) in Figure \[1354\].

![Figure 1354](image)

**Figure 1354**

**Proof of the Lefschetz-Hopf Theorem** \[96.5\]. Let \(M\) be a compact orientable \(n\)-dimensional smooth manifold and let \(f: M \to M\) be a smooth map such that every fixed point is non-degenerate. We pick an orientation. First we assume that \(M\) is closed.

We pick an orientation for \(M\). We equip \(\text{Gr}(f) \subset M \times M\) and \(\Delta_M \subset M \times M\) with the orientation which turns the projection onto the first factor into an orientation-preserving diffeomorphism.

**Claim.** Let \(x\) be a fixed point of \(f\).

1. The point \((x, x)\) is a transverse intersection point of the submanifolds \(\text{Gr}(f)\) and \(\Delta_M\) if and only if \(x\) is non-degenerate.
2. If \((x, x)\) is a transverse intersection point of \(\text{Gr}(f)\) and \(\Delta_M\), then the sign of the intersection point is given by \(\text{index}(f, x) = \frac{\det(id - Df_x)}{\|\det(id - Df_x)\|}\).

Note that we have a natural identification \(T_{(x,x)}(M \times M) = T_x M \times T_x M\). We pick a positive basis \(v_1, \ldots, v_n\) for \(T_{x} M\). By the definition of the product orientation on \(M \times M\), see page \[304\], we see that the basis \((v_1, 0), \ldots, (v_n, 0), (0, v_1), \ldots, (0, v_n)\) is a positive basis for \(T_{(x,x)}(M \times M)\). Next note that with respect to this basis we have

\[
\begin{pmatrix}
\text{id}_n \\
D\left(f_x\right)
\end{pmatrix}
\]

followed by

\[
\begin{pmatrix}
\text{id}_n \\
\text{id}_n
\end{pmatrix}
\]

which gives us the matrix

\[
\begin{pmatrix}
\text{id}_n & \text{id}_n \\
D\left(f_x\right) & \text{id}_n
\end{pmatrix}
\]

which has the same determinant as

\[
\begin{pmatrix}
\text{id}_n & 0 \\
\text{id}_n & -D\left(f_x\right)
\end{pmatrix}
\]

The desired statements follow immediately from this observation and the definitions. □

---

We refer to pages \[2270\] and \[2271\] for the definition of a transverse intersection point and the sign of a transverse intersection point.
Now we perform the following calculation:

\[
\Lambda(f) = \operatorname{Gr}(f) \cdot \Delta_M = \sum_{(x,x) \text{ an intersection point of } \operatorname{Gr}(f) \text{ and } \Delta_M} \text{sign of } (x,x) = \sum_{x \text{ a fixed point of } f} \text{index}(f,x).
\]

Proposition 96.1 by Theorem 94.5 and Claim (1) by Claim (2)

We have thus proved the theorem in the special case that \(M\) is closed and orientable.

Now we allow that the smooth manifold \(M\) has non-empty boundary. As on page 1163 we consider the double \(D M := (M \times \{1\}) \sqcup_{\partial M \times \{1\} = \partial M \times \{2\}} (M \times \{2\})\). By Lemma 44.12 we know that \(D M\) is a closed orientable smooth manifold. We also consider the double of \(f\), i.e. we consider the map

\[
\psi: D M \to D M \quad [(P, \epsilon)] \mapsto [(f(P), \epsilon)].
\]

Let \(x_1, \ldots, x_k\) be the fixed points of \(f: M \to M\). Recall that we demand that no fixed point of \(f\) lies on \(\partial M\). It follows immediately that the fixed points of \(\psi\) are precisely \((x_1, 1), (x_k, 1), (x_1, 2), \ldots, (x_k, 2)\). Now we see that

\[
2 \cdot \sum_{i=1}^{k} \text{index}(f, x_i) = \sum_{i=1}^{k} \text{index}(\psi, (x_i, 1)) + \sum_{i=1}^{k} \text{index}(\psi, (x_i, 2)) = \Lambda(\psi: D M \to D M)
\]

it is elementary to see that 

\[
\text{index}(f, x_i) = \text{index}(\psi, (x_i, 1)) = \text{index}(\psi, (x_i, 2))
\]

by the above, since \(D M\) is a closed orientable smooth manifold

\[
= 2 \cdot \Lambda(f: M \to M) + \Lambda(f: \partial M \to \partial M) = 2 \cdot \Lambda(f).
\]

follows from Exercise 65.15 since there are no fixed points on \(\partial M\) and since \(\partial M\) is a closed orientable smooth manifold

we know by the above that \(\Lambda(f: \partial M \to \partial M) = 0\)

Dividing both sides by 2 gives us the desired equality.

96.3. The Lefschetz-Hopf Theorem II. In this section we will formulate and prove an advanced version of the Lefschetz-Hopf Theorem 96.5 which puts fewer restrictions on the fixed points. The down-side is that in general we need to work with a more tricky definition of the index of a fixed point.

We start out with the following not overly exciting lemma.

**Lemma 96.6.** Let \(M\) be an \(n\)-dimensional topological manifold and let \(f: M \to M\) be a map. Let \(z \in M \setminus \partial M\) be an isolated fixed point of \(f: M \to M\). Given any neighborhood \(U\) of \((z, z) \in M \times M\) there exists a neighborhood \(V\) of \(z \in M\) and a neighborhood \(W\) of \(z \in M\) with the following properties:

1. We have \(V \times W \subset U\).
2. \(z\) is the only fixed point of \(f\) contained in \(V\).
3. \(V\) and \(W\) are both submanifolds of \(M\) and both are homeomorphic to \(\overline{B^n}\).
4. We have \(V \subset \hat{W}\) and \(f(V) \subset \hat{W}\).

**Proof.** This lemma follows fairly easily from Exercise 6.6. We leave it to the reader to fill in the details.

\[\Box\]
Let $z \in V$.

Furthermore let $z \in M \setminus \partial M$ be an isolated fixed point of $f$. We pick neighborhoods $V$ and $W$ of $z$ that satisfy Properties (2) and (4) of Lemma [96.6]. Furthermore we pick an embedding $\Phi : W \rightarrow \mathbb{R}^n$ with $\Phi(z) = 0$. We define the index $\text{index}(f, z)$ of the fixed point $z$ as the degree of the following homomorphism:

\[
\Phi : H_n(\{0\}) \rightarrow H_n(\Phi(V), \Phi(V) \setminus \{0\}),
\]

this map is induced by the inclusion $\Phi(V) \subset \mathbb{R}^n$, it is an isomorphism by the Excision Theorem [43.20] here we also use that we obtain from the Topological Invariance of Domain Theorem [50.6] that $\Phi(V)$ is a neighborhood of $0$.

We illustrate this definition in Figure 1356.

**Example.** Let $n \in \mathbb{N}$. We consider the map

\[
f : \mathbb{R}^2 = \mathbb{C} \rightarrow \mathbb{C} = \mathbb{R}^2, \quad z \mapsto z + z^n.
\]

The point $z = 0$ is evidently an isolated fixed point. Note that $f'(z) = 1 + nz^{n-1}$. It follows that for $n \geq 2$ we have $\text{id} - Df_0 = \text{id} - \text{id} = 0$. Thus we see that for $n \geq 2$ the fixed point $0$ is degenerate. Since $0$ is an isolated fixed point we can nonetheless define the index using the approach above. We set $V = \mathbb{B}^2$ and $W = \mathbb{B}^3$ and $\Phi = \text{id}$. Since

\[
\text{id} - (\Phi \circ f \circ \Phi^{-1}) = \text{id} - f = \text{id} - (\text{id} + (z \mapsto z^n)) = -(z \mapsto z^n)
\]

we obtain easily from Lemma [45.10] that $\text{index}(f, 0) = -n$. 
The following lemma says that the above index is well-defined.

**Lemma 96.7.** Let $M$ be an $n$-dimensional topological manifold and let $f: M \to M$ be a map. For an isolated fixed point $z \in M \setminus \partial M$ of $f$ the above definition of $\operatorname{index}(f, z)$ does not depend on any choices.

**Proof:** Let $V_1, W_1$ and $V_2, W_2$ be neighborhoods of $z$ that satisfy the properties stated in Lemma 96.6 (2) and (4). We pick embeddings $\Phi_1: W_1 \to \mathbb{R}^n$ and $\Phi_2: W_2 \to \mathbb{R}^n$ as in the definition of the index. We need to show that the choices lead to the same index.

First note that by the “given any neighborhood” feature of Lemma 96.6 we can assume that $V_1 \times W_1 \subset V_2 \times W_2$. Next we set $\epsilon := +1$ if $\Phi_2 \circ \Phi_1^{-1}$ is orientation-preserving, otherwise we set $\epsilon := -1$. Next we consider the following diagram:

We make the following clarifications and observations:

1. The maps indicated by $\iota$ are the natural inclusion induced maps.
2. Since $\Phi_1: W_1 \to \mathbb{R}^n$ is an embedding and since $V_1 \subset W_1$ we can consider the inverse $\Phi_1^{-1}: \Phi_1(V_1) \to V_1$. Furthermore, since $V_1 \subset V_2$ we can consider $\Phi_2(\Phi_1(V_1))$ and we have $\Phi_2(V_1) \subset \Phi_2(V_2)$.
3. It follows fairly immediately from the definition of $\epsilon$ that the diagram commutes.
4. The left horizontal maps are isomorphisms by the Excision Theorem 43.20.

It follows from the above that the top and the bottom horizontal maps from left to right agree. But this means that we obtain the same degree. 

The following lemma shows that the two notions of the index of a fixed point of a smooth map, introduced on pages 2333 and 2338 are consistent.

**Lemma 96.8.** Let $M$ be a smooth manifold, let $f: M \to M$ be a smooth map and let $z \in M \setminus \partial M$ be a non-degenerate fixed point of $f$. The fixed point $z$ is isolated, and the index of $z$, as defined on page 2333, agrees with the index of $z$ as defined on page 2338.

**Proof:** Let $M$ be a smooth manifold, let $f: M \to M$ be a smooth map and let $z \in M \setminus \partial M$ be a non-degenerate fixed point of $f$. For the purpose of this proof we denote
by $\text{index}^{\text{sm}}(z)$ the index of $z$ as defined on page 2333 and we denote by $\text{index}^{\text{top}}(z)$ the index of $z$ as defined on page 2338.

First note that we already showed in Lemma 96.4 that $z$ is an isolated fixed point. Thus it remains to show that $\text{index}^{\text{top}}(z) = \text{index}^{\text{sm}}(z)$. From our smooth atlas for $M$ we pick a chart $\Phi : \mathbb{R}^n \to \mathbb{R}^n$ around $z$ with $\Phi(z) = 0$. It follows fairly easily from the hypothesis that $z$ is a non-degenerate fixed point that there exists an open neighborhood $V$ around $z$ such that $V \subset W$, such that $\Phi(V) \subset W$, and such that $V$ contains no other fixed point of $f$. We set $\Theta := D \Phi|_z : T_z M \to T_0 \mathbb{R}^n = \mathbb{R}^n$.

Now we consider the following diagram:

We make the following clarifications and observations:

1. By construction $V$ and $W$ satisfy the properties of Lemma 96.6 (2) and (4). This implies that the composition of the top two horizontal maps is given by multiplication by $\text{index}^{\text{top}}(z)$.

2. It follows immediately from Lemma 43.17 that there exists an open neighborhood $Y$ of $0$, contained in $\Phi(V)$, such that the map $\text{id} - \Phi \circ f \circ \Phi^{-1}$ is homotopic, as a map of pairs $(\Phi(V), \Phi(V) \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$, to the map $D(\text{id} - \Phi \circ f \circ \Phi^{-1})_0$.

3. By the chain rule we have $D(\text{id} - \Phi \circ f \circ \Phi^{-1})_0 = \text{id} - \Theta \circ D f_z \circ \Theta^{-1}$.

4. It follows from (2) together with Proposition 43.17 and some elementary considerations that the diagram commutes.

5. It follows from the Excision Theorem 43.20 that the two maps decorated with \(\cong\) are indeed isomorphisms.

We see that

by the above diagram and the above discussion  
by Lemma 45.18

\[
\begin{align*}
\text{index}^{\text{top}}(z) & \doteq \deg((\text{id}_{\mathbb{R}^n} - \Theta \circ D f_z \circ \Theta^{-1})_*) \\
& \doteq \text{sign}(\det(\text{id}_{\mathbb{R}^n} - \Theta \circ D f_z \circ \Theta^{-1})) \\
& \doteq \text{index}^{\text{sm}}(z).
\end{align*}
\]

By Lemma 96.8 the following theorem is a generalization of our previous Lefschetz-Hopf Theorem 96.9.

**Theorem 96.9. (Lefschetz-Hopf Theorem II)** Let $M$ be a compact orientable topological manifold and let $f : M \to M$ be a map which has no fixed points on $\partial M$. If $f$ has
finitely many fixed points, then
\[ \sum_{x \text{ a fixed point of } f} \text{index}(f, x) = \Lambda(f). \]

Remark.
(1) The Lefschetz-Hopf Theorem has its origin in the work of Heinz Hopf \[\text{[Hopf29]}\] Section 8. Various variations on the Lefschetz-Hopf Theorem \[\text{[GD03, Chapter V.16]}\] and \[\text{[JM06, Chapter 2.4]}\].
(2) As on page \[2303\] we see that the Lefschetz-Hopf Theorem \[\text{[96.9]}\] is a generalization of the Lefschetz Fixed Point Theorem \[\text{[85.11]}\] for compact orientable topological manifolds.

Example. This time we consider \( S^2 \) with the avatar given by \( \overline{B^2}/S^1 \). We consider the map \( f: \overline{B^2}/S^1 \to \overline{B^2}/S^1 \) that is illustrated, to the best of the author’s abilities, in Figure \[1357\].\[1357\] It has precisely one fixed point, namely \( P := [S^1] \). We see that
\[ \text{index}(f, P) = \Lambda(f) = \Lambda(\text{id}) = \chi(S^2) = 2. \]
Lefschetz-Hopf Theorem \[96.9\] since \( f \) is homotopic to \( \text{id} \).

Note that with a little bit of care, say using Lemma \[6.13\], one can arrange that \( f \) is smooth. Also note that \( Df = \text{id} \). Thus \( P = [S^1] \) is a degenerate fixed point of \( f \).

The proof of the Lefschetz-Hopf Theorem \[96.9\] rests heavily on the shoulders of the following two lemmas.

Lemma \[96.10\]. Let \( V \subset \mathbb{R}^n \) and \( W \subset \mathbb{R}^n \) be two compact connected \( n \)-dimensional topological submanifolds of \( \mathbb{R}^n \) that contain \( 0 \) in the interior. We assume that \( V \subset \hat{W} \). Let \( f: V \to \mathbb{R}^n \) be a map with \( f(V) \subset \hat{W} \) and which has a unique fixed point, namely \( 0 \). We set \( G := \{(v, f(v)) \mid v \in V\} \) and we set \( D := \{(v, v) \mid v \in V\} \).

(1) \( G \) and \( D \) are well-behaved proper submanifolds of \( V \times W \), in the sense of the definition on page \[2303\].

\[1356\] An alternative description of this map is given by considering \( S^2 = \mathbb{R}^2 \cup \{\infty\} \). In this setting our map corresponds to the map \( f: \mathbb{R}^2 \cup \{\infty\} \to \mathbb{R}^2 \cup \{\infty\} \) that is given by \( f(x) = x + (1, 0) \) for all \( x \in \mathbb{R}^2 \) and \( f(\infty) = \infty \).

\[1357\] Incidentally this example gives an affirmative answer to the question asked in Exercise \[2.12\].
The following equality holds:

\[
\langle \text{PD}_{V \times W}(\{G\}) \cup \text{PD}_{V \times W}(\{D\}), [V \times W]\rangle = \deg \left( \begin{array}{c}
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\
\uparrow \cong \\
H_n(V, V \setminus \{0\}) \\
\downarrow (\text{id} - f)_* \\
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})
\end{array} \right).
\]

**Sketch of proof.** First we prove Statement (1). More precisely, we will show that \(G\) is a well-behaved proper submanifold of \(V \times W\). The proof that \(D\) is also a well-behaved submanifold is basically identical. Note that by Exercise 6.10 we know that \(G\) is a proper submanifold of \(V \times W\). Next note by definition of a well-behaved submanifold we need to show that given any open neighborhood \(U\) of \(\partial G \subset \partial (V \times W) = (\partial V \times W) \cup (V \times \partial W)\) the submanifold \(\partial G\) of \(\partial (V \times W)\) admits a regular neighborhood \(N\) with \(N \subset U\). Note that using the fact that \(\partial V\) is compact and using the hypothesis that \(f(V) \subset \tilde{W}\) it is fairly elementary to see that there exists an \(\epsilon > 0\) such that for every \(x \in \partial G\) we have \(\{x\} \times \overline{B}_\epsilon(f(x)) \subset U\). It is straightforward to verify that given any \(\nu \in (0, \epsilon)\) the set

\[N_\nu := \{(x, y) \in \partial V \times W \mid x \in \partial V \text{ and } y \in \overline{B}_\nu(f(x))\} \subset \partial (V \times W)\]

is a regular neighborhood of \(\partial G\) with \(N_\nu \subset U\). This concludes the proof of Statement (1).

Next we turn to the proof of Statement (2). The key idea is to “tilt” the situation to turn the diagonal \(D\) into a “horizontal submanifold”. Afterwards we can use Proposition 88.2 to perform the desired calculation.

Now we carry out the details. To do so we introduce the following objects:

(a) We pick a compact submanifold \(\tilde{W}\) of \(\mathbb{R}^n\) with \(W \subset \tilde{W}\) and \((\text{id} - f)(W) \subset \tilde{W}\).

(b) We consider the maps

\[
l: V \to G \\
v \mapsto (v, f(v))
\]

\[
\Theta: V \times W \to V \times \tilde{W} \\
(v, w) \mapsto (v, w - f(v))
\]

\[
q: V \times \tilde{W} \to \tilde{W} \\
(v, w) \mapsto w.
\]

(c) Note that by (1) we can pick a regular neighborhood \(N_G\) for \(\partial G \subset \partial (V \times W)\) with \(N_G \subset \partial V \times W\) and with \(N_G \cap \partial D = \emptyset\).

---

By (1) we know that \(G\) is a well-behaved proper submanifold of \(V \times W\). Thus we can consider the isomorphism \(\text{PD}_{V \times W}: H_n(V \times W, \partial G) \to H_n(V \times W, (V \times W) \setminus \partial G)\) that we introduced in Proposition 85.2 Similarly we consider the isomorphism \(\text{PD}_{V \times W}\) with \(G\) replaced by \(D\).

Since 0 is the only fixed point of \(f\) we see that \((\text{id} - f)(V \setminus \{0\}) \subset \mathbb{R}^n \setminus \{0\}\).
(d) We denote by $\mu_{\widehat{W},0} \in H_n(\widehat{W}, \widehat{W} \setminus \{0\}) \cong \mathbb{Z}$ the standard generator, as defined on page 2097. Furthermore we denote by $\mu_{\widehat{W},0}^* \in H^n(\widehat{W}, \widehat{W} \setminus \{0\}; \mathbb{Z}) \cong \mathbb{Z}$ the corresponding dual.

Many of the above objects are illustrated in Figure [1359] Now we can perform the desired calculation:

by Lemmas 83.4 and 83.7 under the natural identification $H_0(V \times W) = \mathbb{Z}$

$$\langle PD_{V \times W}([G]) \cup PD_{V \times W}([D]), [V \times W] \rangle$$

by Lemma 83.8 and since the map $\Theta : V \times W \to \Theta(V \times W) \subset V \times \widehat{W}$ is an orientation-preserving homeomorphism

$$\Theta_*([D]) \cap \Theta_*([G]) = PD_{V \times \widehat{W}}([V \times \{0\}] \cap \Theta_*([V]))$$

since $\Theta(D) = V \times \{0\}$ and $l(V) = G$ and both maps are orientation-preserving

$$\langle \mu_{\widehat{W},0}^*, q_*\Theta_*([V]) \rangle = \langle \mu_{\widehat{W},0}^*, (id - f)_*([V]) \rangle.$$  

by Lemmas 83.4 and 74.6(3)

$$\deg \left( H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \cong H_n(V, V \setminus \{0\}) \right) \cong \mathbb{Z} \left( \mathbb{R}^n, \mathbb{R}^n \setminus \{0\} \right) \xrightarrow{(id - f)_*} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$$

this follows from the following commutative diagram

$$H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \xrightarrow{\cong} H_n(V, V \setminus \{0\}) \xrightarrow{(id - f)_*} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$$

$$H_n(V, \partial V) \xrightarrow{(id - f)_*} H_n(\widehat{W}, \widehat{W} \setminus \{0\})$$

$$H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \xrightarrow{\cong} H_n(V, V \setminus \{0\}) \xrightarrow{(id - f)_*} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$$

$$H_n(V, \partial V) \xrightarrow{(id - f)_*} H_n(\widehat{W}, \widehat{W} \setminus \{0\})$$

as well as the fact that $[V]$ and $\mu_{\widehat{W},0}$ are both mapped to the standard generator of $H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$

Thus we have proved the desired equality.

---

1300 Careful reading of the inequalities shows that it is in fact at times difficult to determine which relative (co-)homology groups the objects lie in. In particular on several occasions we implicitly use Lemma 83.8 and Lemma 74.6(3) to go from one relative homology group to another. Writing down the calculation in full detail would make the proof even more unreadable that it already is.
Lemma 96.11. Let $M$ be a closed oriented $n$-dimensional topological manifold. Furthermore let $f: M \rightarrow M$ be a map. Finally let $z \in M$ be an isolated fixed point of $f$. We consider the two submanifolds $\text{Gr}(f)$ and $\Delta_M$ of the $2n$-dimensional topological manifold $M \times M$. The following two statements hold:

1. The point $(z,z) \in M \times M$ is a nice intersection point of the two submanifolds $\text{Gr}(f)$ and $\Delta_M$, in the sense of the definition on page 2304.

2. We have the equality

$$\text{index}(f, z) = \underbrace{\text{index}(\text{Gr}(f), \Delta_M, (z,z))}_{\text{index of the nice intersection point } (z,z), \text{ as defined on page 2306}}.$$

Remark. On page 2341 we gave an example of a map $f: S^2 \rightarrow S^2$ that has a unique fixed point $P$, which has index 2. It follows from Lemma 96.11 that $(P,P)$ is a nice intersection point of the submanifolds $\text{Gr}(f)$ and $\Delta_{S^2}$ of $S^2 \times S^2$ of index 2. This gives an affirmative answer to the question posed in Exercise 96.5.

Proof (*).

(1) Let $z \in M$ be an isolated fixed point of $f: M \rightarrow M$. We need to show that the point $(z,z) \in M \times M$ is a nice intersection point of the two submanifolds $\text{Gr}(f)$ and $\Delta_M$. Thus let $U$ be an open neighborhood of $(z,z)$ in $M \times M$. By Lemma 96.6 there exists a neighborhood $V$ of $z \in M$ and a neighborhood $W$ of $z \in M$ with the following properties:

(i) We have $V \times W \subset U$.

(ii) $z$ is the only fixed point of $f$ contained in $V$.

(iii) $V$ and $W$ are both submanifolds of $M$ and both are homeomorphic to $\mathcal{B}^n$.

(iv) We have $V \subset \hat{W}$ and $f(V) \subset \hat{W}$.

By (i) it remains to show that $Z := V \times W$ is a nice neighborhood of $(z,z)$ in the sense of the definition on page 2304. Most of the conditions are easily verified. For example by (iii) we know that $V \times W$ is homeomorphic to $\mathcal{B}^{2n}$. Furthermore, by (ii) we know that $\text{Gr}(f) \cap \Delta_M \cap (V \times W) = \{(z,z)\}$. Finally note that it follows almost immediately from Lemma 96.10 (1) that $\text{Gr}(f)$ and $\Delta_M$ are both well-behaved proper submanifolds of $V \times W$.

![Figure 1360. Illustration for the proof of Lemma 96.11](image-url)
To simplify the notation we can and will assume that \( V \subset \mathbb{R}^n \), \( W \subset \mathbb{R}^n \), \( z = 0 \) and \( \Phi = \text{id} \). But now in this setting the desired equality is an immediate consequence of Lemma 96.10 (2).

Now that we have Lemma 96.11 under our belt the proof of the Lefschetz-Hopf Theorem 96.9 is formally very similar to the proof of the Lefschetz-Hopf Theorem 96.5.

**Proof of the Lefschetz-Hopf Theorem 96.9.** Let \( M \) be a compact orientable topological manifold and let \( f: M \to M \) be a map which has only finitely many fixed points \( z_1, \ldots, z_k \), and all of them lie in \( M \setminus \partial M \). We pick an orientation for \( M \).

First we assume that \( M \) is actually closed. Now we easily obtain the desired equality:

\[
\Lambda(f) = Q_{M \times M}([\text{Gr}(f)], [\Delta_M]) - \sum_{i=1}^{k} \text{index}(\text{Gr}(f), \Delta_M, (z_i, z_i)) = \sum_{i=1}^{k} \text{index}(f, z_i).
\]

by Proposition 96.1 by Lemma 96.11 (1) by definition, see page 2307 by Lemma 96.11 (2) and Theorem 95.7

Now we assume that \( M \) has non-empty boundary. Once again we consider the double \( D M := (M \times \{1\}) \sqcup \partial M \times \{1\} = \partial M \times \{2\} \). By Lemma 44.12 we know that \( D M \) is a closed orientable topological manifold. We consider the map

\[
\psi: D M 
\to \quad D M

[(P, \epsilon)] \mapsto [(f(P), \epsilon)].
\]

Since all of the fixed points of \( f \) lie in \( M \setminus \partial M \) we see that the fixed points of \( \psi \) are \((z_1, 1), (z_k, 1), (z_1, 2), \ldots, (z_k, 2)\). Now we see that

\[
2 \cdot \sum_{i=1}^{k} \text{index}(f, z_i) = \sum_{i=1}^{k} \text{index}(\psi, (z_i, 1)) + \sum_{i=1}^{k} \text{index}(\psi, (z_i, 2)) = \Lambda(\psi: D M \to D M)
\]

by the above, since \( D M \) is a closed orientable topological manifold

\[
\text{index}(f, z_i) = \text{index}(\psi, (z_i, 1)) = \text{index}(\psi, (z_i, 2))
\]

follows from Exercise 65.15 since there are no fixed points on \( \partial M \) and since \( \partial M \) is a closed orientable topological manifold

we know by the above that \( \Lambda(f: \partial M \to \partial M) = 0 \)

Dividing both sides by 2 yields the desired result.

**Exercises for Chapter 96**

**Exercise 96.1.** We consider the surface \( M \subset \mathbb{R}^3 \) as shown in Figure 1361. Furthermore we consider the map \( \varphi: M \to M \) which is given by “rotating \( M \) around the skewer by an angle of \( \pi \”).

(a) For \( i = 0, 1, 2 \) determine \( \text{tr}(\varphi_*: H_i(M; \mathbb{Z}) \to H_i(M; \mathbb{Z})) \).

(b) For each fixed point \( x \) of \( \varphi \) determine \( \text{index}(\varphi, x) \).

**Remark.** Evidently you should use the Lefschetz-Hopf Theorem 96.9 to check your calculations in (a) and (b) for consistency.
Exercise 96.2.

(a) Let $k, l \in \mathbb{Z}$. We consider the sphere $S^3 = \{(z, w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1\}$ and the self-map

\[ f : S^3 \rightarrow S^3 \]
\[ (z, w) \mapsto (z^k, w^l). \]

(b) We view $S^2$ as a subset of $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$. We consider the map

\[ g : S^2 \rightarrow S^2 \]
\[ (z, t) \mapsto (z^2, t) \]

(c) Let $n \in \mathbb{N}$. We consider the maps

\[ h : \mathbb{C} \cup \{\infty\} \rightarrow \mathbb{C} \cup \{\infty\} \]
\[ z \mapsto \begin{cases} z^n, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \]

\[ k : \mathbb{C} \cup \{\infty\} \rightarrow \mathbb{C} \cup \{\infty\} \]
\[ z \mapsto \begin{cases} z + z^n, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty. \end{cases} \]

In each case determine all fixed points, determine whether they are non-degenerate and determine the index of each fixed point.
97. The Poincaré-Hopf Theorem

Now we return to the study of vector fields on smooth manifolds. Recall that the Hairy Ball Theorem says that there does not exist a nowhere vanishing vector field on any even-dimensional sphere. Also recall that later on we proved a significant generalization of this result. Namely, using the Lefschetz Fixed Point Theorem we proved the following proposition.

**Theorem 65.17.** Let $M$ be a closed smooth manifold. If $M$ admits a nowhere vanishing vector field, then $\chi(M) = 0$.

In Chapter 65 we proved the Lefschetz-Hopf Theorem which is a significant generalization of the Lefschetz Fixed Point Theorem that we had just mentioned. In this chapter we will use this recently acquired theorems to prove the Poincaré-Hopf Theorem which is a significant generalization of the above Theorem 65.17.

97.1. The index of a zero of a vector field. In the following discussion it will be helpful to study zeros of vector fields in more detail. As we will, not all zeros are created equal but they actually come in different flavors. More precisely, we have the following definition.

**Definition.** Let $M$ be an $n$-dimensional smooth manifold, let $v$ be a vector field on $M$ and let $x \in M \setminus \partial M$ be an isolated zero of $v$. We pick a smooth embedding $\Psi : B^n \to M \setminus \partial M$ with $\Psi(0) = x$ and such that $x$ is the only zero of $v$ on $\Psi(B^n)$. We denote by $w = \Psi^*(v)$ the pullback vector field on $B^n$ as defined on page 1632. In other words, given $y \in B^n$ we write $w(y) := D\Psi^{-1}(v(\Psi(y)))$. We define

$$\text{index}(v, x) := \text{degree of the map } \Theta_{\Psi, v} : S^{n-1} \to S^{n-1}$$

$$y \mapsto \frac{w(y)}{\|w(y)\|}.$$  

![Figure 1362](image)

**Example.** We consider the vector fields on $\mathbb{R}^2 = \mathbb{C}$ with isolated zero at the origin that are shown in Figure 1363. In the following we use the identity chart $\Psi = \text{id}$ to determine the various indices. In fact, using Lemmas 15.10 and 15.11 we obtain the following table:

<table>
<thead>
<tr>
<th>vector field $v$ at $(x, y) = z$</th>

---

1361 We refer to page 1631 for the definition of a vector field on a given smooth manifold $M$. 
**Lemma 97.1.** Let $M$ be an $n$-dimensional smooth manifold.

1. Let $v$ be a vector field on $M$. The definition of the index $\text{index}(v, x)$ of an isolated zero $x \in M \setminus \partial M$ of a vector field $v$ does not depend on the choice of the smooth embedding $\Psi : \mathbb{B}^n \to M$.

2. If $v$ and $w$ are two vector fields on $M$ that agree on an open subset $U \subset M$ and if $z$ is an isolated zero of $v$ in $U$, then $\text{index}(v, z) = \text{index}(w, z)$.

**Proof** (1). The second statement is a straightforward consequence of the first statement. Thus it remains to prove the first statement. Let $\Psi : \mathbb{B}^n \to M$ be a smooth embedding as in the definition of $\text{index}(v, x)$. We need to show that any other such smooth embedding leads to the same index. The proof is performed in two stages.

(a) Let $A \in O(n)$ be an orthogonal matrix. We denote by $\rho_A : \mathbb{R}^n \to \mathbb{R}^n$ the map that is given by multiplication by the matrix $A$. Next we consider the smooth embedding $\Psi \circ \rho_A : \mathbb{B}^n \to M$. A straightforward calculation using the chain rule, see Proposition 6.15, shows that $\Theta_{\Psi \circ \rho_A, v} = \rho_A^{-1} \circ \Theta_{\Psi, v} \circ \rho_A : S^{n-1} \to S^{n-1}$. It follows from Lemma 45.11 that $\deg(\Theta_{\Psi \circ \rho_A, v}) = \deg(\Theta_{\Psi, v})$.

(b) Now assume we are given some other smooth embedding $\Xi : \mathbb{B}^n \to M$. We consider

$$N := \{ y \in M \mid v(y) \neq 0 \} \cup \{ x \}.$$ 

open subset by Exercise 65.16

It follows from Exercise 65.16 and the fact that $x$ is an isolated zero that $N$ is an open subset of $M$. In particular we see that $N$ is an $n$-dimensional submanifold of $M$. Since $x$ is the only zero of $v$ in $\Psi(\mathbb{B}^n)$ and $\Xi(\mathbb{B}^n)$ we see that $\Psi : \mathbb{B}^n \to M$ and $\Xi : \mathbb{B}^n \to M$ are tubular maps, in the sense of the definition on page 367 for the 0-dimensional submanifold $\{ x \}$ of $N$. By Proposition 8.26 there exists a diffeotopy $H : N \times [0, 1] \to N$ rel $\{ x \}$ and a matrix $A \in O(n)$ such that $H_0 = \text{id}$ and such that $H_1 \circ \Xi = \Psi \circ \rho_A : \mathbb{B}^n \to N$. Now we see that

$$\deg(\Theta_{\Xi, v}) = \deg(\Theta_{H_0 \circ \Xi, v}) = \deg(\Theta_{H_1 \circ \Xi, v}) = \deg(\Theta_{\Psi \circ \rho_A, v}) \uparrow = \deg(\Theta_{\Psi, v}).$$

the maps $\Theta_{H_t \circ \Xi, v}$ with $t \in [0, 1]$ define a homotopy between $\Theta_{H_0 \circ \Xi, v}$ by (1) and $\Theta_{H_1 \circ \Xi, v}$, thus by Lemma 45.11 (3) the maps have the same degree.

The next example shows that any integer can occur as the index of an isolated zero of a vector field.
Example. Let \( n \in \mathbb{N}_{\geq 2} \) and let \( d \in \mathbb{Z} \). It follows from Lemmas 45.10 and 45.12 that there exists a self-map \( \varphi : S^{n-1} \to S^{n-1} \) of degree \( d \). Let \( \lambda \in \mathbb{R}_{>0} \). It is straightforward to verify that

\[
v(\varphi) : \mathbb{R}^n \to \mathbb{R}^n \\
x \mapsto \begin{cases} 0, & \text{if } x = 0, \\ \lambda \cdot x \cdot \varphi\left(\frac{x}{\|x\|}\right), & \text{if } x \neq 0\end{cases}
\]

is a continuous map, in particular it defines a vector field on \( \mathbb{R}^n \). Evidently it has a single isolated zero at the origin and the corresponding index is precisely \( d = \deg(\varphi) \).

The next lemma can be convenient for calculating the index of a zero of a vector field.

**Lemma 97.2.** Let \( X \subseteq \mathbb{R}^n \) be an open subset and let \( \epsilon > 0 \). Furthermore suppose we are given a vector field \( w = (u, v) : X \times (-\epsilon, \epsilon) \to \mathbb{R}^n \times \mathbb{R} \) with an isolated zero at \((P, 0)\).

1. If \( v(x, t) > 0 \) whenever \( t > 0 \) and if \( v(x, t) < 0 \) whenever \( t < 0 \), then

\[
\text{index}(w, (P, 0)) = \text{index}(u, P).
\]

2. If \( v(x, t) < 0 \) whenever \( t > 0 \) and if \( v(x, t) > 0 \) whenever \( t < 0 \), then

\[
\text{index}(w, (P, 0)) = -\text{index}(u, P).
\]

**Figure 1364. Illustration of Lemma 97.2.**

**Proof.** We leave it to the reader to verify that the two statements follow easily from the definitions together with Exercise 45.13.

The following lemma says that isolated zeros of a vector field of index 0 can be eliminated by adjusting the vector field in the neighborhood of the zero.

**Lemma 97.3.** Let \( M \) be an \( n \)-dimensional smooth manifold, let \( v \) be a vector field on \( M \) and let \( x \) be an isolated zero of \( v \) with \( \text{index}(v, x) = 0 \). Let \( \Psi : \overline{B}^n \to M \setminus \partial M \) be a smooth embedding with \( \Psi(0) = x \) and such that \( x \) is the only zero of \( v \) in \( \Psi(\overline{B}^n) \). There exists a vector field \( w \) on \( M \) that agrees with \( v \) on \( M \setminus \Psi(\overline{B}^n) \) and which has no zeros on \( \Psi(\overline{B}^n) \).

**Figure 1365. Illustration of Lemma 97.3.**
Sketch of proof. By Corollary 53.6 we know that the map deg: \( \pi_{n-1}(S^{n-1}) \to \mathbb{Z} \) is an isomorphism. In particular this implies, using our hypothesis that \( \text{index}(v, x) = 0 \), that there exists a homotopy \( H: S^{n-1} \times [0, 1] \to S^{n-1} \) from the map \( \Theta_{\Psi, v}: S^{n-1} \to S^{n-1} \) to a constant map. Using the homotopy \( H \) it is now straightforward to write down an explicit vector field \( w \) on \( M \) with the following properties:

1. On \( M \setminus \Psi(B^n) \) the vector field \( w \) equals \( v \).
2. On \( \Psi(B^n) \) the vector field \( w \) is “constant” and non-zero.
3. On \( \Psi(B^n \setminus B_{\frac{1}{2}}) \) the vector field interpolates between (1) and (2).

We leave it to the reader to fill in the details.

The following proposition gives in particular a converse to Theorem 65.17.

**Proposition 97.4.** Let \( M \) be a closed connected smooth manifold.

1. There exists a smooth vector field \( u \) on \( M \) with finitely many zeros such that
   \[
   \sum_{x \text{ a zero of } u} \text{index}(u, x) = \chi(M).
   \]
2. If \( \chi(M) = 0 \), then \( M \) admits a nowhere vanishing smooth vector field.

Sketch of proof. Let \( M \) be a closed connected smooth manifold.

1. First note that by Theorem 64.2 we know that \( M \) admits a smooth simplicial structure \( (K = (V, S), \Theta: |K| \to M) \). Inductively we can define a smooth vector field \( u \) on \( M \) with the following properties:
   a. The vector field \( u \) is defined to be the zero vector field on the vertices of the triangulation.
   b. Suppose the vector field \( u \) is defined on the \( k \)-skeleton of \( M \), then on every \((k+1)\)-simplex \( s \) we extend the vector field \( u \) in the following way:
      i. the vector field vanishes on the barycenter \( \bar{s} \) of \( s \),
      ii. for all other points in the open simplex the vector field “points towards” the barycenter \( \bar{s} \) of \( s \).

   This can be done explicitly.

   We sketch the construction of the vector field \( u \) in Figure 1366. Note that the zeros of the vector field \( u \) are precisely the barycenters of the original simplices. Furthermore,

\[1362\] For the resilient reader we provide the gory details. Suppose we are given a vector field \( v \) on \( \partial \Delta^{k+1} \).

We denote by \( b := (\frac{1}{k+1}, \ldots, \frac{1}{k+1}) \) the barycenter of \( \Delta^{k+1} \). We denote by \( r: \Delta^{k+1} \setminus \{b\} \to \partial \Delta^{k+1} \) the map that is given by sending \( x \) to the unique intersection point of the ray \( b + \mathbb{R}_{\geq 0} \cdot (x - b) \) with \( \partial \Delta^{k+1} \).

Next we consider the map
\[
\Delta^{k+1} \to \mathbb{R}^{k+2}
\]
\[
x \mapsto \begin{cases}
\frac{\|x - b\|}{\|r(x) - b\|} \cdot (v(r(x)) + (b - x) \cdot \|x - r(x)\|), & \text{if } x \neq b, \\
0, & \text{if } x = b.
\end{cases}
\]

It is now fairly elementary to see that this vector field, transported back to \( M \), has the desired properties. As always, with a little more care, using say Lemma 6.13 one can arrange that the vector field is actually smooth.
one can fairly easily verify that given a $k$-simplex $s$ we have \[^{363}\] \[
\text{index}(u, s) = (-1)^k.
\]
Thus we see that
\[
\sum_{x \text{ a zero of } u} \text{index}(u, x) = \sum_{s \text{ a } k\text{-simplex}} \text{index}(u, s) = \sum_{s \text{ a } k\text{-simplex}} (-1)^k = \chi(M).
\]

Corollary 61.25 (5)

This argument is also sketched in [Stee51 p. 202].

Figure 1366. First illustration for the proof of Proposition 97.4.

(2) The second statement is proved in [Bre93 Corollary VII.14.5], [Stee51 Coro-

lary 39.8], [Hirs76 Theorem 5.2.10] and alternatively also in [Tur90 Lemma 6.3.4].

In the following we provide a terse sketch of the proof given in [Tur90 Lemma 6.3.4].

We continue with the discussion of (1) and we make the following observations and con-
structions.

(a) Some thought shows that it follows from our hypothesis that $M$ is connected and

that $\chi(M) = 0$ that we can find a perfect match between adjacent barycenters.

More precisely, we can find a decomposition $S = \bigsqcup_{i \in I} \{s_i, t_i\}$ of the simplex set,

such that each $s_i$ is a codimension one face of $t_i$.

(b) Given each pair $\{s_i, t_i\}$ we consider a small suitable neighborhood of the 1-simplex

$\{s_i, t_i\}$ of the barycentric subdivision. This neighborhood contains two critical

points. As of right now, on this 1-simplex the vector field points from $s_i$ to $t_i$.

We can replace the vector field $u$ on this neighborhood by a different vector

field $v$ that agrees with $u$ on the boundary, which on the 1-simplex now points from

$t_i$ to $s_i$ and which has no critical points. This replacement is illustrated in

Figure 1367.

Hopefully this outline is convincing. Evidently filling in all details is a nightmarish

task. Thankfully the details are provided in [Tur90 Lemma 6.3.4].

97.2. The Poincaré-Hopf Theorem. Now we can formulate the namesake of this chapter.

Theorem 97.5. (Poincaré-Hopf Theorem) Let $M$ be compact smooth manifold. Let $v$

be a vector field \[^{1364}\] on $M$ with finitely many zeros. If $M$ has boundary, then we insist that

---

\[^{363}\] The fact that $\text{index}(u, s) = (-1)^k$ can be seen as follows. First note that the vector field $u$

points in $k$ directions towards $s$ and in $(n - k)$ directions away from $s$. Using a suitable embedding $\Psi: B^n \to M$

with $\Psi(0) = s$ we see that the corresponding map $\Theta_{u, \Psi}: S^{n-1} \to S^{n-1}$ is given by the diagonal matrix

with $k$ entries equal to $-1$ and $(n - k)$-entries equal to $+1$. Thus it follows from Lemma 45.11 that the

degree of this map equals $(-1)^k$. 

---

\[^{1364}\] The notation $[\text{vector field}]$ is used here to indicate that the vector field $v$ is defined on $M$. 

---
Remark.

(1) In the 2-dimensional setting the Poincaré-Hopf Theorem was first proved by Henri Poincaré [Poi1885] in the late 19th century. The generalization to the higher-dimensional case was first proved by Heinz Hopf [Hopf27] in 1927. There are many different proofs of the Poincaré-Hopf Theorem, sometimes with somewhat different hypotheses, in the literature, see e.g. [BoT82 Theorem 11.25], [Vic94 Theorem 7.27], [Bre93 Theorem VI.12.13], [Miln65a, p. 35], [DFN85 Theorem 15.3.2], [BaT03 Theorem 7.6.5] and [MT97 Theorem 12.1]. See also the sketch in [Bra07, p. 69]. The proof we provide is partly inspired by the proofs in [DFN85] and [Vic94].

(2) The proof of the Poincaré-Hopf Theorem [97.5] relies very much on the Lefschetz-Hopf Theorem [96.9]. For readers who prefer to work with the weaker Lefschetz-Hopf Theorem [96.5] we leave it as a little challenge to deduce from it the conclusion of the Poincaré-Hopf Theorem [97.5] under the stronger hypotheses that the vector field is smooth and that the indices of the zeros are ±1.

Examples.

(1) In Figure 1000 we see two vector fields v and w on S^2. Each of these vector fields has precisely two zeros, namely the North Pole N and the South Pole S. Furthermore, considering the table on page 2347 it is pretty clear that for both vector fields both zeros have index +1. In particular we see that for both vector fields these two indices add up reassuringly to χ(S^2) = 2.

(2) In Figure 1000 we see a vector field on the surface Σ of genus two with two zeros P and Q. The table on page 2347 strongly suggests that index(v, P) = −2. By the discussion on page 1363 we also know that χ(Σ) = −2. Thus it follows from the Poincaré-Hopf Theorem [97.5] that index(v, Q) = 0. By Lemma [97.3] this means that we can modify the vector field v to obtain a vector field which has no zero at Q.

---

[^1364]: It is perhaps worth recalling that for us vector fields are assumed to be continuous. We do not make any assumptions on differentiability.
Thus we have found a vector field on $\Sigma$ with a single zero, namely at $P$. This gives a belated solution to Exercise 65.12.

It is perhaps worth stating the following immediate corollary to the Poincaré-Hopf Theorem 97.5. Note that this corollary generalized the statement of Theorem 65.17 to smooth manifolds with non-empty boundary.

**Corollary 97.6.** Let $M$ be a compact smooth manifold. If $M$ admits a nowhere vanishing vector field $v$ that either points outward along all of $\partial M$ or that points inward along all of $\partial M$, then $\chi(M) = 0$.

**Proof.** First note that after possibly replacing the vector field $v$ by $-v$ we can assume that $v$ points outward along $\partial M$. If $v$ has no zeros, then the sum over the indices of the zeros is also zero. Thus it follows from the Poincaré-Hopf Theorem 97.5 that $\chi(M) = 0$. $lacksquare$

In preparation for the proof of the Poincaré-Hopf Theorem 97.5 let us first let us make a little remark and prove a useful lemma.

**Remark.** Let $M$ be a topological manifold. Furthermore let $U \subset M$ be an open subset and let $f: U \to M$ be map. If $x$ is an isolated fixed point of $f$, then we can define $\text{index}(f, x) \in \mathbb{Z}$ the same way as we did for the case $U = M$ on page 2338.

**Lemma 97.7.** Let $U$ be an open neighborhood of the origin $0 \in \mathbb{R}^n$ which contains the closed ball $B^n$. Furthermore let $v: U \to \mathbb{R}^n$ be a vector field on $U$ which has a single zero, namely at $0$. We consider the map

$$f: U \to \mathbb{R}^n, \quad x \mapsto x - v(x).$$
The point $x = 0$ is an isolated fixed point of $f$ and we have the following equality:

$$\text{index}(v, 0) = \text{index}(f, 0).$$

**Proof.** Since $v$ has a single zero at $x = 0$ we see that $x = 0$ is the only fixed point of $f$, in particular it is an isolated fixed point. We consider the embedding $\Psi = \text{id}: \mathbb{R}^n \to \mathbb{R}^n$ to compute the indices $\text{index}(v, 0)$ and $\text{index}(f, 0)$. We consider the map $\Theta: S^{n-1} \to S^{n-1}$ that is given by $x \mapsto \frac{v(x)}{\|v(x)\|}$. Furthermore we consider the following diagram:

$$
\begin{array}{cccc}
H_{n-1}(S^{n-1}) & \overset{\iota}{\rightarrow} & H_{n-1}(\mathbb{R}^n \setminus \{0\}) & \overset{\partial_n \approx}{\leftarrow} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\
\downarrow \text{id} & & \downarrow \iota \cong & & \downarrow \iota \cong \\
H_{n-1}(S^{n-1}) & \overset{\iota}{\rightarrow} & H_{n-1}(\mathbb{B}^n \setminus \{0\}) & \overset{\partial_n \cong}{\leftarrow} & H_n(\mathbb{B}^n, \mathbb{B}^n \setminus \{0\}) \\
\downarrow \Theta_* & & \downarrow (\text{id} - f)_* & \overset{\partial_n \approx}{\leftarrow} & \downarrow \text{id} - f_* \\
H_{n-1}(\mathbb{R}^n \setminus \{0\}) & \overset{\iota}{\rightarrow} & H_{n-1}(\mathbb{R}^n \setminus \{0\}) & \overset{\partial_n \approx}{\leftarrow} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}).
\end{array}
$$

We make the following observations and clarifications:

1. The maps $\iota$ are the various inclusion induced maps.
2. The map

$$H: S^{n-1} \times [0, 1] \to \mathbb{R}^n \setminus \{0\},
(x, t) \mapsto \frac{v(x)}{1 - t \cdot \|v(x)\| + t}$$

is a homotopy between $H_0 = \Theta$ and $H_1 = v = \text{id} - f$. It follows from the existence of such a homotopy together with Proposition 42.5 that we have the equality $\Theta_* = (\text{id} - f)_*: H_{n-1}(S^{n-1}) \to H_{n-1}(\mathbb{R}^n \setminus \{0\})$.
3. It follows from the naturality of the connecting homomorphisms, see Corollary 43.16 that the squares to the right commute. All the remaining parts of the diagram commute by the functoriality of homology groups.

It follows from the above discussion that

$$\text{index}(v, 0) = \text{deg} \left( \begin{array}{c}
H_{n-1}(S^{n-1}) \\
\downarrow \Theta_* \\
H_{n-1}(S^{n-1})
\end{array} \right) = \text{deg} \left( \begin{array}{c}
H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) \\
\downarrow \iota \approx \\
H_n(\mathbb{B}^n, \mathbb{B}^n \setminus \{0\})
\end{array} \right) = \text{index}(f, 0).$$

by the definition on page 2347 by the above discussion see definition on page 2338

Now we can provide the proof of the Poincaré-Hopf Theorem 97.5. To simplify the discussion we first deal with the special case that the smooth manifold is closed and oriented. We will deal with the general case right afterwards.
Proof of the Poincaré-Hopf Theorem for closed orientable $M$. Let $M$ be a closed orientable $n$-dimensional smooth manifold. Let $v$ be a vector field on $M$ with finitely many zeros $P_1, \ldots, P_k$. The idea now is similar to the idea behind the proof of Theorem 65.17. Namely we intend to use the vector field $v$ to produce a self-map $f$ of $M$. We will then roll out the Lefschetz-Hopf Theorem 96.5 to obtain the desired result.

As the reader surely remembers, in Proposition 65.18 we gave two different constructions of a self-map $f$ from a given vector field $v$. The first approach used more machinery whereas the second proof was much more hands-on. It is technically slightly trickier to adapt the first approach to our current needs. Thus in the following we present a slight refinement of the second construction of the self-map $f$. We refer to the proof of Proposition 65.18 for details.

(1) By Exercise 9.4, which is a variation on Proposition 9.1, we can assume the following:
   (a) $M$ is a submanifold of some $\mathbb{R}^m$.
   (b) For each zero $P_i$ there exists an open neighborhood $U_i$ of $P_i$ that is “flat”, in the sense that there exists a $y_i \in \mathbb{R}^{m-n}$ such that $U_i \subset \mathbb{R}^n \times \{y_i\}$.

(2) We consider the map

$$F: M \times \mathbb{R}_{\geq 0} \to \mathbb{R}^m$$

$$(P, t) \mapsto P - t \cdot v(P).$$

(3) There exists an $\epsilon > 0$ such that $Z := \{P + w | P \in M \text{ and } w \in (V_P M)^\perp \text{ with } \|w\| \leq \epsilon\}$ is a neighborhood of $M$ and such that the map

$$q: Z \to M$$

$$P + w \mapsto P$$

where $P \in M$ and $w \in (V_P M)^\perp$ with $\|w\| \leq \epsilon$

is well-defined and continuous.

(4) There exists a $\mu > 0$ such that $F(M \times [0, \mu]) \subset Z$.

(5) We set $f := q \circ F_{\mu}: M \to M$.

(6) The map $q \circ F: M \times [0, \mu] \to M$ defines a homotopy between the identity and $f$.

Claim. Let $P \in M$.

(i) $P$ is a zero of $v$ if and only if $P$ is a fixed point of $f$.

(ii) If $P$ is a zero of $v$, then $\text{index}(v, P) = \text{index}(f, P)$.

Now we provide the proof of the two statements.

(i) Evidently if $P$ is a zero of $v$, then it is a fixed point of $f$. Now suppose that $P$ is not a zero of $v$. We can write $F_{\mu}(P) = P - \mu \cdot v(P) =: Q + w$ with $Q \in M$ and $w \in (V_Q M)^\perp$ with $\|w\| \leq \epsilon$. Since $V_P M \cap V_Q M^\perp = \{0\}$ and since $v(P)$ is a non-zero vector in $V_P M$ we see that $P \neq Q$. By the definition in (5) we have $f(P) = Q$. Thus we have shown that $f(P) \neq P$.

(ii) It follows from (1b) and our explicit construction of $f$ that we are essentially in the setting of Lemma 97.7, which then provides us with the desired equality. ⊙
Now we see that

\[ \sum_{P \text{ a zero of } v} \text{index}(v, P) = \sum_{P \text{ a fixed point of } f} \text{index}(f, P) = \Lambda(f) = \Lambda(id) = \chi(M). \]

by the claim

by the Lefschetz-Hopf Theorem 96.9

see Lemma 65.6

Next we drop the hypothesis that \( M \) needs to be closed.

**Proof of the Poincaré-Hopf Theorem 97.5 for compact orientable \( M \).** In the following let \( M \) be a compact orientable \( n \)-dimensional smooth manifold and let \( v \) be a vector field on \( M \) that points outward on \( \partial M \) and that has only finitely many zeros \( P_1, \ldots, P_k \).

We perform the following steps:

1. By the Collar Neighborhood Theorem 8.12 we know that there exists a collar neighborhood \([-1, 0] \times \partial M \) for \( \partial M = \{0\} \times \partial M \). Possibly after rescaling the collar neighborhood we can arrange that none of the points \( P_1, \ldots, P_k \) lies in \([-1, 0] \times \partial M \).

2. Given \((t, x) \in [-1, 0] \times \partial M \) we can use the isomorphism from Proposition 6.51 (3) to make the identification \( T_{(t,x)}([-1,0] \times \partial M) = (T_t \mathbb{R}) \times T_x \partial M = \mathbb{R} \times T_x \partial M \).

In particular on \([-1, 0] \times \partial M \) we can write the vector field \( v \) as \( v(t, x) = (v_1(t, x), v_2(t, x)) \)

with \( v_1(t, x) \in \mathbb{R} \) and \( v_2(t, x) \in T_x \partial M \).

3. It follows easily from the hypothesis that \( v \) points outward, see page 291 for the definition of an outward pointing tangent vector, and the fact that \( \partial M \) is compact that there exists an \( \epsilon \in [-1,0) \) such that \( v_1(t, x) > 0 \) for every \( x \in \partial M \) and every \( t \in [\epsilon, 0] \).

4. After further rescaling the collar neighborhood we might as well assume that \( \epsilon = -1 \).

5. By Proposition 97.4 we know that there exists a vector field \( u \) on \( \partial M \) with finitely many zeros \( Q_1, \ldots, Q_l \) and such that the sum of the indices of the zeros of \( u \) equals precisely \( \chi(\partial M) \).

6. We consider the double \( D M := M \cup_{\partial M = \partial M'} M' \) where \( M' \) is a copy of \( M \). By Lemma 44.12 we know that \( D M \) is a closed orientable \( n \)-dimensional smooth manifold.

7. We denote by \( \rho \): \( D M \to D M \) the natural involution swapping the two copies of \( M \).
(8) Our next goal is to construct a vector field $w$ on $M$ that equals $v$ outside of the collar neighborhood, that equals $u$ on $\partial M$ and that interpolates between these vector fields on the collar neighborhood without creating new zeros. In fact the following vector field has precisely those properties:

$$w(x) := \begin{cases} v(x), & \text{if } x \in M \setminus ([-1, 0] \times \partial M), \\ (|t| \cdot v_1(y, t), |t| \cdot v_2(y, t) + (1 + t) \cdot u(y)), & \text{if } x = (t, y) \text{ with } t \in [-1, 0] \& y \in \partial M. \end{cases}$$

We use the natural involution $\rho: D M \to D M$ to extend this vector field to $D M$. More precisely, given $x' \in M'$ we set $w(x') = D \rho(x')(w(\rho(x)))$. Note that $w$ is indeed a vector field on $D M$, i.e. there are no continuity issues along $\partial M = \partial M'$.

(9) The zeros of $w$ are $P_1, \ldots, P_k, \rho(P_1), \ldots, \rho(P_k)$ and $Q_1, \ldots, Q_l$. We make the following three observations:

(a) We have $\text{index}(w, P_i) = \text{index}(v, P_i)$, since $w$ equals $v$ in a neighborhood of $P_i$.

(b) We have $\text{index}(w, \rho(P_i)) = \text{index}(w, P_i)$, since $\rho$ is a diffeomorphism.

(c) It follows from our hypothesis that $v$ points outward together with Lemma 97.2 that we have $\text{index}(w, Q_j) = -\text{index}(u, Q_j)$.

Now we have the following equality:

$$\sum_{i=1}^{k} \text{index}(w, P_i) + \sum_{i=1}^{k} \text{index}(w, \rho(P_i)) + \sum_{j=1}^{l} \text{index}(w, Q_j) = \chi(D M).$$

From this equality, together with (8a), (8b) and (8c) and Lemma 55.5 we obtain the following equality:

$$2 \cdot \sum_{i=1}^{k} \text{index}(v, P_i) - \sum_{j=1}^{l} \text{index}(u, Q_j) = 2 \cdot \chi(M) - \chi(\partial M).$$

Cleaning up the bottom equality we obtain the desired equality.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{1371.png}
\caption{Figure 1371}
\end{figure}
Finally we drop the hypothesis that $M$ needs to be orientable.

**Proof of the Poincaré-Hopf Theorem.** Let $M$ be a compact $n$-dimensional smooth manifold and let $v$ be a vector field on $M$ that points outward on $\partial M$ and that has only finitely many zeros $P_1, \ldots, P_k$. Evidently we only need to consider the case that $M$ is connected. Furthermore, by the previous discussions it remains to consider the case that $M$ is non-orientable.

By Proposition 17.3 there exists a 2-fold covering $p: \widetilde{M} \to M$ where $\widetilde{M}$ is a compact orientable smooth manifold and $p$ is a local diffeomorphism. We equip $\widetilde{M}$ with the vector field $p^*v$ that is the pullback of $v$ under $p$, see Lemma 65.14. In other words, $p^*v$ is the unique vector field on $\widetilde{M}$ that satisfies $Dp_x(p^*v(x)) = v(p(x))$ for every $x \in \widetilde{M}$. We see that

$$2 \cdot \sum_{i=1}^{k} \text{index}(v, P_i) = \sum_{i=1}^{k} \sum_{Q \in p^{-1}(P_i)} \text{index}(p^*v, Q) = \chi(\widetilde{M}) = 2 \cdot \chi(M).$$

Each $P_i$ has two preimages and the indices of the preimages agree with the index of $P_i$ by the above discussion, since $M$ is orientable and Proposition 37.4.

97.3. **The Gauss map** (*). In this section we will introduce the Gauss map and we will determine its degree. We will not make use of the results of this section. Hence on several occasions we will skip some details.

The following definition introduces the protagonist of this section.

**Definition.** Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented submanifold of codimension one. We refer to

$\mathfrak{G}: M \to S^n$

the unique $\mathfrak{G}(P) \in \mathbb{R}^{n+1}$ that has the following properties:

1. $\mathfrak{G}(P)$ is normal to the visual tangent space $V_PM$,
2. $\mathfrak{G}(P)$ has length one, i.e. $\mathfrak{G}(P) \in S^n$,
3. $\mathfrak{G}(P)$ followed by a positive basis for $V_PM$ is a positive basis for $\mathbb{R}^{n+1}$

as the *Gauss map* of $M$. Using charts one can write down an explicit local description of the Gauss map which can be used to show that the Gauss map is smooth.

![Gauss map](image)

**Figure 1372**

**Example.** Let $n \in \mathbb{N}$. We consider the submanifold $S^n \subset \mathbb{R}^{n+1}$ with the usual orientation introduced on page 299. It follows almost immediately from the definitions and conventions that the corresponding Gauss map $\mathfrak{G}: S^n \to S^n$ is the identity.

The following theorem was first proved by Heinz Hopf [Hopf25] in 1925.
\textbf{Theorem 97.8.} Let $M \subset \mathbb{R}^{n+1}$ be a closed oriented submanifold of codimension one. If $n$ is even, then
\[
\deg(\text{Gauss map } \mathcal{G} : M \to S^n) = \frac{1}{2} \chi(M).
\]

\textbf{Remark.}
(1) Alternative proofs of Theorem 97.8 are given in [Bre93 Theorem VI.12.11], [Cib16], [Sakk90], [Tu11] p. 174] and [GP74] p. 198.
(2) Note that in general the conclusion of Theorem 97.8 does not hold if $n$ is odd. For example if we consider $M = S^1 \subset \mathbb{R}^2$, then we know by the above that the Gauss map $\mathcal{G}$ is the identity, hence its degree equals one, whereas $\chi(S^1) = 0$.

\textbf{Sketch of a proof of Theorem 97.8.} Let $n \in \mathbb{N}_0$ and let $M \subset \mathbb{R}^{n+1}$ be a closed oriented submanifold of codimension one. Recall that above we observed that the Gauss map $\mathcal{G} : M \to S^n$ is smooth. Thus we can appeal to Sard’s Theorem [6.63] which implies in particular that there exists some $z \in S^n$ such that $z$ and $-z$ are both regular values of the Gauss map $\mathcal{G}$. Note that $O(n + 1)$ acts transitively on $S^n$. Thus, after a rotation, we can assume that $z = e_{n+1} = (0, \ldots, 0, 1) \in \mathbb{R}^{n+1}$. Next we consider the vector field
\[
v : M \to \mathbb{R}^{n+1} \\
P \mapsto \text{the orthogonal projection of } z = e_{n+1} \text{ to } V_P M.
\]
Note that for $Q \in M$ we have $v(Q) = 0$ if and only if $\mathcal{G}(Q) = z$ or $\mathcal{G}(Q) = -z$.

Let $Q \in M$ with $\mathcal{G}(Q) = \pm z$. By design we know that $Q$ is a regular value of $\mathcal{G}$. By Lemma [6.54] (1) we know that $\mathcal{G}$ is a local diffeomorphism at $Q$, thus it makes sense to introduce the following definition:
\[
\deg(\mathcal{G}, Q) = \begin{cases} 
+1, & \text{if } \mathcal{G} \text{ is orientation-preserving at } Q \\
-1, & \text{if } \mathcal{G} \text{ is orientation-reversing at } Q.
\end{cases}
\]

\textbf{Claim.} Let $Q \in M$.
(1) If $\mathcal{G}(Q) = z$, then $\text{index}(v, Q) = (-1)^n \cdot \deg(\mathcal{G}, Q)$.
(2) If $\mathcal{G}(Q) = -z$, then $\text{index}(v, Q) = \deg(\mathcal{G}, Q)$.

First we consider the case that we are given $Q \in M$ with $\mathcal{G}(Q) = z$. We make the following observations and preparations.
(a) We denote by \( p: \mathbb{R}^{n+1} \to \mathbb{R}^n \) the projection onto the first \( n \) coordinates.

(b) It follows fairly easily from Exercise 6.15 that there exists a neighborhood \( U \) of \( Q \in M \), a neighborhood \( V \) of \( z \in S^n \) and an \( r \in \mathbb{R}_{>0} \) with the following properties:

(i) \( U \) contains no other point \( x \) with \( \mathcal{G}(x) = z \).

(ii) We have \( \mathcal{G}(U) \subset V \).

(iii) The restriction of the projection \( p: \mathbb{R}^{n+1} \to \mathbb{R}^n \) to \( U \) and \( V \) defines diffeomorphisms \( p: U \to \mathcal{B}_r^n \) and \( p: V \to \mathcal{B}_r^n \). It follows immediately from the orientation conventions and some elementary linear algebra that both maps are orientation-preserving if \( n \) is even and both maps are orientation-reversing if \( n \) is odd.

(c) We set \( \Psi := p^{-1}: \mathcal{B}_r^n \to U \).

(d) Note that by (b) we know that \( M \) is locally a graph around \( Q \). More precisely, there exists a map \( f: \mathcal{B}_r^n \to \mathbb{R} \) such that \( M \cap U = \{(x, f(x)) \mid x \in \mathcal{B}_r^n \} \). Using this observation one can write down an explicit expression of \( \mathcal{G} \). This explicit calculation then shows that for \( x \in M \) we have

\[
\mathcal{G}(x) = \mathcal{G}(Q) - v(x) + s(x) \quad \text{with} \quad s(x) = O(\|x - Q\|^2).
\]

Hopefuly Figure 1374 makes this assertion plausible. We leave it to the reader to fill in the details.

(e) We denote by \( \rho: \mathcal{B}_r^n \to \overline{\mathcal{B}}_r^n \) the map given by \( \rho(x) = -x \).

(f) It follows almost immediately from (c), the observation that \( p(\mathcal{G}(Q)) = 0 \) and from Exercise 18.10 that, after possibly shrinking \( r \), the maps \( p \circ v \) and \( \rho \circ p \circ \mathcal{G} \) are homotopic as maps of pairs \( (U, U \setminus \{Q\}) \to (\mathcal{B}_r^n, \mathcal{B}_r^n \setminus \{0\}) \).

\[\text{Figure 1374. Second illustration for the proof of Theorem 97.8.}\]
We now see that

\[ \text{definition of } \text{index}(v, Q), \text{see page } 2347, \text{ by Exercises } 97.1 \text{ and together with Proposition } 43.17 \]

applied with our given \( \Psi \)
\[ \downarrow \]
\[ \text{index}(v, Q) = \deg \left( \frac{S^n_r \to S^n_r \to \{x \to \frac{p(v(\Psi(x)))}{\|p(v(\Psi(x)))\|}} \right) \]
\[ \downarrow \]
\[ = \deg \left( (p \circ v \circ \Psi)_* \cup H_n(B^n_r, B^n_r \setminus \{0\}) \right) \]
\[ = \deg \left( (p \circ p \circ \mathcal{G} \circ \Psi)_* \cup H_n(B^n_r, B^n_r \setminus \{0\}) \right) \]
\[ = (-1)^n \cdot \deg \left( (p \circ \mathcal{G} \circ \Psi)_* \cup H_n(B^n_r, B^n_r \setminus \{0\}) \right) \]
\[ = \deg(\Psi) \]

by Lemma 45.18
\[ \uparrow \]
\[ \text{this follows from the definition of } \deg(\mathcal{G}, Q) \text{ together with Proposition } 45.16 \text{ and the fact that we know } p \text{ and } \Psi \text{ are either both orientation-preserving or they are both orientation-reversing} \]

Now we consider the case that \( \mathcal{G}(Q) = -z \). The calculation is basically identical to the above. We only need to make the observation that in this setting the map \( p \) is orientation-preserving if and only if \( n \) is odd, whereas before \( p \) was orientation-preserving if and only if \( n \) is even. Thus we obtain the same result as above, except that by Lemma 45.18 we pick up a sign \((-1)^n\).

Now finally we assume that \( n \) is even. We perform the following calculation:

\[ 2 \cdot \deg(\text{Gauss map } \mathcal{G} : M \to S^n) \]
\[ = \sum_{Q \in M \text{ with } \mathcal{G}(Q) = z} \text{index}(\mathcal{G}, Q) + \sum_{Q \in M \text{ with } \mathcal{G}(Q) = -z} \text{index}(\mathcal{G}, Q) \]
\[ = \sum_{Q \in M \text{ with } \mathcal{G}(Q) = z} \text{index}(\mathcal{G}, Q) = \sum_{Q \in M \text{ with } \mathcal{G}(Q) = -z} \text{index}(\mathcal{G}, Q) = \chi(M). \]

since \( v(Q) = 0 \) if and only if \( \mathcal{G}(Q) = z \) or \( \mathcal{G}(Q) = z \) since \( n \) is even by the claim and by the Poincaré-Hopf Theorem 97.3

\[ \square \]

Exercises for Chapter 97

Exercise 97.1. We consider the two vector fields \( v \) and \( w \) that are shown in Figure 1375 with a single zero at \( P \). On page 2347 we already saw that \( \text{index}(v, P) = +1 \). What is \( \text{index}(w, P) \)?

Exercise 97.2.

(a) We consider the vector field \( v \) on \( \mathbb{R}^2 \) shown in Figure 1376. What is the index of \( v \) at the unique zero?
(b) Sketch a vector field \( v \) on \( \mathbb{R}^2 \) with a zero at some point \( P \), such the corresponding index equals +3.
(c) Let $n \geq 2$. Show that for every $k \in \mathbb{Z}$ there exists a vector field $v$ on $\mathbb{R}^n$ with a single zero at the origin $0$ such that \( \text{index}(v, 0) = k \).

![vector field v]

**Figure 1376.** Illustration of Exercise 97.2 (a).

**Exercise 97.3.** Let $M$ be a closed oriented $n$-dimensional smooth manifold. We consider the tangent bundle

\[
TM := \bigsqcup_{x \in M} (T_x M \times \{x\}).
\]

(a) Show that $TM$ is naturally an oriented $2n$-dimensional smooth manifold such that the map $\varphi : M \to TM$ given by $x \mapsto (0, x) \in T_x M \times \{x\}$ is a smooth embedding.

(b) Show that there exists a smooth embedding $\psi : M \to TM$, that is homotopic to $\varphi$, such that the submanifolds $\varphi(M)$ and $\psi(M)$ of $TM$ intersect transversally and such that $\varphi(M) \cdot \psi(M) = \chi(M)$. Here the left-hand side is the algebraic intersection number as defined on page 2271.

**Hint.** Use Proposition 97.4.

**Remark.** In the literature the statement we just proved sometimes gets shortened to “$M \cdot M = \chi(M)$”.

**Exercise 97.4.** We say that two vector fields $v$ and $w$ on a smooth manifold $M$ are equivalent if there exists a diffeotopy $H : M \times [0, 1] \to M$ with $H_0 = \text{id}$ and such that $(H_1)_x(v) = w$, i.e. such that for every $x \in M$ we have $(D H_1)_x(v)(x)) = w_{H_1(x)}$. Are all nowhere vanishing smooth vector fields on the torus $S^1 \times S^1$ equivalent?
98. HOMOLOGY, COHOMOLOGY AND SUBMANIFOLDS

In this chapter, given an oriented, compact smooth manifold \( M \) we will relate the following objects:

1. Codimension one submanifolds of \( M \),
2. cohomology classes in \( H^1(M; \mathbb{Z}) \) of dimension one,
3. homology classes in \( H_{n-1}(M, \partial M; \mathbb{Z}) \) of codimension one,
4. maps \( M \to S^1 \).

98.1. Codimension one submanifolds. Let \( M \) be a compact oriented connected \( n \)-dimensional topological manifold. Every compact oriented proper submanifold \( Y \subset M \) of codimension \( k \) gives rise to a homomorphism

\[
H_k(M; \mathbb{Z}) \to \mathbb{Z}
\]

\[
\sigma \mapsto \langle \text{PD}_M([Y]), \sigma \rangle \in H^k(M; \mathbb{Z})
\]

In many circumstances the next proposition gives an explicit description of this homomorphism \( H_k(M; \mathbb{Z}) \to \mathbb{Z} \):

**Proposition 98.1.** Let \( M \) be a compact oriented connected \( n \)-dimensional topological manifold and let \( Y \subset M \) be a compact oriented proper submanifold of codimension \( k \). Let \( f : X \to M \) be a map from a closed \( k \)-dimensional topological manifold \( X \) to \( M \). If \( f \) is transverse to \( Y \), then

\[
\langle \text{PD}_M([Y]), f_*([X]) \rangle \in H^k(M; \mathbb{Z})
\]

\[
\mathbb{Z}
\]

\[
f \cdot Y = 1
\]

**Remark.** Let \( M \) be a compact oriented connected \( n \)-dimensional topological manifold and let \( Y \subset M \) be a compact oriented proper submanifold of codimension one. In Proposition 10.9 we saw that \( Y \) admits a tubular neighborhood of the form \([-1, 1] \times Y \) such that the product orientation of \([-1, 1] \times Y \) matches the orientation of \( M \). If \( f : S^1 \to M \) is a map, then loosely speaking, the algebraic intersection number \( f \cdot Y \) counts (with signs) how often \( f \) goes from \( Y \times \{\pm 1\} \) to \( Y \times \{\pm 1\} \).

\[
\text{Figure 1377}
\]
Proof. We have
\[ f \cdot Y = \epsilon_M((\text{PD}_M(f_*([X])) \cup \text{PD}_M([Y])) \cap [M]) = \epsilon_M(\text{PD}_M([Y]) \cap (\text{PD}_M(f_*([X]) \cap [M]))) \]
by Theorem 85.7 since \( f \) and \( Y \) are transverse
\[ = \epsilon_M(\text{PD}_M([Y]) \cap f_*([X])) \]
by definition of \( \text{PD}_M(f_*([X])) \)
\[ = (\text{PD}_M([Y]), f_*([X])). \]
by Lemma 83.7 and the discussion on page 2026
\[ \text{Lemma 83.4} \]

Now we can prove the following proposition which gives an easy criterion for showing that a codimension-one submanifold represents a non-trivial class in homology.

**Proposition 98.2.** Let \( M \) be a compact oriented \( n \)-dimensional smooth manifold and let \( N \) be a compact orientable non-empty proper submanifold of codimension one. If the complement \( M \setminus N \) is connected, then \([N] \in H_{n-1}(M, \partial M; \mathbb{Z})\) is a primitive element of infinite order.

**Example.** Proposition 98.2 can in particular be seen as a generalization of the argument given on page 2277.

**Remark.** In any statement of a lemma, proposition or theorem it is always a good exercise to see whether the hypothesis stated are actually necessary. In the following we will discuss whether the conditions in Proposition 98.2 that \( M \) needs to be compact and oriented are necessary.

1. We consider the real projective plane \( \mathbb{R}P^2 \) and the 1-dimensional submanifold \( N \) that is illustrated in Figure 1378 to the left. We see that \( \mathbb{R}P^2 \setminus N \) is connected, but since \( H_1(\mathbb{R}P^2; \mathbb{Z}) \cong \mathbb{F}_2 \) we see that \( N \) cannot possibly represent an element of infinite order. On the other hand, an “\( \mathbb{F}_2 \)-version” of Proposition 86.13 also applies to non-orientable smooth manifolds, shows that \( N \) represents a non-trivial element in \( H_1(\mathbb{R}P^2; \mathbb{F}_2) \).

2. Let \( M \) be a non-compact oriented \( n \)-dimensional smooth manifold and let \( N \) be a compact orientable non-empty proper submanifold of codimension one. If \( \partial M \) is compact, then we will see in Exercise 98.1 using Proposition 11.4 and 98.2 that the homology class \([N] \in H_{n-1}(M; \mathbb{Z})\) is still an element of infinite order.

\[ \text{Figure 1378} \]

\[ \text{\textsuperscript{1365}Recall that an element } g \text{ of an additive abelian group } G \text{ is called primitive if there does not exist an } h \in G \text{ and an } n \geq 2 \text{ with } n \cdot h = g. \]
PROOF. Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $N$ be a compact orientable proper submanifold of codimension one such that $M \setminus N$ is connected. By Proposition 10.9 we can find a trivial tubular neighborhood $[-1, 1] \times N$ in $M$. By hypothesis $M \setminus N$ is connected. It follows from Proposition 10.11, Lemma 10.1 and Lemma 6.9 (3) that $M \setminus (-1, 1) \times N$ is path-connected.

It follows from our hypothesis that $N$ is non-empty, together with Proposition 44.2 (5), that we can pick a point $P \in N \setminus \partial N$. We write $P_\pm = P \times \{\pm 1\} \in [-1, 1] \times N$. We denote by $\alpha: [0, \frac{1}{2}] \to [-1, 1] \times N$ the “horizontal path” in $[-1, 1] \times N$ from $P_-$ to $P_+$. Since $M \setminus (-1, 1) \times N$ is path-connected we can connect the two points $P_+$ to $P_-$ via a path $\beta: [\frac{1}{2}, 1] \to M \setminus (-1, 1) \times N$. We refer to Figure 1379 for an illustration.

We consider the map $\gamma: S^1 = [0, 1] \to M$ that is defined by $\alpha$ on $[0, \frac{1}{2}]$ and that is given by $\beta$ on $[\frac{1}{2}, 1]$. We consider the following homomorphism

$$\Psi: H_{n-1}(M, \partial M; \mathbb{Z}) \to \mathbb{Z}$$

$$\sigma \mapsto \langle PD_M(\sigma), \gamma_*([S^1]) \rangle \in H^1(M; \mathbb{Z}) \in H_1(M; \mathbb{Z})$$

We want to show that $[N] \in H_{n-1}(M, \partial M; \mathbb{Z})$ is a primitive element of infinite order. It suffices to show that $\Psi([N]) = \pm 1 \in \mathbb{Z}$. In fact we have

$$\Psi([N]) = \langle PD_M([N]), \gamma_*([S^1]) \rangle = \gamma \cdot N = \pm 1,$$

by definition, by Proposition 98.1, since $\gamma$ and $N$ are clearly transverse,

as desired.

We conclude this section with the following lemma.

**Lemma 98.3.** (*) Let $M$ be a compact orientable $n$-dimensional smooth manifold with at most one boundary component and which furthermore satisfies $H_1(M; \mathbb{Z}) = 0$. (For example we could take $M = \overline{B^n}$ or $M = S^n$). Then for every connected submanifold $N$ of codimension one with $N \cap \partial M = \emptyset$ there exists a compact $n$-dimensional submanifold $W$ of $M$ with $\partial W = N$.

**Proof (†).** By Proposition 10.9 we can find a trivial tubular neighborhood $[-1, 1] \times N$ in $M$. It follows from the argument of the proof of Proposition 98.2 and our assumption that $M$ is orientable and the fact that $M$ is compact that $X := M \setminus (-1, 1) \times N$ is disconnected. Furthermore it follows from Proposition 6.30 that $X$ is a submanifold of $M$ with $\partial X = \partial M \cup (\{-1\} \times N) \cup (\{1\} \times N)$. Since $\partial M$ consists of at most one component,
since $M$ is connected and since $X$ is disconnected we see that there exists a component $Y$ of $X$ with $\partial X = \{\epsilon\} \times N$ for some $\epsilon \in \{-1, 1\}$. By adding “half” of the tubular neighborhood to $Y$ we obtain a submanifold with $\partial Y = M$. 

**Figure 1380.** Illustration for the proof of Lemma 98.3.

98.2. **Representing homology classes by submanifolds II.** First we recall the following definition from page 1760.

**Definition.** Let $M$ be a smooth manifold and let $A$ be a union of components of $\partial M$.

1. If $N$ is a compact oriented $k$-dimensional submanifold of $M$ with $\partial N \subset A$, then we denote by $[N]$ the image of the fundamental class $[N]$ in $H_k(M, A; \mathbb{Z})$ under the inclusion induced map $H_k(N, \partial N; \mathbb{Z}) \to H_k(M, A; \mathbb{Z})$.
2. We say that a homology class $z \in H_k(M, A; \mathbb{Z})$ is represented by a submanifold if there exists a compact oriented proper $k$-dimensional submanifold $N$ with $\partial N \subset A$ such that $[N] = z$.

Let $M$ be an orientable, compact $n$-dimensional smooth manifold. We saw in Theorem 94.5 that we can calculate the cup product of $\alpha \in H^k(M, \partial M; \mathbb{Z})$ and $\beta \in H^{n-k}(M; \mathbb{Z})$ if the Poincaré duals $PD_M(\alpha) \in H_{n-k}(M; \mathbb{Z})$ and $PD_M(\beta) \in H_k(M, \partial M; \mathbb{Z})$ are represented by transverse submanifolds. This rekindles our interest in the following question.

**Question [70.11].** Let $M$ be an $n$-dimensional smooth manifold and let $A$ be a union of components of $\partial M$. For which $k \in \mathbb{N}_0$ can homology classes in $H_k(M, A; \mathbb{Z})$ be represented by submanifolds?

We already studied Question [70.11] in great detail in Section 70.4. For example in Corollary 70.14 and Corollary 70.17 we proved the following:

1. If $n \geq 2$, then every class in $H_1(M, A; \mathbb{Z})$ can be represented by a submanifold.
2. If $n \geq 4$, then every class in $H_2(M, A; \mathbb{Z})$ can be represented by a connected submanifold.

Instead of moving on to the next highest dimension, we now actually consider homology classes of **codimension one**. More precisely, we want to prove the following proposition.

**Proposition 98.4.** Let $M$ be a compact orientable $n$-dimensional smooth manifold and let $A \subset \partial M$ be a union of boundary components. Every class in $H_{n-1}(M, A; \mathbb{Z})$ can be represented by a submanifold.

**Remark.**

1. In Proposition 98.6 we will prove a refinement of Proposition 98.4.
2. In Proposition ?? we will prove the codimension-two analogue of Proposition 98.4.

Furthermore in Proposition ?? we will prove an “$\mathbb{F}_2$-coefficient”-analogue of Proposition 98.4.
Proof. Let $M$ be a compact orientable $n$-dimensional smooth manifold. In the following we deal with the case that $A = \partial M$. The general case is proved in a similar fashion, but now one needs to use Exercise 79.5 (4) instead of Proposition 79.10. We leave it to the reader to work out the details.

Now let $\sigma \in H_{n-1}(M, \partial M; \mathbb{Z})$. We write $\phi = PD_M(\sigma) \in H^1(M; \mathbb{Z})$. By Proposition 79.10 or alternatively by Proposition 120.20 there exists a smooth map $f: M \to S^1$ such that $\phi = f^*([S^1]^*)$ where $[S^1]^* \in H^1(S^1; \mathbb{Z})$ is the dual fundamental class.

By Sard’s Theorem 6.63 and Proposition 6.62 (2) there exists a regular value $z \in S^1$. To simplify the notation we assume that in fact $z = 1$ is a regular value. We write $N := f^{-1}\{1\}$. By the Regular Value Theorem 11.3 (1), (2), (3) we know that $N$ is a compact orientable $(n-1)$-dimensional smooth manifold. Furthermore we know from Theorem 11.3 (4) that there exists an $\epsilon \in (0, \pi)$ and a tubular neighborhood $[\epsilon, \epsilon] \times N$ of $N$ such that the following diagram commutes

$$
\begin{array}{ccc}
[-\epsilon, \epsilon] \times N & \xleftarrow{(s,x) \mapsto s} & M \\
\downarrow{(s,x) \mapsto s} & & \downarrow{f} \\
[-\epsilon, \epsilon] & \xrightarrow{s \mapsto e^{2\pi is}} & S^1.
\end{array}
$$

We pick the orientation for $N$ such that the inclusion map $[-\epsilon, \epsilon] \times N \to M$ is orientation-preserving. It remains to prove that $[N] = \sigma \in H_{n-1}(M, \partial M; \mathbb{Z})$. Recall that $\phi = PD_M(\sigma)$, i.e. $\sigma = \phi \cap [M]$. Therefore it suffices to show that $[N] = \phi \cap [M] \in H_{n-1}(M, \partial M; \mathbb{Z})$.

We introduce the following notation:

(1) We write $I = [-\epsilon, \epsilon]$ and $\tilde{I} = (-\epsilon, \epsilon)$,
(2) we denote by $i: I \times N \to M$ the inclusion map and we denote by $\tilde{i}$ also all maps of pairs where the first map is given by the inclusion map,
(3) we denote by $q$ all maps of pairs of topological spaces where the first map is just the identity on $M$,
(4) finally we denote by $p: I \times N \to I$ the projection map.

Figure 1381. Illustration for the proof of Proposition 98.4.
We consider the following diagram:

\[
\begin{array}{ccc}
H^1(M) \times H_n(M, \partial M) & \mapsto & H_{n-1}(M, \partial M) \\
q^* \uparrow & & \downarrow q_* \\
H^1(M, M \setminus (\hat{I} \times N)) \times H_n(M, M \setminus (\hat{I} \times N) \cup \partial M) & \mapsto & H_{n-1}(M, \partial M) \\
i^* \downarrow \cong & & i_* \downarrow \\
H^1(I \times N, \partial I \times N) \times H_n(I \times N, \partial (I \times N)) & \mapsto & H_{n-1}(I \times N, I \times \partial N) \\
p^* \uparrow & & \downarrow \times[N] \\
H^1(I, \partial I) \times H_1(I, \partial I) & \mapsto & H_0(I).
\end{array}
\]

The proposition follows from the following claim.

**Claim.**

1. The diagram commutes.
2. The map \(i^* : H^1(M, M \setminus (\hat{I} \times N)) \to H^1(I \times N, \partial I \times N)\) is an isomorphism.
3. We have \((q^* \circ i_*^{-1} \circ p^*)([I]^*) = \phi\).
4. We have \(i_*([I] \times [N]) = q_*([M])\).

We turn to the proof of these four statements:

1. The top two squares commute by Lemma 83.8 applied to the two maps
   \[
   q : (M, \emptyset, \partial M) \to (M, M \setminus (\hat{I} \times N), \partial M)
   \]
   and
   \[
   i : (I \times N, \partial I \times N, I \times \partial N) \to (M, M \setminus (\hat{I} \times N), \partial M).
   \]

Finally regarding the bottom square, note that

\[
p^*([I]^*) \cap ([I] \times [N]) = p^*([I]^*) \cap ([I] \times [N]) = \{0\} \times N = ([I]^* \cap [I]) \times [N].
\]

Since \([I]^* \in H^1(I, \partial I)\) and \([I] \in H_1(I, \partial I)\) are generators it follows from this calculation that the bottom square commutes.

2. It follows from excision for cohomology groups, see page 1840, that \(i^*\) is indeed an isomorphism. We leave it to the reader to verify the details.

3. We identify the interval \(I\) with its image in \(S^1\) under the orientation-preserving map defined by \(s \mapsto e^{2\pi i s}\). We denote by \(j : I \to S^1\) and \(j : (I, \partial I) \to (S^1, S^1 \setminus \hat{I})\) the inclusion maps. Furthermore we denote by \(r : (S^1, \emptyset) \to (S^1, S^1 \setminus \hat{I})\) the obvious map.
of pairs of topological spaces. We consider the following diagram
\[
\begin{array}{ccc}
H^1(S^1) & \xrightarrow{f^*} & H^1(M) \\
\uparrow r^* & & \uparrow q^* \\
H^1(S^1, S^1 \setminus \tilde{I}) & \xrightarrow{f^*} & H^1(M, M \setminus (\tilde{I} \times N)) \\
\cong j^* \downarrow & & \cong i^* \downarrow \\
H^1(I, \partial I) & \xrightarrow{f^* = p^*} & H^1(I \times N, \partial I \times N).
\end{array}
\]

Here the map \( j^* \) is an isomorphism by excision for cohomology groups. Also note that at the bottom horizontal map we have \( f^* = p^* \) by the discussion on page 2367. Furthermore we note that by the functoriality of cohomology groups both squares commute. Finally we point out that it follows immediately from Lemma 87.24 that \( r^* (j^* - 1([I]^*)) = [S^1]^* \). The desired statement is a consequence of the observation that \( \phi = f^*([S^1]^*) \).

(4) This statement follows immediately from Lemma 87.24.

98.3. **The basic Thom-Pontryagin Theory.** In the proof of Proposition 98.4 we saw that a map from a smooth manifold \( N \) to \( S^1 \) gives rise to a codimension-one submanifold. In this section we will go in the opposite direction.

**Definition.** Let \( M \) be a compact oriented \( n \)-dimensional smooth manifold and let \( N \) be a proper oriented \( (n-1) \)-dimensional submanifold. By Proposition 10.9 there exists a trivial tubular neighborhood of the form \([-1,1] \times N\) such that the product orientation of \([-1,1] \times N\) matches the orientation of \([-1,1] \times N\), viewed as a codimension-zero submanifold of \( M \). We refer to the map \( \rho_N: M \rightarrow S^1 \)

\[
\begin{align*}
P \mapsto \{ & e^{\pi i}, \text{ if } P = (t, Q) \in [-1,1] \times N, \\
& -1, \text{ otherwise} \}
\end{align*}
\]

as the **Thom-Pontryagin map**. The definition of \( \rho_N \) is illustrated in Figure 1382.

**Remark.** The Thom-Pontryagin map \( \rho_N \) that we had just constructed depends on the choice of a tubular neighborhood. But it follows from the uniqueness of tubular neighborhoods, see Proposition 10.7 together with Lemma 10.4 (2) that any other choice of a tubular neighborhood \([-1,1] \times N\) leads to a map \( M \rightarrow S^1 \) that is homotopic to the original map.
Lemma 98.5. Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $N$ be a proper oriented proper $(n - 1)$-dimensional submanifold. We have
\[ \rho_{N*} = \text{PD}_M([N]) \in \text{Hom}(H_1(N;\mathbb{Z}),\mathbb{Z}) = H^1(N;\mathbb{Z}). \]

Proof. We had implicitly verified this lemma in the above proof of Proposition 98.4. □

Example. We return to the example that we had discussed on page 394. More precisely, let $\Sigma$ be the surface of genus $2$. The closed curves $x_1, y_1, x_2, y_2$ shown in Figure 1383 represent a basis for $H_1(\Sigma;\mathbb{Z})$. We consider the epimorphism $\phi: H_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0$, $\phi(y_1) = 1$, $\phi(x_2) = -2$ and $\phi(y_2) = 1$. By Proposition 98.10, we know that $\phi$ can be realized by some map $g: \Sigma \to S^1$. Now we will construct such a map explicitly.

We consider the closed curve $C$ that is illustrated in Figure 1383. We claim that the corresponding map $\rho_C: \Sigma \to S^1$ has the desired property. Put differently, we claim that $\rho_{C*} = \phi \in \text{Hom}(H_1(N;\mathbb{Z}),\mathbb{Z})$. It suffices to show that the two homomorphisms agree on the basis $[x_1], [y_1], [x_2], [y_2]$ of $H_1(\Sigma;\mathbb{Z})$. For example we have
\[ \rho_{C*}([x_2]) = \langle \text{PD}_M([C]), [x_2] \rangle = x_2 \cdot C = -2 = \phi(x_2). \]

It is straightforward to verify that the same equalities hold for all the other basis elements.

Proposition 98.6. Let $M$ be a compact orientable $n$-dimensional smooth manifold and let $\phi \in H_{n-1}(M,\partial M;\mathbb{Z})$. Let $\partial \phi \in H_{n-2}(\partial M)$ be the image of $\phi$ under the connecting homomorphism in the long exact sequence of the pair $(M,\partial M)$. If $F \subset \partial M$ is a submanifold that represents $\partial \phi \in H_{n-2}(A)$, then $\phi$ can be represented by a submanifold $N$ of $M$ with $\partial N = F$. 

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure1382.png}
\caption{Figure 1382}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure1383.png}
\caption{Figure 1383}
\end{figure}
We consider the following diagram:

\[
\begin{align*}
\rho_F: \partial N & \to S^1 \\
P & \mapsto \begin{cases} 
\mathrm{e}^{\pi i t}, & \text{if } P = (t, Q) \in [-1, 1] \times F, \\
-1, & \text{otherwise}
\end{cases}
\end{align*}
\]

Note that \(\rho_F\) is smooth on the closed subset \([-\frac{1}{2}, \frac{1}{2}]\) \times F\. It follows quite easily from the Whitney Approximation Theorem \(9.3\) (1d) that \(\rho_F\) is homotopic rel \([-\frac{1}{2}, \frac{1}{2}]\) \times F to a smooth map \(f: \partial N \to S^1\) which is “close to \(\rho_F^s\)” in the sense that it has the property that for \(P \not\in [-\frac{1}{2}, \frac{1}{2}]\) \times F we have \(f(P) \not\in \{\mathrm{e}^{\pi i t} | t \in [-\frac{1}{2}, \frac{1}{2}]\}\). Now note that it follows from Proposition \(88.26\) together with Proposition \(79.10\) (3) that there exists a smooth map \(g: M \to S^1\) that represents \(\text{PD}_M(\phi) \in \Omega^1(M, \partial M; \mathbb{Z})\) and that agrees with \(f\) on \(\partial M\).

By Sard’s Theorem \(6.63\) and Proposition \(6.62\) (2) there exists an \(s \in (-\frac{1}{2}, \frac{1}{2})\) such that \(\mathrm{e}^{\pi i s}\) is a regular value of \(g\). We write \(N := g^{-1}\{s\}\). By the proof of Proposition \(98.4\) (1) we know that \(N\) is a smooth proper submanifold that represents \(\phi\). Note that by construction we have \(\partial N = N \cap \partial M = \{s\} \times F\). Using a collar neighborhood of \(\partial M\) it is straightforward to find an isotopy that arranges that \(\partial N = \{0\} \times F = F\). We leave it to the reader to fill in the few remaining details.

Later on we will make use of the following useful corollary.

**Corollary 98.7.** Let \(M\) be a closed orientable \(n\)-dimensional smooth manifold and let \(C\) and \(D\) be two closed oriented \((n-1)\)-dimensional submanifolds. If \([C] = [D] \in H_n(M; \mathbb{Z})\), then there exists a compact oriented proper \(n\)-dimensional submanifold \(W \subset [0, 1] \times M\) such that \(\partial W = (\{0\} \times C) \cup (\{1\} \times -D)\).

**Proof.** We consider the following diagram:

\[
\ldots \to H_n([0, 1] \times M) \xrightarrow{\partial} H_{n-1}((\{0\} \times M) \cup (\{1\} \times M)) \xrightarrow{i_*} H_{n-1}([0, 1] \times M) \xrightarrow{p_2 \downarrow \cong} H_n(M) \to \ldots
\]
Here the horizontal sequence is the long exact sequence in homology corresponding to the pair \( ([0, 1] \times M, (\{0\} \times M) \cup (\{1\} \times M)) \). Furthermore \( p: [0, 1] \times M \to M \) denotes the obvious projection. Our hypothesis that \( [C] = [D] \in H_n(M; \mathbb{Z}) \) implies immediately that \( p_*(\{0\} \times C)) = p_*(\{1\} \times D)) \). Since \( p_* \) is an isomorphism and since the sequence is exact we see that there exists a homology class \( \varphi \in H_n([0, 1] \times M) \) with \( \partial \varphi = \{0\} \times C \) - \( \{1\} \times D \). Finally note that it follows immediately from Proposition 98.6 that there exists in particular a compact oriented proper \( n \)-dimensional submanifold \( W \) of \([0, 1] \times M \) with \( [W] = \varphi \) and with \( \partial W = (\{0\} \times C) \cup (\{1\} \times -D) \).

In the remainder of this chapter we study an amusing generalization of the above Thom-Pontryagin map.

**Definition.** Let \( M \) be a compact oriented \( n \)-dimensional smooth manifold. Furthermore let \( N_1, \ldots, N_k \) be disjoint proper oriented \((n - 1)\)-dimensional submanifolds. As on page 2369 we pick a trivial tubular neighborhood of the form \([-1, 1] \times (N_1 \cup \cdots \cup N_k) \). We consider the wedge \( \bigvee_{j=1}^k S^1_j \) given by identifying the points \(-1 \in S^1_j \) to a single point \(* \). We again refer to the map

\[
\rho_{N_1, \ldots, N_k}: M \to \bigvee_{j=1}^k S^1_j
\]

\[
P \mapsto \begin{cases} 
 e^{\pi i t} \in S^1_j, & \text{if } P = (t, Q) \in [-1, 1] \times N_j, \\
 * & \text{otherwise}
\end{cases}
\]

as the *Thom-Pontryagin map*. The definition of \( \rho_N \) is illustrated in Figure 1385.

\[\begin{tikzpicture}
\draw[red, thick, fill=red!20] (-1,0) circle (1);
\draw[blue, thick, fill=blue!20] (1,0) circle (1);
\draw[black, thick] (-1,0) -- (1,0);
\draw[black, thick] (0,-1) -- (0,1);
\node at (-2,0) {\(M\)};
\node at (-1,-1) {\(N_1 \times [-1,1]\)};
\node at (1,-1) {\(N_2 \times [-1,1]\)};
\node at (2,0) {\(\rho_{N_1,N_2}\)};
\node at (4,0) {\(\bigvee_{j=1}^k S^1_j\)};
\node at (4,2) {\(S^1_1\)};
\node at (4,-2) {\(S^1_2\)};
\node at (6,0) {\(*\)};
\end{tikzpicture}\]

**Figure 1385**

Before we continue we recall that in Lemma 20.4 we gave an identification

\[
\langle t_1, \ldots, t_k \rangle = \pi_1(\bigvee_{j=1}^k S^1_j, *)
\]

where each \( t_j \) is represented by a loop that goes once around the \( j \)-th circle \( S^1_j \) in a positive direction.

**Proposition 98.8.** Let \( M \) be a compact oriented connected \( n \)-dimensional smooth manifold and let \( N_1, \ldots, N_k \) be disjoint proper oriented non-empty \((n - 1)\)-dimensional submanifolds. If \( M \setminus (F_1 \cup \cdots \cup F_k) \) is connected, then for any \( x_0 \in M \) the map

\[
\rho_{N_1,\ldots,N_k}: \pi_1(M, x_0) \to \pi_1(\bigvee_{j=1}^k S^1_j, *) = \langle t_1, \ldots, t_k \rangle
\]

is an epimorphism.
The previous example raises the following thought-provoking question.

**Question 98.9.** Let \( g \in \mathbb{N} \) and let \( \Sigma_g \) be the surface of genus \( g \).

1. What is the maximal number \( k = k(g) \in \mathbb{N}_0 \) for which we can find \( k \) disjoint curves \( F_1, \ldots, F_k \) on \( \Sigma_g \) such that \( \Sigma_g \setminus (F_1 \cup \cdots \cup F_k) \) is connected?

2. What is the maximal \( l = l(g) \in \mathbb{N}_0 \) for which there exists an epimorphism from \( \pi_1(\Sigma_g) \) onto a free group of \( k \) generators?
In summary, as of right now we know the following:
\[ g \leq k(g) \leq l(g) \leq 2g. \]
by the above Proposition 98.8 Proposition 21.20

98.4. **Cyclic coverings of manifolds** (*). Our goal in this section is to give explicit constructions of cyclic coverings of manifolds. To simplify the language will use the following conventions throughout this section.

**Convention.**

1. We will not distinguish between two coverings \( p: X \to B \) and \( q: T \to B \) that are equivalent in the sense of the definition on page 832.
2. We will use Proposition 14.11 as an excuse to suppress all base points from our notation.

The following proposition combines several results on coverings that we proved a while ago.

**Proposition 98.10.** Let \( M \) be a connected smooth manifold and let \( \varphi: \pi_1(M) \to G \) be an epimorphism onto an abelian group. There exists a unique covering \( p: \tilde{M} \to M \) such that \( p_*(\pi_1(\tilde{M})) = \ker(\varphi) \). Furthermore this covering has the following properties:

1. The covering is regular and the deck transformation group is isomorphic to \( G \).
2. The index of the covering is precisely \( |G| \).

**Proof.** The proposition follows immediately from Propositions 29.5 and 29.8 and 34.6 together with Corollary 34.7.

We sort-of introduced the following definition on page 911.

**Definition.** We say a covering \( p: X \to Y \) is (infinite) cyclic if \( p \) is a regular covering and if the deck transformation group is an (infinite) cyclic group.

Let \( M \) be a smooth manifold \( M \). Given any primitive \( \phi \in H^1(M; \mathbb{Z}) = \text{Hom}(\pi_1(M), \mathbb{Z}) \) and given \( n \in \mathbb{N} \) we know by Proposition 98.10 that there exist corresponding (infinite) cyclic covers of \( M \). Our goal is to a very explicit constructions of these (infinite) cyclic covers for many smooth manifolds.

In the remainder of this section we will use the following notation:

**Notation.** Let \( M \) be a connected smooth manifold.

1. We use Proposition 75.18 to make the identification \( H^1(M; \mathbb{Z}) = \text{Hom}(\pi_1(M), \mathbb{Z}) \).
   It follows almost immediately from the definitions that under this identification the primitive elements in \( H^1(M; \mathbb{Z}) \) correspond to the epimorphisms \( \pi_1(M) \to \mathbb{Z} \).

---

More precisely, using Proposition 14.11 it is not difficult to show that for any topological space \( X \), any abelian group \( G \) and any two paths \( p, q: [0, 1] \to X \) from a point \( x_0 \) to a point \( x_1 \) we have \( p_* = q_*: \text{Hom}(\pi_1(X, x_0), G) \to \text{Hom}(\pi_1(X, x_1), G) \). In particular, given a path-connected topological space \( X \) and \( x_0, x_1 \in X \) the groups \( \text{Hom}(\pi_1(X, x_0), G) \) and \( \text{Hom}(\pi_1(X, x_0), G) \) are canonically isomorphic.
(2) Let $\phi \in H^1(M; \mathbb{Z})$ again be a primitive element. Furthermore let $n \in \mathbb{N}$. In the following we denote by $\phi_n: \pi_1(M) \to \mathbb{Z}_n$ the epimorphism that is given by the composition $\pi_1(M) \xrightarrow{\phi} \mathbb{Z} \to \mathbb{Z}_n$.

At this stage it is worth recalling the following definitions from page 360.

**Definition.** Let $M$ be an oriented smooth manifold and let $F \subset M$ be a compact oriented proper submanifold of codimension one. We pick an orientation-preserving tubular map $\Phi: [-1, 1] \times F \to M$. We define

$$M \setminus F := (M \setminus F) \sqcup (F \times \{\pm 0\})$$

with the topology that is generated by the following sets:

1. the usual open subset of $M \setminus F$,
2. the sets of the form $\Phi(U \times (0, \epsilon)) \cup (U \times \{+0\})$ where $U$ is an open subset of $F$ and where $\epsilon \in (0, 1)$,
3. the sets of the form $\Phi(U \times (-\epsilon, 0)) \cup (U \times \{-0\})$ where $U$ is an open subset of $F$ and where $\epsilon \in (0, 1)$.

We refer to $M \setminus F$ as $M$ cut along $F$. This definition is illustrated in Figure 1388. We also introduce the following extra notation:

1. We denote by $F_\pm$ the images of $F \times \{\pm 0\}$ in $M \setminus F$. Furthermore we denote by $i_\pm: F_\pm \to M \setminus F$ the obvious inclusion maps.
2. We denote by $\sim_F$ the equivalence relation on the set $M \setminus F$ that is generated by $(P, +0) \sim (P, -0)$ for $P \in F$.
3. We denote by $\chi_F$ the map

$$\chi_F: M \setminus F \to M$$

$$P \mapsto \begin{cases} P, & \text{if } P \in M \setminus F, \\ Q, & \text{if } P = (Q, \pm 0). \end{cases}$$

**Figure 1388**

Now we can give the explicit construction of the cyclic coverings.

**Proposition 98.11.** Let $M$ be compact oriented connected smooth manifold. Furthermore let $\phi \in H^1(M; \mathbb{Z}) = \text{Hom}(\pi_1(M), \mathbb{Z})$ be a primitive element. Finally let $F \subset M$ be a
compact oriented proper codimension-one submanifold\textsuperscript{[1371]} that is dual to $\phi$ in the sense that $\text{PD}_M([F]) = \phi$. We denote by $i_{\pm}: F \to F_{\pm} \subset M \setminus F$ the two obvious inclusion maps.

(1) We write

$$\widetilde{M}_{\infty} := \left( \bigsqcup_{k \in \mathbb{Z}} (M \setminus F) \times \{k\} \right) / \sim \quad \text{where} \ (i_{-}(P), k) \sim (i_{+}(P), k + 1) \quad \text{for} \ P \in F \text{ and } k \in \mathbb{Z}.$$ 

The map

$$p: \widetilde{M}_{\infty} \to M \quad [(P, k)] \mapsto [\chi_{F}(P)]$$

is the infinite cyclic covering corresponding to $\phi$.

(2) Let $n \in \mathbb{N}$. We write

$$\widetilde{M}_{n} := \left( \bigsqcup_{k \in \mathbb{Z}_{n}} (M \setminus F) \times \{k\} \right) / \sim \quad \text{where} \ (i_{-}(P), k) \sim (i_{+}(P), k + 1) \quad \text{for} \ P \in F \text{ and } k \in \mathbb{Z}_{n}.$$ 

The map

$$p: \widetilde{M}_{n} \to M \quad [(P, k)] \mapsto [\chi_{F}(P)]$$

is the finite cyclic covering corresponding to $\phi_{n}$.

**Example.** We consider the 2-dimensional smooth manifold $M$ together with the submanifold $F$ that are shown in Figure 1389. We illustrate the explicit construction of the infinite cyclic covering $\widetilde{M}_{\infty}$. The reader will not fail to spot the uncanny similarities with Lemma 25.12 and Figure 184.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1389.png}
\caption{Illustration of Proposition 98.11}
\end{figure}

**Proof.**

(1) We pick a tubular map $\Phi: [-1, 1] \times F \to M$ for $F$. It follows almost immediately from the definitions that the open sets $M \setminus F$ and $\Phi((-1, 1) \times F)$ are uniformly covered in the sense of the definition on page 493. Since these two open subsets cover all of $M$ we see that $p: \widetilde{M}_{\infty} \to M$ is indeed a covering.

\textsuperscript{[1371]}Note that we do not assume that $F$ is connected.
In the following we will show that \( p : \widetilde{M}_\infty \to M \) is indeed the covering corresponding to \( \ker(\phi) \). We consider the following map:

\[
\alpha : M \to S^1
\]

\[
P \mapsto \begin{cases} 
   e^{\pi i t}, & \text{if } P = \Phi(t, Q) \text{ with } t \in [-1, 1] \text{ and } Q \in F, \\
   -1, & \text{otherwise}
\end{cases}
\]

This is of course the Thom-Pontryagin map corresponding to the tubular map that we introduced on page 2369. Let \( q : \mathbb{R} \to S^1 \) be the universal covering that is given by \( t \mapsto e^{\pi i t} \). Furthermore let

\[
r : \alpha^* \mathbb{R} = \{(P, t) \in M \times \mathbb{R} | \alpha(P) = p(t)\} \to M
\]

be the pullback of the covering \( q \). Note that by Lemma 25.16 (3) we know that \( r : \alpha^* \mathbb{R} \to M \) is also a covering.

**Claim.** The covering \( p : \widetilde{M}_\infty \to M \) is equivalent to the covering \( r : \alpha^* \mathbb{R} \to M \).

The key to proving the claim is to consider the map

\[
\beta : \widetilde{M}_\infty \to \mathbb{R}
\]

\[
[P] \mapsto \begin{cases} 
   2i - 1, & \text{if } P \in (M \setminus \Phi([-1, 1] \times F)) \times \{i\}, \\
   2i + t, & \text{if } P \in \Phi(\{t\} \times F) \times \{i\} \text{ for some } t \in [-1, 0], \\
   2i + t - 2, & \text{if } P \in \Phi(\{t\} \times F) \times \{i\} \text{ for some } t \in (0, 1], \\
   2i, & \text{if } P \in F_- \times \{i\} \text{ or } P \in F_+ \times \{i + 1\}.
\end{cases}
\]

Using Lemma 2.35 (2) one easily verify that this map is continuous. We refer to Figure 1390 for an illustration. Next we consider the map

\[
(M \setminus F) \times \{0\} \to (M \setminus F) \times \{1\}
\]

\[
\beta
\]

\[
-3 \to -2 \to -1 \to 0 \to 1 \to 2 \to p
\]

\[
t \mapsto e^{\pi i t}
\]

\[
\Theta : \widetilde{M}_\infty \to \alpha^* \mathbb{R}
\]

\[
P \mapsto (p(P), \beta(P)).
\]

It is straightforward to see that \( \Theta \) is a bijection. We leave it to the reader to show that \( \Theta \) is actually a homeomorphism. One can easily verify that \( \Theta \circ r = p \). In summary we conclude that the two coverings \( q \) and \( r \) are indeed equivalent. \( \square \)

---

An alternative proof of this statement is given in [Herr19, Lemma 1.31].
Now we see that
\[ q_*(\pi_1(\tilde{M}_\infty)) = r_*(\pi_1(\alpha^*\mathbb{R})) = \alpha_*^{-1}(\pi_1(\mathbb{R})) = \ker(\alpha_*) = \ker(\phi). \]

since \( q \) and \( r \) are equivalent coverings

We have thus shown that \( q_* : \tilde{M}_\infty \to M \) is indeed the covering corresponding to \( \ker(\phi) \).

(2) The proof of this statement is very similar to the proof of (1). We just need to replace the covering \( q : \mathbb{R} \to S^1 \) by the covering \( q : S^1 \to S^1 \) given by \( z \mapsto z^n \). We leave it to the reader to once again lessen the burden on the author by filling in the details. ■

98.5. Curves on 2-dimensional smooth manifolds (*). We conclude this chapter with a discussion of curves on 2-dimensional smooth manifolds. The results of this section are nice-to-have, but they will not be used in the remainder of these notes. Thus it is safe to skip this section in the unlikely event that the reader is in a hurry.

Let us now recall the following definition from page 544: A closed oriented curve \( C \) in a smooth manifold \( M \) is a closed oriented connected 1-dimensional submanifold of \( M \) or of \( \partial M \). In this section we want to study curves on 2-dimensional smooth manifolds. Our main focus will be curves on the torus.

Before we state the results we recall that on page 1223 we saw that a closed oriented curve \( C \) in a smooth manifold \( M \) defines a homology class \([C] \in H_1(M; \mathbb{Z})\). We start out with the following lemma.

**Lemma 98.12.** Let \( T = S^1 \times S^1 \) be the torus and let \( C \) be a closed oriented curve on \( T \).

1. If \( T \setminus C \) is connected, then \([C] \) is a primitive element of \( H_1(T; \mathbb{Z}) \).
2. If \( T \setminus C \) is disconnected, then \( C \) is the boundary of an embedded disk.

![Figure 1391. Illustration of Lemma 98.12](image)

**Proof.** If \( T \setminus C \) is connected, then it follows from Proposition 98.2 that \([C] \) is a primitive element of \( H_1(T; \mathbb{Z}) \). Now suppose that \( T \setminus C \) is disconnected. By the Tubular Neighborhood Theorem 8.24 there exists a tubular neighborhood \([-1, 1] \times C \). From Lemma 10.1 and Proposition 10.11 we obtain that \( T \setminus (-1, 1) \times C \) is also disconnected. Since \( C \) is connected this implies that \( T \setminus (-1, 1) \times C \) has two components \( A \) and \( B \), one of which contains \([-1] \times C \) and one which contains \([1] \times C \). By Proposition 6.30 we know that \( A \) and \( B \) are compact 2-dimensional smooth manifolds, in particular they are finite CW-complexes.

---

1373 Why is that?
We have
\[
\chi(A) + \chi(B) = \chi(T) + \chi((-1) \times C) + \chi(1 \times C) = 0.
\]

Since \( A \) and \( B \) have boundary it follows from the classification of compact 2-dimensional smooth manifolds and the calculation of Euler characteristics, see Lemma 55.5, that one of \( A \) or \( B \) is diffeomorphic to the disk \( D^2 \).

Lemma 98.13. Let \( T = S^1 \times S^1 \) be the torus. Let \( C \) and \( D \) be two closed oriented curves on \( T \). If \( C \) and \( D \) are disjoint and if \( [C] \) and \( [D] \) are both non-zero in \( H_1(T; \mathbb{Z}) \), then \( [C] = \pm [D] \).

Proof. From Theorem 94.5 together with our hypothesis that \( C \cap D = \emptyset \) we obtain that
\[
\text{PD}_T([C]) \cup \text{PD}_T([D]) = 0.
\]
It follows easily from the calculation of the cup product of the torus, see Lemma 81.14, that \( \text{PD}_T([C]) = k \cdot \text{PD}_T([D]) \) for some \( k \in \mathbb{Z} \). We obtain from Lemma 98.12 that \( k \in \{-1, 1\} \).

Lemma 98.14. Let \( T = S^1 \times S^1 \) be the torus. Let \( C \) and \( D \) be two closed oriented curves on \( T \). Suppose that \( [C] = [D] \neq 0 \), then the following hold:

1. The two closed oriented curves are smoothly isotopic.
2. If \( C \) and \( D \) are furthermore disjoint, then there exists an embedded annulus \( X \subset T \) with \( \partial X = C \cup -D \).

Furthermore, the same statements also hold if we replace the torus \( T = S^1 \times S^1 \) by the annulus \( S^1 \times [-1, 1] \).

Sketch of proof. We provide a sketch of a proof for the various statements:

1. By the Transversality Theorem 91.10 (2) we can assume that \( C \) and \( D \) are already transverse. It follows from the calculation of the cup product of the torus and Theorem 94.5 that the algebraic intersection number is 0. The argument is now similar to the argument of the proof of Theorem 94.16, but this time we use Lemma 98.12 to find the desired embedded disks. We refer to Figure 1393 for an illustration.

It is a good, and not entirely trivial, mental exercise to fill in the details. The argument is sketched in more detail in [Rol90] Lemma 5 of Chapter 2.C.

2. The proof of this statement is similar to the proof of Lemma 98.12 (2). We leave it to the reader to fill in the details.

The proof in the case that \( T = S^1 \times [-1, 1] \) is easier. We will discuss it in Exercise 99.1.■
For completeness sake’ we state the following proposition, even though we will not make use of it.

**Proposition 98.15.** (*) Let $F$ be a 2-dimensional smooth manifold and let $C$ and $D$ be two closed oriented curves on $F$.

1. If $C$ and $D$ are homotopic, then $C$ and $D$ are smoothly isotopic.
2. If $C$ and $D$ are furthermore disjoint and if they are not null-homotopic, then there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$.

**Proof.**

1. This statement is [FaM11, Proposition 1.10]. (Closely related statements are also proved in [Baer28, Eps66, Theorem 2.1].) Unfortunately all the references are somewhat cavalier when it comes to distinguishing continuous and smooth maps, but with some effort one can see that all the references provide smooth isotopies.

2. If $F$ is orientable, then we will provide the proof in Exercise 98.7. The proof of the non-orientable case is not much harder. ■

**Exercises for Chapter 98**

**Exercise 98.1.** Let $M$ be a non-compact oriented $n$-dimensional smooth manifold with compact boundary. Furthermore let $N$ be a compact orientable non-empty proper submanifold of codimension-one such that $M \setminus N$ is connected. Show that $[N] \in H_{n-1}(M; \mathbb{Z})$ is an element of infinite order.

*Hint.* Use Propositions 11.4 and 98.2.

**Exercise 98.2.** Let $g \in \mathbb{N}$ and let $\Sigma_g$ be the surface of genus $g$. By Proposition 22.3 we know that there exists an isomorphism

\[ \pi_1(\Sigma_g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle. \]

Use this isomorphism to give a purely algebraic proof that $\pi_1(\Sigma_g)$ admits an epimorphism onto a free group on $g$ generators.

**Exercise 98.3.** Here is one possible approach to answering Question 98.9 (1). Let $g \in \mathbb{N}$ and let $\Sigma_g$ be the surface of genus $g$. Let $F_1, \ldots, F_k$ be disjoint curves on $\Sigma_g$ such that $\Sigma_g \setminus (F_1 \cup \cdots \cup F_k)$ is connected. By the Tubular Neighborhood Theorem 8.24 we can pick a tubular neighborhood $\bigcup_{i=1}^{k} [-1, 1] \times F_i$ for the submanifold $F_1 \cup \cdots \cup F_k \subset \Sigma_g$. We consider

---

1374 Is this condition that $[C]$ and $[D]$ are both non-zero necessary?
the compact orientable 2-dimensional smooth manifold $X := \Sigma g \setminus \bigcup_{i=1}^{k} (-1,1) \times F_i$. What can you say about the Euler characteristic of $X$? What does the classification of compact orientable 2-dimensional smooth manifolds tell you?

**Exercise 98.4.** Let $\Sigma$ be a compact orientable connected 2-dimensional smooth manifold and let $A, B \subset \Sigma$ be two disjoint non-separating curves.

(a) Show that there exists a closed 1-dimensional smooth manifold $C \subset \Sigma$ that intersects each of $A$ and $B$ transversally in a single point.

*Remark.* Exercise 48.7 might come in handy.

(b) Can one also arrange that $C$ is connected?

![Figure 1394. Illustration for Exercise 98.4](image)

**Exercise 98.5.** Let $M$ be a compact oriented connected smooth manifold and let $F$ be a compact oriented proper submanifold. We use the notation from page 2375. In particular we denote by $i_{\pm}: F \to M \setminus F$ the two inclusion maps and we denote by $\chi_F: M \setminus F \to M$ the obvious projection map. Show that there exists a long exact sequence of the form

$$
\ldots \to H_i(F) \xrightarrow{i_i} H_i(M \setminus F) \xrightarrow{\chi_F} H_i(M) \xrightarrow{\partial} H_{i-1}(F) \to \ldots
$$

**Exercise 98.6.** Let $(X, x_0)$ be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let $\phi: \pi_1(X, x_0) \to \langle t \rangle$ be an epimorphism. We denote by $p: \tilde{X}_\infty \to X$ the covering corresponding to $\ker(\phi)$. By Proposition 34.6 we have an explicit identification of the group $\langle t \rangle$ with the deck transformation group of $p: \tilde{X}_\infty \to X$. Given $\sigma \in C_n(\tilde{X}_\infty)$ and given $k \in \mathbb{Z}$ we write $t^k \cdot \sigma := (t^k)_* (\sigma)$.

(a) Let $n \in \mathbb{N}_0$ and let $\sigma, \mu \in C_n(\tilde{X}_\infty)$. Show that $p_* (\sigma) = p_* (\mu) \in C_n(X)$ if and only if there exists a $k \in \mathbb{Z}$ with $\sigma = t^k \cdot \mu$.

(b) Let $n \in \mathbb{N}_0$. Show that the following sequence is exact:

$$
0 \to C_n(\tilde{X}_\infty) \xrightarrow{\cdot \text{id}} C_n(\tilde{X}_\infty) \xrightarrow{p_*} C_n(X) \to 0.
$$

*Remark.* By Proposition 43.11 we obtain a corresponding long exact sequence

$$
\ldots \to H_{n+1}(X) \xrightarrow{\partial} H_n(\tilde{X}_\infty) \xrightarrow{\cdot \text{id}} H_n(\tilde{X}_\infty) \xrightarrow{p_*} H_n(X) \xrightarrow{\partial} H_{n-1}(\tilde{X}_\infty) \to \ldots
$$

(c) As a reality check, what does the long exact sequence in (b) look like for the covering $p: \mathbb{R} \to S^1$?

(d) Let $r \in \mathbb{N}$. We denote by $\tilde{X}_r$ the covering of $X$ corresponding to the epimorphism $\ker(\phi: \pi_1(X, x_0) \to \langle t \rangle = \mathbb{Z} \to \mathbb{Z}_r)$. Show that there exists an exact sequence relating the homology groups of $\tilde{X}_\infty$ and $\tilde{X}_r$. 

Exercise 98.7. Let $F$ be an oriented 2-dimensional smooth manifold and let $C$ and $D$ be two closed oriented disjoint curves on $F$ that are not null-homotopic. Assume that $C$ and $D$ are homotopic. Show that there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$. Hint. Use Exercise 99.2. You might also want to use some of the ideas of the proof of Lemma 98.12.

Exercise 98.8. Let $T = S^1 \times S^1$ be the torus and let $C$ and $D$ be two closed oriented 1-dimensional submanifolds of $T$ with $|C| = |D| \in H_1(T; \mathbb{Z})$. Use the results from Section 98.5 to give a down-to-earth proof of the statement that there exists a compact oriented proper 2-dimensional submanifold $\Omega$ of $T \times [0, 1]$ such that

$$\partial \Omega = (\{0\} \times ) \cup (\{1\} \times -D).$$

Remark. Evidently this is just a special case of Corollary 98.7. But it is fun to give a bare-hands proof in this special case.

Exercise 98.9. Let $\Sigma$ be the surface of some genus $g \in \mathbb{N}_0$ and let $f: \Sigma \to \Sigma$ be some orientation-preserving self-diffeomorphism. We consider the corresponding mapping torus

$$\text{Tor}(\Sigma, f) := (\Sigma \times [0, 1]) / \sim \quad \text{where} \quad (x, 0) \sim (f(x), 1) \quad \text{for all} \quad x \in \Sigma.$$

Let $F$ be a surface of some genus $k$. Suppose that there exists a map $\varphi: F \to \text{Tor}(\Sigma, f)$ such that $\varphi_*([F]) = \{0\} \times \Sigma \in H_2(\text{Tor}(\Sigma, f))$. Show that $k \geq g$.

Hint. Make clever use of Proposition 98.11 and Exercise 70.3.

Exercise 98.10. Let $M$ be a closed oriented $n$-dimensional smooth manifold. Furthermore let $\phi \in H_{n-1}(M; \mathbb{Z})$, let $k \in \mathbb{N}$ and let $F$ be a closed oriented $(n-1)$-dimensional submanifold that represents $k \cdot \phi$. Show that we can decompose $F = F_1 \sqcup \cdots \sqcup F_k$ where each $F_i$ represents $\phi$.

Hint. Consider the Thom-Pontryagin map $\rho = \rho_F: M \to S^1$ that we introduced on page 2369. Note that $\rho^{-1}(\{1\}) = F$. Let $p: S^1 \to S^1$ be the covering map given by $z \mapsto z^k$. Show that there exists a map $\tilde{\rho}: M \to S^1$ such that $\rho = p \circ \tilde{\rho}$.

Exercise 98.11. Given a closed oriented 2-dimensional smooth manifold $S$ with components $S_1, \ldots, S_m$ we define

$$\chi(S) := \sum_{i=1}^m \max\{-\chi(S_i), 0\}.$$

Let $M$ be a closed oriented 3-dimensional smooth manifold. We consider the map

$$x_M: H_2(M; \mathbb{Z}) \to \mathbb{N}_0 \quad \sigma \mapsto \min \left\{ \chi(-S) \mid S \text{ is a closed oriented 2-dimensional submanifold of } M \text{ with } [S] = \sigma \right\}.$$

Show that the map $x_M$ is a seminorm, i.e. show that it has the following two properties:

(a) Given any $\sigma \in H_2(M; \mathbb{Z})$ and $k \in \mathbb{Z}$ we have $x_M(k \cdot \sigma) = |k| \cdot x_M(\sigma)$.

Hint. Use Exercise 98.10.

(b) Given $\mu, \nu \in H_2(M; \mathbb{Z})$ we have $x_M(\mu + \nu) \leq x_M(\mu) + x_M(\nu)$.

Hint. Use the Transversality Theorem 9.10 and Proposition 70.21.
(c) Show that there exists a unique seminorm $x_M : H_2(M; \mathbb{R}) \to \mathbb{R}_{\geq 0}$ such that the map $H_2(M; \mathbb{Z}) \xrightarrow{[\sigma] \mapsto [\sigma \otimes 1_\mathbb{R}]} H_2(M; \mathbb{R}) \to \mathbb{R}_{\geq 0}$ agrees with the above map $x_M$.

**Remark.** This seminorm $x_M : H_2(M; \mathbb{Z}) \to \mathbb{R}_{\geq 0}$ is usually called the *Thurston norm* of $M$. It was introduced by William Thurston [Thu86] in 1976 and, as is shown in [Thu86] and [Gab83], it has many remarkable properties.

**Exercise 98.12.** We continue with the definitions introduced in Exercise 98.11. Let $\Sigma$ be a closed connected 2-dimensional smooth manifold with $\chi(\Sigma) \leq 0$.

1. Let $f : \Sigma \to \Sigma$ be a diffeomorphism. We consider the mapping torus $\text{Tor}(\Sigma, f)$. Show that $x(\Sigma) = \chi(\Sigma)$.
   
   **Hint.** Let $F$ be any closed oriented 2-dimensional submanifold of $\text{Tor}(\Sigma, f)$ with $[F] = [\Sigma]$. Using Proposition 98.11 we obtain a map $F \to \Sigma \times \mathbb{R} \to \Sigma$ and use Exercise 69.4.

2. We can consider the Thurston norm of $N \times S^1$.
   
   (a) Show that $x_{\Sigma \times S^1}([\Sigma \times \{\ast\}]) = \chi(\Sigma)$.
   
   (b) Show that for any $\sigma \in H_1(\Sigma)$ we have $x_{\Sigma \times S^1}([S^1] \times \sigma) = 0$.
   
   (c) Show that for any $\phi \in H_2(\Sigma \times S^1; \mathbb{R})$ we have
   
   $$x_{\Sigma \times S^1}(\phi) = \inf_{\phi \in H_2(\Sigma \times S^1; \mathbb{R})} \left\langle \text{PD}_{\Sigma \times S^1}([\{\ast\} \times S^1]), \phi \right\rangle.$$  
   
   **Hint.** Either use Proposition 79.12 and (1). Alternatively use (2a) and (2b) together with Exercise 98.11 (b).

**Exercise 98.13.** Let $M$ be a closed oriented $n$-dimensional smooth manifold. Given $\phi \in H^1(M; \mathbb{Z})$ we define

$$x_M(\sigma) = \inf \{ \|N\|_{\mathbb{R}} \mid N \text{ is a closed oriented submanifold of } M \text{ with } \text{PD}_M([N]) = \phi \}.$$  

**simplicial volume as defined in Exercise 68.16**

Let $N$ be a closed oriented connected $(n-1)$-dimensional smooth manifold. Given any cohomology class $\phi \in H^1(N \times S^1)$ determine $x_{N \times S^1}(\phi)$ in terms of $\|N\|_{\mathbb{R}}$ and $\phi(\{\ast\} \times S^1)$.

**Hint.** Use Proposition 79.12 and (a).
99. Applications to knot theory

After so much theory we want to practice what we have learned by applying our recent results to knot theory.

99.1. The longitude of a knot. We start out our discussion of knots with the following definition.

**Definition.** Let \( K \subset S^3 \) be an oriented knot.

1. A thickening of \( K \) is an orientation-preserving smooth embedding \( F: \overline{B}^2 \times K \to S^3 \) such that \( F(0, P) = P \) for all \( P \in K \).
2. Given a thickening \( F \) of \( K \) we refer to \( X_K := S^3 \setminus F(\overline{B}^2 \times K) \) as the knot exterior.
3. Given a thickening \( F \) of \( K \) and given \( \ast \in K \) we refer to the oriented submanifold \( \mu_K := F(S^1 \times \{\ast\}) \) of \( S^3 \setminus K \) as the meridian of \( K \).
4. By Lemma 68.16 (5) the inclusion induced map \( H_1(X_K; \mathbb{Z}) \iso H_1(S^3 \setminus K; \mathbb{Z}) \) is an isomorphism and we have \( H_1(X_K; \mathbb{Z}) = \mathbb{Z} \cdot [\mu_K] \). We denote by \( \phi_K \) the isomorphism \( \phi_K: H_1(S^3 \setminus K; \mathbb{Z}) \iso H_1(X_K; \mathbb{Z}) \iso \mathbb{Z} \cdot [\mu_K] \to 1 \).
5. Suppose we are given a thickening \( F \) for \( K \). We define

\[
\text{self-linking number of } F := \phi_K(F_*([1] \times K)).
\]

**Remark.** It follows from the uniqueness of tubular neighborhoods, see Proposition 8.26, that the exterior \( X_K \) and the meridian \( \mu_K \) are, in an appropriate sense, independent of the choice of the thickening. Therefore often we just say “the exterior” and “the meridian”.

**Lemma 99.1.** Let \( K \) be an oriented knot in \( S^3 \).

1. Let \( F: \overline{B}^2 \times K \to S^3 \) be a thickening of \( K \) and let \( s \in \mathbb{Z} \). Let \( \gamma: S^1 \to K \) be an orientation-preserving diffeomorphism. Similar to Lemma 10.4 we consider the diffeomorphism

\[
\Psi: \overline{B}^2 \times K \to \overline{B}^2 \times K
\]

\[
(w, \gamma(z)) \mapsto (w \cdot \gamma(z^s), \gamma(z)).
\]

\[
\uparrow
\]

where \( z \in S^1 \)

The map \( F \circ \Psi \) is a thickening with

\[
\text{self-linking number of } F \circ \Psi = \text{self-linking number of } F + s.
\]

2. Given any \( n \in \mathbb{Z} \) there exists a thickening of \( K \) with self-linking number \( n \).

3. If \( F, F': \overline{B}^2 \times K \to S^3 \) are two thickenings of \( K \) with self-linking number \( n \), then there exists a diffeotopy \( H: S^3 \times [0, 1] \to S^3 \) rel \( K \) with \( H_0 = \text{id} \) and \( H_1 \circ F = F' \).

Given \( K \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\} \) the analogous statements hold if we consider thickenings that are contained in \( \mathbb{R}^3 \). Furthermore, in this setting the diffeotopy in (3) of \( \mathbb{R}^3 \) can be assumed to have compact support.
Remark. Given an oriented knot $K$ and $n \in \mathbb{Z}$, sometimes we use the uniqueness statement of Lemma 99.1 to talk about the thickening of $K$ with self-linking number $n$. Sometimes we shorten this cumbersome expression to the $n$-thickening of $K$.

Proof.

(1) We denote by $m$ the self-linking number of $F$. We write $\lambda := F(\{1\} \times K)$ and $\mu := F(S^1 \times \{1\})$ and we view $\lambda$ and $\mu$ as oriented 1-dimensional submanifolds with the orientations given by $K$ and $S^1$. We calculate that

$$\text{self-linking number of } F \circ \Psi = \phi_K(F_*(\Psi_*([\{1\} \times K]))) = \phi_K(s \cdot [\mu] + [\lambda]) = s + m.$$

follows from Lemma 52.7 (2) since $\phi_K(\mu) = 1$ and by definition of $m$.

(2) From the Tubular Neighborhood Theorem 8.24 we know that there exists a thickening $F : B^2 \times K \to S^3$. We denote by $m$ the self-linking number of $F$. The desired statement now follows from (1) applied to $n - m$.

(3) The uniqueness statement is an immediate consequence of (1) together with Proposition 10.7 and Lemma 10.4 (3).

The same arguments as above also apply if we replace $S^3$ by $\mathbb{R}^3$.

Definition. Let $K \subset S^3$ be an oriented knot. We pick a thickening $F : B^2 \times K \to S^3$ of self-linking number zero. We refer to $\lambda_K = F(\{1\} \times K)$ as a longitude of $K$.

Examples.

(1) In Figure 1395 we show the longitude and the meridian for the trivial knot and the figure-8 knot.

![Figure 1395](image)

(2) In Figure 1396 we show the trefoil knot with three wannabe longitudes. It is not entirely clear which one is the right longitude. We will soon develop a tool with which it will be straightforward to settle this issue.

On several occasions the following lemma comes in handy.

Lemma 99.2. Let $K$ be an oriented knot and let $F : \overline{B}^2 \times K \to S^3$ be a thickening with self-linking number zero. We denote by $X_K = S^3 \setminus F(B^2 \times K)$ the corresponding knot.

---

It follows from Lemma 99.1 (3) that the longitude is in an appropriate way uniquely determined.
exterior. Furthermore we denote as usual by $\mu_K = F(S^1 \times \{\ast\})$ and $\lambda_K = F(\{1\} \times K)$ the corresponding meridian and longitude.

1. The classes $[\mu_K]$ and $[\lambda_K]$ form a basis for $H_1(\partial X_K; \mathbb{Z})$.
2. There exists a short exact sequence of the following form

$$
0 \rightarrow H_2(X_K, \partial X_K; \mathbb{Z}) \rightarrow \mathbb{Z} \cdot [\mu_K] \rightarrow H_1(\partial X_K; \mathbb{Z}) \rightarrow H_1(X_K; \mathbb{Z}) \rightarrow 0
$$

3. The longitude $\lambda_K$ is the unique, up to smooth isotopy, closed oriented curve on the torus $F(S^1 \times K)$ that is homologous to $K = \{0\} \times K$ in $F(B^2 \times K)$ and that is null-homologous in $X_K$.
4. If we view $\mu_K$ and $\lambda_K$ as closed oriented curves on the oriented torus $F(S^1 \times K)$, then the algebraic intersection number equals $\mu_K \cdot \lambda_K = +1$.
5. If denote by $i: \mu_K \rightarrow \partial X_K$ the inclusion map, then $i^*([\mu_K]) \cap [\partial X_K] = -[\lambda_K] \in H_1(\partial X_K; \mathbb{Z})$.
6. Recall that given an oriented curve $C$ we denote by $-C$ the curve with the opposite orientation. With this notation we have $\mu_{-K} = -\mu_K$ and $\lambda_{-K} = -\lambda_K$.

**Proof.**

1. This statement follows from Lemma [16.12](2).
2. We consider the long exact sequence of homology groups of the pair $(X_K, \partial X_K)$:

$$
H_2(X_K; \mathbb{Z}) \rightarrow H_2(X_K, \partial X_K; \mathbb{Z}) \rightarrow H_1(\partial X_K; \mathbb{Z}) \rightarrow H_1(X_K; \mathbb{Z}) \rightarrow 0
$$

By definition we have $\phi([\lambda_K]) = 0$. Furthermore we know from Lemma [68.16](4) that the right-hand map is an epimorphism. The statement follows immediately from these observations.
3. It follows from (1) that the kernel of $H_1(\partial X_K; \mathbb{Z}) \rightarrow H_1(X_K; \mathbb{Z})$ equals $\mathbb{Z} \cdot [\lambda_K]$. Since $H_1(F(B^2 \times K); \mathbb{Z}) = \mathbb{Z} \cdot [K] = \mathbb{Z} \cdot [\lambda_K]$ we see that there exists a unique homology class that has the properties we are interested in. The desired statement now follows from Lemma [98.14](1).
(4) This statement follows from the definitions and the easy observation that the oriented submanifolds \( S^1 \times \{1\} \) and \( \{1\} \times S^1 \) of the oriented smooth manifold \( S^1 \times S^1 \) have algebraic intersection number one.

(5) We calculate that
\[
i^*(\mu_K) \cap [\partial X_K] = i^*(\mu_K) \cap F_*(\{-[S^1 \times K]\}) = F_*(\{S^1 \times \{\}\}^* \cap (-[S^1 \times K]))
\]
since \( F_*(\{S^1 \times S^1\}) = [\partial F(\mathbb{B}^2 \times K)] = -[\partial X_K] \) \( \uparrow \) Lemma \( \Box 3.8 \)
\[
= -F_*(\{1\} \times K) \quad \uparrow \quad \text{by definition of } \lambda_K.
\]
\[
\uparrow \quad \text{see page 2022}
\]

(6) This statement follows easily from the definitions. We leave it to the reader to provide the details.

99.2. Detecting non-invertible and chiral knots. Now that we have the notion of the self-linking number of thickening a knot we can also outline how to answer several questions on symmetries of knots we had asked a long time ago.

We start out with the following definition.

**Definition.** Let \( K \) be an oriented knot.

1. The **mirror** \( K^{\text{mir}} \) is defined as the reflection of \( K \) in any hyperplane of \( \mathbb{R}^4 \).
   
   We give the mirror \( K^{\text{mir}} \) the orientation that turns the reflection into an orientation-preserving diffeomorphism \( K \to K^{\text{mir}} \).

2. The **reverse** \( K^{\text{rev}} \) is defined as the knot \( K \) with the reverse orientation.

3. The **inverse** \( K^{\text{inv}} \) is defined as the mirror of the reverse of \( K \).

**Remark.** The names “reverse” and “inverse” at times also get used with different meanings. We follow [Con70, p. 336] for our naming convention.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{knots.png}
\caption{Figure 1397}
\end{figure}

Now the question arises whether an oriented knot is smoothly isotopic to any of its doppelganger. This leads us to the following definition.

**Definition.** Let \( K \) be an oriented knot.

1. We say that \( K \) is **amphichiral** if it is smoothly isotopic to its mirror image. Otherwise we call the knot \( K \) **chiral**.

\footnote{Note that it follows from Exercise 27.1 that, up to a smooth isotopy, the definition of \( K^{\text{mir}} \) does not depend on the choice of the hyperplane.}

\footnote{Note that on page 1807 we introduced the mirror of an unoriented knot. For the purpose of this section it is better to work with oriented knots.}
We say $K$ is reversible if it is smoothly isotopic to its reverse.

We say $K$ is invertible if it is smoothly isotopic to its inverse.

**Example.** As we saw in Figure 225, it is basically clear that the trivial knot is amphichiral and reversible. Furthermore, in Figure 504 we showed that the figure-8 knot $J$ is amphichiral. Also note that in Exercise 8.29 we showed that the trefoil and the figure-8 knot are reversible.

This lead us to the following two questions.

**Question 8.41.** Is every knot reversible?

**Question 27.9.** Is the trefoil chiral?

Before we show how to answer both questions let us introduce the following simple-minded definition.

**Definition.**

1. A group system is a system $(G, g_1, g_2)$ consisting of a group $G$ together with two elements $g_1, g_2 \in G$.
2. An isomorphism between group systems $(G, g_1, g_2)$ and $(H, h_1, h_2)$ is a group isomorphism $\varphi : G \to H$ with $\varphi(g_1) = h_1$ and $\varphi(g_2) = h_2$.

The following proposition explains why we care about group systems.

**Proposition 99.3.**

1. Let $K \subset S^3$ be an oriented knot. We pick a thickening $F : \mathbb{B}^2 \times K \to S^3$ of $K$ with self-linking number zero. Furthermore we pick an orientation-preserving diffeomorphism $\gamma : S^1 \to K$. We write

   \[
   x_{K,F} := F(1, \gamma(1)), \quad \mu_{K,F} : S^1 \to S^3 \setminus K \quad \text{with} \quad z \mapsto F(z, \gamma(1)), \quad \lambda_{K,F,\gamma} : S^1 \to S^3 \setminus K \quad \text{with} \quad z \mapsto F(1, \gamma(z)).
   \]

   The isomorphism type of the group system

   \[
   (\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])
   \]

   depends only on the choice of the oriented knot $K$. Any group system that is isomorphic to the above group system is called a group system for $K$.

2. Let $K$ and $J$ be two oriented knots. If $K$ and $J$ are smoothly isotopic, then the corresponding group systems are isomorphic.

3. Given an oriented knot $K$ with a group system $(\pi_K, \mu_K, \lambda_K)$ the following hold:
   
   a. a group system for the mirror $K^{\text{mir}}$ is given by $(\pi_K, \mu_K^{-1}, \lambda_K)$
   
   b. a group system for the reverse $K^{\text{rev}}$ is given by $(\pi_K, \mu_K^{1}, \lambda_K^{-1})$
   
   c. a group system for the inverse $K^{\text{inv}}$ is given by $(\pi_K, \mu_K, \lambda_K^{-1})$.

**Remark.** Friedhelm Waldhausen [Wald68b, Corollary 6.5] (see also [BZH14, Theorem 3.16]) showed in 1968 that the converse to Proposition 99.3 (2) holds. Thus we are certainly on the right track.

---

1378 On page 781 we introduced these notions of unoriented knots.

1379 We know by Lemma 99.1 (2) that such a thickening always exists.
Proof.

(1) This statement follows easily from Lemma 99.1 (3).
(2) This statement follows equally easily from the Isotopy Extension Theorem 8.27.
(3) Let \( F : \mathbb{B}^2 \times K \to S^3 \) be a thickening of \( K \) with self-linking number zero and let \( \gamma : S^1 \to K \) be an orientation-preserving diffeomorphism. Throughout the proof of (3) we work with the group system \((\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])\) for \( K \).

In the following we denote by \( \rho \) the reflection in a hyperplane of \( \mathbb{R}^4 \) and we set \( K^{\text{mir}} = \rho(K) \). Finally we denote by \( \varphi : S^1 \to S^1 \) and \( \psi : \mathbb{B}^2 \to \mathbb{B}^2 \) the maps given by complex conjugation.

(a) First note that the map \( F^{\text{mir}} : \mathbb{B}^2 \times K^{\text{mir}} \to S^3 \)

\[
(x, y) \mapsto \rho(F(\psi(x), \rho(y)))
\]

is a thickening of \( K^{\text{mir}} \) with self-linking number zero. Furthermore note that \( \gamma^{\text{mir}} := \rho \circ \gamma : S^1 \to K^{\text{mir}} \) is orientation-preserving. Thus we see that \( \rho_* \) induces an isomorphism between the group system \((\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])\) and the group system \((\pi_1(S^3 \setminus K^{\text{mir}}, x_{K^{\text{mir}}, F^{\text{mir}}}, [\mu_{K^{\text{mir}}, F^{\text{mir}}}], [\lambda_{K^{\text{mir}}, F^{\text{mir}}, \gamma^{\text{mir}}}])\).

(b) First note that the map \( F^{\text{rev}} : \mathbb{B}^2 \times K^{\text{rev}} \to S^3 \)

\[
(x, y) \mapsto F(\psi(x), y)
\]

is a thickening of \( K^{\text{rev}} \) with self-linking number zero. Furthermore note that \( \gamma^{\text{rev}} := \gamma \circ \varphi : S^1 \to K^{\text{rev}} \) is orientation-preserving. Finally note that the group system \((\pi_1(S^3 \setminus K^{\text{rev}}, x_{K^{\text{rev}}, F^{\text{rev}}}, [\mu_{K^{\text{rev}}, F^{\text{rev}}}], [\lambda_{K^{\text{rev}}, F^{\text{rev}}, \gamma^{\text{rev}}}])\) equals the group system \((\pi_1(S^3 \setminus K, x_{K,F}), [\mu_{K,F}], [\lambda_{K,F,\gamma}])\).

(c) This statement follows immediately from (a) and (b). \( \blacksquare \)

On page 800 we saw that looking at finite quotients of groups can be a convenient tool for distinguishing groups. We now apply the same idea to group systems. There are various ways of making this idea precise. We will work with the following approach.

**Definition.** Let \( G \) be a finite group and let \( x \in G \).

(1) Given a group system \((\pi, g_1, g_2)\) where \( \pi \) is a finitely generated group we define

\[
P_G^\pi(\pi, g_1, g_2) := \sum_{\varphi \in \text{Hom}(\pi, G) \mid \varphi(g_1) = x} \varphi(g_2) \in \mathbb{Z}[G].
\]

It is clear that isomorphic group systems give the same element in \( \mathbb{Z}[G] \).

(2) Let \( K \) be a knot. Following [Eis07, Definition 1.2] we refer to

\[
P_G^\pi(K) := P_G^\pi(\text{group system of } K) \in \mathbb{Z}[G],
\]

as the \((G, x)\)-coloring polynomial of \( K \).

\[\text{In particular note that the "extra } \psi \text{" ensures this map } F^{\text{mir}} \text{ is indeed orientation-preserving.}\]
The art now is to find, given a knot, a finite group \( G \) and element \( x \in G \) such that the \((G,x)\)-coloring polynomial has content.

**Example.** We consider the Kinoshita-Terasaka knot and the Conway knot that are shown in Figure 1398. This pair of knots is notoriously hard to distinguish. Now let \( G \) be the Mathieu group \( M_{11} \), this is the unique simple group of order \( 7920 = 2^4 \cdot 3^2 \cdot 5 \cdot 11 \) and the smallest of the sporadic simple groups, see [CCNPW85] for details. As is explained in [Eis07, p. 315], one way of describing \( G = M_{11} \) is to note that it is the subgroup of the alternating group \( A_{11} \) that is generated by

\[
x = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 1 
\end{pmatrix} \quad \text{and} \quad y = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
2 & 3 & 5 & 7 & 10 & 1 & 8 & 6 & 11 & 9 & 4 
\end{pmatrix}.
\]

Note that \( x \) has order 11 in \( A_{11} \) and thus also in \( G = M_{11} \). By [Eis07, p. 317] we have the following table:

\[
\begin{align*}
P^x_G(K) &= 1 + 11x^3 + 11x^7, \\
P^x_G(K_{\text{mir}}) &= 1 + 11x^4 + 11x^8, \\
P^x_G(K_{\text{rev}}) &= 1 + 11x^4 + 22x^8, \\
P^x_G(K_{\text{inv}}) &= 1 + 22x^3 + 11x^7,
\end{align*}
\quad \begin{align*}
P^x_G(C) &= 1 + 11x^3 + 11x^7, \\
P^x_G(C_{\text{mir}}) &= 1 + 11x^4 + 11x^8, \\
P^x_G(C_{\text{rev}}) &= 1 + 11x^4 + 11x^6 + 11x^8, \\
P^x_G(C_{\text{inv}}) &= 1 + 11x^3 + 11x^5 + 11x^7.
\end{align*}
\]

Since \( x \) has order 11 in \( G \) we see that all these elements of \( \mathbb{Z}[G] \) are different. This shows that these eight oriented knots are pairwise non-smoothly isotopic. In particular this shows that the Kinoshita-Terasaka knot and the Conway knot are neither amphichiral, nor reversible nor invertible.

![Kinoshita-Terasaka knot](image1.png) ![Conway knot](image2.png)

**Figure 1398**

For the record let us formulate the following proposition.

**Proposition 99.4.** There exists an oriented knot that is neither amphichiral, nor reversible nor invertible.

We can now finally answer Question 27.9 in the affirmative.

**Proposition 99.5.** The trefoil is chiral.

**Proof.** We equip the trefoil \( K \) with either orientation. In Proposition 27.6 we showed that there exists an epimorphism \( \pi_1(\mathbb{S}^3 \setminus K) \to S_3 \). For a suitable choice of \( x \in S_3 \) one sees, using Proposition 99.3 and using the knot coloring polynomial \( P^x_{S_3} \) that \( K \) is neither smoothly isotopic to it mirror nor to its inverse. Thus the unoriented trefoil is chiral. We will work out the details in Exercise 99.4.

99.3. **Seifert surfaces.** The following is the key object in this section.
**Definition.** Let $K \subset S^3$ be a knot. A *Seifert surface*\(^{1381}\) for $K$ is a compact orientable connected 2-dimensional submanifold $F$ of $S^3$ such that $\partial F = K$. If $K$ itself is oriented, then we equip a Seifert surface $F$ with the orientation such that $\partial F = K$ as oriented smooth manifolds.

**Examples.**

1. In Figure 1399 we show Seifert surfaces for the trivial knot, the trefoil and the figure-8 knot.

2. In Figure 1400 we see two surfaces of minimal surface area that bound the trefoil, both were manufactured by Jürgen Neukirch. The one on the left is orientable, thus it is a Seifert surface. The one on the right is diffeomorphic to the Möbius band, thus it is not a Seifert surface.

The following proposition is arguably one of the most useful results in knot theory.

**Proposition 99.6.** Every knot $K \subset S^3$ admits a Seifert surface.

**Remark.**

1. The proposition was first proved in 1930 by F. Frankl and Lev Pontryagin [FPo30] in 1930. Shortly afterwards Herbert Seifert [Sei34] gave a different proof. More precisely Seifert found an algorithm that given a diagram for a knot produces an explicit Seifert surface for the knot. Seifert’s algorithm is also described in most books on knot theory, see e.g. [Rol90] p. 120 or [Lic97a] Theorem 2.2.

2. A slight generalization of the argument we give proves the following stronger statement: given any closed orientable $n$-dimensional smooth manifold $V \subset S^{n+2}$ there

\(^{1381}\)Seifert surfaces are named after Herbert Seifert (1907-1996) whom we had already encountered at the Mayer–Vietoris Theorem [30.2]
exists a compact orientable \((n + 1)\)-dimensional submanifold \(W \subset S^{n+2}\) such that \(\partial W = V\). We refer to [Bre93 Theorem VII.14.7], [Er69 Lemma 2.2] and [BDR17] for details. The proof in these two references is close to the approach taken in the proof of Proposition 99.6, but it circumvents the use of Proposition 98.4 by a more formal argument.

**Proof.** Let \(K\) be a knot. We need to show that there exists a compact orientable connected 2-dimensional submanifold \(F\) of \(S^3\) such that \(\partial F = K\).

First note that by Lemma 99.1 (2) we can pick a thickening \(B^2 \times K\) of the knot \(K\) with self-linking number zero. We denote by \(X := S^3 \setminus (B^2 \times K)\) the knot exterior. Note that by Lemma 99.2 (2) we know that there exists a unique homology class \(\sigma \in H_2(X, \partial X; \mathbb{Z})\) such that \(\partial \sigma = \{1\} \times K \in H_1(\partial X; \mathbb{Z})\). It follows from Proposition 98.6 that there exists a compact oriented proper 2-dimensional submanifold \(\Sigma\) of \(X\) such that \([\Sigma] = \sigma\) and such that \(\partial \Sigma = \{1\} \times K\). We apply Proposition 8.22 to 
\[
([0, 1] \times K) \cup \Sigma \subset (B^2 \times K) \cup X = S^3
\]
and we obtain a compact orientable 2-dimensional submanifold \(Z\) whose boundary equals \(K\). This submanifold might not be connected, but the component of \(Z\) that contains \(K\) is the desired Seifert surface. 

---

**Definition.** Let \(F\) be a compact orientable connected 2-dimensional smooth manifold with \(m\) boundary components. By the Surface Classification Theorem [23.4] there exists a unique \(g \in \mathbb{N}_0\) such that \(F\) is homeomorphic to the surface of genus \(g\) minus \(m\) open disks. We refer to \(g\) as the *genus of \(F\)*.

Given a Seifert surface it is sometimes not entirely obvious how to determine the genus. The following lemma gives an easy criterion to determine the genus of a Seifert surface.

**Lemma 99.7.** Let \(F\) be a compact orientable connected 2-dimensional submanifold with one boundary component. If \(\Gamma \subset F\) is a topological graph that is a deformation retract of \(F\), then

\[
\text{genus of } F = \frac{1}{2}(1 - \chi(F)) = \frac{1}{2}(1 - \#\text{vertices of } \Gamma + \#\text{edges of } \Gamma).
\]

**Proof.** We have

\[
\text{genus of } F = \frac{1}{2}(1 - \chi(F)) = \frac{1}{2}(1 - \chi(\Gamma)).
\]

↑ by Proposition 48.9 we have \(\chi(F) = 1 - 2g\)

↑ by Corollary 55.2 since \(\Gamma\) is a deformation retract of \(F\)
If a knot $K$ bounds a Seifert surface of genus $g$, then the construction sketched in Figure 1403 shows pretty convincingly that $K$ also bounds Seifert surfaces of any genus $h \geq g$.

So the interesting question is, what is the minimal genus of a Seifert surface for a given knot? This leads us to the following definition.

**Definition.** Given a knot $K \subset S^3$ we define

$$\text{genus}(K) := \text{minimal genus of a Seifert surface of } K.$$ 

**Examples.**

1. As we have seen in Figure 1402, the trivial knot has genus 0. More interestingly, we showed in Proposition 8.47 that if a knot has genus 0, then it is smoothly isotopic to the trivial knot.

2. We had also just seen that the trefoil admits a Seifert surface of genus 1. Furthermore in Proposition 27.6 (2) we saw that the trefoil is not equivalent to the trivial knot. It follows from (1) that

$$\text{genus}(\text{trefoil}) = 1.$$ 

We conclude this section with the following question.

**Question 99.8.** We consider the knot $K$ in Figure 1404. It admits a Seifert surface of genus two. Does it also admit a Seifert surface of genus one?

99.4. **Linking numbers.** We recall the following definition from page 2233.

**Definition.** An $m$-component link is a closed 1-dimensional submanifold of $S^3$. 
Remark. It follows from Theorem 7.5 that a link is the same as a 1-dimensional submanifold of $S^3$ that is diffeomorphic to the disjoint union of finitely many copies of $S^1$.

Convention. When we write, “let $L = L_1 \sqcup \cdots \sqcup L_m$ be an $m$-component link”, then it is understood that each $L_i$ is non-empty. In particular each $L_i$ is a knot in its own right.

The following definition is the obvious generalization of the definition on page 386.

**Definition.** We say that two $m$-component links $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ are smoothly isotopic if there exists a smooth map

$$F: (S^3_1 \sqcup \cdots \sqcup S^3_m) \times [0, 1] \to S^3$$

such that the following hold:

1. for each $i \in \{1, \ldots, m\}$ we have $F(S^3_i \times \{0\}) = K_i$ and $F(S^3_i \times \{1\}) = J_i$, and
2. for each $t \in [0, 1]$ the map $F_t: S^3_1 \sqcup \cdots \sqcup S^3 \to S^3$ is a smooth embedding.

If $L$ and $J$ are oriented links, then we also demand that the isotopy is orientation-preserving, i.e. the map $F_1 \circ F_0^{-1}: K \to J$ is orientation-preserving.

**Examples.**

1. We say $L = L_1 \sqcup \cdots \sqcup L_m \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ is a trivial link if it lies in $\mathbb{R}^2 \times \{0\} \subset \mathbb{R}^3$ and if it bounds $m$ disjoint disks in $\mathbb{R}^2 \times \{0\}$. Using Theorem 8.36 one can easily verify that all trivial links are in fact smoothly isotopic.

2. In Figure 1405 we show four examples of oriented links: the 2-component trivial link, two versions $H'$ of the Hopf link and one further link. The Hopf link is in fact related to the Hopf map

$$H: S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\} \to S^2 = \mathbb{CP}^1$$

from page 1071. More precisely, if $P, Q$ are two distinct points in $S^2$, then the preimage $H^{-1}\{\{P, Q\}\}$ is a 2-component link that is smoothly isotopic to the Hopf links without orientation. This can be seen as follows: for $P = [1 : 0]$ and $Q = [0 : 1]$ one can verify “by hand” that the preimage is smoothly isotopic to a Hopf link. Given any two other distinct points $P'$ and $Q'$ in $S^2$ we can find disjoint smooth paths from $P$ to $P'$ and $Q$ to $Q'$, the preimages of these paths give rise to a smooth isotopy of links.

---

1382 Is the second condition necessary?
Our goal now is to distinguish links that are not smoothly isotopic. It follows immediately from the definition that if two links \( L = L_1 \sqcup \cdots \sqcup L_m \) and \( J = J_1 \sqcup \cdots \sqcup J_m \) are smoothly isotopic, then the components are smoothly isotopic knots. Therefore we are mostly interested in distinguishing links for which the components are smoothly isotopic.

The following proposition generalizes Proposition 8.43. The proof is verbatim the same.

**Proposition 99.9.** Let \( L = L_1 \sqcup \cdots \sqcup L_m \) and \( J = J_1 \sqcup \cdots \sqcup J_m \) be two \( m \)-component links. If the links are smoothly isotopic, then the following two statements hold:

1. There exists an orientation-preserving diffeomorphism \( \Phi: S^3 \rightarrow S^3 \) with \( \Phi(L_i) = J_i \) for \( i = 1, \ldots, m \). If \( L \) and \( J \) are oriented, then there exists such a diffeomorphism \( \Phi \) which for each \( i \in \{1, \ldots, m\} \) restricts to an orientation-preserving diffeomorphism \( L_i \rightarrow J_i \).
2. The link complements \( S^3 \setminus L \) and \( S^3 \setminus J \) are diffeomorphic, in particular homeomorphic.

**Remark.** By the Gordon-Luecke Theorem 8.46 we pointed out that for knots the converse to Proposition 8.43 (2) holds. More precisely, if \( K \) and \( J \) are two knots such that there exists an orientation-preserving diffeomorphism between the knot complements \( S^3 \setminus K \) and \( S^3 \setminus J \), then \( K \) and \( J \) are smoothly isotopic. The analogous statement is no longer true for links. In Figure 1406 we show two links \( L = K \sqcup J \) and \( L' = K' \sqcup J' \). In Exercise 99.7 we will see that \( S^3 \setminus L \) and \( S^3 \setminus L' \) are diffeomorphic. Even though we cannot prove it at the moment, it should be fairly clear that \( L \) and \( L' \) are not smoothly isotopic. This shows in particular that the problem of classifying links cannot be reduced to the problem of classifying the complements of links.

To distinguish links with components that are smoothly isotopic we will now introduce an invariant of oriented links.

**Definition.** Let \( K \subset S^3 \) be an oriented knot. As before we denote by \( \mu_K \) the meridian as defined on page 390 and as above we denote by \( \phi_K \) the epimorphism \( \phi_K: H_1(S^3 \setminus K; \mathbb{Z}) \rightarrow \mathbb{Z} \).
that is given by \( \phi_K([\mu_K]) = 1 \). If \( J \subset S^3 \) is an oriented knot that is disjoint from \( K \), then we define the **linking number** of \( K \) and \( J \) to be

\[
\text{lk}(K, J) := \phi_K([J])
\]

where \([J] \in H_1(S^3 \setminus K; \mathbb{Z})\) denotes the image of the fundamental class of the oriented smooth manifold \( J \) under the inclusion \( J \to S^3 \setminus K \).

**Remark.** We continue with the above notation. If we denote by \([\mu_K^*] \in H^1(S^3 \setminus K; \mathbb{Z})\) the unique generator with \( \langle [\mu_K^*], [\mu_K] \rangle = 1 \), then it follows immediately from the definitions that for any oriented knot \( J \) disjoint from \( K \) we have

\[
\text{lk}(K, J) = \langle [\mu_K^*], [J] \rangle.
\]

**Example.** If \( K \) is the trivial knot, then we saw in Proposition 99.9 that \( S^3 \setminus K \) is diffeomorphic to the open solid torus \( B^2 \times S^1 \) and it is fairly straightforward to determine \( \phi_K : H_1(S^3 \setminus K; \mathbb{Z}) \to \mathbb{Z} \) applied to a given curve. This allows us to determine the linking numbers of the oriented links shown in Figure 1407.

\[
\begin{align*}
\text{lk}(K, J) &= 0 \\
\text{lk}(K, J) &= -1 \\
\text{lk}(K, J) &= 1 \\
\text{lk}(K, J) &= 2
\end{align*}
\]

**Figure 1407**

**Proposition 99.10.**

1. Let \( L = L_1 \sqcup \cdots \sqcup L_m \) and \( J = J_1 \sqcup \cdots \sqcup J_m \) be two \( m \)-component oriented links. If the links \( L \) and \( J \) are smoothly isotopic, then for all \( r, s \in \{1, \ldots, m\} \) we have

\[
\text{lk}(L_r, L_s) = \text{lk}(J_r, J_s).
\]

2. Let \( K \sqcup J \) be an oriented 2-component link. If we change the orientation of one of the components of the link, then the sign of the linking number flips.

**Proof.** The first statement is an immediate consequence of Proposition 99.9 (1). The second statement follows easily from the definitions. \(\blacksquare\)

**Example.** It follows from Proposition 99.10 together with the calculation of the linking numbers in Figure 1407 that the two Hopf links \( H^- \) and \( H^+ \) are not smoothly isotopic.

The following proposition says that the linking number \( \text{lk}(K, J) \) is symmetric in the oriented knots \( K \) and \( J \).

**Proposition 99.11.** For any oriented 2-component link \( J \sqcup K \) we have

\[
\text{lk}(J, K) = \text{lk}(K, J).
\]
PROOF (*). We pick a thickening for the link \( L = J \sqcup K \) and use it to define the exteriors \( X_L, X_K \) and \( X_J \). Throughout the proof we consider the following inclusion maps

\[
\begin{align*}
\partial X_K & \xrightarrow{f} X_L \xleftarrow{g} \partial X_J \xrightarrow{j} X_J, \\
\partial X_J & \xrightarrow{g} X_L \xleftarrow{k} \partial X_K.
\end{align*}
\]

Furthermore, throughout the proof we use the isomorphisms from Proposition 41.5 and page 1088 to make the identifications \( H_0(\partial X_J; \mathbb{Z}) = H_0(X_L; \mathbb{Z}) = H_0(X_J; \mathbb{Z}) = \mathbb{Z} \). We start out with the following claim.

**Claim.** We have

\[
\text{lk}(K, J) = \left( k^*([\mu_K^*]) \cup j^*([\mu_J^*]) \right) \cap g_*([\partial X_J]),
\]

where

\[
\begin{align*}
\text{Proposition 82.3} & \quad (k^*([\mu_K^*]) \cup j^*([\mu_J^*])) \cap g_*([\partial X_J]) = \langle -j^*([\mu_J^*]) \cup k^*([\mu_K^*]) \rangle \cap g_*([\partial X_J]) \quad \text{by the claim} \\
\text{Lemma 83.7} & \quad k^*([\mu_K^*]) \cap g_*([\lambda_J]) = \langle [\mu_K^*], k_*g_*([\lambda_J]) \rangle = \langle [\mu_K^*], k_*g_*(J) \rangle = \text{lk}(K, J) \quad \text{by Proposition 82.3 \ and \ since \ Corollary 87.28} \\
\text{Lemma 99.2 (3)} & \quad \text{Lemmas 74.6 (3) \ and \ 83.4 \ since \ [\lambda_J] = [J] \in H_1(X_K) \ see \ page 2396}.
\end{align*}
\]

Now we conclude that

\[
\text{lk}(K, J) = \left( j^*([\mu_J^*]) \cup k^*([\mu_K^*]) \right) \cap g_*([\partial X_J]) = \langle -k^*([\mu_K^*]) \cup j^*([\mu_J^*]) \rangle \cap (-f_*([\partial X_K]))
\]

by the claim by Proposition 82.3 and since by Corollary 87.28 we have \( g_*([\partial X_J]) + f_*([\partial X_K]) = 0 \in H_2(X_L; \mathbb{Z}) \)

\[
\begin{align*}
\text{by \ the \ claim} & \quad \text{by \ the \ claim} \\
\text{Proposition 99.12.} & \quad \text{Let } K \sqcup J \text{ be an oriented 2-component link. If } F \text{ is a Seifert surface for } K \text{ that is transverse to } J, \text{ then}
\end{align*}
\]

\[
\text{lk}(K, J) = F \cdot J
\]

where \( F \cdot J \) denotes the algebraic intersection number of \( F \) and \( J \).

**Example.** In Figure 1408 we show an oriented link \( K \sqcup J \) and a Seifert surface \( F \) for \( K \). Clearly we have \( F \cdot J = 0 \), thus it follows from Proposition 99.12 that \( \text{lk}(K, J) = 0 \).
**Remark.** The combination of Proposition ?? and Theorem[94.5], and some mild massaging, generalizes the statement of Proposition 99.12 to the higher-dimensional setting and it gives an alternative proof of Proposition 99.12.

**Proof.** Let $K \sqcup J$ be an oriented 2-component link. We pick a tubular neighborhood $B^2 \times K$ for $K$. After possibly shrinking the tubular neighborhood we can and will assume that $S^3 \times K$ intersects $F$ transversally in a single curve and that $\overline{B}^2 \times K$ does not intersect $J$. We write $X := S^3 \setminus (B^2 \times K)$ and we write $F' := F \cap X$. It follows from our choice of tubular neighborhood and from Lemma 6.32 that $F'$ is a compact proper submanifold of $F$.

We start out with the following claim.

**Claim.** We have $\text{PD}_X([F']) = [\mu_K^*] \in H^1(X; \mathbb{Z})$.

By definition of the Poincaré duality isomorphism $\text{PD}_X$ the claim is equivalent to showing that $[\mu_K^*] \cap [X] = [F']$. From Lemma 99.2 (2) we know that the connecting homomorphism $\partial: H_2(X, \partial X; \mathbb{Z}) \to H_1(\partial X; \mathbb{Z})$ is a monomorphism. Therefore it suffices to show that $\partial([\mu_K^*] \cap [X]) = \partial[F']$. We denote by $i: \partial X \to X$ the inclusion map. We calculate that

$$\partial([\mu_K^*] \cap [X]) = -i^*([\mu_K^*]) \cap [\partial X] = [\lambda_K] = [\partial F'] = \partial([F']).$$

Now we calculate that

$$F \cdot J = J \cdot F = \text{PD}_X([J]) \cap \text{PD}_X([F']) \cap [X] = \text{PD}_X([F']) \cap (\text{PD}_X([J]) \cap [X]).$$

by the claim we have $\text{PD}_X([F']) = [\mu_K^*]$ and

$$[\mu_K^*] \cap [J] = \langle [\mu_K^*], [J] \rangle = \text{lk}(K, J).$$

We have thus proved the desired equality.

Next we will formulate a proposition that in many “real-life” situations is often the most efficient way to compute linking numbers. Before we formulate the proposition, recall that on page 787 we introduced the notion of a knot diagram and the notion of an over- and undercrossing. These notion can be generalized in a pretty obvious way to the notion of a link diagram.

---

\[\text{This last statement requires a little bit of thought. We leave the technical details to the reader.}\]
To enhance readability we will formulate the next proposition in a slightly informal way.

**Proposition 99.13.** Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the $xy$-plane. Then

$$\text{lk}(K, J) = \frac{1}{2} \cdot \text{number of positive crossings between } K \text{ and } J - \frac{1}{2} \cdot \text{number of negative crossings between } K \text{ and } J$$

where a crossing $P$ is called a positive (respectively negative) crossing if the direction of the upper strand together with the direction of the lower strand give a positive (respectively negative) basis for $\mathbb{R}^2$. We refer to Figure 1409 for an illustration.

![Figure 1409. Illustration for Proposition 99.13.](image)

**Examples.**

(1) In Figure 1410 we show two oriented links and we compute the linking number using Proposition 99.13 by considering the signs of the crossings between $K$ and $J$. As a reality check, on the left we consider the Hopf link that we had already considered in Figure 1407. In both cases we obtain that the linking number equals $-1$.

![Figure 1410](image)

(2) Now we can settle the question from page 2385, which of the three closed curves shown in Figure 1411 is actually the longitude of the trefoil. More precisely, by definition the longitude $\lambda_K$ satisfies $\phi_K([\lambda_K]) = 0$, but again by definition this means that $\text{lk}(K, \lambda_K) = 0$. Conversely, loosely speaking any curve that runs “parallel to $K$” and that has linking number zero with $K$, is a longitude. Using Proposition 99.13 we calculate the linking numbers of the oriented knot $K$ with the oriented curves $A$, $B$ and $C$. We obtain that $C$ is the only curve with linking number zero. Thus $C$ is the longitude.

**Remark.** Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the $xy$-plane. An amusing exercise shows that

$$\text{lk}(K, J) = \text{number of positive crossings where } K \text{ crosses over } J - \text{number of negative crossings where } K \text{ crosses over } J.$$
Sketch of proof. We introduce the following notation:

1. Given \( t \in \mathbb{R} \) we consider the map
   \[
   \lambda_t : \mathbb{R}^3 \to \mathbb{R}^3
   \]
   \[
   (x, y, z) \mapsto (x, y, z + t).
   \]
   We extend this definition to a homeomorphism of \( S^3 \) by setting \( \lambda_t(\infty) = \infty \).

2. By Proposition 99.6, the knot \( J \) admits a Seifert surface \( F \).

3. We pick \( r \in \mathbb{R} \) such that the minimal \( z \)-coordinate of any point on \( \lambda_r(F) \) is greater than the maximal \( z \)-coordinate of any point in \( K \).

4. We write \( F' = ((J \times [0, 1]) \cup F) / \sim \) where we identify any point in \( J \subset F \) with the corresponding point in \( J \times \{1\} \). Note that \( F' \) is a compact 2-dimensional smooth manifold that inherits an orientation from \( F \).

5. We write
   \[
   \Psi : F' = ((J \times [0, 1]) \cup F) / \sim \to \mathbb{R}^3
   \]
   \[
   Q \mapsto \begin{cases} 
   \lambda_{t,r}(P) & \text{if } Q = (P, t) \in J \times [0, 1], \\
   \lambda_r(Q) & \text{if } Q \in F.
   \end{cases}
   \]
   Then
   \[
   \text{lk}(K, J) = K \cdot \Psi = K \cdot \Psi|_{J \times [0,1]}.
   \]
   By the same argument as in Proposition 99.12, we have
   \[
   K \cap \Psi(F) = \varnothing.
   \]

The right-hand side can be computed easily, in fact the points in \( K \cap \Psi(J \times [0, 1]) \) correspond precisely to the crossings of the diagrams where \( K \) crosses over \( J \) and one can easily convince oneself that the signs agree. The proposition now follows from the reformulation of the linking number in the remark preceding the proof.

In the following lemma we give a 4-dimensional interpretation of the linking number.

---

1384 A proof can evidently only be as precise as the input. Since we did not bother to completely rigorously formulate the statement we can also not expect a completely rigorous proof. But with some effort one can formulate both the statement and the proof rigorously.

1385 Why is this map continuous?

1386 Note that the map \( \Psi : F' \to S^3 \) is not necessarily injective. In particular the image is not necessarily a Seifert surface for \( J \).

1. There exist oriented proper 2-dimensional submanifolds $S$ and $S'$ of $\overline{B^4}$ with $\partial S = K$ and $\partial S' = K'$ such that $S$ and $S'$ are transverse.

2. Let $S, S'$ be two oriented proper 2-dimensional submanifolds of $\overline{B^4}$ with $\partial S = K$ and $\partial S' = K'$. If $S$ and $S'$ are transverse, then

$$\text{lk}(K, K') = S \cdot _{\overline{B^4}} S'.$$

Remark. The combination of Proposition 99.6 and Theorem 99.5 generalizes the statement of Lemma 99.14 to the higher-dimensional setting and it gives an arguably mathematically purer proof of Lemma 99.14.

Sketch of proof. Let $K, K'$ be two disjoint oriented knots.

1. By Proposition 99.6 and the Transversality Theorem 9.10 (2) there exists a Seifert surface $F$ for $K$ that is transverse to $K'$. Furthermore let $F'$ be a Seifert surface for $K'$. We pick a collar neighborhood $[0, 2] \times S^3$ for $S^3 = \partial B^4$. We use the collar neighborhood $[0, 1] \times S^3$ to define the push-in $\Psi(F)$ and we use the collar neighborhood $[0, 2] \times S^3$ to define the push-in $\Psi(F')$ of $F'$. It follows easily from Lemma 8.23 that $\widetilde{F}$ and $\widetilde{F}'$ have the desired properties.

2. First we note that

$$\text{lk}(K, K') = F \cdot _{S^3} K' = \widetilde{F} \cdot _{\overline{B^4}} \widetilde{F}' = -(-\widetilde{F}) \cdot _{\overline{B^4}} (-\widetilde{F}').$$

Proposition 99.12 by inspection of the intersection points

Now let $S, S'$ be two oriented proper 2-dimensional submanifolds of $\overline{B^4}$ with $\partial S = K$ and $\partial S' = K'$. We think of $S^4 = \overline{B^4} \cup (-\overline{B^4})$ as the union of two copies of $\overline{B^4}$ with opposite orientations, the first copy contains $S, S'$ and the second contains $-\widetilde{F}, -\widetilde{F}'$. (See Figure 1413 for an illustration.) It follows fairly easily from the Collar Neighborhood Theorem 8.20 that $S \cup -\widetilde{F}$ and $S' \cup -\widetilde{F}'$ are oriented submanifolds of $\overline{B^4}$.

\[\text{We refer to page 367 for the definition of push-ins.}\]
We calculate that
\[ S' \cdot B S' - \text{lk}(K, K') = S' \cdot B' S' + (\bar{F}) \cdot (\bar{F}') = (S' \cup \bar{F}) \cdot S' (S' \cup \bar{F}') = 0. \]

by the above since \( S \cap \bar{F}' = S' \cap \bar{F} = \emptyset \) by Theorem 95.7 and since \( H^2(S^4; \mathbb{Z}) = 0 \)

We have thus shown the desired equality \( S' \cdot B S' = \text{lk}(K, K') \).

\[ \quad \]

\textbf{Figure 1413. Illustration for the proof of Lemma 99.14}

The following proposition gives two alternative ways to define or calculate or interpret the linking number.

\textbf{Proposition 99.15.} Let \( K \sqcup J \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{ \infty \} \) be an oriented 2-component link.

1. If \( \varphi: S^1 \to K \) and \( \psi: S^1 \to J \) are two orientation-preserving diffeomorphisms, then
\[ \text{lk}(K, J) = \text{deg} \left( S^1 \times S^1 \to S^2 \right. \]
\[ \left( z, w \mapsto \frac{\varphi(z) - \psi(w)}{\|\varphi(z) - \psi(w)\|} \right). \]

2. Let \( f: [0, 2\pi] \to K \) and \( g: [0, 2\pi] \to J \) be two maps such that \( f \) and \( g \) descend to orientation-preserving diffeomorphisms from \([0, 2\pi]/0 \sim 2\pi\) to \( K \) and \( J \). Then
\[ \text{lk}(K, J) = \frac{1}{4\pi} \int_{s=0}^{2\pi} \int_{t=0}^{2\pi} \frac{\det \begin{pmatrix} (f(s) - g(t)) & f'(s) \end{pmatrix} \begin{pmatrix} g'(t) \end{pmatrix}}{\|f(s) - g(t)\|^3} \, dt \, ds. \]

\textbf{Proof.}

1. We will prove this statement in Exercise 99.14. Alternatively see \cite{Rolf90} p. 133.

2. In Exercise 99.15 we will see that this statement can be deduced from Statement (1).

\cite{RN11} Section 5, \cite{Rolf90} p. 133 and \cite{tD00} p. 284.

\textbf{Remark.}

1. The linking number of an oriented 2-component link was initially introduced by Gauss in 1833 by the integral in Proposition 99.15. We refer to Figure 1414 for a scan of the relevant paragraphs in \cite{Gaus1877} p. 605]. The term \textit{geometria situs} is hereby

\cite{1388} The word “submanifold of \( S^4 \) is used in a slightly ambiguous way since it depends on whether we view \( S^4 \) as a topological manifold or a smooth manifold. In this case we view \( S^4 \) only as a topological manifold.

\cite{1389} Here we use the notion of “degree” that we introduced on page 1737.
the earlier name for topology. We refer to [Epp99, p. 73] for more information on the work of Gauss regarding the linking number.

(2) It is not immediately clear why the integral in Proposition 99.15 is an invariant of the equivalence class of the link $K \sqcup J$. How would you prove this statement, without using Proposition 99.15 (2)?

(3) It is clear from the second reformulation of the linking number given in Proposition 99.15 that the linking number is symmetric. How does the symmetry follow from the first reformulation?

Example. Given any topological invariant the question that arises is, how good is it at distinguishing objects. It is quite easy to find examples of links which show that the linking number is far from being a complete invariant. In Figure 1415 we show the Whitehead link and the Borromean rings. Both are links with zero linking numbers and unknotted components but which are appear to be non-trivial. The Whitehead link is named after John Henry Constantine Whitehead who also introduced the concept of CW-complexes. The Borromean rings are named after the Borromeo family that carries the Borromean rings in its coat of arms since medieval days.

We record the following question for later on.

**Question 99.16.** How can we show that neither the Whitehead link nor the Borromean rings are smoothly isotopic to the trivial link?
Remark. We can of course try to determine the fundamental groups of the complements of the trivial links and the Whitehead link and the Borromean rings. But then the question arises, how can we distinguish these groups?

99.5. Alexander duality and linking numbers \((*)\). Let \(Y\) be a compact non-empty subset of \(S^3\) that admits a regular neighborhood. (For example, by Propositions \([10.13, 10.9, 10.11]\) the subset \(Y\) could be a link or a spatial graph.) We can compute the isomorphism types of the first homology group of the complement \(S^3 \setminus Y\) as follows:

\[
\begin{align*}
H_1(S^3 \setminus Y; \mathbb{Z}) & \cong H^1(Y; \mathbb{Z}) \cong \text{Hom}(H_1(Y; \mathbb{Z}), \mathbb{Z}) \cong H_1(Y; \mathbb{Z})/\text{torsion.}
\end{align*}
\]

Alexander Duality \hspace{1cm} Universal Coefficient \hspace{1cm} non-natural isomorphism

\(\text{Theorem 92.1}\) \hspace{1cm} \(\text{Theorem 75.13}\)

The catch with the Alexander Duality Theorem \(92.1\) is that it is quite hard to “see” the isomorphism. For example, suppose we are given a basis for \(H_1(Y; \mathbb{Z})/\text{torsion}\), how do we get a basis for \(H_1(S^3 \setminus Y; \mathbb{Z})\)? In many situations the following lemma resolves that issue.

**Lemma 99.17.** Let \(Y\) be a compact non-empty subset of \(S^3\) that admits a regular neighborhood \(N(Y)\). We suppose that \(H_1(Y; \mathbb{Z})\) is a free abelian group of rank \(k\). Let \(v(x), C_1, \ldots, C_k\) be oriented curves in \(N(Y)\) and let \(D_1, \ldots, D_k\) be oriented curves in \(S^3 \setminus N(Y)\). If

\[
\det \left( \begin{array}{c|c|c|c}
\text{link}(C_i, D_j) & \cdots & \text{link}(C_i, D_k) \\
\hline
\vdots & \ddots & \vdots \\
\text{link}(C_k, D_i) & \cdots & \text{link}(C_k, D_j)
\end{array} \right)_{k \times k} = \pm 1,
\]

then \([D_1], \ldots, [D_k]\) form a basis of \(H_1(S^3 \setminus Y; \mathbb{Z})\).

**Proof.** Let \(Y\) be a compact non-empty subset of \(S^3\) that admits a regular neighborhood \(N = N(Y)\). We denote by \(\hat{N}\) the interior of \(N\). We consider the homomorphisms

\[
\begin{align*}
\Omega: \mathbb{Z}^k & \to H_1(S^3 \setminus \hat{N}; \mathbb{Z}) \\
(a_1, \ldots, a_k) & \mapsto \sum_{i=1}^{k} a_i \cdot [D_i]
\end{align*}
\]

\[
\Theta: H_1(S^3 \setminus \hat{N}; \mathbb{Z}) \to \mathbb{Z}^k \\
\sigma & \mapsto (\phi_{C_1}(\sigma), \ldots, \phi_{C_k}(\sigma)).
\]

It follows from our hypothesis and the definition of linking numbers that \(\Theta \circ \Omega\) is an epimorphism. Furthermore we know from the Alexander Duality Theorem \(92.1\) and the Universal Coefficient Theorem \(75.13\) that \(H_1(S^3 \setminus \hat{N}; \mathbb{Z})\) is also isomorphic to \(\mathbb{Z}^k\). But by

\[\text{Is it possible that } H_1(Y; \mathbb{Z}) \text{ is not a free abelian group?}\]
Lemma 99.8 (5) an epimorphism between two free abelian groups of the same rank is an isomorphism. Thus we see that \( \Theta \) and \( \Omega \) are isomorphisms.

Since \( \{[D_1], \ldots, [D_k]\} \) is the image under \( \Omega \) of the standard basis of \( \mathbb{Z}^k \) we see that \( [D_1], \ldots, [D_k] \) form a basis for \( H_1(S^3 \setminus \hat{N}; \mathbb{Z}) \). But by Lemma 10.1 the inclusion induced map \( H_1(S^3 \setminus Y; \mathbb{Z}) \to H_1(S^3 \setminus \hat{N}; \mathbb{Z}) \) is an isomorphism. Thus we see that \( [D_1], \ldots, [D_k] \) form a basis of \( H_1(S^3 \setminus Y; \mathbb{Z}) \).

**Example.** In Figure 1416 we consider a spatial graph \( G \) together with a regular neighborhood \( N \). By Lemma 55.12 we know that \( H_1(G; \mathbb{Z}) \cong \mathbb{Z}^2 \). In Figure 1416 we also see two oriented curves \( C_1 \) and \( C_2 \) in \( N \) and two oriented curves \( D_1 \) and \( D_2 \) in \( S^3 \setminus \hat{N} \). Using Proposition 99.13 one can easily calculate that

\[
\begin{pmatrix}
\text{lk}(C_1, D_1) & \text{lk}(C_1, D_2) \\
\text{lk}(C_2, D_1) & \text{lk}(C_2, D_2)
\end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.
\]

It follows from Lemma 99.17 that \( [D_1], [D_2] \) form a basis for \( H_1(S^3 \setminus G; \mathbb{Z}) \).

**Figure 1416**

Spatial graph \( G \) regular neighborhood \( N \)

In Lemma 92.3 we computed the homology groups of the complement of a link, but we could not determine explicit generators. The following lemma now solves that problem. In particular it gives an answer to Question 92.4.

**Lemma 99.18.** Let \( L = L_1 \sqcup \cdots \sqcup L_m \) be an \( m \)-component link. We pick a thickening \( \mathbb{B}^2 \times L \) for \( L \).

1. A basis for \( H_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m \) is given by the homology classes that are represented by the meridians \( \mu_1, \ldots, \mu_m \).
2. A basis for \( H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1} \) is given by considering the fundamental classes of all but one of the tori \( S^1 \times L_i \), \( i \in \{1, \ldots, m\} \). More precisely, for any \( j \in \{1, \ldots, m\} \) a basis for \( H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1} \) is given by \( [S^1 \times L_1], \ldots, [S^1 \times L_{i-1}], [S^1 \times L_{i+1}], \ldots, [S^1 \times L_m] \).

**Figure 1417**

The alert reader will have noticed that the proof resembles the argument given in Lemma 74.7.
Sketch of proof. Let \( L = L_1 \sqcup \cdots \sqcup L_m \) be an \( m \)-component link. We know from Lemma 92.3 that \( H_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m \) and that \( H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1} \). We pick a thickening \( \mathcal{B}^2 \times L \) for \( L \). By the Collar Neighborhood Theorem 8.12 we can extend this thickening to a thickening \( 2\mathcal{B}^2 \times L \).

(1) The first statement follows from Lemma 99.17 applied to \( C_i = \{0\} \times L_i, i = 1, \ldots, m \) and \( D_i := \mu_i, i = 1, \ldots, m \).

(2) To simplify the notation we consider the case \( j = m \). We write \( X' := S^3 \setminus \frac{1}{2} \mathcal{B}^2 \times L \).

For \( i = 1, \ldots, m \) we write \( T_i := S^1 \times L_i \). For \( i = 1, \ldots, m \) we pick a point \( P_i \) on \( \frac{1}{2} S^1 \times L_i \subset \partial X' \). Since \( S^3 \setminus (2\mathcal{B}^2 \times L) \) is path-connected we can pick for each \( i \in \{1, \ldots, m-1\} \) a path \( \gamma_i \) from \( P_i \) to \( P_m \) that intersects \( T_i \) transversally in a single point and that does not intersect any of the \( T_j \) with \( j \neq i, m \). Now we consider the map

\[
\Psi : H_1(X', \partial X'; \mathbb{Z}) \times H_2(X'; \mathbb{Z}) \to \mathbb{Z} \\
(\sigma, \tau) \mapsto \langle \text{PD}_{X'}(\sigma) \cup \text{PD}_{X'}(\tau), [X'] \rangle.
\]

It follows easily from Theorem 95.7 that if \( i, j \in \{1, \ldots, m-1\} \) we have the equality \( \Psi([\gamma_i], [T_j]) = \delta_{ij} \). By Lemma 74.8 this implies that \([T_1], \ldots, [T_{m-1}]\) do indeed form a basis of \( H_2(X'; \mathbb{Z}) \).

Exercises for Chapter 99

Exercise 99.1. Let \( A = S^1 \times [-1, 1] \) be the annulus. Let \( C \) and \( D \) be two closed oriented curves on \( A \). Suppose that \([C] = [D] \neq 0\). Show that the following two statements hold:

(a) the two closed oriented curves are smoothly isotopic,

(b) if \( C \) and \( D \) are furthermore disjoint, then there exists an embedded annulus \( X \subset A \) with \( \partial A = C \cup -D \).

Hint. Using the fact that \( A \) is an annulus you can find a smooth isotopy that makes the curves disjoint. At that point it is perhaps better to first prove (2).

Exercise 99.2. Let \( F \) be an oriented connected 2-dimensional smooth manifold and let \( C \) and \( D \) be distinct boundary curves. Suppose that \( C \) and \( D \) are homotopic. Show that \( F \) is diffeomorphic to the annulus \( S^1 \times [-1, 1] \).
Exercise 99.3. Let $K$ be a knot together with a diagram. In Section 27.6 we gave an explicit algorithm that determines the Wirtinger presentation for $\pi_1(S^3 \setminus K)$. Explain what element in this presentation corresponds to the longitude. Alternatively, for readers who like more explicit questions, determine the group system for the trefoil and the figure-8 knot.

![Figure 1419. Illustration for Exercise 99.3](image)

Exercise 99.4. Show that the trefoil $K$ is chiral.

*Hint.* In Proposition 27.6 we showed that there exists an epimorphism $\pi_1(S^3 \setminus K) \to S_3$.

Exercise 99.5. Find explicit Seifert surfaces for the knots $K_1$ and $K_2$ shown in Figure 1420.

*Remark.* The answer to a question can only be as rigorous as the input. Since the input is a picture it suffices here of course to draw a convincing picture of a Seifert surface.

![Figure 1420](image)

Exercise 99.6. Let $\varphi : \overline{B}^3 \to S^3$ and $\psi : \overline{B}^3 \to S^3$ be two smooth embeddings with disjoint images. Let $K \subset \varphi(\overline{B}^3)$ and $J \subset \psi(\overline{B}^3)$ be oriented knots. Show that $\text{lk}(K, J) = 0$.

Exercise 99.7. We consider the two links shown in Figure 1406. Show that the link complements are diffeomorphic.

![Figure 1421](image)

Exercise 99.8. Is every knot $K \subset S^3$ the boundary of a *non-orientable* compact surface that is smoothly embedded in $S^3$?

Exercise 99.9. The Borromean rings, shown in Figure 1415 have the property that if you remove one component, then the remaining two knots form a trivial link. Does there exist a four component link with the property that if you remove any of the four components, then you get a three component trivial link?
Exercise 99.10. Let \( L = K \sqcup J \) and \( L' = K' \sqcup J' \) be two oriented links such that the complements are diffeomorphic. Does it follow that \( \text{lk}(K, J) = \pm \text{lk}(K', J') \)?

Exercise 99.11. An \( m \)-component link \( L = L_1 \sqcup \cdots \sqcup L_m \subset S^3 \) is called split link if there exist disjoint closed balls \( B_1, \ldots, B_m \) such that each \( L_i \) is contained in \( B_i \). Furthermore \( L \) is called a boundary link if there exist \( m \) disjoint Seifert surfaces \( F_1, \ldots, F_m \).

(a) A split link is easily seen to be a boundary link. Do there exist boundary links that are not split?

(b) Show that if \( L = L_1 \sqcup \cdots \sqcup L_m \) is a boundary link, then there exists an epimorphism from \( \pi_1(S^3 \setminus L) \) onto a free group of rank \( m \).

\[ \text{Hint.} \quad \text{You could try to find an interesting map from } S^3 \setminus L \text{ onto the wedge of } m \text{ circles.} \]

Exercise 99.12. Let \( L \) and \( M \) be two links in \( S^3 \). We pick an orientation-preserving embedding \( \varphi: \overline{B}^3 \to S^3 \) with \( L \subset \varphi(B^3) \) and we pick an orientation-preserving embedding \( \psi: \overline{B}^3 \to S^3 \) with \( M \subset \psi(B^3) \). Finally we pick two orientation-preserving embeddings \( \alpha, \beta: \overline{B}^3 \to S^3 \) with disjoint images. We refer to \( \alpha(\varphi^{-1}(L)) \cup \beta(\psi^{-1}(M)) \) as the split union \( L \sqcup M \) of the links \( L \) and \( M \). Show that the smooth isotopy class of the split union \( L \sqcup M \) is independent of all the choices and that the smooth isotopy class of the split union only depends on the smooth isotopy type of \( L \) and \( M \).

\[ \text{Remark.} \quad \text{Evidently you want to use Theorem 8.36. But is that really enough?} \]

![Figure 1422. Illustration of Exercise 99.12](image)

Exercise 99.13. Let \( K \sqcup J \) be an oriented link in \( \mathbb{R}^3 \) and let \( K^* \sqcup J^* \) be a mirror image as defined on page 1780. As usual we view \( \mathbb{R}^3 \) as a subset of \( \mathbb{R}^3 \cup \{\infty\} = \overline{S}^3 \). Determine the relationship between \( \text{lk}(K, J) \) and \( \text{lk}(K^*, J^*) \).

Exercise 99.14. Let \( K \sqcup J \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\} \) be an oriented 2-component link. Show that if \( \varphi: S^1 \to K \) and \( \psi: S^1 \to J \) are two orientation-preserving diffeomorphisms, then

\[
\text{lk}(K, J) = \deg \left( S^1 \times S^1 \rightarrow S^2, (z, w) \mapsto \frac{\varphi(z) - \psi(w)}{||\varphi(z) - \psi(w)||} \right).
\]

\[ \text{Hint.} \quad \text{Use Sard’s Theorem 6.63, Proposition 99.13 and Proposition 69.7.} \]

Exercise 99.15. Let \( K \sqcup J \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\} \) be an oriented 2-component link. Furthermore let \( f: [0, 2\pi] \to K \) and \( g: [0, 2\pi] \to J \) be two maps such that \( f \) and \( g \) descend

\[ ^{1392} \text{Here we use the notion of “degree” that we introduced on page 1737.} \]
to orientation-preserving diffeomorphisms from \([0, 2\pi]/0 \sim 2\pi\) to \(K\) and \(J\). Show that the following equality holds:

\[
\text{lk}(K, J) = \frac{1}{4\pi} \int_{s=0}^{s=2\pi} \int_{t=0}^{t=2\pi} \begin{vmatrix} f(s) - g(t) & f'(s) & g'(t) \end{vmatrix} \frac{dt ds}{\|f(s) - g(t)\|^3}.
\]

**Hint.** Use Exercise 99.14 together with Proposition 79.7, Exercises 78.4 and 78.5.

**Exercise 99.16.** Let \(n \geq 4\) and let \(K \subset S^n\) be a closed orientable smooth submanifold of codimension 2. Show that there exists a compact orientable submanifold \(W\) of \(S^n\) with \(\partial W = K\).

**Remark.** Note that in general the analogous statement is not true if we do not impose any conditions on the codimension. For example by Proposition 9.1 we can view \(\mathbb{CP}^2\) as a smooth submanifold of some \(S^n = \mathbb{R}^n \cup \{\infty\}\). But by the proof of Corollary ?? we know that \(\mathbb{CP}^2\) is not the boundary of any compact orientable smooth manifold, let alone one which is embedded in \(S^n\).

**Exercise 99.17.** In Figure 99.17 we show two smooth embeddings of the genus two handlebody into \(\mathbb{R}^3\). Are these two embeddings smoothly isotopic?

**Figure 1423.** Illustration of Exercise 99.17
100. The intersection form I: Definition and calculations

In this chapter we will introduce and study the intersection form of compact oriented even-dimensional topological manifolds. Before we do so it is convenient to remind ourselves of a few basic notions and results in algebra.

100.1. Pairings and forms. On page 2192 we introduced the notion of a pairing over a commutative ring \( R \). We recall the definition and we introduce some new notions.

**Definition.** Let \( R \) be a commutative ring.

1. A **pairing over \( R \)** is an \( R \)-bilinear map \( V \times W \to S \) where \( V, W \) and \( S \) are \( R \)-modules.
2. We say that a pairing \( \varphi: V \times V \to S \) is **symmetric** if \( \varphi(v, w) = \varphi(w, v) \) for all \( v, w \in V \). Furthermore we call the pairing **anti-symmetric** if \( \varphi(v, w) = -\varphi(w, v) \) for all \( v, w \in V \).
3. We say that two pairings \( (V, \varphi) \) and \( (W, \psi) \) are **isometric**, written \( (V, \varphi) \cong (W, \psi) \), if there exists an isometry, i.e. an isomorphism \( f: V \to W \) of \( R \)-modules such that 
   \[ \varphi(v_1, v_2) = \psi(f(v_1), f(v_2)) \]
   for all \( v_1, v_2 \in V \).
4. Given a pairing \( \varphi: V \times V \to S \) we denote by \( -\varphi \) the pairing that is given by 
   \[ (-\varphi)(v, w) := -\varphi(v, w) \]
   for all \( v, w \in V \).
5. Given two pairings \( \varphi: V \times V \to S \) and \( \psi: W \times W \to S \) we define the **direct sum** of \( \varphi \) and \( \psi \) to be the pairing
   \[ \varphi \oplus \psi: (V \oplus W) \times (V \oplus W) \to S \]
   \[ (v \oplus w, v' \oplus w') \mapsto \varphi(v, v') + \psi(w, w') \]
6. Given a pairing \( (V, \varphi) \) and \( n \in \mathbb{Z} \) we define
   \[ n \cdot (V, \varphi) := \underbrace{(V, \varphi) \oplus \cdots \oplus (V, \varphi)}_{\text{\( n \)-summands}} \]
   if \( n \geq 0 \),
   \[ \underbrace{(V, -\varphi) \oplus \cdots \oplus (V, -\varphi)}_{\text{\(|n|\)-summands}} \]
   if \( n \leq 0 \).
7. Given a pairing \( (V, \varphi: V \times V \to S) \) and a submodule \( W \) of \( V \) we denote by \( \varphi|_W \) the pairing that is given by restricting the map \( \varphi: V \times V \to S \) to \( W \times W \to S \).

In this chapter we will mostly be interested in the following special type of a pairing.

**Definition.** Let \( R \) be a commutative ring. A **form** is a finitely generated free \( R \)-module \( V \) together with a pairing \( \varphi: V \times V \to R \) which is either symmetric or anti-symmetric. We refer to the rank of \( V \) also as the rank of the form.

For the reader's convenience we recall the following definition from page 2192.

\[ \text{The various definitions of “form” in the literature vary wildly. It is always a good idea, reading a paper or a book, to look up the precise definition of “form” that is used by the author.} \]

\[ \text{The rank of a finitely generated free module over a commutative ring is well-defined, see e.g. [Lam99] p. 4]. Note though that the rank of a finitely generated free module over a non-commutative ring is not necessarily well-defined. More precisely, there exists a non-commutative ring \( R \) and \( m \neq n \in \mathbb{N} \) such that \( R^m \) is isomorphic to \( R^n \). We refer to [Lam99] p. 4 for such examples.} \]
Definition. Let \( R \) be a commutative ring. A form \( \varphi : V \times V \to R \) is called non-singular if the map
\[
V \to \text{Hom}_R(V, R)
\]
\[
v \mapsto \left( \begin{array}{c} V \to R \\ w \mapsto \varphi(v, w) \end{array} \right)
\]
is an isomorphism.\(^{1394}\)

In many situations it is convenient to represent a form by a matrix. We recall the relevant definition from the linear algebra courses.

Definition. Let \( R \) be a commutative ring and let \( \varphi : V \times V \to R \) be a form. Given any basis \( \{v_1, \ldots, v_k\} \) of the free \( R \)-module \( V \) we refer to the \( (k \times k) \)-matrix
\[
(\varphi(v_i, v_j))_{i,j=1,\ldots,k} \in M(k \times k, R)
\]
as a matrix representing the form \( \varphi \). Note that by Lemma 90.1 the form is non-singular if and only if the matrix representing the form is invertible.

The following elementary lemma is usually proved in a standard course on linear algebra. It is also straightforward to verify it using only the relevant definitions.\(^{1395}\)

**Lemma 100.1.** Let \( R \) be a commutative ring and let \( \varphi : V \times V \to R \) be a form. Let \( \{v_1, \ldots, v_k\} \) and \( \{w_1, \ldots, w_k\} \) be bases of the free \( R \)-module \( V \). We write
\[
A := (\varphi(v_i, v_j))_{i,j=1,\ldots,k} \quad \text{and} \quad B := (\varphi(w_i, w_j))_{i,j=1,\ldots,k}.
\]
If \( P = (p_{ij})_{i,j=1,\ldots,k} \in \text{GL}(k, R) \) denotes the base change matrix that is uniquely defined by the property that \( v_i = \sum_{j=1}^k p_{ij} w_j \) for \( i = 1, \ldots, k \), then
\[
A = P^T B P.
\]

The following lemma is even more elementary, it follows basically immediately from the definitions.

**Lemma 100.2.**

1. Let \( \varphi : V \times V \to R \) be a form. If \( A \) is a matrix that represents \( \varphi \), then the matrix \( -A \) represents the form \( -\varphi \).
2. Let \( \varphi : V \times V \to R \) and \( \psi : W \times W \to R \) be two forms. If \( A \) is a matrix that represents \( \varphi \) and if \( B \) is a matrix that represents \( \psi \), then the matrix \( A \oplus B := \left( \begin{array}{cc} A & 0 \\ 0 & B \end{array} \right) \) represents the form \( \varphi \oplus \psi \).
3. Let \( \varphi : V \times V \to R \) be a form and let \( n \in \mathbb{N}_0 \). If \( A \) is a matrix that represents \( \varphi \), then the matrix \( n \cdot A := \underbrace{A \oplus \cdots \oplus A}_{n\text{-times}} \) represents the form \( n \cdot \varphi \).

Before we can turn to topology we need to recall the following definition from page 1621.

\[^{1394}\text{Note that a form is by definition (anti-)symmetric. It follows from this fact that the given condition is satisfied if and only if the condition with the two entries of \( \varphi \) swapped is satisfied. Thus the definition we give here is indeed consistent with the definition from page 2192.}\]

\[^{1395}\text{It is easy though to get confused.}\]
Definition. Given a finitely generated abelian group $H$ we refer to

$$FH := H / \text{Tor}(H)$$

where Tor$(H)$ denotes the torsion subgroup of $H$ as the \textit{maximal torsion-free quotient} of $H$.

The following lemma summarizes everything we need to know about maximal torsion-free quotients.

Lemma 100.3.

1. The maps

$$H \mapsto FH \quad \text{and} \quad (\alpha : G \to H) \mapsto \left( \alpha : FG \to FH \quad [g] \mapsto [\alpha(g)] \right)$$

define a covariant functor from the category of finitely generated abelian groups to the category of finitely generated free abelian groups.

2. For every homomorphism $\alpha : A \to B$ between two finitely generated abelian groups the following diagram commutes:

$$\begin{array}{ccc}
A & \xrightarrow{\alpha} & B \\
\downarrow{\alpha \mapsto [a]} & & \downarrow{\beta \mapsto [b]} \\
FA & \xrightarrow{\alpha} & FB.
\end{array}$$

3. Any (anti-) symmetric pairing

$$\varphi : H \times H \to \mathbb{Z}$$

over a finitely generated abelian group descends to a well-defined form

$$FH \times FH \to \mathbb{Z}$$

$$([g], [h]) \mapsto \varphi(g, h).$$

Proof. In Lemma 65.4 we already showed that if $H$ is a finitely generated abelian group, then $FH$ is a finitely generated free abelian group. The remaining statements of the lemma are basically elementary.

Convention. On many occasions we do not distinguish in the notation between an element in an abelian group $H$ and the element it represents in the maximal torsion-free quotient $FH$. Furthermore, given a homomorphism $\alpha : A \to B$ between two finitely generated abelian groups we often denote the induced map $FA \to FB$ by $\alpha$ as well.

100.2. \textbf{The definition of the intersection form of topological manifolds.} Let $M$ be a compact oriented $m$-dimensional topological manifold and let $A$ and $B$ be compact $(m - 1)$-dimensional submanifolds of $\partial M$ with $A \cup B = \partial M$ and with $A \cap B = \partial A = \partial B$.

\footnote{In fancy speak this means that the projection maps $H \to FH$ define a natural transformation from the identity functor to the functor $H \mapsto FH$.}
Recall that by the Poincaré Duality Theorem we know that for any \( k \in \mathbb{N}_0 \) the map
\[
H^{m-k}(M, A; \mathbb{Z}) \to H_k(M, B; \mathbb{Z})
\]
\( \varphi \mapsto \varphi \cap [M] \)
is an isomorphism. As on page 2153 we denote by
\[
\text{PD}_M : H_k(M, A; \mathbb{Z}) \to H^{m-k}(M, B; \mathbb{Z})
\]
the inverse of this isomorphism. This leads us to the following definition.

**Definition.** Let \( M \) be a compact oriented topological manifold of the even dimension \( 2n \). We refer to the map
\[
Q_M : \text{FH}_n(M; \mathbb{Z}) \times \text{FH}_n(M; \mathbb{Z}) \to \mathbb{Z}
\]
\( (a, b) \mapsto \langle \text{PD}_M(a) \cup \text{PD}_M(b), [M] \rangle \)
as the *intersection form* of \( M \).

**Remark.** Since \( \text{PD}_M : H_n(M; \mathbb{Z}) \to H^n(M, \partial M; \mathbb{Z}) \) is an isomorphism it is clear that the intersection form is basically just a reformulation of the cup product pairing
\[
H^n(M, \partial M; \mathbb{Z}) \times H^n(M, \partial M; \mathbb{Z}) \to H^{2n}(M, \partial M; \mathbb{Z})
\]
\( (\alpha, \beta) \mapsto \alpha \cup \beta \)
on cohomology groups in the middle dimension that we introduced in Proposition 90.2. The big psychological advantage of homology is that very often one can “see homology classes”. For example, in many cases homology classes are represented by submanifolds and we can then use Theorem 94.5 to compute the intersection form of a smooth manifold. Sometimes we can also represent homology classes by explicit cycles and we can use Theorem 95.9 to compute the intersection form.

**Examples.**

(1) First we consider the surface \( M \) of genus 3. In principle we could obtain the intersection form from the calculation of the cup product that we had performed in Lemma 81.16. But it is much more fun and instructive to use Theorem 94.5 instead. More precisely, we consider the surface \( M \) that is illustrated in Figure 1424. We give it the usual orientation. We already saw in the discussion on page 1270 that the closed oriented curves \( a_1, b_1, a_2, b_2, a_3, b_3 \) illustrated in Figure 1424 represent a basis for \( H_1(M; \mathbb{Z}) \). It follows easily from Theorem 94.5 that with respect to this basis the intersection form is represented by the matrix shown in Figure 1424. An analogous statement holds of course for any surface of genus \( g \geq 1 \).

---

1397 Note that the homology group \( H_n(M; \mathbb{Z}) \) in the middle dimension is not necessarily torsion-free. For example \( M = S^1 \times \mathbb{R}^3 \) is orientable, but it follows easily from the Künneth Formula and the calculation of the homology groups of \( \mathbb{R}^3 \) in Proposition 48.10 that \( H_2(S^1 \times \mathbb{R}^3; \mathbb{Z}) \cong \mathbb{Z} \).

1398 As mentioned above, in the notation usually we do not distinguish between an element in \( H_n(M; \mathbb{Z}) \) and the element it represents in \( \text{FH}_n(M; \mathbb{Z}) \).

1399 What do the curves \( a_i \) and \( b_i \) look like in the more precise description of the surface of genus 3 as a dodecagon with identified sides?
In both cases we see that with respect to this basis the intersection form of $\mathcal{H}^c$ is represented by the matrix given in Figure 1425.

$$Q_M = \begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & -1 & 0
\end{pmatrix}$$

Figure 1425

(2) Next we let $M$ be the surface of genus two with three disks removed that is shown in Figure 1424. By the discussion on page 1274 we know that a basis for $H_1(M; \mathbb{Z})$ is represented by the curves $a_1, b_1, a_2, b_2$ together with two out of the three boundary curves $c_1, c_2, c_3$. It follows from Theorem 94.5 that with respect to the basis $[a_1], [b_1], [a_2], [b_2], [c_1], [c_2]$ the intersection form is represented by the matrix given in Figure 1425.

$$Q_M = \begin{pmatrix}
0 & 1 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}$$

Figure 1425

(3) Next let us consider the $2n$-dimensional torus $M = S^n \times S^n$. By the Künneth Formula 58.8 we know that a basis for $H_n(S^n \times S^n; \mathbb{Z})$ is given by $a = [S^n \times \{\ast\}]$ and $b = [\{\ast\} \times S^n]$. We have two approaches for determining the intersection with respect to this basis:

(a) We can use the Product Theorem 84.1 and its corollaries. More precisely, we first determine the Poincaré duals of $[S^n \times \{0\}]$ and $[\{0\} \times S^n]$ as in Proposition 84.2 (2) and then we can apply Lemma 84.3.

(b) As on page 2278 we can use algebraic intersection numbers and Theorem 94.5 to determine the intersection form.

In both cases we see that with respect to this basis the intersection form of $S^n \times S^n$ is represented by the matrix

$$\begin{pmatrix}
Q_M(a,a) & Q_M(a,b) \\
Q_M(b,a) & Q_M(b,b)
\end{pmatrix} = \begin{pmatrix}
0 & 1 \\
(-1)^n & 0
\end{pmatrix}.$$

(4) We consider the complex manifold $\mathbb{C}P^2$. As always we equip $\mathbb{C}P^2$ with the natural orientation coming from Proposition 12.7. It follows from Proposition 94.11 that the intersection form

$$Q_{\mathbb{C}P^2}: H_2(\mathbb{C}P^2; \mathbb{Z}) \times H_2(\mathbb{C}P^2; \mathbb{Z}) \to \mathbb{Z}$$
is represented by the $1 \times 1$-matrix $(1)$.

(5) Let $M$ be a closed oriented $2n$-dimensional topological manifold. As usual we denote by $-M$ the same topological manifold with the opposite orientation. It follows immediately from the definitions together with Proposition 72.2 that $Q_{-M} = -Q_M$.

(6) For the complex projective space $\mathbb{CP}^2$ we use the common notation that we write $\mathbb{CP}^2$ instead of $-\mathbb{CP}^2$. With this notation it follows from (4) and (5) that the intersection form

$$Q_{\mathbb{CP}^2}: H_2(\mathbb{CP}^2; \mathbb{Z}) \times H_2(\mathbb{CP}^2; \mathbb{Z}) \to \mathbb{Z}$$

is represented by the $1 \times 1$-matrix $(-1)$.

100.3. **Properties of the intersection form.** In the following proposition we summarize some of the key properties of the intersection form. The proposition shows in particular that the intersection form is a form in the sense of the definition on page 2410.

**Proposition 100.4.** Let $M$ be a compact oriented $2n$-dimensional topological manifold. Then the following hold:

1. The group $H_n(M; \mathbb{Z})$ is finitely generated and $FH_n(M; \mathbb{Z})$ is a finitely generated free abelian group.
2. If $n$ is even, then the intersection form $Q_M$ is symmetric, otherwise it is antisymmetric.
3. If $M$ is closed, then the intersection form is non-singular.

The proof of Proposition 100.4 (3) relies on the following reformulation of the intersection form, which will also be useful later, on a separate occasion.

**Lemma 100.5.** (*) Let $M$ be a compact oriented connected $2n$-dimensional topological manifold. We denote by $i: (M, \emptyset) \to (M, \partial M)$ the inclusion map. We write

$$\Phi: H_n(M; \mathbb{Z}) \xrightarrow{i^*} H_n(M, \partial M; \mathbb{Z}) \xrightarrow{PD_M} H^n(M; \mathbb{Z}) \xrightarrow{ev} \text{Hom}(FH_n(M; \mathbb{Z}), \mathbb{Z}).$$

For any $a, b \in FH_n(M; \mathbb{Z})$ we have

$$Q_M(a, b) = \Phi(b)(a).$$

**Proof of Lemma 100.5** (*). First we consider the following diagram:

$$
\begin{array}{ccc}
H_n(M; \mathbb{Z}) \times H_n(M; \mathbb{Z}) & \xrightarrow{id \times i^*} & H_n(M; \mathbb{Z}) \times H_n(M, \partial M; \mathbb{Z}) \\
\downarrow{PD_M \times PD_M} & & \downarrow{PD_M \times PD_M} \\
H^n(M, \partial M; \mathbb{Z}) \times H^n(M, \partial M; \mathbb{Z}) & \xrightarrow{id \times i^*} & H^n(M, \partial M; \mathbb{Z}) \times H^n(M; \mathbb{Z}) \\
\downarrow{\cup} & & \downarrow{\cup} \\
H^{2n}(M, \partial M; \mathbb{Z}) & = & H^{2n}(M, \partial M; \mathbb{Z}).
\end{array}
$$

By Proposition 88.26 we know that the upper square commutes. We obtain from Proposition 82.4 applied to the inclusion map $f: (M, \emptyset, \partial M) \to (M, \partial M, \partial M)$, that the lower square also commutes.
Now let $a, b \in \text{FH}_n(M; \mathbb{Z})$. We calculate that

$$Q_M(b, a) \equiv \langle \text{PD}_M(b) \cup \text{PD}_M(a), [M] \rangle$$

by the above commutative diagram

$$\uparrow \quad \text{Lemma 83.7}$$

$$= \text{PD}_M(i_*(a)) \cap b$$

$$\uparrow \quad \text{definition of PD}_M(b)$$

$$= \langle \text{PD}_M(i_*(a)), b \rangle = \Phi(a)(b).$$

Proof of Proposition 100.4.

(1) We proved this statement in Proposition 85.13.

(2) Given $v, w \in \text{FH}_n(M; \mathbb{Z})$ we have the following equality:

$$\langle \text{PD}_M(v) \cup \text{PD}_M(w), [M] \rangle = (-1)^{n-n} \cdot \langle \text{PD}_M(w) \cup \text{PD}_M(v), [M] \rangle.$$

The statement follows from the observation that $(-1)^{n-n} = (-1)^n$.

(3) Now suppose that $M$ is closed. We consider the following diagram:

$$\begin{array}{ccc}
\text{FH}_n(M; \mathbb{Z}) & \xrightarrow{\text{PD}_M} & \text{FH}^n(M; \mathbb{Z}) \\
\downarrow^{=} & \uparrow^{\text{ev}} & \downarrow^{\text{ev}} \\
\text{Hom}(\text{FH}_n(M; \mathbb{Z}), \mathbb{Z}).
\end{array}$$

We make the following observations:

(a) Since $M$ is closed the map $\text{PD}_M$ does indeed take values in the cohomology of $M$. Furthermore, by the Poincaré Duality Theorem 88.1 the map $\text{PD}_M$ is an isomorphism.

(b) It follows from the Universal Coefficient Theorem 75.13 for Cohomology Groups together with Lemma 75.5 (5) and Proposition 85.13 (4) that the evaluation map

$$\text{ev}: \text{FH}^n(M; \mathbb{Z}) \to \text{Hom}(\text{FH}_n(M; \mathbb{Z}), \mathbb{Z}).$$

is an isomorphism.

(c) The diagram commutes by Lemma 100.5.

(d) We had just seen that the two diagonal maps are isomorphisms and that the diagram commutes. Thus we obtain that the top map is an isomorphism. By the definition on page 2411 this means precisely that the intersection form is non-singular.

\[\boxed{\text{Remark.}}\]

Let $M$ be a compact oriented $2n$-dimensional topological manifold. In Proposition 100.4 we just saw that if $M$ is closed, then the intersection form is non-singular. If $M$ is not closed, then this conclusion does not necessarily hold. For example in Figure 1426 we let $M$ be the torus minus two open disks. We show a basis $\{a, b, c\}$ for $H_1(M; \mathbb{Z})$. Using Theorem 94.5 one can easily see that the intersection form of $M$ with respect to the
given basis is represented by the matrix given in the figure. We see that the intersection form is anything but non-singular, in fact it is not even non-degenerate.\footnote{In fact the annulus \([0, 1] \times S^1\) also works as an example, but it is less fun.} Note though that in Proposition \footnote{Note that by Corollary \ref{cor:induced-map} we know that the induced map \(f_* : H_2(M, \partial M; \mathbb{Z}) \to H_2(N, \partial N; \mathbb{Z})\) is an isomorphism. By Corollary \ref{cor:generator} the fundamental classes are generators of the homology groups. Thus one of the two cases has to occur.} \footnote{The proof is perhaps slightly longer than one might expect. In a sense the statement of the lemma is basically trivial, but we have to pay a price for using the slightly awkward Poincaré Duality isomorphism \(PD_M : H_0(M; \mathbb{Z}) \to H^{2n-n}(M, \partial M; \mathbb{Z})\).} Proposition \ref{prop:two-pairings} we will see that even to a topological manifold that is not closed we can associate two pairings that are non-singular or at least non-degenerate.

In the next lemma we want to see to what degree the isometry type of the intersection form is an invariant of the homeomorphism type of the smooth manifold.

**Lemma 100.6.** Let \(M\) and \(N\) be compact oriented connected \(2n\)-dimensional topological manifolds. Let \(f : (M, \partial M) \to (N, \partial N)\) be a homotopy equivalence of pairs of topological spaces.\footnote{\textsuperscript{1401}Note that by Corollary \ref{cor:induced-map} we know that the induced map \(f_* : H_2(M, \partial M; \mathbb{Z}) \to H_2(N, \partial N; \mathbb{Z})\) is an isomorphism. By Corollary \ref{cor:generator} the fundamental classes are generators of the homology groups. Thus one of the two cases has to occur.}

1. If \(f_*([M]) = [N]\), then \(f\) induces an isometry \(Q_M \cong Q_N\).
2. If \(f_*([M]) = -[N]\), then \(f\) induces an isometry \(Q_M \cong -Q_N\).

Note that if \(f\) is a homeomorphism, then it follows from Proposition \ref{prop:homeomorphism} that the first case occurs precisely when \(f\) is orientation-preserving and the second case occurs precisely when \(f\) is orientation-reversing.

**Proof.**\footnote{\textsuperscript{1402}The proof is perhaps slightly longer than one might expect. In a sense the statement of the lemma is basically trivial, but we have to pay a price for using the slightly awkward Poincaré Duality isomorphism \(PD_M : H_0(M; \mathbb{Z}) \to H^{2n-n}(M, \partial M; \mathbb{Z})\).} Let \(f : (M, \partial M) \to (N, \partial N)\) be a homotopy equivalence of pairs of topological spaces. It follows from Corollary \ref{cor:induced-map} together with Corollary \ref{cor:generator} (3) that there exists an \(\varepsilon \in \{-1, 1\}\) which satisfies \(f_*([M]) = \varepsilon \cdot [N]\).

**Claim.** For any \(c \in H_n(M; \mathbb{Z})\) we have \(PD_N(f_*(c)) = \varepsilon \cdot (f^{-1})^*(PD_M(c)) \in H^n(N, \partial N; \mathbb{Z})\).

So let \(c \in H_n(M; \mathbb{Z})\). We have

\[
(f^{-1})^*(PD_M(c)) \cap [N] = (f^{-1})^*(PD_M(c)) \cap \varepsilon \cdot f_*([M]) = \varepsilon \cdot f_*(PD_M(c) \cap [M]) = \varepsilon \cdot f_*(c).
\]

by the definition of \(\varepsilon\), \textsuperscript{\ref{lemma:3.8}} definition of \(PD_M\)

It follows from the definition of \(PD_N\) that we get the desired equality. \(\square\)
Now let \(a, b \in FH_n(M; \mathbb{Z})\). Then

\[
Q_N(f_*(a), f_*(b)) = \langle PD_N(f_*(a)) \cup PD_N(f_*(b)), [N] \rangle
\]

by definition of \(Q_N\)

by the claim

\[
Q_N(f_*(a), f_*(b)) = \varepsilon \cdot ((f^{-1})^*(PD_M(a)) \cup \varepsilon \cdot (f^{-1})^*(PD_M(b)), \varepsilon \cdot f_*([M]))
\]

The lemma now follows from the observation that it follows from the hypothesis that \(f\) is a homotopy equivalence together with Corollary \[42.8\] that \(f_* : FH_n(M; \mathbb{Z}) \to FH_n(N; \mathbb{Z})\) is an isomorphism.

\(\square\)

100.4. The intersection form and degree-one maps. As we remarked on page 2413, the intersection form of a compact oriented \(2n\)-dimensional topological manifold contains basically the same information as the cup product pairing

\[
H^n(M, \partial M; \mathbb{Z}) \times H^n(M, \partial M; \mathbb{Z}) \to H^{2n}(M, \partial M; \mathbb{Z})
\]

\((\alpha, \beta) \mapsto \alpha \cup \beta.\)

Given a map \(f : X \to Y\) between topological spaces it follows from Lemma \[81.10\] that the cup product behaves well under the induced maps \(f^*\) on cohomology groups. It stands to reason that the intersection form should also behave well with respect to induced maps on homology.

So suppose we are given a degree-one map \(f : X \to Y\) between closed oriented connected \(2n\)-dimensional topological manifolds. By the aforementionedLemma \[81.10\] we know that for any \(\alpha \in FH^i(Y; \mathbb{Z})\) and \(\beta \in FH^j(Y; \mathbb{Z})\) we have \(f^*\alpha \cup f^*\beta = f^*(\alpha \cup \beta)\). It seems reasonable to expect that given \(\alpha \in H_n(X; \mathbb{Z})\) and \(\beta \in H_n(X; \mathbb{Z})\) the following equality holds:

\[
(\ast) \quad Q_X(\alpha, \beta) = Q_Y(f_*(\alpha), f_*(\beta)).
\]

In fact here is a diagram that looks awfully relevant:

\[
\begin{array}{ccc}
H_n(X; \mathbb{Z}) \times H_n(X; \mathbb{Z}) & \xrightarrow{PD \times PD} & H^n(X; \mathbb{Z}) \times H^n(X; \mathbb{Z}) \\
\downarrow f_* \times f_* & & \downarrow f^* \times f^* \\
H_n(Y; \mathbb{Z}) \times H_n(Y; \mathbb{Z}) & \xrightarrow{PD \times PD} & H^n(Y; \mathbb{Z}) \times H^n(Y; \mathbb{Z})
\end{array}
\]

\[
\begin{array}{cc}
\xrightarrow{\sim} & \quad \xrightarrow{\sim} \\
\downarrow f_* \times f_* & \downarrow f^* \times f^* \\
\downarrow f_* \times f_* & \downarrow f^* \times f^* \\
\end{array}
\]

\[
\begin{array}{cc}
H^{2n}(X; \mathbb{Z}) & \xrightarrow{\sim} \\
\downarrow f^* \times f^* & \downarrow f^* \times f^* \\
H^{2n}(Y; \mathbb{Z}) & \xrightarrow{\sim}
\end{array}
\]

\[
\begin{array}{cc}
\xrightarrow{\langle -[X]\rangle} & \quad \xrightarrow{\langle -[Y]\rangle} \\
\downarrow & \downarrow \\
\mathbb{Z} & \mathbb{Z}
\end{array}
\]

If this diagram did commute, then \((\ast)\) would hold. One could now waste a lot of time trying to convince oneself that the diagram commutes. Or alternatively one might notice, as we do in the following example, that \((\ast)\) just does not hold in general.

**Example.** We consider the map \(f : S^1 \times S^1 \to S^2\) that is illustrated in Figure \[1427\].

It follows easily from Lemma \[72.3\] that this is a degree-one map. We consider the two homology classes \(\alpha\) and \(\beta\) on the torus that are sketched in Figure \[1427\]. Note that it follows easily from Theorem \[94.5\] that \(Q_{S^1 \times S^1}(\alpha, \beta) = +1\). On the other hand note that we
have \( f_*(\alpha) = f_*(\beta) = 0 \in H_1(S^2;\mathbb{Z}) \), which evidently implies that \( Q_{S^2}(f_*(\alpha), f_*(\beta)) = 0 \). Thus in this case the equality \((*)\) does not hold.\footnote{1403}

\[
\begin{array}{c}
\begin{array}{c}
\text{Figure 1427}
\end{array}
\end{array}
\]

**Remark.** With this discussion we also learned an interesting lesson:

\begin{quote}
Not every diagram commutes, not even up to sign.
\end{quote}

100.5. **The connected sum of topological manifolds.** To get more examples of interesting intersection forms we want to study the intersection forms of the connected sum of smooth and topological manifolds. Recall that on page 377 we introduced the connected sum of two smooth manifolds. In this section we will now also define the connected sum of topological manifolds. The reader who is not interested in topological manifolds can safely move on to the next section.

For those who are staying, let us recall the definition of the connected sum of two oriented smooth manifolds.

**Definition.** Let \( n \in \mathbb{N} \) and let \( M \) and \( N \) be two connected oriented non-empty \( n \)-dimensional smooth manifolds. Furthermore let \( \varphi: \overline{B}^n \to M \setminus \partial M \) and \( \psi: \overline{B}^n \to N \setminus \partial N \) be smooth embeddings such that \( \varphi \) is orientation-preserving and such that \( \psi \) is orientation-reversing. We define the connected sum of the oriented smooth manifolds \( M \) and \( N \) as

\[
M \# N := (M \setminus \varphi(B^n)) \sqcup (N \setminus \psi(B^n)) / \sim \quad \text{where } \varphi(P) \sim \psi(P) \text{ for all } P \in S^{n-1}.
\]

In Proposition 8.35 we showed that the connected sum of two oriented smooth manifolds is again a smooth manifold.

\[
\begin{array}{c}
\begin{array}{c}
\text{Figure 1428}
\end{array}
\end{array}
\]

Now we intend to generalize this notion to the setting of topological manifolds. The idea is to suitably adapt the concepts used in the above definition. Browsing through earlier chapters we see the following:

1. On page 116 we defined an embedding to be a map \( f: X \to Y \) between two topological spaces that is a homeomorphism onto its image.
2. On page 2105 we introduced the notion of an orientation of a topological manifold and of an orientation-preserving map.

\footnote{1403} This still begs the question, in the above diagram, which of the squares does not commute?
So are we done? Can we just copy-paste the above definition?

As we had just mentioned, in Proposition 8.35 we showed that the connected sum of two oriented smooth manifolds is again a smooth manifold. Recall that the proof of Proposition 8.35 relied heavily on Proposition 8.1 which says that the image of a smooth embedding \( f : X \to Y \setminus \partial Y \) is a smooth submanifold of the smooth manifold \( Y \).

The question arises, whether the analogous statement holds for topological manifolds. In other words, we have the following question.

**Question 100.7.** Let \( X \) be an \( n \)-dimensional topological manifold. Is the image of an embedding \( f : \overline{B}^n \to X \setminus \partial X \) necessarily a topological submanifold of \( X \)?

For better or worse the answer to Question 100.7 is no\(^{1404}\). Namely consider the embedding \( f : \overline{B}^3 \to \mathbb{R}^3 \) that is illustrated in Figure 1429. We refer to the image \( f(\overline{B}^3) \) as the Alexander horned ball\(^{1405}\). It is clear that this is a weird embedding. We leave it to the reader to make the embedding precise and to show that \( f(\overline{B}^3) \) is not a topological submanifold of \( \mathbb{R}^3 \). But even without filling in all details this map should shatter the reader’s confidence that Question 100.7 has a positive answer.

\[
\begin{align*}
\overline{B}^3 & \xrightarrow{f} \text{Alexander horned ball} \\
\end{align*}
\]

Figure 1429

This stupefying example leads us to the following definition.

**Definition.** Let \( X \) and \( Y \) be topological manifolds. We say an embedding \( f : X \to Y \) is locally flat if \( f(X) \) is a submanifold of \( Y \).

With this definition we can now finally give a reasonable definition of the connected sum of two topological manifolds. For completeness’ sake we now also define the connected sum if one or both topological manifolds involved are non-orientable.

**Definition.** Let \( n \in \mathbb{N} \). Let \( M \) and \( N \) be two connected non-empty \( n \)-dimensional topological manifolds.

1. Suppose that at least one of \( M \) or \( N \) is non-orientable. We pick two locally flat embeddings \( \varphi : \overline{B}^n \to M \setminus \partial M \) and \( \psi : \overline{B}^n \to N \setminus \partial N \) and we define the connected sum of \( M \) and \( N \) as

\[
M \# N := (M \setminus \varphi(B^n)) \cup (N \setminus \psi(B^n)) / \sim \quad \text{where} \quad \varphi(P) \sim \psi(P) \quad \text{for all} \quad P \in S^{n-1}.
\]

\(^{1404}\)That is not really a surprise, on page 2065 we already saw wild knots in \( \mathbb{R}^3 \) and on page 1297 we saw the Alexander horned sphere. Both give examples of embeddings of topological manifolds such that the image is not a submanifold.

\(^{1405}\)On page 1297 we referred to \( f(S^2) \) as the Alexander horned sphere.
We always equip the connected sum of the oriented topological manifolds $M$ and $N$ as

$$M \# N := (M \setminus \varphi(B^n)) \sqcup (N \setminus \psi(B^n))/ \sim \quad \text{where } \varphi(P) \sim \psi(P) \text{ for all } P \in S^{n-1}.$$  

We refer to Figure 1430 for an illustration. For completeness we define the connected sum of an empty manifold with another connected topological manifold $M$ to be $M$, i.e. we set $\emptyset \# M := M \# \emptyset := M$.

**Figure 1430**

The following proposition is the analogue of Proposition 8.35

**Proposition 100.8.** Let $n \in \mathbb{N}$. Let $M$ and $N$ be two connected $n$-dimensional topological manifolds. (If both $M$ and $N$ are orientable, then we demand that $M$ and $N$ are oriented.) Let $\varphi: \overline{B}^n \to M \setminus \partial M$ and $\psi: \overline{B}^n \to N \setminus \partial N$ be two locally flat embeddings. (If $M$ and $N$ are orientable, then we demand that $\varphi$ is orientation-preserving and that $\psi$ is orientation-reversing.) The following five statements hold:

1. The resulting connected sum $M \# N$ is an $n$-dimensional topological manifold such that $M \setminus \varphi(B^n)$ and $N \setminus \psi(B^n)$ are submanifolds.
2. If $M$ and $N$ are closed, then $M \# N$ is also a closed topological manifold.
3. If $n \geq 2$ or if at least one of $M$ or $N$ is closed, then $M \# N$ is also connected.
4. The homeomorphism type of $M \# N$ does not depend on the choice of $\varphi$ and $\psi$.
5. If $M$ and $N$ are both oriented, then the topological manifold $M \# N$ admits a unique orientation that coincides with the orientations of the submanifolds $M \setminus \varphi(B^n)$ and $N \setminus \psi(B^n)$.

**Convention.** We always equip the connected sum of two oriented connected topological manifolds with the orientation from Proposition 100.8 (5).

Most of the statements of Proposition 100.8 are easy to prove.

**Proof of Proposition 100.8** (1), (2), (3) and (5). The proof is basically identical to the proofs of the corresponding statements in the smooth setting that we proved in Proposition 8.35. There are just a few minor modifications that we need to make:

1. We used Proposition 8.2 to show that the image of a smooth embedding is a submanifold. This feature is now built into the definition of a locally flat embedding.
2. We need to replace Propositions 8.2 and 8.15 by Propositions 44.3 and 44.8.  

The fact that the connected sum operation does not really depend on the choice of the locally flat topological embeddings is much more difficult to prove. The key to doing so is the following theorem.

**Theorem 100.9. (Annulus Theorem)** Let \( n \in \mathbb{N} \) and let \( \varphi, \psi : \overline{B}^n \to \mathbb{R}^n \) be two locally flat embeddings. If \( \varphi(\overline{B}^n) \subset \psi(\overline{B}^n) \), then \( \psi(\overline{B}^n) \setminus \varphi(\overline{B}^n) \) is homeomorphic to \([0, 1] \times S^{n-1}\).

![Figure 1431. Illustration of the Annulus Theorem 100.9](image)

**Proof.** The case \( n = 1 \) is trivial. For \( n = 2 \) and \( n = 3 \) the Annulus Theorem follows from the work of Tibor Radó [Rad26] and Edwin Moise [Mois52, Mois77]. The Annulus Theorem was proved for dimensions \( n \geq 5 \) by Rob Kirby [Kir69] and in dimension 4 by Frank Quinn [Quin82, p. 506]. We also refer to [Edw84, p. 247] for more information. □

Using the Annulus Theorem 100.9 one can now prove the following theorem which can be viewed as the topological analogue of Theorem 8.36.

**Theorem 100.10.** Let \( M \) be an \( n \)-dimensional topological manifold. (If \( M \) is orientable, then we pick an orientation for \( M \).) In the following let \( \varphi_1, \ldots, \varphi_m : \overline{B}^n \to M \setminus \partial M \) and \( \psi_1, \ldots, \psi_m : \overline{B}^n \to M \setminus \partial M \) be two sets of \( m \) locally flat embeddings of \( \overline{B}^n \) with disjoint images. (If \( M \) is orientable, then we demand that all \( \varphi_i \) and \( \psi_i \) are orientation-preserving or that all are orientation-reversing.) If \( n \geq 2 \) or if \( m = 1 \), then there exists a homotopy

\[
F : M \times [0, 1] \to M
\]

rel some neighborhood of \( \partial M \) from the identity \( F_0 = \text{id}_M \) to a homeomorphism \( F_1 : M \to M \) such that for each \( i \in \{1, \ldots, m\} \) we have \( F_1 \circ \varphi_i = \psi_i \). (Note that if \( M \) is orientable, then the homeomorphism \( F_1 \) is in fact orientation-preserving by Exercise 86.3).

![Figure 1432. Illustration of Theorem 100.10](image)

**Remark.** We consider \( \overline{B}^3 \) as a submanifold of \( \mathbb{R}^3 \). Since the image of the embedding \( \varphi : \overline{B}^3 \to \mathbb{R}^3 \) that is given by the Alexander horned ball is not a submanifold of the topological manifold we see that there is no homeotopy \( F : \mathbb{R}^3 \times [0, 1] \to \mathbb{R}^3 \) with \( F_1 \circ \varphi = \text{id} \). In particular we see that in the formulation of Theorem 100.10 we cannot drop the hypothesis that the embeddings are locally flat.
Proof of Theorem 100.10. This theorem follows from the Annulus Theorem [100.9] together with reasonably elementary arguments. The details are worked out in [FNP19] Proof of Theorem 5.11. Alternatively the reader is encouraged to assemble the argument by using the obvious analogues Exercise 17.6 and Exercise 8.7, which were both formulated in the setting of smooth manifolds, in the setting of topological manifolds.

Proof of Proposition 100.8 (4). Thanks to our preparations the proof is basically identical to the proof of the corresponding statement in the smooth setting that we proved in Proposition 8.35. All we need to is to replace Theorem 8.36 by Theorem 100.10.

100.6. The intersection form and the connected sum operation. First let use see how the homology groups and fundamental groups behave under the connected sum operation.

Proposition 100.11. Let $n \in \mathbb{N}$ and let $M$ and $N$ be two closed oriented connected $n$-dimensional topological manifolds. Furthermore let $\varphi: \mathbb{B}^n \to M$ be an orientation-preserving locally flat embedding and let $\psi: \mathbb{B}^n \to N$ be an orientation-reversing locally flat embedding. Then $H_0(M \# N; R) \cong H_n(M \# N; R) \cong R$. Furthermore, for any $i \neq 0, n$ and any commutative ring $R$ the following inclusion induced maps are isomorphisms

\[ H_i(M \# N; R) \cong H_i(M \setminus \varphi(B^n); R) \oplus H_i(N \setminus \psi(B^n); R) \cong H_i(M; R) \oplus H_i(N; R). \]

Furthermore if $n \geq 3$, then the following inclusion induced maps are isomorphisms

\[ \pi_1(M \# N) \cong \pi_1(M \setminus \varphi(B^n)) \ast \pi_1(N \setminus \psi(B^n)) \cong \pi_1(M) \ast \pi_1(N). \]

Proof (*). We proved the statements in Proposition 20.12 and Proposition 68.13 for smooth manifolds. The proof for topological manifolds is very similar, we just need to note that it follows from by Proposition 74.12 (5) and the Mayer–Vietoris Theorem 74.14 that the Mayer–Vietoris argument in the proof of Lemma 68.14 works for topological manifolds.

The next proposition says that the isomorphism of homology groups from Proposition 100.11 induces an isometry of intersection forms.

Proposition 100.12. Let $n \geq 1$ and let $M$ and $N$ be closed oriented $2n$-dimensional topological manifolds. Furthermore let $\varphi: \mathbb{B}^n \to M$ be an orientation-preserving locally flat embedding and let $\psi: \mathbb{B}^n \to N$ be an orientation-reversing locally flat embedding. The isomorphism $H_n(M \# N; \mathbb{Z}) \cong H_n(M; \mathbb{Z}) \oplus H_n(N; \mathbb{Z})$ from Proposition 100.11 induces an isometry

\[ Q_{M \# N} \cong Q_M \oplus Q_N \]

of forms.

Example. We consider the surface $\Sigma$ of genus two. In Figure 1433 we recall that we can view $\Sigma$ as the connected sum of two tori. It thus follows from Proposition 100.12, the discussion on page 2414 and Lemma 100.2 (2) that the intersection form on $H_1(\Sigma; \mathbb{Z}) \cong \mathbb{Z}^4$...
is represented by the matrix

\[
\begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix} \oplus \begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix} = \begin{pmatrix}
0 & 1 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & -1 & 0
\end{pmatrix}.
\]

Not surprisingly this recovers the result from page 2413.

**Remark.** Let \( n \geq 1 \) and let \( M \) and \( N \) be closed oriented \( 2n \)-dimensional topological manifolds. Furthermore let \( \varphi: \overline{B}^n \to M \) be an orientation-preserving locally flat embedding and let \( \psi: \overline{B}^n \to N \) be an orientation-reversing locally flat embedding. Figure 1433 suggests the following approach to proving Proposition 100.12:

1. First we pick \( n \)-dimensional cycles \( a_1, \dots, a_k \) in \( M \setminus \varphi(\overline{B}^n) \) such that \([a_1], \dots, [a_k]\) form a basis of \( \text{FH}_n(M; \mathbb{Z}) \) and which intersect nicely, in the sense of the definition on page 2312.
2. Similarly we pick transverse \( n \)-dimensional cycles \( b_1, \dots, b_l \) in \( N \setminus \psi(\overline{B}^n) \) such that \([b_1], \dots, [b_l]\) form a basis of \( \text{FH}_n(N; \mathbb{Z}) \) and which intersect nicely.
3. It follows immediately from Proposition 100.11 that \([a_1], \dots, [a_k], [b_1], \dots, [b_l]\) form a basis for \( \text{FH}_n(M\#N; \mathbb{Z}) \).
4. In Theorem 95.9 we saw that the intersection form of cycles that intersect nicely in terms of the algebraic intersection number that we introduced on page 2312. We use this fact together with the basis from (3) to determine the intersection form of \( M\#N \). Here we make the following observations:
   a. By the orientation conventions from Proposition 100.8 the algebraic intersection numbers of the \( a_i \) in \( M \) are the same as in \( M\#N \).
   b. Similarly the algebraic intersection numbers of the \( b_i \) in \( N \) are the same as in \( M\#N \).
   c. Since the \( a_i \) do not intersect the \( b_j \) we see that the algebraic intersection number \( a_i \cdot b_j = 0 \) for any \( i, j \).

Summarizing we obtain immediately from Theorem 95.9 that \( Q_M \oplus Q_N \cong Q_{M\#N} \).

The above argument sounds very convincing. But there is a major catch: how can we find such \( a_1, \dots, a_k \) and \( b_1, \dots, b_l \)? The problem is not that we need to avoid \( \varphi(\overline{B}^n) \) and \( \psi(\overline{B}^n) \). The problem is to find such cycles that are transverse. Even though we have

\[1406 \text{ Why is this not a problem?} \]
some tools, e.g. we have Theorem 9.15 and the Transversality Theorem 9.10 it is very hard to turn the above approach into a rigorous proof. Furthermore, any attempt to make this approach work would inevitably end up with an unreadable mess.

After the discussion in the previous remark we recall the advice from Rob Kirby [Kir80 p. 21], see page 2276.

“Think with [algebraic] intersection [numbers], prove with cup products.”

Thus we will use cup products to prove Proposition 100.12.

Proof of Proposition 100.12 (*). Throughout the proof let \( n \geq 1 \). We start out with a lengthy preparation. Thus let \( X \) and \( Y \) be two oriented connected \( 2n \)-dimensional topological manifolds such that \( \partial X \) and \( \partial Y \) are both homeomorphic to \( S^{2n-1} \). We equip \( \partial X \) and \( \partial Y \) with the orientation coming from Proposition 86.19. Let \( \theta : \partial X \to \partial Y \) be an orientation-reversing homeomorphism. We write \( Z = X \cup_{\theta} Y \). In the following we view \( X \) and \( Y \) as subsets of \( Z \). By Proposition 44.8 we know that \( X \) and \( Y \) are in fact codimension-zero submanifolds of \( Z \) and that we can equip \( Z \) with an orientation such that the induced orientations on \( X \) and \( Y \) are the given orientations.

![Figure 1434. Illustration for the proof of Proposition 100.12](image)

We start out with the following claim.

Claim. The inclusions \( i : X \to Z \) and \( j : Y \to Z \) induce an isometry

\[
Q_X \oplus Q_Y \cong Q_Z.
\]

As in Proposition 100.12 we see that the two inclusion maps \( i \) and \( j \) induce an isomorphism \( H_n(X; \mathbb{Z}) \oplus H_n(Y; \mathbb{Z}) \to H_n(Z; \mathbb{Z}) \). Evidently this isomorphism descends to an isomorphism \( \text{FH}_n(X; \mathbb{Z}) \oplus \text{FH}_n(Y; \mathbb{Z}) \to \text{FH}_n(Z; \mathbb{Z}) \). Therefore it suffices to prove the following three statements.

1. for \( a, b \in \text{FH}_n(X; \mathbb{Z}) \) we have \( Q_X(a, b) = Q_Z(i_*(a), i_*(b)) \),
2. for \( a, b \in \text{FH}_n(Y; \mathbb{Z}) \) we have \( Q_Y(a, b) = Q_Z(j_*(a), j_*(b)) \),
3. for \( a \in \text{FH}_n(X; \mathbb{Z}) \) and \( b \in \text{FH}_n(Y; \mathbb{Z}) \) we have \( Q_Z(i_*(a), j_*(b)) = 0 \).

We start out with the proof of the first statement. Thus let \( a, b \in \text{FH}_n(X; \mathbb{Z}) \). We write \( \hat{X} = X \setminus \partial X \). We denote by \( p : (Z, \emptyset) \to (Z, Z \setminus \hat{X}) \) and \( i : (X, \partial X) \to (Z, Z \setminus \hat{X}) \) the two obvious inclusion maps of pairs of topological spaces. It is a consequence of the Excision Theorem 43.20 for Topological Manifolds that \( i_* : \text{FH}_k(X, \partial X; \mathbb{Z}) \to \text{FH}_k(Z, Z \setminus \hat{X}; \mathbb{Z}) \) is
an isomorphism for every \( k \in \mathbb{N}_0 \). Then

\[
Q_X(a, b) = \langle \text{PD}_X(a) \cup \text{PD}_X(b), [X] \rangle = \langle (i^*)^{-1}(\text{PD}_X(a)) \cup (i^*)^{-1}(\text{PD}_X(b)), i_*([X]) \rangle
\]

by definition of \( Q_X \)

Lemma 74.6 (3) applied to \( i: (X, \partial X) \to (Z, Z \setminus \overset{\circ}{X}) \), together with Proposition 82.4 (1)

\[
= \langle p^*((i^*)^{-1}(\text{PD}_X(a))) \cup p^*((i^*)^{-1}(\text{PD}_X(b))), [Z] \rangle
\]

first note that by Lemma 87.24 we have, \( i_*([X]) = p_*([Z]) \), next apply

Lemma 4.6 (3) to \( p \), finally apply Proposition 82.4 (1) to \( p \)

\[
= \langle \text{PD}_Z(i_* (a)) \cup \text{PD}_Z(i_* (b)), [Z] \rangle = Q_Z(i_* (a), i_* (b)).
\]

by Lemma 80.5 we know that

\[
p^*((i^*)^{-1}(\text{PD}_X(c)) = \text{PD}_Z(i_* (c))
\]

The second statement is of course proved the same way. We turn to the proof of the third statement. So let \( a \in \text{FH}_n(X; \mathbb{Z}) \) and \( b \in \text{FH}_n(Y; \mathbb{Z}) \). The above argument shows that we can compute \( Q_Z(i_* (a), j_* (b)) \) in terms of the cup product in \( Z \) of an element in the image \( H^n(Z, Z \setminus \overset{\circ}{X}) \to H^n(Z) \) and an element in the image of \( H^n(Z, Z \setminus \overset{\circ}{Y}; \mathbb{Z}) \to H^n(Z; \mathbb{Z}) \). But \( (Z \setminus \overset{\circ}{X}) \cup (Z \setminus \overset{\circ}{Y}) = Z \). So it follows from Proposition 82.4 (1) that this cup product is zero.

After these preparations it is very easy to prove the actual statement of the proposition. Thus let \( M \) and \( N \) be closed oriented \( 2n \)-dimensional topological manifolds and let \( \varphi: \overset{\circ}{B}^{2n} \to M \) be an orientation-preserving locally flat embedding and let \( \psi: \overset{\circ}{B}^{2n} \to N \) be an orientation-reversing locally flat embedding. We write \( X = M \setminus \varphi(B^{2n}) \) and \( Y = N \setminus \psi(B^{2n}) \). It follows from the definition of a locally flat embedding together with Proposition 44.3 that \( X \) and \( Y \) are compact topological manifolds. With this notation we can write \( M = X \cup \overset{\circ}{B}^{2n} \) and \( N = Y \cup \overset{\circ}{B}^{2n} \). It follows from the claim and the fact that \( H_n(\overset{\circ}{B}^{2n}; \mathbb{Z}) = 0 \) that the inclusions induce isometries

\[
Q_{M \# N} \overset{\cong}{\twoheadleftarrow} Q_X \oplus Q_Y \overset{\cong}{\twoheadrightarrow} Q_M \oplus Q_N.
\]

We have thus proved the desired statement.

We recall the following question.

**Question 68.15.** Are the topological spaces \( \mathbb{C}P^2 \# \mathbb{C}P^2 \), \( \mathbb{C}P^2 \# \overline{\mathbb{C}P}^2 \) and \( S^2 \times S^2 \) homeomorphic?

These topological spaces are hard to distinguish since we saw that they are simply connected and that their (co-) homology groups agree. Now we want to look at the intersection forms to see whether they can help us in distinguishing these three smooth manifolds.

**Example.** On page 2415 we saw that the intersection form of \( \mathbb{C}P^2 \) is represented by the \( 1 \times 1 \)-matrix (1) and we saw that the intersection form of \( \overline{\mathbb{C}P}^2 \) is represented by the \( 1 \times 1 \)-matrix \((-1)\). From Proposition 100.12 we thus obtain:

(1) the intersection form of \( \mathbb{C}P^2 \# \mathbb{C}P^2 \) is represented by the matrix \( \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \), whereas
(2) the intersection form of \(\mathbb{CP}^2 \# \overline{\mathbb{CP}}^2\) is represented by the matrix \(\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\).

Finally we recall that on page 2414 we showed that

(3) the intersection form of \(S^2 \times S^2\) is represented by the matrix \(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\).

Motivated by Question 68.15 and Lemma 100.6 the following question arises.

**Question 100.13.** Are the forms over \(\mathbb{Z}^2\) represented by the matrices

\[
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.
\]

isometric (possibly up to a sign reversal)?

In Chapter refc:intersection-forms-ii we will develop the theory of non-singular forms to answer Question 100.13.

100.7. **The asymmetric intersection pairings \(\ast\).** On page 2416 we saw that the intersection form of a topological manifold with non-empty boundary can be degenerate. In this and the following section we will associate to a compact oriented topological manifold the asymmetric intersection pairings which are non-singular and the reduced intersection form which is at least non-degenerate.

Before we provide the definitions let us recall and introduce a new definition.

**Definition.** Let \(R\) be a commutative ring and let \(V, W\) and \(S\) be \(R\)-modules. Recall that according to the definition on page 2192 we say that a pairing \(\langle \cdot , \cdot \rangle : V \times W \to R\) is **non-singular** if the induced maps

\[
V \to \text{Hom}_R(W, S) \quad \text{and} \quad W \to \text{Hom}_R(V, S)
\]

are isomorphisms. We now say that the pairing is **non-degenerate** if the above two maps are both monomorphisms. Otherwise we say that the pairing is **degenerate**.

**Example.** Let \(R\) be a commutative domain and let \(A \in M(n \times n; R)\). Elementary algebra, similar to the proof of Lemma 90.1 shows that the form

\[
R^n \times R^n \rightarrow R, \quad (v, w) \mapsto v^T A w
\]

is non-singular if and only if \(\det(A)\) is a unit in \(R\) and it is non-singular if and only if \(\det(A)\) is non-zero.

For the record let us state the following lemma that follows almost immediately from the definitions.

**Lemma 100.14.** Let \(R\) be a commutative domain. Let \(V, W\) and \(S\) be \(R\)-modules and let

\[
\langle \cdot , \cdot \rangle : V \times W \to S
\]
be a pairing. The following two statements are equivalent:

1. The pairing is non-degenerate.
2. For every \( v \in V \) there exists a \( w \in W \) with \( \langle v, w \rangle \neq 0 \) and for every \( w \in W \) there exists a \( v \in V \) with \( \langle v, w \rangle \neq 0 \).

In Proposition 100.4 we saw that if we are given a closed oriented \( 2n \)-dimensional topological manifold \( M \), then the intersection form

\[
Q_M : FH_n(M; \mathbb{Z}) \times FH_n(M; \mathbb{Z}) \rightarrow \mathbb{Z}
\]

\[
(a, b) \mapsto \langle PD_M(a) \cup PD_M(b), [M] \rangle
\]

is non-singular. On page 2416 we saw that if \( M \) is not closed, then this conclusion does not necessarily hold. More precisely we gave an explicit example of a compact orientable smooth manifold, namely the torus minus two open disks, such that the intersection form is degenerate, in particular it is singular.

We move on to the definition of asymmetric intersection pairings on topological manifolds.

**Definition.** Let \( M \) be a compact oriented \( n \)-dimensional topological manifold and suppose that we are given two compact \((n - 1)\)-dimensional submanifolds \( A \) and \( B \) of \( \partial M \). We suppose that one of the following two conditions is satisfied:

1. We have \( \partial M = A \cup B \) and \( A \cap B = \partial A = \partial B \).
2. We have \( A \cap B = \emptyset \).

We write \( X := \partial M \setminus \breve{A} \) and \( Y := \partial M \setminus \breve{B} \). For each \( k \in \mathbb{N}_0 \) we refer to the pairing

\[
Q^*_M, A, B : FH_k(M, A; \mathbb{Z}) \times FH_{n-k}(M, B; \mathbb{Z}) \rightarrow \mathbb{Z}
\]

\[
(v, w) \mapsto \langle PD_M(v) \cup PD_M(w), [M] \rangle
\]

\[
\in H^{n-k}(M, X; \mathbb{Z}) \in H^k(M, Y; \mathbb{Z})
\]

\[
\in H^n(M, \partial M; \mathbb{Z})
\]

as an asymmetric intersection pairing of \( M \). When \( A \) and \( B \) are clear from the context we write \( Q^*_M \) instead of the cumbersome \( Q^*_M, A, B \).

**Remark.** In the previous definition, if we take \( A = B = \emptyset \), then we obtain precisely the intersection form as introduced on page 2413 in other words, \( Q^*_M, \emptyset, \emptyset = Q_M \).
Example. Let $M$ be the torus minus two open balls. We are interested in the (asymmetric) intersection pairings

$$Q_M : H_1(M; \mathbb{Z}) \times H_1(M; \mathbb{Z}) \to \mathbb{Z}$$

and

$$Q_{M,A,B}^{as} : H_1(M; \mathbb{Z}) \times H_1(M, \partial M; \mathbb{Z}).$$

We consider the four curves $a, b, c, d$ on $M$ that are shown in Figure 1436. Note that the curves $a, b, c$ represent a basis for $H_1(M; \mathbb{Z})$, whereas the curves $a, b, d$ represent a basis for $H_1(M, \partial M; \mathbb{Z})$. Using these bases and using Theorem 94.5 we see that

$$Q_M \text{ is represented by } \begin{pmatrix} a & b & c \\ 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad Q_{M,A,B}^{as} \text{ is represented by } \begin{pmatrix} a & b & d \\ 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Note that the former matrix has determinant zero whereas the latter matrix has determinant 1. This calculation, together with Lemma 90.1 shows that the former pairing is degenerate whereas the latter pairing is non-singular. As we will see in the next proposition, it is not a coincidence that in this particular example the asymmetric intersection pairing is non-singular.

**Proposition 100.15.** Let $M$ be a compact oriented $n$-dimensional topological manifold. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$.

1. Given any $k \in \mathbb{N}_0$ the following pairing is non-singular:

$$Q_{M,A,B}^{as} : FH_k(M, A; \mathbb{Z}) \times FH_{n-k}(M, B; \mathbb{Z}) \to \mathbb{Z}.$$

\[1430\] Why is that?

\[1411\] In fact, using this observation and Exercise 90.1 (c) one can easily answer the previous footnote.
For the remaining two statements of the proposition we assume that \( n = 2k \) is even. We denote by \( p_* : H_k(M;\mathbb{Z}) \to H_k(M,\partial M;\mathbb{Z}) \) the obvious map.

(2) The following diagram commutes:

\[
\begin{array}{ccc}
\text{FH}_k(M;\mathbb{Z}) \times \text{FH}_k(M;\mathbb{Z}) & \xrightarrow{Q_M} & \mathbb{Z} \\
\downarrow\text{id} \times p_* & & \downarrow\text{id} \\
\text{FH}_k(M;\mathbb{Z}) \times \text{FH}_k(M,\partial M;\mathbb{Z}) & \xrightarrow{Q_{M,\partial M}} & \mathbb{Z}.
\end{array}
\]

(3) Let \( v_1, \ldots, v_m \) be a basis of the free abelian group \( \text{FH}_k(M;\mathbb{Z}) \). By (1) together with Exercise 90.1 (a) there exists a unique “dual” basis \( v_1^*, \ldots, v_m^* \) of the free abelian group \( \text{FH}_k(M,\partial M;\mathbb{Z}) \) with \( Q_{M,\partial M}(v_j, v_j^*) = \delta_{ij} \) for all \( i, j \in \{1, \ldots, m\} \). With this notation the following diagram commutes:

\[
\begin{array}{ccc}
\text{FH}_k(M;\mathbb{Z}) & \xrightarrow{P_*} & \text{FH}_k(M,\partial M;\mathbb{Z}) \\
\cong \mathbb{Z}^m & \xrightarrow{\text{multiplication by } e_i \mapsto v_i^*} & \mathbb{Z}^m
\end{array}
\]

Put differently, let \( (Q_M(v_i, v_j))_{i,j=1,\ldots,m} \) be the \((m \times m)\) matrix that represents the intersection form \( Q_M \) with respect to the basis \( v_1, \ldots, v_m \). This matrix represents the map \( P_* : \text{FH}_k(M;\mathbb{Z}) \to \text{FH}_k(M,\partial M;\mathbb{Z}) \) with respect to the bases \( v_1, \ldots, v_m \) and \( v_1^*, \ldots, v_m^* \).

**Proof.**

(1) We consider the map

\[
\Psi : \text{FH}_k(M, A;\mathbb{Z}) \xrightarrow{\text{PD}_M} \text{FH}^{n-k}(M, B;\mathbb{Z}) \xrightarrow{\text{ev}} \text{Hom}(\text{FH}_{n-k}(M, B;\mathbb{Z}),\mathbb{Z}).
\]

First note that basically the same argument as in the proof of Lemma 100.5 shows that for every \( a \in \text{FH}_k(M, A;\mathbb{Z}) \) and every \( b \in \text{FH}_{n-k}(M, B;\mathbb{Z}) \) we have \( Q_{M,A,B}(a,b) = \Psi(b)(a) \). Furthermore note that as in the proof of Proposition 100.4 (3) we see that the two maps \( \text{PD}_M \) and \( \text{ev} : \text{FH}^{n-k}(M, B;\mathbb{Z}) \to \text{Hom}(\text{FH}_{n-k}(M, B;\mathbb{Z}),\mathbb{Z}) \) are isomorphisms. In particular \( \Psi = \text{ev} \circ \text{PD} \) is an isomorphism. Together with the remark on page 2193 this discussion implies that \( Q_{M,A,B} \) is non-singular.

(2) This statement follows easily from the definitions together with Lemma 83.8 and Proposition 82.4. In fact we will work out the details in the proof of Lemma 100.16 (2).

(3) Let \( i \in \{1, \ldots, m\} \). We write \( p_*(v_i) = \sum_{j=1}^m b_{ji} \cdot v_j^* \). Let \( j \in \{1, \ldots, m\} \). We see that

\[
b_{ji} = Q_{M,\partial M}^{\text{as}}(v_j, \sum_{k=1}^m b_{ki} \cdot v_k^*) = Q_{M,\partial M}^{\text{as}}(v_j, p_*(v_i)) = Q_M(v_j, v_i).
\]

Since \( Q_{M,\partial M}^{\text{as}}(v_j, v_j^*) = \delta_{jk} \)

This statement is a generalization of Proposition 100.4 (3).
Since by definition the matrix \((b_{ij})\) represents the map \(p_*\) with respect to the given bases we obtain the desired result.

In the remainder of this section we prove several properties of the asymmetric intersection pairings.

**Lemma 100.16.** Let \(M\) be a compact oriented connected \(n\)-dimensional topological manifold and suppose that we are given two compact \((n - 1)\)-dimensional submanifolds \(A\) and \(B\) of \(\partial M\). We suppose that one of the following two conditions is satisfied:

(i) We have \(\partial M = A \cup B\) and \(A \cap B = \partial A = \partial B\).
(ii) We have \(\mathring{A} \cap \mathring{B} = \emptyset\).

The following two statements hold.

1. If we are given \(v \in H_k(M,A;\mathbb{Z})\) and \(w \in H_{n-k}(M;\mathbb{Z})\), then
   \[ Q_{M,A,B}^{as}(v,w) = (-1)^{k(n-k)} \cdot Q_{M,B,A}^{as}(w,v). \]

2. Suppose we are given two compact \((n - 1)\)-dimensional submanifolds \(A'\) and \(B'\) of \(\partial M\) that also satisfy (i) or (ii) and that furthermore satisfy \(A \subset A'\) and \(B \subset B'\). We denote by \(p_c\) \((M,A) \to (M,A')\) and \(q: (M,B) \to (M,B')\) the obvious maps. For any \(v \in H_k(M,A';\mathbb{Z})\) and \(w \in H_{n-k}(M,B';\mathbb{Z})\) we have the following equality:
   \[ Q_{M,A',B'}^{as}(p_*v, q_*w) = Q_{M,A,B}^{as}(v,w). \]

**Proof.** (1). We write \(X = \partial M \setminus \mathring{A}\) and \(Y = \partial M \setminus \mathring{B}\).

1. Given \(v \in H_k(M,A;\mathbb{Z})\) and \(w \in H_{n-k}(M,B;\mathbb{Z})\) we have the following equality:
   \[
   \left\langle \frac{PD_M(v)}{\in H^{n-k}(M,X;\mathbb{Z})} \cup \frac{PD_M(w)}{\in H^k(M,Y;\mathbb{Z})}, [M] \right\rangle = (-1)^{(n-k)k} \cdot \left\langle \frac{PD_M(w)}{\in H^k(M,Y;\mathbb{Z})} \cup \frac{PD_M(v)}{\in H^{n-k}(M,X;\mathbb{Z})}, [M] \right\rangle.
   \]

   This follows immediately from Proposition 82.4.

2. Not surprisingly we write \(X' = \partial M \setminus \mathring{A}\) and \(Y' = \partial M \setminus \mathring{B}\). Note that by hypothesis we have \(X' \subset X\) and \(Y' \subset Y\). Let \(f: (M,X') \to (M,X)\) and \(g: (M,Y') \to (M,Y)\) be the obvious maps. Given \(v \in H_k(M,A';\mathbb{Z})\) and \(w \in H_{n-k}(M,B';\mathbb{Z})\) we have the following equality:
   \[
   \left\langle \frac{PD_M(p_*v)}{\in H^{n-k}(M,X';\mathbb{Z})} \cup \frac{PD_M(q_*w)}{\in H^k(M,Y';\mathbb{Z})}, [M] \right\rangle = \left\langle \frac{f^*(PD_M(v))}{\in H^{n-k}(M,X';\mathbb{Z})} \cup \frac{g^*(PD_M(w))}{\in H^k(M,Y';\mathbb{Z})}, [M] \right\rangle.
   \]

   This follows immediately from Lemma 83.8.

Our next result on asymmetric intersection pairing deals with the interplay between the asymmetric intersection pairing on a topological manifold and the asymmetric intersection pairings on its boundary.
Proposition 100.17. Let $M$ be a compact oriented $n$-dimensional topological manifold. Suppose that we are given a decomposition $\partial M = A \cup B$ where $A$ and $B$ are compact $(n-1)$-dimensional submanifolds of $\partial M$ such that $A \cap B = \partial A = \partial B$. Let $a \in H_k(A, \partial A; \mathbb{Z})$ and let $c \in H_{n-k+1}(M, A; \mathbb{Z})$. We denote by $w: (A, \partial A) \to (M, B)$ the obvious map and we denote by $\partial: H_{n-k+1}(M, A; \mathbb{Z}) \to H_{n-k}(A; \mathbb{Z})$ the connecting homomorphism of the long exact sequence in homology of the pair $(M, A)$. In this setting the following equality holds:

$$Q^\text{as}_{A, \mathbb{Z}, \partial A}(\partial c, a) = Q^\text{as}_{M, A, B}(c, w_*(a)).$$

In other words, the following diagram commutes in a suitable sense:

$$\begin{array}{ccc}
H_{n-k+1}(M, A; \mathbb{Z}) \times H_k(M, B; \mathbb{Z}) & \xrightarrow{\partial} & H_{n-k}(A; \mathbb{Z}) \times H_k(A, \partial A; \mathbb{Z}) \\
\downarrow w_* & & \downarrow Q^\text{as}_{M, A, B} \\
& \uparrow Q^\text{as}_{A, \mathbb{Z}, \partial A} & \rightarrow \mathbb{Z}.
\end{array}$$

\[\partial M\] is a 2-dimensional manifold

\[M\] is a 3-dimensional manifold

\[\text{Figure 1437. Illustration for Proposition 100.17}\]

In the proof of Proposition 100.17 we will need the following generalization of Lemma 82.6

Lemma 100.18. Let $(X, A, B)$ be an excisive triad of topological spaces and let $R$ be a commutative ring. We denote by $i: (A, A \cap B) \to (X, B)$ and $j: (A, A \cap B) \to (A \cup B, B)$ the inclusion maps and we denote by $\delta$ the connecting homomorphisms in the long exact sequence in cohomology corresponding to the pair $(X, A)$ and the triple $(X, A \cup B, B)$. Note that it follows from Lemma 104.13 (b) that $j^*: H^{p+q}(A \cup B, B; R) \to H^{p+q}(A, A \cap B; R)$ is an isomorphism. The following diagram commutes

$$\begin{array}{ccc}
H^p(A, A \cap B; R) \times H^q(A; R) & \xrightarrow{\cup} & H^{p+q}(A, A \cap B; R) \\
i^* & & \cong (j^*)^{-1} \\
\delta \downarrow & & \delta \\
H^p(X, B; R) \times H^{q+1}(X, A; R) & \xrightarrow{\cup} & H^{p+q+1}(X, A \cup B; R)
\end{array}$$

up to the sign $(-1)^p$. Recall that according to the convention on page 821 “commutes” means that if we start with an element in $H^p(X, B; R)$ and an element in $H^q(A; R)$, then the two routes to $H^{p+q+1}(X, A \cup B; \mathbb{Z})$ lead to the same element up to multiplication by $(-1)^p$.

Proof of Lemma 100.18 (*). We leave it to the long-suffering reader to go through the slightly painful task of modifying the proof of Lemma 82.6 to get the desired result. ■
Proof of Proposition 100.17 (*). We consider the following diagram of maps

\[ \begin{array}{cccc}
H^k(A, \partial A; Z) \times H^{n-k}(A; Z) & \overset{\omega}{\longrightarrow} & H^n(A, \partial A; Z) & \overset{\langle -[A] \rangle}{\longrightarrow} \\
\downarrow^{w^*} & & \downarrow^{(u^*)^{-1}} & \\
H^k(M, B; Z) \times H^{n-k+1}(M, A; Z) & \overset{\omega}{\longrightarrow} & H^{n+1}(M, \partial M) & \overset{\langle -[M] \rangle}{\longrightarrow}
\end{array} \]

We make the following clarifications and observations:

1. By Proposition 74.12 we know that \((M, A, B)\) is an excisive triad.
2. We denote by \(u: (A, \partial A) \to (\partial M, B)\) the inclusion map. It follows from (1) and Lemma 100.18(b) that the map \(u\) induces an isomorphism on cohomology groups.
3. We denote by \(\delta: H^n(A; Z) \to H^{n+1}(M, A; Z)\) and \(\delta: H^n(\partial M, B; Z) \to H^{n+1}(M, \partial M; Z)\) the connecting homomorphisms in cohomology of the pair \((M, A)\) and of the triple \((M, \partial M, B)\).
4. It follows from (1) and Lemma 100.18 that the left part of the diagram commutes up to the sign \((-1)^k\).
5. We denote by \(p: (\partial M, \emptyset) \to (\partial M, B)\) the obvious map. By Lemma 87.24 we have \(p_*([\partial M]) = u_*([A]) \in H_n(\partial M, B; Z)\). Together with Lemma 74.6(3) it follows that the top right triangle commutes.
6. Note that by Proposition 87.27 we know that \(\partial([M]) = [\partial M] \in H_n(\partial M; Z)\). Together with Lemma 83.10 this implies that the bottom right triangle commutes.

Next we consider the following two diagrams:

\[ \begin{array}{ccc}
H_k(M, A; Z) & \overset{\partial}{\longrightarrow} & H_k(A; Z) \\
\overset{PD_A}{\downarrow} & & \overset{PD_A}{\downarrow} \\
H^{n-k}(M, B; Z) & \overset{w^*}{\longrightarrow} & H^{n+1-k}(A, \partial A; Z)
\end{array} \quad \text{and} \quad \begin{array}{ccc}
H_k(A, \partial A; Z) & \overset{w^*}{\longrightarrow} & H_k(M, B; Z) \\
\overset{PD_A}{\downarrow} & & \overset{PD_A}{\downarrow} \\
H^{n-k}(A; Z) & \overset{\delta}{\longrightarrow} & H^{n-k+1}(M, A; Z)
\end{array} \]

By Proposition 88.27 we know that the diagram to the left commutes up to the factor \((-1)^k\) whereas the diagram to the right commutes as it is. With all these preparations we can now easily carry out the desired calculation:

\[
Q_{A,\partial A}(c, a) \downarrow = \langle PD_A(\partial c) \cup PD_A(a), [A] \rangle \downarrow = \langle PD_M(c) \cup \delta(PD_A(a)), [M] \rangle = \langle PD_M(c) \cup PD_M(w^*(a)), [M] \rangle \\
\uparrow \quad \text{by definition of } Q_A \quad \text{since the second diagram commutes up to multiplication by } (-1)^k \quad \text{since the third diagram commutes up to multiplication by } (-1)^k \\
= Q^{as}_{M, A, B}(c, w^*(a)).
\]
Proposition 100.19. Let $M$ be a compact oriented $m$-dimensional topological manifold and let $W \subset M$ be a compact codimension-zero submanifold with corner.\footnote{\begin{enumerate} 
\item[14.13] We refer to Lemma \ref{lemma:oriented-manifold-boundary} for the definition of $\partial_0 W$ and $\partial_1 W$. 
\item[14.14] Here we use that we know by the Excision Theorem \ref{excision-theorem} that the map $w: (W, \partial_0 W) \to (M, M \setminus \breve{W})$ induces an isomorphism on homology groups. \end{enumerate}} Let $A$ and $B$ be disjoint unions of components of $\partial M$ with $\partial_1 W \subset A$. We denote by $i: (W, \partial_1 W) \to (M, A)$, $w: (W, \partial_0 W) \to (M, M \setminus \breve{W})$ and $p: (M, B) \to (M, M \setminus \breve{W})$ the obvious maps. For every $\alpha \in H_k(W, \partial_1 W)$ and $\beta \in H_{n-k}(M, B)$ we have the following equality\footnote{\begin{enumerate} 
\item[14.14] Here we use that we know by the Excision Theorem \ref{excision-theorem} that the map $w: (W, \partial_0 W) \to (M, M \setminus \breve{W})$ induces an isomorphism on homology groups.}:
\[
Q_{W,\partial_1 W,\partial_0 W}^{es}(\alpha, (w_*)^{-1}(p_*(\beta))) = Q_{M,A,B}^{es}(i_*(\alpha), \beta).
\]
In other words, the following diagram commutes in a suitable sense:

\[
\begin{array}{ccc}
Q_{W,\partial_1 W,\partial_0 W}^{es} & \xrightarrow{\alpha} & \\
H_k(W, \partial_1 W; \mathbb{Z}) \times H_{n-k}(W, \partial_0 W; \mathbb{Z}) & \xrightarrow{\approx} & H_{n+k}(M, M \setminus \breve{W}; \mathbb{Z}) \xrightarrow{p_*} \mathbb{Z}.
\end{array}
\]

The analogous statement also holds with the roles of the first and the second entry swapped.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1438}
\caption{Illustration for Proposition 100.19}
\end{figure}

Proof (\*). We perform the following calculation:
\[
Q_{W,\partial_1 W,\partial_0 W}^{es}(\alpha, (w_*)^{-1}(p_*(\beta))) = \langle \text{PD}_W(\alpha) \cup \text{PD}_W((w_*)^{-1}(p_*(\beta))), [W] \rangle
\]
\[
= \langle w^* ((w_*)^{-1}(\text{PD}_W(\alpha)) \cup w^*(\text{PD}_M(\beta)), [W] \rangle = \langle (w^*)^{-1}(\text{PD}_W(\alpha)) \cup \text{PD}_M(\beta), w_*([W]) \rangle
\]
\[
\overset{\text{by Lemma 89.6}}{\uparrow}
\]
\[
\overset{\text{by Lemma 74.6 (3)}}{\uparrow}
\]
\[
\overset{\text{by Lemma 87.24 we have } w_*([W]) = p_*([M])}{\uparrow}
\]
\[
\overset{\text{Lemma 74.6 (3)}}{\uparrow}
\]
\[
\overset{\text{by Lemma 89.5}}{\uparrow}
\]
\[
\overset{\text{by Lemma 89.5}}{\uparrow}
\]
\[
= \langle \text{PD}_M(i_*(\alpha)), \text{PD}_M(\beta), [M] \rangle = Q_{M,A,B}^{es}(i_*(\alpha), \beta).
\]

The case we will use most often is the special case that $\partial_0 W = \partial W$, $\partial_1 W = \emptyset$, $A = \emptyset$ and $B = \partial M$. In this case Proposition 100.20 specializes to the following slightly more readable proposition.
Proposition 100.20. Let $M$ be a compact oriented $m$-dimensional topological manifold and let $W \subset M \setminus \partial M$ be a compact $m$-dimensional submanifold. We denote by $i: W \to M$, $w: (W, \partial W) \to (M, M \setminus \hat{W})$ and $p: (M, \partial M) \to (M, M \setminus \hat{W})$ the obvious maps. For every $\alpha \in H_k(W)$ and $\beta \in H_{n-k}(M, \partial M)$ we have the following equality:

$$Q_{W,\varnothing,\partial W}^{as}(\alpha, (w_*)^{-1}(p_*(\beta))) = Q_{M,\varnothing,\partial M}^{as}(i_*(\alpha), \beta).$$

![Figure 1439. Illustration for Proposition 100.20](image)

100.8. The reduced intersection form $(\ast)$. After the exhaustive and exhausting discussion of the asymmetric intersection pairings in the previous section, let us now move on to our second variation on the intersection form.

Proposition 100.21. Let $M$ be a compact oriented $2n$-dimensional topological manifold. We denote by $i: \partial M \to M$ the inclusion map.

1. Let $\alpha \in FH_n(M; \mathbb{Z})$. The following two statements are equivalent:
   (a) $\alpha \in \text{im}(i_*: FH_n(\partial M; \mathbb{Z}) \to FH_n(M; \mathbb{Z}))$.
   (b) For every $\beta \in FH_n(M; \mathbb{Z})$ we have $Q_M(\alpha, \beta) = 0$.

2. We write $\tilde{H}_n(M; \mathbb{Z}) := \text{coker}(i_*: H_n(\partial M; \mathbb{Z}) \to H_n(M; \mathbb{Z}))$. The form

$$Q_M^{\text{red}}: \tilde{H}_n(M; \mathbb{Z}) \times \tilde{H}_n(M; \mathbb{Z}) \to \mathbb{Z}
\quad ([\varphi], [\psi]) \mapsto Q_M(\varphi, \psi)$$

is well-defined and non-degenerate. We refer to this form as the reduced intersection form of $M$.

3. If the intersection form $Q_M$ is non-degenerate, then the obvious map $FH_n(M; \mathbb{Z}) \to FH_n(M; \mathbb{Z})$ is an isomorphism and it induces an isometry $Q_M \to Q_M^{\text{red}}$.

Proof. We denote by $i: \partial M \to M$ and $j: (M, \varnothing) \to (M, \partial M)$ the obvious maps. Before we do anything else we recall that we have a long exact sequence

$$\ldots \to H_n(\partial M; \mathbb{Z}) \xrightarrow{i_*} H_n(M; \mathbb{Z}) \xrightarrow{j_*} H_n(M, \partial M; \mathbb{Z}) \xrightarrow{\partial} H_{n-1}(\partial M) \to \ldots$$

Now we turn to the actual proofs of the statements.

1. Let $\alpha \in H_n(M; \mathbb{Z})$. First we prove “(a) $\Rightarrow$ (b)”. Thus we assume that $\alpha = i_*(\gamma)$ for some $\gamma \in H_n(\partial M; \mathbb{Z})$. Let $\beta \in H_n(M; \mathbb{Z})$. We perform the following calculation:

$$Q_M(\alpha, \beta) = \langle \text{PD}(i_*(\gamma)) \cup \text{PD}(\beta), [M] \rangle = \langle \text{PD}(\beta), j_*(\text{PD}(i_*(\gamma)) \cap [M]) \rangle$$

by definition of $Q_M$ Lemma 83.7(3) $= i_*(\gamma)$ by definition of PD

$$\quad = 0.$$ 

since $j_* \circ i_* = 0$
Now we prove “(b) ⇒ (a)” Thus we assume that \( Q_M(\alpha, \beta) = 0 \) for all \( \beta \in FH_n(M; \mathbb{Z}) \). This implies for any \( \beta \in FH_n(M; \mathbb{Z}) \) we have the following equalities:

\[
Q_{M, \partial M, \sigma}^{\text{as}}(j_*(\alpha), \beta) = Q_M(\alpha, \beta) = 0.
\]

by Proposition \textbf{100.15} (1) by assumption

By Proposition \textbf{100.15} (1) we know that the pairing \( Q_{M, \partial M, \sigma}^{\text{as}} \) is non-singular, in particular it is non-degenerate. Thus it follows from the above, together with Lemma \textbf{100.14}, that \( j_*(\alpha) = 0 \in FH_n(M; \mathbb{Z}) \). It follows from the above long exact sequence, together with Exercise \textbf{37.2} that \( \text{im}(i_*: FH_n(\partial M; \mathbb{Z}) \rightarrow FH_n(M; \mathbb{Z})) \).

(2) It follows immediately from (1) “(a) ⇒ (b)” that the form \( Q_M^{\text{red}} \) is well-defined. Furthermore it follows from (1) “(b) ⇒ (a)” and Lemma \textbf{100.14} that \( Q_M^{\text{red}} \) is non-degenerate.

(3) This statement follows immediately from (1) and Lemma \textbf{100.14}.

\[\blacksquare\]

**Examples.**

(1) One last time we consider again our favorite example \( M \), namely the torus minus two open disks. We use the notation from Figure \textbf{1440}. A basis for \( H_1(M; \mathbb{Z}) \) is given by \( a, b, c \) and the image of \( H_1(\partial M; \mathbb{Z}) \rightarrow H_1(M; \mathbb{Z}) \) is given by \( \mathbb{Z} \cdot c \). With respect to these bases we see that

\[
Q_M \text{ is represented by } \begin{pmatrix} a & b & c \\ 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \text{and } Q_M^{\text{red}} \text{ is represented by } \begin{pmatrix} a & b \\ 0 & 1 \\ -1 & 0 \end{pmatrix}.
\]

\[\text{Figure 1440}\]

(2) In Exercise \textbf{100.6} we will provide an example of a compact orientable 4-dimensional smooth manifold \( M \) for which the reduced intersection form is not non-singular. We will obtain many more such examples later on in Proposition \textbf{??}.

\[\text{Exercises for Chapter 100.}\]

**Exercise 100.1.** We equip \( H_1(S^1 \times S^1; \mathbb{Z}) \) with the standard basis \( \mu = [S^1 \times \{\ast\}] \) and \( \lambda = [\{\ast\} \times S^1] \). Show that

\[
Q_{S^1 \times S^1}(a \cdot \mu + b \cdot \lambda, c \cdot \mu + d \cdot \lambda) = \det \begin{pmatrix} a & b \\ c & d \end{pmatrix}.
\]

Remark. The exercise is really quite easy, but it does produce a neat formula.

**Exercise 100.2.** Let \( M \) be a compact oriented topological manifold. Recall that we say that \( M \) is \textit{amphichiral} if \( M \) admits an orientation-reversing self-homeomorphism, otherwise
we say that $M$ is \textit{chiral}. For which $k, l \in \mathbb{N}_0$ is the connected sum $k \cdot \mathbb{C}P^2 \# l \cdot \overline{\mathbb{C}}P^2$ chiral? More precisely:

(a) for the values that you exclude, show that $k \cdot \mathbb{C}P^2 \# l \cdot \overline{\mathbb{C}}P^2$ is not chiral,

(b) for all the other values show explicitly that $k \cdot \mathbb{C}P^2 \# l \cdot \overline{\mathbb{C}}P^2$ is chiral.

\textbf{Exercise 100.3.} Let $n \in \mathbb{N}$ and let $M$ and $M'$ be two closed oriented connected non-empty $n$-dimensional topological manifolds. Let $X \subset M$ and $X' \subset M'$ be submanifolds that are homeomorphic to $\overline{B}^n$ and let $\varphi: \partial X \to \partial X'$ be an orientation-preserving homeomorphism. Show that $(M \setminus \hat{X}) \cup_{\varphi: \partial X \to \partial X'} (M \setminus \hat{X}')$ is homeomorphic to the connected sum $M \# N$.

\textit{Hint.} Use the Alexander trick from Exercise 3.29.

\textit{Remark.} Initially it might sound like this statement holds “by definition”. But in fact in Exercise ?? we will see that the obvious analogue in the setting of smooth manifolds does not hold.

\textbf{Exercise 100.4.} Let $R$ be a commutative ring and let $\varphi: V \times V \to R$ be a form. The submodule $R := \{ v \in V \mid \varphi(v, w) = 0 \text{ for all } w \in V \}$ is called the \textit{radical} of the form $\varphi$. Show that if $R$ is a field, then the map

$$V/R \times V/R \to R \quad ([v], [w]) \mapsto \varphi(v, w)$$

is well-defined and non-singular.

\textit{Remark.} Recall that a form is by our definition symmetric or anti-symmetric and $V$ is a finite-dimensional vector space over the field $R$.

\textbf{Exercise 100.5.} Let $M$ be a compact oriented 4-dimensional topological manifold and let $i: \partial M \to M$ be the inclusion map.

(a) Show that if $i_*: H_1(\partial M; \mathbb{Z}) \to H_1(M; \mathbb{Z})$ is a monomorphism, then the intersection form $Q_M$ is non-singular.

(b) Show that if $i_*: H_1(\partial M; \mathbb{Q}) \to H_1(M; \mathbb{Q})$ is a monomorphism, then the intersection form $Q_M$ is non-degenerate.

\textbf{Exercise 100.6.} Let $n \in \mathbb{N}$. We consider the map

$$\varphi: \overline{B}^2 \times S^1 \to \overline{B}^2 \times S^1 \subset \partial(\overline{B}^2 \times \overline{B}^2)$$

$$(z, w) \mapsto (z, w \cdot z^n).$$

Furthermore we consider

$$M := (\overline{B}^2 \times \overline{B}^2) \overline{B}^2 \times S^1 \to \partial(\overline{B}^2 \times \overline{B}^2) \quad (\overline{B}^2 \times \overline{B}^2).$$

$$(z, w) \mapsto \varphi(z, w)$$

One can show by hand that $M$ is a compact orientable 4-dimensional smooth manifold.

(a) Show that $\pi_1(M) = 0$, $H_2(M; \mathbb{Z}) \cong \mathbb{Z}$ and $H_2(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$.

\textsuperscript{1415}Later on page 2475 we will say that $M$ is obtained from the 4-ball $\overline{B}^2 \times \overline{B}^2$ by attaching a 2-handle.

\textsuperscript{1416}We will carry out the details in Proposition 103.1 but this is irrelevant for the present exercise.
(b) Show that $H_1(\partial M; \mathbb{Z}) \cong \mathbb{Z}_n$ and $H_2(\partial M; \mathbb{Z}) = 0$. (In fact very well-trained eyes will spot that $\partial M$ is diffeomorphic to the lens space $L(n, 1)$.)

(c) Show that if $n \geq 2$, then the intersection form $Q_M$ is represented by one of the two $1 \times 1$-matrices $(-n)$ or $(n)$.

Hint. Use Proposition 100.15 (3). Remark. Note that it follows from (b) that the intersection form equals the reduced intersection form. Thus we have shown, as promised on page 2436, that there exists a compact orientable 4-dimensional smooth manifold $M$ for which the reduced intersection form is not non-singular.

Exercise 100.7. Let $M$ be a compact oriented $n$-dimensional topological manifold and let $A, B$ be disjoint unions of components of $\partial M$. Furthermore let $V$ and $W$ be compact codimension-zero submanifolds of $M$ as in Figure 1441 and let $\alpha \in H_k(M, A)$ and $\beta \in H_{n-k}(X, B)$.

(a) Inspired by Figure 1441 state a formula which computes $Q_M(\alpha, \beta)$ in terms of suitable intersection numbers of $V$ and $W$.

Hint. What is the role of $C$ and $D$ in Figure 1441?

(b) Prove (a).
101. THE INTERSECTION FORM II: ALGEBRA AND SOME TOPOLOGY

In Chapter 100 we introduced the intersection form of compact oriented even-dimensional topological manifolds. On page 2426 we considered the intersection forms of $S^2 \times S^2$, $\mathbb{C}P^2 \# \mathbb{C}P^2$ and $\mathbb{C}P^2 \# \mathbb{C}P^2$. At that point it became clear that we have to invest some time to study (anti-) symmetric forms as purely algebraic objects.

We start out with the following lemma that summarizes all the basic facts about the interplay between forms and matrices that we will need in this chapter.

**Lemma 101.1.** Let $R$ be a commutative ring.

1. Let $A$ be a (anti-) symmetric $n \times n$-matrix over $R$. We consider the map
   \[ \varphi(A) : R^n \times R^n \to R, \quad (v, w) \mapsto v^T A w. \]

   The following statements hold:
   (a) $\varphi(A)$ is an (anti-) symmetric form over $R$.
   (b) The form $\varphi(A)$ is non-singular, in the sense of the definition on page 2411, if and only if $A$ is invertible, i.e., if $\det(A)$ is a unit in $R$.
   (c) If $P \in \text{GL}(n, R)$ is an invertible matrix, then the forms $\varphi(P^T A P)$ and $\varphi(A)$ are isometric.
   (d) If $B$ is a (anti-) symmetric $n \times n$-matrix over $R$ such that $\varphi(A)$ and $\varphi(B)$ are isometric, then there exists a $P \in \text{GL}(n, R)$ with $B = P^T A P$.

2. Let $(V, \psi)$ be an (anti-) symmetric form over $R$ of rank $n$. If $A$ is a matrix that represents $\psi$, then $(V, \psi) \cong (R^n, \varphi(A))$. In particular every (anti-) symmetric form over $R$ is isometric to $\varphi(A)$ for some (anti-) symmetric $n \times n$-matrix $A$ over $R$.

**Convention.** Lemma 101.1 allows us to go back and forth between (anti-) symmetric forms and (anti-) symmetric matrices. Thus in the following discussion we will blur the distinction between these two concepts. For example, given a (anti-) symmetric matrix $A$ over a commutative ring we will often just refer to the (anti-) symmetric form $\varphi(A)$ as the form $A$.

**Proof** (*).

1. (a) This statement follows almost immediately from the definitions and the observation that for any $v, w \in R^n$ we have
   \[ \varphi(A)(v, w) = w^T A v = (w^T A^T v)^T = v^T A^T w = \varphi(A^T)(v, w). \]

   for a $(1 \times 1)$-matrix $(x)$ we have $(x)^T = (x)$

   (b) The proof of this statement is an instructive exercise in linear algebra. We will not rob the reader of the joy of doing this exercise.

   (c) We claim that the isomorphism $v \mapsto P v$ defines an isometry from the form $(R^n, \varphi(P^T A P))$ to the form $(R^n, \varphi(A))$. Indeed, for any $v, w \in R^n$ we have
   \[ \varphi(A)(P v, P w) = (P v)^T A P w = v^T (P^T A P) w = \varphi(P^T A P)(v, w). \]

---

1417 Recall that a matrix $A$ is called anti-symmetric if $A^T = -A$. 

(d) Let $B$ be a (anti-) symmetric $n \times n$-matrix over $R$ and let $f : R^n \to R^n$ be an isometry between $\varphi(A)$ and $\varphi(B)$, i.e. let $f$ be an isomorphism such that for all $v, w \in R^n$ we have $v^T A w = \varphi(A)(v, w) = \varphi(B)(f(v), f(w)) = f(v)^T A f(w)$. Let $P$ be the matrix representing $f$ with respect to the standard basis of $R^n$. Since $f$ is an isomorphism we know that $P \in \text{GL}(n, R)$. Finally a straightforward calculation shows that $B = P^T A P$.

(2) Let $\psi : V \times V \to R$ be an (anti-) symmetric form over $R$. Let $v_1, \ldots, v_n$ be a basis of $V$. We denote by $A = (\psi(v_i, v_j))_{i, j = 1, \ldots, n}$ the corresponding matrix representing the form $\psi$. We consider the isomorphism

$$\Theta : R^n \to V, \quad (\lambda_1, \ldots, \lambda_n) \mapsto \lambda_1 v_1 + \cdots + \lambda_n v_n.$$  

We claim that $\Theta$ is an isometry from the form $(R^n, \varphi(A))$ to the form $(V, \psi)$. Indeed, if we denote by $e_1, \ldots, e_n$ the standard basis for $R^n$, then for any $i, j \in \{1, \ldots, n\}$ we have

$$\psi(\Theta(e_i), \Theta(e_j)) = \psi(v_i, v_j) = ij\text{-entry of } A = e_i^T A e_j = \varphi(A)(e_i, e_j).$$

By bilinearity of forms we obtain the corresponding statement for all pairs of elements in $R^n$.

Lemma 101.1 (1b), (1d) and (2) shows that the following definition makes sense.

**Definition.** Let $R$ be a commutative ring. We denote by $R^*$ the multiplicative units of $R$. Let $(V, \psi)$ be a non-singular (anti-) symmetric form over $R$ of rank $n$. We pick a basis $v_1, \ldots, v_n$ of $V$. We refer to

$$\det(\psi) := \det(\psi(v_i, v_j))_{i, j = 1, \ldots, n} \in R^*/\{a^2 | a \in R^*\}$$

as the **determinant of the form** $(V, \psi)$. Note that for $R = \mathbb{Z}$ the determinant is a well-defined element of $\{-1, 1\}$.

**Example.**

1. For a matrix $A \in \text{GL}(n, R)$ we have of course $\det(\varphi(A)) = \det(A) \in R^*/\{a^2 | a \in R^*\}$.  
2. We work with $R = \mathbb{Z}$. We set $A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Since $\det(A) = 1$ and $\det(B) = -1$ we see that $\varphi(A)$ and $\varphi(B)$ are non-isometric forms over $\mathbb{Z}^2$.

101.1. **Non-singular anti-symmetric forms.** In this section we will completely classify non-singular anti-symmetric forms over the real numbers and over the integers.

First we consider the matrix

$$S := \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$  

It is anti-symmetric and it has determinant $1$. From Lemma 101.1 we obtain an anti-symmetric form $\varphi(S)$. The following proposition shows that $\varphi(S)$ is in some sense the only example of a non-singular anti-symmetric form over the real numbers or over the integers.
**Proposition 101.2.** If \((V, \varphi)\) is a non-singular anti-symmetric form over \(\mathbb{R}\) or over \(\mathbb{Z}\), then there exists a \(k \in \mathbb{N}_0\) such that \((V, \varphi) \cong k \cdot \varphi(S)\), i.e. \(\varphi\) is represented by the \(2k \times 2k\)-matrix

\[
\begin{pmatrix}
0 & 1 & \ldots & 0 & 0 \\
-1 & 0 & \ldots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 0 & 1 \\
0 & 0 & \ldots & -1 & 0 \\
\end{pmatrix}
\]

\(k\) diagonal blocks of \(2 \times 2\)-matrices.

*In particular the rank of \(V\) is even.*

**Remark.** Propositions 100.4 and 101.2 imply in particular that the isometry type of the intersection of a surface of genus \(g\) is determined by the formal properties of an intersection form. In particular we did not need to go through the discussion on page 2413 if we just need to know the isometry type of the intersection form.

**Sketch of proof.** First we remark that throughout the proof on many occasions we use Lemma 101.1 without saying so explicitly.

After this preamble, let \((V, \varphi)\) be a non-singular anti-symmetric form over \(\mathbb{R}\) of rank \(n\). We pick an \((n \times n)\)-matrix \(A\) that represents \(\varphi\). Since \(\varphi\) is anti-symmetric we see that all terms of \(A\) on the diagonal are zero. In the following we consider the usual three types of elementary matrices:

\[
D_\lambda := \begin{pmatrix}
\text{id} & 0 & 0 \\
0 & \lambda & 0 \\
0 & 0 & \text{id}
\end{pmatrix}, \lambda \neq 0, \quad P := \begin{pmatrix}
\text{id} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & \text{id} & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \text{id}
\end{pmatrix}
\text{ and } \quad Q_\lambda := \begin{pmatrix}
\text{id} & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & \lambda & 0 \\
0 & 0 & \text{id} & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & \text{id}
\end{pmatrix}.
\]

We make the following elementary observations:

(i) Replacing a matrix \(B\) by \(D_\lambda^T BD_\lambda\) means that first we multiply a column by \(\lambda\), and then we multiply the corresponding row by \(\lambda\).

(ii) Replacing a matrix \(B\) by \(P^T BP\) means that first we exchange two columns, and then we exchange the corresponding two rows.

(iii) Replacing a matrix \(B\) by \(Q_\lambda^T BQ_\lambda\) means that first we add \(\lambda\)-times one column to another column, and then we do the same operation for the corresponding rows.

Now we can perform the following sequence of operations to \(A\):

\[
A \overset{(1)}{\rightarrow} \begin{pmatrix}
0 & \ast & \ldots & \ast \\
\ast & 0 & \ldots & \ast \\
\ast & \ast & 0 & \ast \\
\vdots & \vdots & \ddots & \vdots \\
\ast & \ast & \ast & 0
\end{pmatrix} \overset{(2)}{\rightarrow} \begin{pmatrix}
0 & 1 & \ast & \ldots & \ast \\
-1 & 0 & \ast & \ldots & \ast \\
-1 & 0 & \ast & \text{id} & \ast \\
0 & 0 & \text{id} & 0 & 0 \\
0 & 0 & 0 & 0 & \text{id}
\end{pmatrix} \overset{(3)}{\rightarrow} \begin{pmatrix}
0 & 1 & 0 & \ldots & 0 \\
0 & 1 & 0 & \ast & \ast \\
0 & 0 & \ast & \ast & \ast \\
0 & 0 & \ast & \ast & \ast \\
\end{pmatrix} \overset{(4)}{\rightarrow} \begin{pmatrix}
0 & 1 & 0 & \ldots & 0 \\
0 & 1 & 0 & \ast & \ast \\
0 & 0 & \ast & \ast & \ast \\
0 & 0 & \ast & \ast & \ast \\
\end{pmatrix}
\]

where we perform the following steps:

(1) We write out \(A\), here and throughout the steps we use the convention that \(\ast\) can mean any real number, the only condition being that all matrices are anti-symmetric.

\[\text{Here, when we write } k \cdot \varphi(S) \text{ we use the definition from page } 2410\]
(2) Since \( \det(A) \neq 0 \) there exists at least one entry on the first row which is non-zero.

After operations of type (ii) and (i) we can arrange that the \((1,2)\)-entry equals 1. By
the anti-symmetry we see that the \((2,1)\)-entry now equals \(-1\).

(3) Using operations of type (iii) we can “clean up” the remaining terms on the first row
and column.

(4) Similarly, we can use operations of type (iii) to “clean up” the remaining terms on
the second row and column.

At this stage we can continue with the same process, applied to the \((n-2) \times (n-2)\)-matrix
at the right bottom. Eventually we will have turned \(A\) into a matrix of the promised type.

Now suppose that \((V, \varphi)\) is a non-singular anti-symmetric form over \(\mathbb{Z}\). In Exercise 101.6
we will modify the above proof to deal with this new situation.

In a sense Proposition 101.2 is rather disappointing. We had hoped that intersection
forms will give us new meaningful invariants. But Proposition 101.2 together with Proposition 100.4
shows that intersection forms of closed even-dimensional topological manifolds
do not give us any extra information that would allow us to distinguish manifolds.

Nonetheless, Proposition 101.2 has just enough content to answer Question 88.8 where
we had asked which integers appear as Euler characteristics of closed orientable connected
even-dimensional topological manifolds. Now we can provide a complete answer to this question.

**Proposition 101.3.**

1. Let \( k \in \mathbb{N} \). Given any \( n \in \mathbb{Z} \) there exists a closed orientable connected \(4k\)-dimensional
smooth manifold with Euler characteristic \(n\).

2. (a) The Euler characteristic of any closed orientable connected topological manifold
of dimension 2 is even and \(\leq 2\). Conversely, any even number \(\leq 2\) is the Euler
characteristic of such a smooth manifold.

(b) Let \( k \in \mathbb{N} \). The Euler characteristic of any closed orientable connected topological
manifold of dimension \(4k+2\) is even. Conversely, any even number is the Euler
characteristic of such a smooth manifold.

**Remark.** In Exercise 106.2 we will deal with the possible Euler characteristics of smooth
manifolds with possibly non-empty boundary.

**Proof.** We start out with two claims that give us the stated restrictions on Euler characteristics of closed orientable topological manifolds.

**Claim.** Let \( k \in \mathbb{N}_0 \). The Euler characteristic of every closed orientable topological manifold
\(M\) of dimension \(4k + 2\) is even.

---

This question arose from the fact, shown in Proposition 88.7, that the Euler characteristic of
every closed odd-dimensional topological manifold is necessarily zero. So it was natural to wonder what is
happening for closed even-dimensional topological manifolds.
Indeed, we have

\[ \chi(M) = \sum_{i=0}^{4k+2} (-1)^i \cdot \dim_{\mathbb{R}}(H_i(M; \mathbb{R})) = \dim_{\mathbb{R}}(H_{2k+1}(M; \mathbb{R})) + 2k \sum_{i=0}^k (-1)^i \cdot \dim_{\mathbb{R}}(H_i(M; \mathbb{R})) \]

by Proposition 85.34 (4) and by Theorem 88.6 we have \( \dim_{\mathbb{R}}(H_i(M; \mathbb{R})) = \dim_{\mathbb{R}}(H_{4k+2-i}(M; \mathbb{R})) \).

\[ \equiv 0 \mod 2. \]

by Proposition 100.4 and the facts that \( M \) is closed and that \( 2k+1 \) is odd we know that the intersection form on \( H_{2k+1}(M; \mathbb{R}) \) is anti-symmetric and non-singular.

by Proposition 101.2 we thus know that \( \dim_{\mathbb{R}}(H_{2k+1}(M; \mathbb{R})) \) is even.

Claim. The Euler characteristic of every closed orientable connected 2-dimensional topological manifold \( M \) is \( \leq 2 \).

Of course this statement follows from the Surface Classification Theorem 23.4 together with the calculation of the Euler characteristics on page 1363. But one can prove the claim directly. First the case that \( M \) is empty is trivial. Now assume that \( M \) is non-empty. In this case we have the following (in-)equalities:

\[ \chi(M) = \sum_{i \in \mathbb{N}_0} (-1)^i \cdot \text{rank}(H_i(M)) = \text{rank}(H_0(M)) - \text{rank}(H_1(M)) + \text{rank}(H_2(M)) \leq 2. \]

by Proposition 55.1 by Theorem 87.3.

It remains to show that besides these two restrictions on the possible values of Euler characteristics, all other values can be realized. Our arguments in all of the three cases rely on the following observation.

Observation.

(i) On page 1364 we saw that for every \( m \in \mathbb{N}_0 \) we have \( \chi(\mathbb{C}P^m) = m + 1 \).

(ii) Lemma 55.7 says that if \( M \) and \( N \) are two compact oriented connected even-dimensional smooth manifolds, then \( \chi(M \# N) = \chi(M) + \chi(N) - 2 \).

(iii) There is any number of reasons, e.g. we could use Lemma 55.8 why given any \( m \in \mathbb{N} \) the Euler characteristic of the \( m \)-dimensional torus \( (S^1)^m \) is zero.

Now we turn to the various cases:

(1) Let \( k \in \mathbb{N} \) and let \( n \in \mathbb{Z} \). Note that \( \chi(\mathbb{C}P^k) = 2k + 1 \) is odd and \( \geq 3 \). From the above observations it follows that

\[ \chi(n \cdot \mathbb{C}P^{2k} \# n \cdot (S^1)^k) = n \cdot (2k + 1) - nk \cdot 2 = n. \]

(2) Evidently we have \( \chi(S^2) = 2 \). Note let \( n = 2m \) be an even integer with \( n \leq 0 \).

It follows from the above observations that

\[ \chi((m+1) \cdot (S^1 \times S^1)) = (m+1) \cdot 2 = n. \]

(b) Let \( k \in \mathbb{N} \) and let \( n \) be an even integer. From the above observations it follows that

\[ \chi(n \cdot \mathbb{C}P^{2k+1} \# \frac{n}{2} (2k + 1) \cdot (S^1)^{4k+2}) = n \cdot (2k+2) - \frac{n}{2} (2k+1) \cdot 2 = n. \]
101.2. **Interlude: Sphere-packing.** In this short section we want to consider sphere packings. The relationship with our actual goal of dealing with symmetric forms is arguably tenuous but nonetheless fascinating.

**Definition.** Let \( v_1, \ldots, v_n \) be linearly independent vectors in \( \mathbb{R}^n \). We refer to the group

\[
\mathbb{Z} \cdot v_1 + \cdots + \mathbb{Z} \cdot v_n = \left\{ \sum_{i=1}^{n} a_i \cdot v_i \mid a_1, \ldots, a_n \in \mathbb{Z} \right\}
\]

as the **lattice spanned by** \( v_1, \ldots, v_n \).

We start out with the following theorem. The fact that strictly speaking we did not define all the terms will not bother us.

**Theorem 101.4.**

1. A densest packing of disks of radius \( \frac{1}{2} \) in \( \mathbb{R}^2 \) is given by setting the centers on the “hexagonal” lattice spanned by \( v_1 = (1, 0) \) and \( v_2 = (\frac{1}{2}, \frac{\sqrt{3}}{2}) \) shown in Figure [1442](#) on the left. The density equals \( \frac{\pi}{\sqrt{12}} \).

2. No packing of balls of the same radius in \( \mathbb{R}^3 \) has density greater than that of the “face-centered cubic packing” shown in Figure [1442](#) in the middle and on the right. The density equals \( \frac{\pi}{\sqrt{18}} \).

**Proof.** The first statement was proved by L. Fejes Tóth [FT43, FT72] in 1943. It is much harder to prove the second statement. This statement had been conjectured by Kepler in 1613 and it was finally proved by Thomas Hales [Hale00, Hale05, Hale17] in 2005. ■

For a mathematician it is natural to wonder what are the highest densities of packings in higher dimensions. Not surprisingly this is a very hard problem. Astonishingly the next case that was dealt with is the 8-dimensional setting. More precisely, the following theorem was proved by Maryna Viazovska [Via17] in 2016.

---

\[1420\] This is perhaps not the standard definition of a lattice, but who cares?
Theorem 101.5. We consider the following matrix

\[
E_8 := \begin{pmatrix}
2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 2 & 1 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 2 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 2 \\
\end{pmatrix}
\]

No packing of unit balls in \( \mathbb{R}^8 \) has density greater than that given by the lattice spanned by the eight column vectors of the \( E_8 \)-matrix. Furthermore, this packing has density \( \frac{\pi^4}{384} \).

Remark. We also refer to [Bae17] for other interesting appearances of the \( E_8 \)-matrix, for example its relationship to the regular icosahedron.

Shortly afterwards the 24-dimensional case was settled in [CKMRV17], in this case a densest packing is given by the “Leech lattice”. OK, that was fun, but now let us return to our actual problem, and let us see whether this section was of any use.

101.3. Non-singular symmetric forms over the real numbers. In an earlier section we saw that non-singular anti-symmetric forms are almost depressingly boring mathematical objects. In this and the next section we will consider non-singular symmetric forms. These will, fortunately, turn out to be much more interesting.

Examples. We list some symmetric integral matrices with determinant equal to \( \pm 1 \). By Lemma 101.1 these define in particular non-singular forms over \( \mathbb{R} \) and also over \( \mathbb{Z} \).

1. The \( 1 \times 1 \)-matrices \( (+1) \) and \( (-1) \).
2. The slightly mysterious \( 8 \times 8 \)-matrix \( E_8 \) from the previous section.
3. The matrix

\[
H := \begin{pmatrix}
0 & 1 \\
1 & 0 \\
\end{pmatrix}
\]

is symmetric and it has determinant \( -1 \).

It is natural to ask whether there is some type of analogue of Proposition 101.2 for symmetric forms. In fact using the methods of the proof of Proposition 101.2 one can prove the following statement.

Proposition 101.6. If \((V, \varphi)\) is a non-singular symmetric form over \( \mathbb{R} \) of rank \( n \), then there exists a \( k \in \mathbb{N}_0 \) such that \((V, \varphi) \cong k \cdot (+1) \oplus (n - k) \cdot (-1)\).

Remark. Recall that Proposition 101.2 dealt with anti-symmetric forms over \( \mathbb{R} \) and also with anti-symmetric forms over \( \mathbb{Z} \). In contrast Proposition 101.6 only deals with symmetric forms over \( \mathbb{R} \). It is a very instructive exercise to run through the proof of Proposition 101.6 and to determine where it breaks down if we work over \( \mathbb{Z} \).
Sketch of proof. Let \((V, \varphi)\) be a non-singular symmetric form over \(\mathbb{R}\) of rank \(n\). In the subsequent arguments below we use the conventions and notions we introduced in Proposition \([101.2]\). In particular we will also use the operations of type (i), (ii) and (iii) that we introduced in the proof of Proposition \([101.2]\).

We pick an \((n \times n)\)-matrix \(A\) that represents \(\varphi\). Now we can perform the following sequence of operations to \(A\):

\[
A \overset{(1)}{=} \begin{pmatrix} * & * & \ldots & * \\ * & * & \ldots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \ldots & * \end{pmatrix} \overset{(2)}{\rightarrow} \begin{pmatrix} \epsilon_1 & * & \ldots & * \\ * & * & \ldots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \ldots & * \end{pmatrix} \overset{(3)}{\rightarrow} \begin{pmatrix} \epsilon_1 & 0 & \ldots & 0 \\ 0 & * & \ldots & * \\ \vdots & \vdots & \ddots & \vdots \\ 0 & * & \ldots & * \end{pmatrix}
\]

where we perform the following steps:

1. We write out \(A\). Here and throughout the steps we use the convention that \(*\) can mean anything, the only condition being that all matrices are symmetric.
2. Since \(\det(A) \neq 0\) there exists at least one entry on the first row which is non-zero. After operations of type (iii) and (i) we can arrange that the \((1, 1)\)-entry equals some \(\epsilon_1 \in \{-1, 1\}\).
3. Using operations of type (iii) we can “clean up” the remaining terms on the first row and column.

At this stage we can continue with the same process, applied to the \((n-1) \times (n-1)\)-matrix at the right bottom. Eventually we will have turned \(A\) into a diagonal matrix where all entries lie in \(\{-1, 1\}\). After operations of type (ii) we can arrange that the first diagonal entries are equal to +1 and the final ones are equal to −1.

Let \(n \in \mathbb{N}_0\). Proposition \([101.6]\) raises the question whether or not the symmetric forms defined by \(k \cdot (+1) \oplus (n-k) \cdot (-1)\) are isometric for different values of \(k \in \{0, \ldots, n\}\). To answer this question it is helpful to introduce the following definition.

**Definition.** Let \((V, \varphi)\) be a symmetric form over the real numbers.

1. We say \(\varphi\) is **positive-definite** if \(\varphi(v, v) > 0\) for all \(v \neq 0\).
2. We say \(\varphi\) is **negative-definite** if \(\varphi(v, v) < 0\) for all \(v \neq 0\).
3. We say \(\varphi\) is **indefinite** if \(\varphi\) is neither positive-definite nor negative-definite.

**Examples.**

1. The form \((+1)\) is positive-definite and the form \((-1)\) is negative-definite.
2. The form \(E_8\) is positive-definite. Evidently one can show this by a brute force calculation. A more conceptual proof is given in [HGK10, Theorem 1.16.14].
3. The form \(H\) is indefinite, indeed, we have

\[
\varphi(H)\left(\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 1 \end{pmatrix}\right) = \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = 2
\]

and

\[
\varphi(H)\left(\begin{pmatrix} 1 \\ -1 \end{pmatrix}, \begin{pmatrix} 1 \\ -1 \end{pmatrix}\right) = \begin{pmatrix} 1 & -1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ -1 \end{pmatrix} = -2.
\]

To distinguish non-isometric forms we need to introduce some invariants of forms.
**Definition.** Let \((V, \varphi)\) be a symmetric form over the real numbers. We define
\[
b^+ (\varphi) := \text{maximal dimension of a vector subspace } U \text{ of } V \text{ such that } \varphi_{|U} \text{ is positive-definite,}
\]
\[
b^- (\varphi) := \text{maximal dimension of a vector subspace } U \text{ of } V \text{ such that } \varphi_{|U} \text{ is negative-definite.}
\]
Furthermore we define the signature \(\text{sign}(\varphi)\) as
\[
\text{sign}(\varphi) := b^+ (\varphi) - b^- (\varphi).
\]

**Example.** We consider the symmetric form
\[
\varphi: \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}
\]
\[
\left( \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} \right) \mapsto (v_1 \ v_2) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} (v_1 \ v_2).
\]
In Figure 1443 we show the subsets
\[
X^+ := \{ v \in V \mid \varphi(v,v) > 0 \} \cup \{0\} \quad \text{and} \quad X^- := \{ v \in V \mid \varphi(v,v) < 0 \} \cup \{0\}.
\]
These subsets are evidently not vector subspaces of \(V = \mathbb{R}^2\). The maximal dimension of a vector subspace contained in \(X^+\) and \(X^-\) is in both cases equal to one. Thus we see that \(b^+(\varphi) = b^-(\varphi) = 1\). In particular we see that \(\text{sign}(\varphi) = 0\).

![Figure 1443](image-url)

The following lemma is an immediate consequence of the definitions.

**Lemma 101.7.** Let \((V, \varphi)\) and \((W, \psi)\) be two non-singular symmetric forms over \(\mathbb{R}\). If \((V, \varphi)\) and \((W, \psi)\) are isometric, then
\[
\text{dim}_K (V) = \text{dim}_K (W), \quad b^\pm (\varphi) = b^\pm (\psi) \quad \text{and} \quad \text{sign}(\varphi) = \text{sign}(\psi).
\]
In the following proposition we determine \(b^\pm\) and the signature for a non-singular form that is given by a diagonal matrix.

**Proposition 101.8.** If \(D\) is a diagonal \((n \times n)\)-matrix where the diagonal entries \(d_1, \ldots, d_n\) are non-zero real numbers, then
\[
b^+(\varphi(D)) = \text{number of positive } d_i \text{'s} \quad \text{and} \quad b^-(\varphi(D)) = \text{number of negative } d_i \text{'s}.
\]
In particular
\[
\text{sign}(\varphi(D)) = \text{number of positive } d_i \text{'s} - \text{number of negative } d_i \text{'s}.
\]

**Proof.** After reordering the diagonal entries we can assume that the first \(k\) entries of \(D\) are positive and that the remaining \((n - k)\) entries are negative. We write
\[
V^+ := \{ (x_1, \ldots, x_k, 0, \ldots, 0) \in \mathbb{R}^n \mid x_1, \ldots, x_k \in \mathbb{R} \} \quad \text{and}
\]
\[
V^- := \{ (0, \ldots, 0, y_1, \ldots, y_{n-k}) \in \mathbb{R}^n \mid y_1, \ldots, y_{n-k} \in \mathbb{R} \}
\]
It is clear that \( \varphi(D)|_{V^+} \) is positive-definite and that \( \varphi(D)|_{V^-} \) is negative-definite. Thus \( b^+(\varphi(D)) \geq k \) and \( b^-(\varphi(D)) \geq n - k \). If remains to prove the following claim.

**Claim.** For any symmetric form \((W, \psi)\) over \(\mathbb{R}\) we have \(b^+(\psi) + b^- (\psi) \leq \dim_\mathbb{R} (W)\).

Thus let \(W^+\) be a positive-definite subspace of \(W\) and let \(W^-\) be a negative-definite subspace of \(W\). The intersection \(W^+ \cap W^-\) is a subspace that is positive-definite and negative-definite. So for any non-zero vector \(v \in W^+ \cap W^-\) we have \(\psi(v, v) > 0\) and \(\psi(v, v) < 0\). This is only possible if no such \(v\) exists, i.e. we have shown that the intersection \(W^+ \cap W^- = \{0\}\). Now we see that

\[
\dim(W^+) + \dim(W^-) = \dim(W^+ + W^-) + \dim(W^+ \cap W^-) = \dim(W^+ + W^-) \leq \dim(W).
\]

\[\uparrow\text{linear algebra}\]

\[\uparrow W^+ \cap W^- = \{0\} \quad \text{since } W^+ + W^- \subseteq W\]

**Corollary 101.9.**

1. Let \((V, \varphi)\) be a non-singular symmetric form over \(\mathbb{R}\). We write \(n = \dim_\mathbb{R} (V)\). The following statements hold:
   - (a) We have \(b^+(\varphi) = b^+(\varphi)\), in particular we have \(\text{sign}(-\varphi) = -\text{sign}(\varphi)\).
   - (b) We have \(b^+(\varphi) + b^-(\varphi) = \dim_\mathbb{R} (V)\).
   - (c) We have \(b^+(\varphi) = \frac{1}{2} (n + \text{sign}(\varphi))\).
   - (d) If we write \(k = b^+(\varphi)\), then the form \((V, \varphi)\) is isometric to \(k \cdot (1) \oplus (n - k) \cdot (-1)\).
   - (e) We have \(\text{sign}(\varphi) \equiv n \mod 2\).

2. If \((V, \varphi)\) and \((W, \psi)\) are two non-singular symmetric forms over \(\mathbb{R}\), then

\[
\text{sign}(\varphi \oplus \psi) = \text{sign}(\varphi) + \text{sign}(\psi).
\]

**Proof.**

1. (a) This statement follows immediately from the definitions.
   - (b) By Proposition 101.6 and Lemma 101.7 it suffices to prove the statement for non-singular symmetric forms that are represented by diagonal matrices. But for those forms the statement follows immediately from Proposition 101.8.
   - (c) This statement is an immediate consequence of (b) and the definition of the signature.
   - (d) This statement follows from Proposition 101.6 Lemma 101.7 and Proposition 101.8.
   - (e) We have \(\text{sign}(\varphi) = b^+(\varphi) - b^-(\varphi) \equiv b^+(\varphi) + b^-(\varphi) = n \mod 2\).

2. This statement follows immediately from Statement (1d), Proposition 101.6 applied to \(\varphi\) and \(\psi\) and Proposition 101.8.

**Example.** Given a non-singular symmetric form \(\varphi\) on \(\mathbb{R}^3\) one can visualize it by considering the “unit-sphere”

\[
S(\varphi) := \{ v \in \mathbb{R}^3 \mid \varphi(v, v) = 1 \}.
\]

Corollary 101.9 (3) implies in particular that every non-singular symmetric form on \(\mathbb{R}^3\) is isometric to one of the following four forms

\[
\begin{align*}
(a) \quad & 3 \cdot (1), \\
(c) \quad & 2 \cdot (-1) \oplus (1) \\
(b) \quad & 2 \cdot (1) \oplus (-1) \\
(d) \quad & 3 \cdot (-1)\end{align*}
\]
In the last case the unit-sphere is the empty set. In the other cases the unit-spheres are sketched in Figure 1444.

\[x^2 + y^2 + z^2 = 1\]
\[x^2 + y^2 - z^2 = 1\]
\[-x^2 - y^2 + z^2 = 1\]

**Figure 1444**

The following theorem says that the dimension and the signature are a complete invariant for isometry types of non-singular symmetric forms over \(\mathbb{R}\).

**Theorem 101.10. (Sylvester’s Theorem a. k. a. Sylvester’s law of inertia)** Let \((V, \varphi)\) and \((W, \psi)\) be two non-singular symmetric forms over \(\mathbb{R}\). Then

\[(V, \varphi) \text{ and } (W, \psi) \text{ are isometric } \iff \dim_{\mathbb{R}}(V) = \dim_{\mathbb{R}}(W) \text{ and } \text{sign}(\varphi) = \text{sign}(\psi).\]

**Proof.** The "\(\Rightarrow\)-direction is precisely Lemma 101.7. It remains to prove the "\(\Leftarrow\)-direction. So suppose we are given two non-singular symmetric forms \((V, \varphi)\) and \((W, \psi)\) over \(\mathbb{R}\) with same dimension and same signature. It follows from our hypothesis together with Corollary 101.9 (c) and (d) that there exist \(n, k \in \mathbb{N}_0\) such that \((V, \varphi)\) and \((W, \psi)\) are both isometric to \(k \cdot (+1) \oplus (n - k) \cdot (-1)\). But this implies that \((V, \varphi)\) and \((W, \psi)\) are themselves isometric. \(\blacksquare\)

**Remark.** It is also very easy to classify symmetric forms over \(\mathbb{R}\) that are not necessarily non-singular. More precisely, given a symmetric form \((V, \varphi)\) over \(\mathbb{R}\) we define the nullity \(\sigma(\varphi)\) as

\[\nu(\varphi) := \text{maximal dimension of a subspace } W \text{ of } V \text{ such that } \varphi|_W \text{ is the zero form.}\]

It is an amusing little exercise to modify the proof of Sylvester’s Theorem 101.10 to show that two symmetric forms over \(\mathbb{R}\) are isometric if and only if their dimensions, signatures and nullities agree.

Now it is time to apply our recently acquired knowledge to topology.

**Definition.**

1. If \((V, \varphi)\) is a symmetric form over the integers, then we define

\[g \otimes \mathbb{R} : V \otimes \mathbb{R} \times V \otimes \mathbb{R} \rightarrow \mathbb{R}\]
\[(v \otimes r, w \otimes s) \mapsto r \cdot \varphi(v, w) \cdot s.\]
Furthermore we define
\[ \text{sign}(\phi) := \text{sign}(\phi \otimes \mathbb{R}). \]

(2) Let \( k \geq 1 \) and let \( M \) be a compact oriented \( 4k \)-dimensional topological manifold. We define the *signature* of \( M \) to be\[ \text{sign}(M) := \text{sign}(Q_M). \]

For convenience we define the signature of the empty topological manifold to be zero.

**Remark.** The signature of a manifold was first introduced in 1923 by Hermann Weyl [Wey23, p. 432] in a little known paper written in Spanish. As is explained in [Eckm06], Hermann Weyl deliberately chose this obscurity since at this point, according to Hermann Weyl, algebraic topology was not considered “a respectable field of mathematics”.

**Lemma 101.11.** Let \( k \in \mathbb{N} \).

1. Let \( M \) be a compact oriented \( 4k \)-dimensional topological manifold. The form \( Q_M \otimes \mathbb{R} \) is isometric to the form
\[
H^{2k}(M, \partial M; \mathbb{R}) \times H^{2k}(M, \partial M; \mathbb{R}) \rightarrow \mathbb{R} \\
(\phi, \psi) \mapsto \langle \phi \cup \psi, [M] \rangle.
\]

2. The signature is additive under the connected sum operation and under disjoint union.

3. For every compact oriented \( 4k \)-dimensional topological manifold we have
\[
\text{sign}(-M) = -\text{sign}(M).
\]

4. Let \( M \) and \( N \) be two compact oriented \( 4k \)-dimensional topological manifolds.
   - (a) If \( M \) and \( N \) are homeomorphic, then \( \text{sign}(M) = \pm \text{sign}(N) \).
   - (b) If the pairs \((M, \partial M)\) and \((N, \partial N)\) are homotopy equivalent, then we have the equality \( \text{sign}(M) = \pm \text{sign}(N) \).

**Proof.**

1. This statement follows easily from the various definitions and Corollary [57.21]
2. It follows easily from Lemma [83.9] that the signature is additive under disjoint union.
   If we are given closed topological manifolds, then it follows immediately from Proposition [100.12] and Corollary [101.9] that the signature is additive under the connected sum operation.
3. The third statement is an immediate consequence of Lemma [100.6] and Corollary [101.9].
4. The last statement is also an immediate consequence of Lemma [100.6] and Corollary [101.9].

---

\[1422\] Recall that on page 2413 we introduced the intersection form \( Q_M : FH_{2k}(M; \mathbb{Z}) \times FH_{2k}(M; \mathbb{Z}) \rightarrow \mathbb{Z} \). Furthermore, recall that by Proposition [100.4] the intersection form \( Q_M \) is indeed symmetric, so it makes sense to consider its signature.
Examples. We have
\[
\text{sign}(\mathbb{C}P^2 \# \mathbb{C}P^2) = \text{sign}(\mathbb{C}P^2) + \text{sign}(\mathbb{C}P^2) = \text{sign}(1) + \text{sign}(1) = 1 + 1 = 2
\]
\[ \overset{\text{Lemma 101.11 (2) and (3) see page 2415}}{\uparrow} \]
\[
\text{sign}(\mathbb{C}P^2 \# \mathbb{C}P^2) = \text{sign}(\mathbb{C}P^2) - \text{sign}(\mathbb{C}P^2) = \text{sign}(1) - \text{sign}(1) = 1 - 1 = 0.
\]
Furthermore we have
\[
\text{sign}(S^2 \times S^2) = \text{sign}\left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\right) = \text{sign}\left(\left(\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\right) \cdot \left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\right) \cdot \left(\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\right)\right) = \text{sign}\left(\begin{pmatrix} 2 & 0 \\ 0 & -2 \end{pmatrix}\right) = 0.
\]
\[ \overset{\text{Lemma 101.1 and Proposition 101.8 see page 2414}}{\uparrow} \]

The above examples, together with Lemmas 100.6 and 101.11 (4) now allow us to give a partial answer to Question 68.15.

Corollary 101.12. The topological space $\mathbb{C}P^2 \# \mathbb{C}P^2$ is neither homotopy equivalent (in particular it is not homeomorphic) to $\mathbb{C}P^2 \# \mathbb{C}P^2$ nor to $S^2 \times S^2$.

Remark. Corollary 101.12 shows in particular that in the definition of the connected sum of two orientable (topological) smooth manifolds we needed to work with oriented (topological) smooth manifolds.

Unfortunately we are not yet able to distinguish the two smooth manifolds $S^2 \times S^2$ and $\mathbb{C}P^2 \# \mathbb{C}P^2$. In fact Sylvester’s Theorem 101.10 might suggest that we are again at a dead end. But this is not the case since Sylvester’s Theorem is a statement about real symmetric forms, but we are really dealing with symmetric forms defined over the integers. We will exploit this extra piece of information in the next section.

101.4. Non-singular symmetric forms over the integers. We consider the matrices
\[
H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad D = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.
\]

It follows from Sylvester’s Theorem 101.10 that the matrices give rise to isometric forms over the real numbers. The question arises, whether the forms on $\mathbb{Z}^2$ defined by these matrices are isometric. To get an idea let us consider what we can say about the “squares $\varphi(v, v)$” defined by these forms. Note that given any $v = \begin{pmatrix} a \\ b \end{pmatrix} \in \mathbb{R}^2$ we have
\[
\varphi(H)(v, v) = (a \ b) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} = 2ab \quad \text{and} \quad \varphi(H)(v, v) = (a \ b) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} = a^2 - b^2.
\]

We see that for the form to the left we only get even integers whereas to the right any integer can occur. This already shows that the two forms are not isometric over the integers. It follows immediately from this discussion and the earlier calculations of the intersection forms that the intersection forms of $S^2 \times S^2$ and $\mathbb{C}P^2 \# \mathbb{C}P^2$ are not isometric, not even up to sign. This allows us to settle the remaining case of Question 68.15. More precisely, by Lemma 100.6 we have the following proposition.
Proposition 101.13. The topological space $S^2 \times S^2$ is not homotopy equivalent (in particular it is not homeomorphic) to $\mathbb{C}P^2 \# \mathbb{C}P^2$.

This encouraging discussion leads us to the following definition.

Definition. A symmetric form $(V, \varphi)$ over the integers is called even if

$$\varphi(v, v) \equiv 0 \mod 2 \quad \text{for all } v \in V,$$

otherwise the intersection form is called odd. We refer to the property of $\varphi$ being even or odd as the parity of the form.

The following lemma summarizes some basic facts about the parity of symmetric forms.

1. Isometric forms have the same parity.
2. For a symmetric form $\varphi$ the parities of $\varphi$ and $-\varphi$ agree.
3. The direct sum of an odd form with any other form is also odd.
4. If $A$ is a symmetric square matrix over the integers, then

$$\varphi(A) \text{ is even } \iff \text{all diagonal entries of } A \text{ are even.}$$

Examples. It follows from Lemma 101.14 that the forms $(+1)$, $(-1)$ and $\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}$ are odd and that the forms $E_8$ and $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ are even.

Proof. The only statement which requires a little thought is the fact that if $A = (a_{ij})$ is a symmetric $(n \times n)$-matrix with even diagonal entries, then $\varphi(A)$ is even. Thus let $v = (v_1, \ldots, v_n) \in \mathbb{Z}^n$. We calculate that

$$\varphi(A)(v, v) = v^T Av = \sum_{i=1}^{n} \sum_{j=1}^{n} v_i v_j \cdot a_{ij} = 2 \sum_{i=1}^{n} \sum_{j=1}^{i-1} v_i v_j \cdot a_{ij} + \sum_{i=1}^{n} v_i^2 a_{ii} \equiv 0 \mod 2.$$  

since $A$ is symmetric

$$\uparrow$$

since the $a_{ii}$ are even

We just saw that the two matrices

$$H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad D = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

give rise to isometric forms over the real numbers and that the two matrices give rise to non-isometric forms over the integers. The question arises, how much more complicated is the classification of non-singular symmetric forms over the integers than the classification of non-singular forms over the real numbers. In particular the following question arises.

Question 101.15. Can we classify non-singular symmetric forms over the integers?

The following is the key theorem in the classification of non-singular indefinite symmetric forms over $\mathbb{Z}$.

Theorem 101.16. If $\varphi_1$ and $\varphi_2$ are two non-singular indefinite symmetric forms over the integers, then the following holds:

$$\varphi_1 \text{ and } \varphi_2 \text{ are isometric } \iff \varphi_1 \text{ and } \varphi_2 \text{ have the same rank, signature and parity.}$$
Example. Using the parity we had just seen that the intersection forms of the closed oriented 4-dimensional smooth manifolds $M = S^2 \times S^2$ and $N = \mathbb{CP}^2 \# \mathbb{CP}^2$ are not isometric, even up to sign. Now we consider the closed oriented 4-dimensional smooth manifolds that we obtain from $M$ and $N$ by performing the connected sum with $\mathbb{CP}^2$. In other words, we are considering $M \# \mathbb{CP}^2 = (S^2 \times S^2) \# \mathbb{CP}^2$ and $N \# \mathbb{CP}^2 = \mathbb{CP}^2 \# \mathbb{CP}^2 \# \mathbb{CP}^2$. It follows from Proposition 100.12 that the intersection forms of these two smooth manifolds are represented by the matrices

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. $$

Both forms are non-singular indefinite and odd. Thus it follows from Theorem 101.16 or alternatively from Exercise 101.11 that the intersection forms are isometric. Thus we cannot distinguish $M \# \mathbb{CP}^2 = (S^2 \times S^2) \# \mathbb{CP}^2$ and $N \# \mathbb{CP}^2 = \mathbb{CP}^2 \# \mathbb{CP}^2 \# \mathbb{CP}^2$ using their intersection forms. In fact, it turns out that there is a good reason why we have a hard time distinguishing them: as is shown in [GoS99, p. 151] the two smooth manifolds $(S^2 \times S^2) \# \mathbb{CP}^2$ and $\mathbb{CP}^2 \# \mathbb{CP}^2 \# \mathbb{CP}^2$ are in fact diffeomorphic, in fact with good eyes one can write down an explicit diffeomorphism.

Proof. The proof of the theorem is provided in [MH73, Theorem II.5.3] (see also [GoS99, Theorem 1.2.14] for an outline of the proof). The proof relies crucially on a significant input from algebraic number theory, namely the Hasse-Minkowski theorem. This theorem says that given $a_1, \ldots, a_n \in \mathbb{Q} \setminus \{0\}$ the equation

$$x_1^2 \cdot a_1 + \cdots + x_n^2 \cdot a_n = 0$$

has a non-trivial integral solution if and only if it has a non-trivial real solution and if for each prime $p$ the equation has also a non-trivial solution over the $p$-adic numbers $\mathbb{Q}_p$. A proof of the Hasse-Minkowski theorem is given in [Ser73, Chapter IV Theorem 8], [BSh66, Section 7.1] or [Neuk99, p. 385].

As an immediate corollary to Theorem 101.16 we obtain the classification of non-singular indefinite odd forms. More precisely, we have the following corollary.

Corollary 101.17. If $\varphi$ is a non-singular indefinite odd symmetric form over the integers, then

$$\varphi \cong b^+(\varphi) \cdot (1) \oplus b^-\varphi \cdot (-1).$$

Proof. Let $\varphi$ be a non-singular indefinite odd symmetric form. It follows from Proposition 101.8 that the rank, signature and parity of the two non-singular indefinite odd forms in the statement of the corollary agree. So these two forms are isometric by Theorem 101.16.

Now we turn to the study of even forms. We have the following, perhaps somewhat surprising proposition.

Proposition 101.18. Let $\varphi$ be a non-singular symmetric form over the integers. If $\varphi$ is even, then $\text{sign}(\varphi) \equiv 0 \pmod{8}$. 
Example. As a reality check, the two even non-singular symmetric forms that we are acquainted with are $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $E_8$. These forms a non-singular even forms and the signatures are 0 and 8, so that matches Proposition 101.18.

Proof. Given a non-singular symmetric form $(W, \psi)$ over $\mathbb{Z}$ we say that an element $v \in W$ is characteristic if for all $w \in W$ we have

$$\varphi(v, w) \equiv \varphi(w, w) \mod 2.$$ 

We make the following observations:

(1) It follows immediately from the definitions that $(W, \psi)$ is even if and only if 0 is a characteristic element.

(2) If $W = k \cdot (1) \oplus l \cdot (-1)$, then it follows from a straightforward calculation as in the proof of Lemma 101.14 that an element $u \in \mathbb{Z}^{k+l}$ is characteristic if and only if all its entries are odd.

It follows from Observation (1) that the following claim implies in particular the desired statement of Proposition 101.18.

Claim. Let $(V, \varphi)$ be a non-singular symmetric form over $\mathbb{Z}$. If $v \in V$ is a characteristic element, then

$$\varphi(v, v) \equiv \text{sign}(\varphi) \mod 8.$$ 

Let $v \in V$ be a characteristic element of $(V, \varphi)$. It is straightforward to verify that $v + e_- + e_+$ is a characteristic element in $(V \oplus \mathbb{Z} \oplus \mathbb{Z}, \varphi \oplus (1) \oplus (-1))$, where $e_-$ and $e_+$ are generators of the first respectively the second $\mathbb{Z}$-summand. Note that, regardless of $\varphi$, the form $\varphi \oplus (1) \oplus (-1)$ is indefinite and odd. Thus by Corollary 101.17 there exists an isometry

$$\Phi: \varphi \oplus (1) \oplus (-1) \rightarrow (b^+(\varphi) + 1) \cdot (1) \oplus (b^- (\varphi) + 1) \cdot (-1).$$ 

We write $u := \Phi(v + e_- + e_+)$. It is clear that $u$ is a characteristic element for the form on the right-hand side. The above Observation (2) tells us that each entry of $u$ is an odd integer. Now we calculate that

$$\varphi(v, v) = \varphi(u, u) \equiv \sum_{i=1}^{b^+(\varphi)+1} (i\text{-th entry of } u)^2 + \sum_{i=b^+(\varphi)+2}^{b^+(\varphi)+b^- (\varphi)+2} (-1) \cdot (i\text{-th entry of } u)^2 \mod 8.$$ 

Note that both sides are non-singular odd indefinite forms, regardless of what non-singular symmetric form $\varphi$ we actually consider.
Now we can provide the classification of non-singular indefinite even symmetric forms.

**Corollary 101.19.** If \( \varphi \) is a non-singular indefinite even symmetric form over the integers, then
\[
\varphi \cong \frac{\text{sign}(\varphi)}{8} \cdot E_8 \oplus \frac{\text{rank}(\varphi) - |\text{sign}(\varphi)|}{2} \cdot H.
\]

**Proof.** First let \( \varphi \) be a non-singular even symmetric form over the integers. Note that it follows from Proposition 101.18 that \( \text{sign}(\varphi) \) is indeed divisible by 8. Furthermore it follows from \( \text{rank}(\varphi) = b^+(\varphi) + b^-(\varphi) \) and \( \text{sign}(\varphi) = b^+(\varphi) - b^-(\varphi) \) that \( \text{rank}(\varphi) - |\text{sign}(\varphi)| \) is divisible by 2. So it makes sense to write down the right-hand side.

Next we recall that the two non-singular symmetric forms \( E_8 \) and \( H \) are even, that \( \text{rank}(E_8) = \text{sign}(E_8) = 8 \) and that \( \text{rank}(H) = 2 \) and \( \text{sign}(H) = 0 \). Now assume that \( \varphi \) is furthermore indefinite. It follows from the above observation regarding \( E_8 \) and \( H \) that the rank, signature and parity of the two non-singular indefinite even forms in the statement of the corollary agree. So these two forms are isometric by Theorem 101.16.

Now we turn to the study of non-singular definite symmetric forms over the integers. We start out with some more examples of such forms. The following lemma is proved in [MH73, Lemmas 6.1 and 6.2] and [Ser73, p. 51].

**Lemma 101.20.** We denote by \( e_1, \ldots, e_{4m} \) the standard basis for \( \mathbb{Z}^{4m} \). We denote by \( \Gamma_{4m} \) the submodule of \( \mathbb{Z}^{4m} \) spanned by the vectors \( \{e_i + e_j\}_{i,j=1,...,4m} \) and \( \frac{1}{2}(e_1 + \cdots + e_{4m}) \).

1. The restriction of the usual form \( \langle , \rangle \) on \( \mathbb{Z}^{4m} \) to \( \Gamma_{4m} \) is a non-singular positive-definite symmetric form.
2. The form \( \Gamma_{4m} \) is odd if and only if \( m \) is odd.
3. The form \( \Gamma_8 \) is isometric to \( E_8 \).
4. The form \( \Gamma_{16} \) is not isometric to \( E_8 \oplus E_8 \).

It turns out that there are many more definite symmetric forms than indefinite symmetric forms and that there is no known classification of such forms. For example, by [MH73, p. 28] and [Ser73, p. 55] we have the following table

<table>
<thead>
<tr>
<th>dimension</th>
<th>8</th>
<th>16</th>
<th>24</th>
<th>32</th>
<th>40</th>
</tr>
</thead>
<tbody>
<tr>
<td>number of isometry types of non-singular positive-definite even symmetric forms</td>
<td>1</td>
<td>2</td>
<td>24</td>
<td>( \geq 10^7 )</td>
<td>( \geq 10^{51} )</td>
</tr>
</tbody>
</table>

Here in dimension 8, up to isometry, the unique example is \( \Gamma_8 = E_8 \) whereas in dimension 16 the unique examples are \( \Gamma_8 \oplus \Gamma_8 = E_8 \oplus E_8 \) and \( \Gamma_{16} \).

Similar results are also known for the number of isometry classes of non-singular positive-definite odd symmetric forms of a given rank. We refer to [CSl99, p. 416] and [Kin03, Table 2] for details.

\[1424\] Why is it true that for each odd number \( k \) we have \( k^2 \equiv 1 \mod 8 \)?
101.5. **Forms over** \( \mathbb{F}_2 \). Considering the power of the intersection form of a closed oriented even-dimensional topological manifold it is natural to ask, whether one can obtain similar results for closed (possibly) non-orientable even-dimensional topological manifolds. In fact we have the following definition.

**Definition.** Let \( M \) be a closed \( 2n \)-dimensional topological manifold \( M \) (not necessarily orientable). We denote by \([M]_{\mathbb{F}_2} \in \mathrm{H}_{2n}(M;\mathbb{F}_2)\) the \( \mathbb{F}_2 \)-fundamental class given by Corollary \( \text{87.5} \). Given \( k \in \mathbb{N}_0 \) we denote by

\[
\mathrm{PD}^{\mathbb{F}_2}_M: \mathrm{H}_k(M;\mathbb{F}_2) \to \mathrm{H}^{2n-k}(M;\mathbb{F}_2)
\]

the inverse of the isomorphism given by the Poincaré Duality Theorem \( \text{88.1} \). We can now define the \( \mathbb{F}_2 \)-valued intersection form as follows:

\[
Q^\mathbb{F}_2_M: \mathrm{H}_{n}(M;\mathbb{F}_2) \times \mathrm{H}_{n}(M;\mathbb{F}_2) \to \mathbb{F}_2
\]

\[ (a,b) \mapsto \langle \mathrm{PD}^{\mathbb{F}_2}_M(a) \cup \mathrm{PD}^{\mathbb{F}_2}_M(b), [M]_{\mathbb{F}_2} \rangle. \]

The above definition is completely analogous to the definition of the \( \mathbb{Z} \)-valued intersection form on page \( \text{2413} \). Not surprisingly the \( \mathbb{F}_2 \)-valued intersection forms shares many properties of the \( \mathbb{Z} \)-valued intersection form.

**Proposition 101.21.**

1. The \( \mathbb{F}_2 \)-valued intersection form \( Q^\mathbb{F}_2_M \) on a closed \( 2n \)-dimensional topological manifold \( M \) is symmetric and non-singular.

2. The \( \mathbb{F}_2 \)-valued intersection forms of homeomorphic closed topological manifolds are isometric.

**Proof.** The proof is a very mild variation on the proofs of Proposition \( \text{100.4} \) and Lemma \( \text{100.6} \).

**Examples.**

1. Similar to the discussion on page \( \text{2414} \) one can show that the \( \mathbb{F}_2 \)-valued intersection form of the torus \( S^1 \times S^1 \) is represented by the matrix \( \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \).

2. Proposition \( \text{90.16} \) together with the obvious analogue of Proposition \( \text{100.12} \) implies that the \( \mathbb{F}_2 \)-valued intersection form of \( \mathbb{R}P^2 \# \mathbb{R}P^2 \) is represented by the matrix \( \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \).

The question arises, whether we can classify non-singular symmetric forms over \( \mathbb{F}_2 \). For better or worse it turns out that there is a straightforward classification. To state the classification we need the following definition which is inspired by our definition on page \( \text{2452} \).

**Definition.** Let \( V \) be a finite-dimensional \( \mathbb{F}_2 \)-vector space. We say a form \( \lambda: V \times V \to \mathbb{F}_2 \) is even if \( \lambda(v,v) = 0 \in \mathbb{F}_2 \) for all \( v \in V \). Otherwise we say that the symmetric form is odd. We call the property of a form to be even or odd to be the parity of the form.

**Example.** As we had just seen, the \( \mathbb{F}_2 \)-valued intersection form of the torus \( S^1 \times S^1 \) is even whereas the \( \mathbb{F}_2 \)-valued intersection form of the torus \( \mathbb{R}P^2 \# \mathbb{R}P^2 \) is odd. Thus we have found
a new, and particularly complicated, proof that these two 2-dimensional smooth manifolds are not homeomorphic.

The following proposition gives a complete classification of non-singular symmetric forms over \( \mathbb{F}_2 \) up to isometry.

**Proposition 101.22.** Two non-singular symmetric forms \((V, \kappa)\) and \((W, \lambda)\) over \( \mathbb{F}_2 \) are isometric if and only if \( \dim(V) = \dim(W) \) and if \( \kappa \) and \( \lambda \) have the same parity.

**Proof.** We will prove Proposition 101.22 in Exercise 101.13. For peace of mind we point out that the proposition is proved in [Hopk15, Theorem 2.7]. It can also be deduced from [Szy97, Corollary 6.3.1].

The proposition shows that, unfortunately, we extract only very little information from the \( \mathbb{F}_2 \)-valued intersection form.

**Remark.** Let \( V \) be a finite-dimensional vector space over \( \mathbb{F}_2 \) and let \((\cdot, \cdot) : V \times V \to \mathbb{F}_2\) be an even form. It follows from Proposition 101.22 that \( V \) admits a symplectic basis, i.e. there exists a basis \( a_1, \ldots, a_k, b_1, \ldots, b_k \) for \( V \) such that the following conditions are satisfied:

1. For every \( i, j \in \{1, \ldots, k\} \) we have \( \langle a_i, a_j \rangle = \langle b_i, b_j \rangle = 0 \).
2. For every \( i, j \in \{1, \ldots, k\} \) we have \( \langle a_i, a_j \rangle = \delta_{ij} \).

This observation will come in handy later on.

---

**Exercises for Chapter 101.**

**Exercise 101.1.** Let \( \varphi \) be a symmetric form on a finite-dimensional real vector space \( V \). Prove the following statement: If \( \varphi \) is positive-definite, then \( \varphi \) is non-singular.

**Exercise 101.2.** Let \( R \) be a commutative ring. In this exercise we will see that non-singular symmetric forms over \( R \) give rise to a group. (We refer to page 2410 for the definition of a non-singular symmetric form.) Note that the set of symmetric non-singular forms \( \varphi : R^k \times R^k \to R \) with the direct sum operation is a monoid.

We say a symmetric form \( \varphi \) is hyperbolic if it is isometric to a form of the form

\[
\psi : (V \oplus V) \times (V \oplus V) \to \mathbb{R} \\
(v_1 \oplus v_2, w_1 \oplus w_2) \mapsto (v_1^T v_2) \begin{pmatrix} 0 & \text{id} \\ \text{id} & 0 \end{pmatrix} \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}.
\]

(a) Show that the monoid of symmetric non-singular forms \( \varphi : R^k \times R^k \to R \) modulo the submonoid generated by hyperbolic forms is an abelian group. We refer to this group as the Witt group \( W(R) \).

(b) Show that the maps

\[
W(\mathbb{R}) \to \mathbb{Z} \\
\varphi \mapsto \text{sign}(\varphi)
\]

and

\[
W(\mathbb{Z}) \to \mathbb{Z} \\
\varphi \mapsto \text{sign}(\varphi \otimes \mathbb{R})
\]

are isomorphisms.
(c) Show that $W(\mathbb{Q})$ admits an epimorphism onto $\mathbb{Z} \oplus (\mathbb{Z}_2)^\infty$.

*Hint.* Consider determinants of matrices representing a given form.

*Remark.* The group $W(\mathbb{Q})$ is computed in [MH73, Chapter IV.2] or alternatively in [Lam05, Chapter VI.4].

**Exercise 101.3.** Let $M$ be a closed oriented 3-dimensional smooth manifold. Show that $\text{sign}(M \times [0,1]) = 0$.

**Exercise 101.4.**

(a) Let $M$ be a closed oriented connected $4k$-dimensional topological manifold and let $N$ be a closed oriented $4l$-dimensional topological manifold. Show that

$$
\text{sign}(M \times N) = \text{sign}(M) \cdot \text{sign}(N).
$$

(b) We extend the definition of the signature from page 2450 by defining $\text{sign}(M) = 0$ for any closed oriented connected topological manifold whenever $\dim(M) \not\equiv 0 \mod 4$. Show that the conclusion of (a) holds without any restrictions on the dimensions of $M$ and $N$.

*Remark.* This exercise is carried out in [Brun05, Lemma 2.6].

**Exercise 101.5.** Let $M$ be a closed non-orientable $4k$-dimensional smooth manifold. Let $p: \tilde{M} \to M$ be the orientation covering that we introduced on page 531. Show that $\text{sign}(\tilde{M}) = 0$.

**Exercise 101.6.**

(a) Explain how to modify the proof of Proposition 101.2 so that it also holds for the integers.

(b) Explain why the proof of Proposition 101.6 cannot be generalized to the integers.

**Exercise 101.7.** Let $A$ and $C$ be invertible real $k \times k$-matrices. We assume that $C$ is symmetric.

(a) Show that the signature of the matrix \[
\begin{pmatrix}
0 & A \\
A^T & C
\end{pmatrix}
\] is zero.

(b) Does the conclusion of (a) still hold if $A$ and $C$ are not invertible?

**Exercise 101.8.** For which $k \in \mathbb{Z}$ does there exist a closed oriented 3-dimensional smooth manifold $N$ with $\text{sign}(S^1 \times N) = k$?

**Exercise 101.9.** Let $A \in GL(n, \mathbb{R})$. Show that

$$
b^+(\varphi(A)) = \max \left\{ k \in \mathbb{N}_0 \left| \, \text{there exists a } k\text{-dimensional subspace } V \text{ of } \mathbb{R}^n \text{ with } v^T Av > 0 \text{ for all } v \in V \cap S^{n-1} \right. \right\}.
$$

**Exercise 101.10.** Show that the map

$$
\{ A \in GL(n, \mathbb{R}) \,|\, A = A^T \} \to \mathbb{Z}
$$

$$
A \mapsto \text{sign}(A)
$$

is continuous.

*Hint.* You can work either with the definition of the signature (or better, with the reformulation given in Exercise 101.9) or you could use Proposition 3.37.
Exercise 101.11. Show “by hand” that the forms on \( \mathbb{Z}^3 \) defined by the matrices
\[
A = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}
\]
are isometric.

Exercise 101.12. Let \( \varphi : V \times V \to \mathbb{Z} \) be a form over \( \mathbb{Z} \). Show that there exists a non-degenerate form \( \psi : W \times W \to \mathbb{Z} \) such that \( \varphi \) is isometric to the orthogonal sum of \( \psi \) with a form that is identically zero.

Exercise 101.13. Show that two non-singular symmetric forms \((V, \kappa)\) and \((W, \lambda)\) over \( \mathbb{F}_2 \) are isometric if and only if \( \dim(V) = \dim(W) \) and if \( \kappa \) and \( \lambda \) have the same parity.
102. The intersection form III: 4-dimensional manifolds

We have now introduced lots of invariants of topological spaces, namely the fundamental group, higher homotopy groups, homology groups and the cohomology groups together with the cup product. The question arises, whether we are done at some point, or whether this list of ever new invariants continues forever.

In an attempt to respond to this question we want to consider closed oriented simply connected 4-dimensional (topological) smooth manifolds and their intersection forms. What follows is a long survey on some amazing results. Unfortunately the proofs of any of these statements goes well beyond what we can cover in these introductory notes.

The following question will guide us through the chapter.

Question 102.1.

1. Is the intersection form a complete invariant of closed oriented simply connected 4-dimensional (topological) smooth manifolds?\footnote{Note that for a simply connected 4-dimensional topological manifold \( M \) we have \( H_1(M; \mathbb{Z}) = 0 \) by the Hurewicz Theorem \[52.5\]. If \( M \) is closed and orientable, then we have \( H_3(M; \mathbb{Z}) = 0 \) by the Poincaré Duality Theorem \[88.1\]. Thus we see that for closed oriented simply connected 4-dimensional topological manifolds the intersection form contains all the (co-) homological data we could ask for.}

2. Which isometry types of non-singular symmetric forms are realized by closed oriented simply connected 4-dimensional (topological) smooth manifolds?
